About the HP 5500 EI & 5500 SI configuration guides-Release 2215

The HP 5500 EI & 5500 SI configuration guides describe the software features for the HP 5500 EI & 5500 SI Switch Series, software release train 2215, and guide you through the software configuration procedures. These configuration guides also provide configuration examples to help you apply the software features to different network scenarios.

Configuration guide	Content
01 Fundamentals Configuration Guide	<p>Describes how to use the command line interface of the switch, log in to and set up the switch. This guide includes:</p> <ul style="list-style-type: none">• CLI (command line interface overview and how to use the CLI)• Login methods• CLI login• Web login• NMS login• User login control• FTP• TFTP• File system management• Configuration file management• Software upgrade• ISSU• ISSU configuration example• Device management• Automatic configuration
02 IRF Configuration Guide	<p>Describes the HP proprietary IRF technology, IRF fabric setup and configuration procedure, restrictions and guidelines, and IRF fabric configuration procedure.</p>
03 Layer 2 – LAN Switching Configuration Guide	<p>Covers Layer 2 technologies and features used on a LAN switched network, including VLAN technology, port isolation, and spanning tree. You can use these features to divide broadcast domains, remove Layer 2 loops, isolate users within a VLAN, re-mark VLAN tags, implement VLAN VPNs over the Internet, and so on. This guide includes:</p> <ul style="list-style-type: none">• Ethernet interface• Loopback and null interfaces• Bulking configuring interfaces• MAC address table• MAC Information• Ethernet link aggregation• Port isolation• Spanning tree• BPDU tunneling• VLAN

Configuration guide	Content
	<ul style="list-style-type: none"> • Super VLAN • Isolate-user-VLAN • Voice VLAN • GVRP • QinQ • VLAN mapping • LLDP • Service loopback group • MVRP
04 Layer 3 – IP Services Configuration Guide	<p>Describes IP addressing (including static and dynamic IPv4 and IPv6 address assignment), IRDP, UDP helper, DNS, network performance optimization, ARP, and interoperation between IPv4 and IPv6. This guide includes:</p> <ul style="list-style-type: none"> • ARP • Gratuitous ARP • Proxy ARP • ARP snooping • IP addressing • DHCP overview • DHCP server • DHCP relay agent • DHCP client • DHCP snooping • BOOTP client • IPv4 DNS • IRDP • IP performance optimization • UDP helper • IPv6 basics • DHCPv6 overview • DHCPv6 server • DHCPv6 relay agent • DHCPv6 client • DHCPv6 snooping • IPv6 DNS • Tunneling
05 Layer 3 – IP Routing Configuration Guide	<p>Covers the routing technologies for IPv4 and IPv6 networks of different sizes, route filtering, route control, and policy based routing. This guide includes:</p> <ul style="list-style-type: none"> • IP routing basics • Static routing • RIP • OSPF • IS-IS • BGP • IPv6 static routing • RIPng • OSPFv3 • IPv6 IS-IS • IPv6 BGP

Configuration guide	Content
	<ul style="list-style-type: none"> • Routing policy • Policy-based routing • MCE • IPv6 MCE
06 IP Multicast Configuration Guide	<p>Covers Layer 3 IPv4 multicast protocols (IGMP, PIM, MSDP, and MBGP), Layer 3 IPv6 multicast protocols (MLD, IPv6 PIM, and IPv6 MBGP), Layer 2 IPv4 multicast protocols (IGMP snooping, PIM snooping, and multicast VLAN), and Layer 2 IPv6 multicast protocols (MLD snooping, IPv6 PIM snooping, and IPv6 multicast VLAN). This guide includes:</p> <ul style="list-style-type: none"> • Multicast overview • IGMP snooping • PIM snooping • Multicast VLAN • Multicast routing and forwarding • IGMP • PIM • MSDP • MBGP • MLD snooping • IPv6 PIM snooping • IPv6 multicast VLAN • IPv6 multicast routing and forwarding • MLD • IPv6 PIM • IPv6 MBGP
07 ACL and QoS Configuration Guide	<p>Describes how to classify traffic with ACLs, and allocate network resources and manage congestions with QoS technologies to improve network performance and network use efficiency. You can use ACLs to help other function modules (such as QoS and IP routing) classify or filter traffic. This guide includes:</p> <ul style="list-style-type: none"> • ACL • QoS overview • QoS configuration approaches • Priority mapping • Traffic policing, traffic shaping, and line rate • Congestion management • Congestion avoidance • Traffic filtering • Priority marking • Traffic redirecting • Class-based accounting • Data buffer • Appendix

Configuration guide	Content
08 Security Configuration Guide	<p>Covers security features. The major security features available on the switch include identity authentication (AAA), access security (802.1X, MAC authentication, portal, and port security), secure management (SSH), and attack protection (IP source guard, ARP attack protection, and URPF). This guide includes:</p> <ul style="list-style-type: none">• AAA• 802.1X fundamentals• 802.1X• EAD fast deployment• MAC authentication• Portal• Triple authentication• Port security• User profile• Password control• HABP• Public key• PKI• IPsec• SSH2.0• SFTP• SCP• SSL• TCP attack protection• IP source guard• ARP attack protection• ND attack defense• URPF• SAVI• Blacklist
09 High Availability Configuration Guide	<p>Describes high availability technologies and features available on the switch for failure detection and failover. Failure detection technologies focus on fault detection and isolation. Failover technologies focus on network recovery. This guide includes:</p> <ul style="list-style-type: none">• High availability overview• Ethernet OAM• CFD• DLDP• RRPP• Smart Link• Monitor Link• VRRP• Stateful failover• BFD• Track

Configuration guide	Content
10 Network Management and Monitoring Configuration Guide	<p data-bbox="608 230 1422 383">Describes features that help you manage and monitor your network, for example, manage system events, sample packets, assess network performance, synchronize the clock for all devices with the clock in the network, supply power for attached devices by using PoE, and test network connectivity. This guide includes:</p> <ul data-bbox="608 398 1023 887" style="list-style-type: none"> <li data-bbox="608 398 1023 432">• System maintenance and debugging <li data-bbox="608 439 687 472">• NTP <li data-bbox="608 479 831 512">• Information center <li data-bbox="608 519 711 553">• SNMP <li data-bbox="608 560 719 593">• RMON <li data-bbox="608 600 783 633">• Port mirroring <li data-bbox="608 640 807 674">• Traffic mirroring <li data-bbox="608 680 703 714">• NQA <li data-bbox="608 721 703 754">• sFlow <li data-bbox="608 761 679 795">• IPC <li data-bbox="608 801 679 835">• PoE <li data-bbox="608 842 935 875">• Cluster managementCWMP <li data-bbox="608 882 695 916">• Stack

Automatic configuration work flow	146
Using DHCP to obtain an IP address and other configuration information	147
Obtaining the configuration file from the TFTP server.....	148
Executing the configuration file.....	150
Index	151

Using the CLI

At the command-line interface (CLI), you can enter text commands to configure, manage, and monitor your device.

Figure 1 CLI example

Logging in to the CLI

You can log in to the CLI in a variety of ways. For example, you can log in through the console port, or by using Telnet or SSH. For more information about login methods, see "Logging in to the CLI "

Command conventions

Command conventions help you understand the syntax of commands. Commands in product manuals comply with the conventions listed in [Table 1](#).

Table 1 Command conventions

Convention	Description
Boldface	Bold text represents commands and keywords that you enter literally as shown.
<i>Italic</i>	<i>Italic</i> text represents arguments that you replace with actual values.
[]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x y ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.

Convention	Description
[x y ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x y ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select at least one.
[x y ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

Command keywords are case insensitive.

The following example analyzes the syntax of the **clock datetime** *time date* command according to [Table 1](#).

Figure 2 Understanding command-line parameters

For example, to set the system time to 10:30:20, February 23, 2011, enter the following command line at the CLI and press **Enter**:

```
<Sysname> clock datetime 10:30:20 2/23/2011
```

Using the undo form of a command

Most configuration commands have an **undo** form for canceling a configuration, restoring the default, or disabling a feature. For example, the **info-center enable** command enables the information center, and the **undo info-center enable** command disables the information center.

CLI views

Commands are grouped in different views by function. To use a command, you must enter the view of the command.

CLI views are organized in a hierarchical structure, as shown in [Figure 3](#). Each view has a unique prompt, from which you can identify where you are and what you can do. For example, the prompt [Sysname-vlan100] shows that you are in the view of VLAN 100 and can configure attributes for the VLAN.

You are placed in user view immediately after you are logged in to the CLI. The user view prompt is <Device-name>, where the *Device-name* argument defaults to **HP** and can be changed by using the **sysname** command. In user view, you can perform some basic operations, including display, debug, file

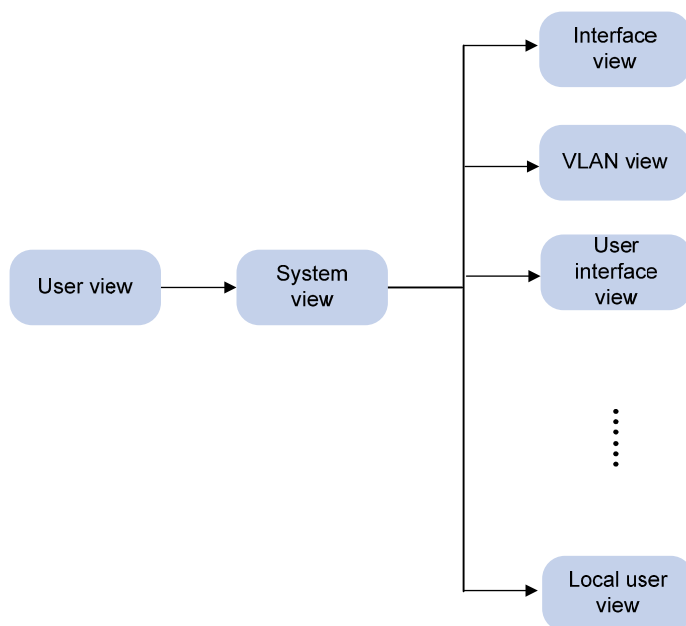

management, FTP, Telnet, clock setting, and reboot. For more information about the **sysname** command, see *Fundamentals Command Reference*.

From user view, you can enter system view to configure global settings, including the daylight saving time, banners, and hotkeys. The system view prompt is `[Device-name]`.

From system view, you can enter different function views. For example, you can enter interface view to configure interface parameters, enter VLAN view to add ports to the specific VLAN, enter user interface view to configure login user attributes, or create a local user and enter local user view to configure attributes for the local user.

To display all commands available in a view, enter a question mark (?) at the view prompt.

Figure 3 CLI view hierarchy

Entering system view from user view

Task	Command
Enter system view from user view.	system-view

Returning to the upper-level view from any view

Task	Command
Return to the upper-level view from any view.	quit

Executing the **quit** command in user view terminates your connection to the device.

NOTE:

In public key code view, use the **public-key-code end** command to return to the upper-level view (public key view). In public key view, use the **peer-public-key end** command to return to system view.

Returning to user view from any other view

You can return to user view from any other view by using the **return** command, instead of using the **quit** command repeatedly. Pressing **Ctrl+Z** has the same effect.

To return to user view from any other view:

Task	Command
Return to user view.	return

Accessing the CLI online help

The CLI online help is context sensitive. You can enter a question mark at any point of a command to display all available options.

To access the CLI online help, use one of the following methods:

- Enter a question mark at a view prompt to display the first keywords of all commands available in the view. For example:

```
<Sysname> ?
User view commands:
  archive          Specify archive settings
  backup           Backup next startup-configuration file to TFTP server
  boot-loader      Set boot loader
  bootrom          Update/read/backup/restore bootrom
  cd               Change current directory
...

```

- Enter some keywords of a command and a question mark separated by a space to display available keywords and arguments.
 - Example 1: The question mark is in the place of a keyword, and the CLI displays all possible keywords with a brief description for each keyword.

```
<Sysname> terminal ?
  debugging  Send debug information to terminal
  logging    Send log information to terminal
  monitor    Send information output to current terminal
  trapping   Send trap information to terminal

```

- Example 2: The question mark is in the place of an argument, and the CLI displays the description of the argument.

```
<Sysname> system-view
[Sysname] interface vlan-interface ?
  <1-4094>  VLAN interface
[Sysname] interface vlan-interface 1 ?
  <cr>
[Sysname] interface vlan-interface 1

```

The string **<cr>** indicates that the command is complete, and you can press **Enter** to execute the command.

- Enter an incomplete keyword string followed by a question mark to display all keywords starting with the string. For example:

```

<Sysname> f?
    fixdisk
    format
    free
    ftp
<Sysname> display ftp?
    ftp
    ftp-server
    ftp-user

```

Entering a command

When you enter a command, you can use some keys or hotkeys to edit the command line, or use abbreviated keywords or keyword aliases.

Editing a command line

You can use the keys listed in [Table 2](#) or the hotkeys listed in [Table 3](#) to edit a command line.

Table 2 Keys for editing a command line

Key	Function
Common keys	If the edit buffer is not full, pressing a common key inserts the character at the position of the cursor and moves the cursor to the right.
Backspace	Deletes the character to the left of the cursor and moves the cursor back one character.
Left arrow key or Ctrl+B	Moves the cursor one character to the left.
Right arrow key or Ctrl+F	Moves the cursor one character to the right.
Tab	<p>If you press Tab after entering part of a keyword, the system automatically completes the keyword:</p> <ul style="list-style-type: none"> • If a unique match is found, the system substitutes the complete keyword for the incomplete one and displays what you entered in the next line. • If there is more than one match, you can press Tab repeatedly to choose the keyword you want to enter. • If there is no match, the system does not modify what you entered but displays it again in the next line.

Entering a STRING type value for an argument

Generally, a STRING type argument value can contain any printable character (in the ASCII code range of 32 to 126) other than the question mark (?), quotation mark ("), backward slash (\), and space. However, a specific STRING type argument might have more strict requirements. For example, the domain name is of the STRING type. Invalid characters for it include the vertical bar (|), slash (/), colon (:), asterisk (*), less-than sign (<), greater-than sign (>), and at sign (@), as well as the question mark (?), quotation mark ("), backward slash (\), and space. For more information about the specific requirements for a STRING type argument, see the relevant command reference.

```

<Sysname> system-view
[Sysname] domain ?

```

STRING<1-24> Domain name

Abbreviating commands

You can enter a command line quickly by entering incomplete keywords that can uniquely identify the complete command. In user view, for example, commands starting with an **s** include **startup saved-configuration** and **system-view**. To enter system view, you only need to enter **sy**. To set the configuration file to be used at the next startup, you can enter **st s**.

You can also press **Tab** to have an incomplete keyword automatically completed.

Configuring and using command keyword aliases

The command keyword alias function allows you to replace the first keyword of a non-undo command or the second keyword of an **undo** command with your preferred keyword when you execute the command. For example, if you configure **show** as the alias for the **display** keyword, you can enter **show** to execute a **display** command.

Usage guidelines

- After you successfully execute a command by using a keyword alias, the system saves the keyword, instead of its alias, to the running configuration.
- If you press **Tab** after entering part of an alias, the keyword is displayed.
- If a string you entered partially matches a keyword and an alias, the command indicated by the alias is executed. To execute the command indicated by the keyword, enter the complete keyword.
- If a string you entered exactly matches a keyword but partially matches an alias, the command indicated by the keyword is executed. To execute the command indicated by the alias, enter the complete alias.
- If you enter a string that partially matches multiple aliases, the system gives you a prompt.

Configuration procedure

To configure a command keyword alias:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the command keyword alias function.	command-alias enable	By default, the command keyword alias function is disabled.
3. Configure a command keyword alias.	command-alias mapping <i>cmdkey</i> <i>alias</i>	By default, no command keyword alias is configured. You must enter the <i>cmdkey</i> and <i>alias</i> arguments in their complete form.

Configuring and using hotkeys

To facilitate CLI operation, the system defines some hotkeys and provides five configurable command hotkeys. Pressing a command hotkey equals entering a command. For system-reserved hotkeys, see [Table 3](#).

To configure hotkeys:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure hotkeys.	hotkey { CTRL_G CTRL_L CTRL_O CTRL_T CTRL_U } <i>command</i>	By default: <ul style="list-style-type: none"> • Ctrl+G is assigned the display current-configuration command. • Ctrl+L is assigned the display ip routing-table command. • Ctrl+O is assigned the undo debugging all command. No command is assigned to Ctrl+T or Ctrl+U .
3. Display hotkeys.	display hotkey [{ begin exclude include } <i>regular-expression</i>]	Optional. Available in any view. See Table 3 for hotkeys reserved by the system.

The hotkeys in Table 3 are defined by the device. If a hotkey is also defined by the terminal software that you are using to interact with the device, the definition of the terminal software takes effect.

Table 3 Hotkeys reserved by the system

Hotkey	Function
Ctrl+A	Moves the cursor to the beginning of the line.
Ctrl+B	Moves the cursor one character to the left.
Ctrl+C	Stops the current command.
Ctrl+D	Deletes the character at the cursor.
Ctrl+E	Moves the cursor to the end of the line.
Ctrl+F	Moves the cursor one character to the right.
Ctrl+H	Deletes the character to the left of the cursor.
Ctrl+K	Aborts the connection request.
Ctrl+N	Displays the next command in the command history buffer.
Ctrl+P	Displays the previous command in the command history buffer.
Ctrl+R	Redisplays the current line.
Ctrl+V	Pastes text from the clipboard.
Ctrl+W	Deletes the word to the left of the cursor.
Ctrl+X	Deletes all characters to the left of the cursor.
Ctrl+Y	Deletes all characters to the right of the cursor.
Ctrl+Z	Returns to user view.
Ctrl+]	Terminates an incoming connection or a redirect connection.
Esc+B	Moves the cursor back one word.
Esc+D	Deletes all characters from the cursor to the end of the word.
Esc+F	Moves the cursor forward one word.

Hotkey	Function
Esc+N	Moves the cursor down one line (available before you press Enter)
Esc+P	Moves the cursor up one line (available before you press Enter)
Esc+<	Moves the cursor to the beginning of the clipboard.
Esc+>	Moves the cursor to the ending of the clipboard.

Enabling redisplaying entered-but-not-submitted commands

After you enable redisplaying entered-but-not-submitted commands:

- If you entered nothing at the command-line prompt before the system outputs system information such as logs, the system does not display the command-line prompt after the output.
- If you entered some information (except Yes or No for confirmation), the system displays a line break and then display what you have entered after the output.

To enable redisplaying entered-but-not-submitted commands:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable redisplaying entered-but-not-submitted commands.	info-center synchronous	By default, the feature is disabled. For more information about this command, see <i>Network Management and Monitoring Command Reference</i> .

Understanding command-line error messages

If a command line fails the syntax check, the CLI displays error messages.

Table 4 Common command-line error messages

Error message	Cause
% Unrecognized command found at '^' position.	The keyword in the marked position is invalid.
% Incomplete command found at '^' position.	One or more required keywords or arguments are missing.
% Ambiguous command found at '^' position.	The entered character sequence matches more than one command.
Too many parameters	The entered character sequence contains excessive keywords or arguments.
% Wrong parameter found at '^' position.	The argument in the marked position is invalid.

Using the command history function

The system can automatically save successfully executed commands to the command history buffer for the current user interface. You can view them and execute them again, or set the maximum number of commands that can be saved in the command history buffer.

A command is saved to the command history buffer in the exact format as it was entered. For example, if you enter an incomplete command, the command saved in the command history buffer is also incomplete; if you enter a command by using a command keyword alias, the command saved in the command history buffer also uses the alias.

If you enter a command in the same format repeatedly in succession, the system buffers the command only once. If you enter a command repeatedly in different formats, the system buffers each command format. For example, **display cu** and **display current-configuration** are buffered as two entries but successive repetitions of **display cu** create only one entry in the buffer.

By default, the command history buffer can save up to 10 commands for each user. To set the capacity of the command history buffer for the current user interface, use the **history-command max-size** command.

Viewing history commands

You can use arrow keys to access history commands in Windows 200x and Windows XP Terminal or Telnet. In Windows 9x HyperTerminal, the arrow keys are invalid, and you must use **Ctrl+P** and **Ctrl+N** instead.

To view command history, use one of the following methods:

Task	Command
Display all commands in the command history buffer.	display history-command [{ begin exclude include } <i>regular-expression</i>]
Display the previous history command.	Up arrow key or Ctrl+P
Display the next history command.	Down arrow key or Ctrl+N

Setting the command history buffer size for user interfaces

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter user interface view.	user-interface { <i>first-num1</i> [<i>last-num1</i>] { aux vty } <i>first-num2</i> [<i>last-num2</i>] }	N/A
3. Set the maximum number of commands that can be saved in the command history buffer.	history-command max-size <i>size-value</i>	Optional. By default, the command history buffer can save up to 10 commands.

Controlling the CLI output

This section describes the CLI output control features that help you quickly identify the desired output.

Pausing between screens of output

If the output being displayed is more than will fit on one screen, the system automatically pauses after displaying a screen. By default, up to 24 lines can be displayed on a screen. To change the screen length, use the **screen-length** *screen-length* command. For more information about this command, see *Fundamentals Command Reference*. To control output, use keys in Table 5.

Table 5 Keys for controlling output

Keys	Function
Space	Displays the next screen.
Enter	Displays the next line.
Ctrl+C	Stops the display and cancels the command execution.
<PageUp>	Displays the previous page.
<PageDown>	Displays the next page.

To display all output at one time and refresh the screen continuously until the last screen is displayed:

Task	Command	Remarks
Disable pausing between screens of output for the current session.	screen-length disable	<p>The default for a session depends on the setting of the screen-length command in user interface view. The default of the screen-length command is pausing between screens of output and displaying up to 24 lines on a screen.</p> <p>This command is executed in user view, and takes effect only for the current session. When you relog in to the device, the default is restored.</p>

Filtering the output from a display command

You can use one of the following methods to filter the output from a **display** command:

- Specify the | { **begin** | **exclude** | **include** } *regular-expression* option at the end of the command.
- When the system pauses after displaying a screen of output, enter a forward slash (/), minus sign (-), or plus sign (+) plus a regular expression to filter subsequent output. The forward slash equals the keyword **begin**, the minus sign equals the keyword **exclude**, and the plus sign equals the keyword **include**.

The following definitions apply to the **begin**, **exclude**, and **include** keywords:

- **begin**—Displays the first line that matches the specified regular expression and all lines that follow.
- **exclude**—Displays all lines that do not match the specified regular expression.
- **include**—Displays all lines that match the specified regular expression.

A regular expression is a case-sensitive string of 1 to 256 characters that supports the special characters in Table 6.

Table 6 Special characters supported in a regular expression

Character	Meaning	Remarks
^string	Starting sign. Matches a line that starts with <i>string</i> .	For example, regular expression "^user" matches a line beginning with "user", not "Auser".
string\$	Ending sign. Matches a line that ends with <i>string</i> .	For example, regular expression "user\$" only matches a line ending with "user", not "userA".
.	Matches any single character, such as a single character, a special character, and a blank.	For example, ".s" matches both "as" and "bs".
*	Matches the preceding character or character group zero or multiple times.	For example, "zo*" matches "z" and "zoo"; "(zo)*" matches "zo" and "zozo".
+	Matches the preceding character or character group one or multiple times	For example, "zo+" matches "zo" and "zoo", but not "z".
	Matches the preceding or succeeding character string	For example, "def int" only matches a character string containing "def" or "int".
_	If it is at the beginning or the end of a regular expression, it equals ^ or \$. In other cases, it equals comma, space, round bracket, or curly bracket.	For example, "a_b" matches "a b" or "a(b"; "_ab" only matches a line starting with "ab"; "ab_" only matches a line ending with "ab".
-	It connects two values (the smaller one before it and the bigger one after it) to indicate a range together with [].	For example, "1-9" means 1 to 9 (inclusive); "a-h" means a to h (inclusive).
[]	Matches a single character contained within the brackets.	For example, [16A] matches a string containing any character among 1, 6, and A; [1-36A] matches a string containing any character among 1, 2, 3, 6, and A (- is a hyphen). "]" can be matched as a common character only when it is put at the beginning of characters within the brackets, for example []string]. There is no such limit on "[".
()	A character group. It is usually used with "+" or "*".	For example, (123A) means a character group "123A"; "408(12)+" matches 40812 or 408121212. But it does not match 408.
\index	Repeats the character string specified by the index. A character string refers to the string within () before \. <i>index</i> refers to the sequence number (starting from 1 from left to right) of the character group before \. If only one character group appears before \, <i>index</i> can only be 1; if n character groups appear before <i>index</i> , <i>index</i> can be any integer from 1 to n.	For example, (string)\1 repeats <i>string</i> , and a matching string must contain <i>stringstring</i> . (string1)(string2)\2 repeats <i>string2</i> , and a matching string must contain <i>string1string2string2</i> . (string1)(string2)\1\2 repeats <i>string1</i> and <i>string2</i> respectively, and a matching string must contain <i>string1string2string1string2</i> .

Character	Meaning	Remarks
[^]	Matches a single character not contained within the brackets.	For example, [^16A] means to match a string containing any character except 1, 6 or A, and the matching string can also contain 1, 6 or A, but cannot contain only these three characters. For example, [^16A] matches "abc" and "m16", but not 1, 16, or 16A.
\<string	Matches a character string starting with <i>string</i> .	For example, "\<do" matches word "domain" and string "doa".
string\>	Matches a character string ending with <i>string</i> .	For example, "do\>" matches word "undo" and string "abcdo".
\bcharacter2	Matches <i>character1character2</i> . <i>character1</i> can be any character except number, letter or underline, and \b equals [^A-Za-z0-9_].	For example, "\ba" matches "a" with "-" being <i>character1</i> , and "a" being <i>character2</i> , but it does not match "2a" or "ba".
\Bcharacter	Matches a string containing <i>character</i> , and no space is allowed before <i>character</i> .	For example, "\Bt" matches "t" in "install", but not "t" in "big top".
character1\w	Matches <i>character1character2</i> . <i>character2</i> must be a number, letter, or underline, and \w equals [A-Za-z0-9_].	For example, "v\w" matches "vlan" ("v" is <i>character1</i> and "l" is <i>character2</i>) and "service" ("i" is <i>character2</i>).
\W	Equals \b.	For example, "\Wa" matches "a", with "-" being <i>character1</i> , and "a" being <i>character2</i> , but does not match "2a" or "ba".
\	Escape character. If a special character listed in this table follows \, the specific meaning of the character is removed.	For example, "\\\" matches a string containing "\", "\\^" matches a string containing "^", and "\\b" matches a string containing "b".

The following are several regular expression examples:

Use | **begin user-interface** in the **display current-configuration** command to match the first line of output that contains **user-interface** to the last line of output.

```
<Sysname> display current-configuration | begin user-interface
user-interface aux 0
user-interface vty 0 15
  authentication-mode none
  user privilege level 3
#
return
```

Use | **exclude Direct** in the **display ip routing-table** command to filter out direct routes and display only the non-direct routes.

```
<Sysname> display ip routing-table | exclude Direct
Routing Tables: Public
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
1.1.1.0/24	Static	60	0	192.168.0.0	Vlan1

Use | **include Vlan** in the **display ip routing-table** command to filter in route entries that contain **Vlan**.

```
<Sysname> display ip routing-table | include Vlan
```

```
Routing Tables: Public
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
192.168.1.0/24	Direct	0	0	192.168.1.42	Vlan999

Configuring user privilege and command levels

To avoid unauthorized access, the device defines the user privilege levels and command levels in Table 7. User privilege levels correspond to command levels. A user who has been logged in with a specific privilege level can use only the commands at that level or lower levels.

All commands are categorized into four levels: visit, monitor, system, and manage, and are identified from low to high, respectively by 0 through 3.

Table 7 Command levels and user privilege levels

Level	Privilege	Default set of commands
0	Visit	Includes commands for network diagnosis and commands for accessing an external device. Configuration of commands at this level cannot survive a device restart. Upon device restart, the commands at this level are restored to the default settings. Commands at this level include ping , tracert , telnet and ssh2 .
1	Monitor	Includes commands for system maintenance and service fault diagnosis. Commands at this level are not saved after being configured. After the device is restarted, the commands at this level are restored to the default settings. Commands at this level include debugging , terminal , refresh , and send .
2	System	Includes service configuration commands, including routing configuration commands and commands for configuring services at different network levels. By default, commands at this level include all configuration commands except for those at manage level.
3	Manage	Includes commands that influence the basic operation of the system and commands for configuring system support modules. By default, commands at this level involve the configuration commands of file system, FTP, TFTP, Xmodem download, user management, level setting, and parameter settings within a system (which are not defined by any protocols or RFCs).

Configuring a user privilege level

If the authentication mode on a user interface is scheme, configure a user privilege level for users who access the interface by using the AAA module or directly on the user interface. For SSH users who use public-key authentication, the user privilege level configured directly on the user interface always takes effect. For other users, the user privilege level configured in the AAA module has priority over the one configured directly on the user interface.

If the authentication mode on a user interface is none or password, configure the user privilege level directly on the user interface.

For more information about user login authentication, see "Logging in to the CLI." For more information about AAA and SSH, see *Security Configuration Guide*.

Configuring a user privilege level for users by using the AAA module

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter user interface view.	user-interface { <i>first-num1</i> [<i>last-num1</i>] { aux vty } <i>first-num2</i> [<i>last-num2</i>] }	N/A
3. Specify the scheme authentication mode.	authentication-mode scheme	By default, the authentication mode for VTY users is password , and no authentication is needed for AUX users.
4. Return to system view.	quit	N/A
5. Configure the authentication mode for SSH users as password .	For more information, see <i>Security Configuration Guide</i> .	This task is required only for SSH users who are required to provide their usernames and passwords for authentication.
6. Configure the user privilege level by using the AAA module.	<ul style="list-style-type: none"> • To use local authentication: <ol style="list-style-type: none"> a. Use the local-user command to create a local user and enter local user view. b. Use the level keyword in the authorization-attribute command to configure the user privilege level. • To use remote authentication (RADIUS or HWTACACS): Configure the user privilege level on the authentication server 	<p>User either approach.</p> <p>For local authentication, if you do not configure the user privilege level, the user privilege level is 0.</p> <p>For remote authentication, if you do not configure the user privilege level, the user privilege level depends on the default configuration of the authentication server.</p> <p>For more information about the local-user and authorization-attribute commands, see <i>Security Command Reference</i>.</p>

For example:

Configure the device to use local authentication for Telnet users on VTY 1 and set the user privilege level to 3.

```
<Sysname> system-view
[Sysname] user-interface vty 1
[Sysname-ui-vty1] authentication-mode scheme
[Sysname-ui-vty1] quit
[Sysname] local-user test
[Sysname-luser-test] password simple 123
[Sysname-luser-test] service-type telnet
```

When users Telnet to the device through VTY 1, they must enter username **test** and password **12345678**. After passing the authentication, the users can only use level-0 commands of level 0.

Assign commands of levels 0 through 3 to the users.

[Sysname-user-test] authorization-attribute level 3

Configuring the user privilege level directly on a user interface

To configure the user privilege level directly on a user interface that uses the scheme authentication mode:

Step	Command	Remarks
1. Configure the authentication type for SSH users as publickey .	For more information, see <i>Security Configuration Guide</i> .	Required only for SSH users who use public-key authentication.
2. Enter system view.	system-view	N/A
3. Enter user interface view.	user-interface { <i>first-num1</i> [<i>last-num1</i>] vtty <i>first-num2</i> [<i>last-num2</i>] }	N/A
4. Enable the scheme authentication mode.	authentication-mode scheme	By default, the authentication mode for VTY users is password , and no authentication is needed for AUX users.
5. Configure the user privilege level.	user privilege level <i>level</i>	By default, the user privilege level for users logged in through the AUX user interface is 3, and that for users logged in through the other user interfaces is 0.

To configure the user privilege level directly on a user interface that uses the **none** or **password** authentication mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter user interface view.	user-interface { <i>first-num1</i> [<i>last-num1</i>] { aux vtty } <i>first-num2</i> [<i>last-num2</i>] }	N/A
3. Configure the authentication mode for any user who uses the current user interface to log in to the device.	authentication-mode { none password }	Optional. By default, the authentication mode for VTY user interfaces is password , and no authentication is needed for AUX users.
4. Configure the privilege level of users logged in through the current user interface.	user privilege level <i>level</i>	Optional. By default, the user privilege level for users logged in through the AUX user interface is 3, and that for users logged in through the other user interfaces is 0.

For example:

```
# Display the commands a Telnet user can use by default after login.
```

```
<Sysname> ?
```

```
User view commands:
```

```
display Display current system information
```

```

ping      Ping function
quit      Exit from current command view
rsh       Establish one RSH connection
ssh2      Establish a secure shell client connection
super     Set the current user priority level
telnet    Establish one TELNET connection
tftp      Open TFTP connection
tracert   Trace route function

```

Configure the device to perform no authentication for Telnet users, and to authorize authenticated Telnet users to use level-0 and level-1 commands. (Use no authentication mode only in a secure network environment.)

```

<Sysname> system-view
[Sysname] user-interface vty 0 15
[Sysname-ui-vty0-15] authentication-mode none
[Sysname-ui-vty0-15] user privilege level 1

```

Display the commands a Telnet user can use after login. Because the user privilege level is 1, a Telnet user can use more commands now.

```
<Sysname> ?
```

User view commands:

```

debugging      Enable system debugging functions
dialer         Dialer disconnect
display        Display current system information
ping           Ping function
quit           Exit from current command view
refresh        Do soft reset
reset          Reset operation
rsh            Establish one RSH connection
screen-length  Specify the lines displayed on one screen
send           Send information to other user terminal interface
ssh2           Establish a secure shell client connection
super          Set the current user priority level
telnet         Establish one TELNET connection
terminal       Set the terminal line characteristics
tftp           Open TFTP connection
tracert        Trace route function
undo           Cancel current setting

```

Configure the device to perform password authentication for Telnet users, and to authorize authenticated Telnet users to use the commands of privilege levels 0, 1, and 2.

```

<Sysname> system-view
[Sysname] user-interface vty 0 15
[Sysname-ui-vty0-15] authentication-mode password
[Sysname-ui-vty0-15] set authentication password simple 123
[Sysname-ui-vty0-15] user privilege level 2

```

After the configuration is complete, when users Telnet to the device, they must enter the password **12345678**. After passing authentication, they can use commands of levels 0, 1, and 2.

Switching the user privilege level

Users can switch to a different user privilege level without logging out and terminating the current connection. After the privilege level switching, users can continue to manage the device without relogging in, but the commands they can execute have changed. For example, with the user privilege level 3, a user can configure system parameters. After switching to user privilege level 0, the user can execute only basic commands like **ping** and **tracert** and use a few **display** commands. The switching operation is effective for the current login. After the user relogs in, the user privilege restores to the original level.

To avoid problems, HP recommends that administrators log in with a lower privilege level to view switch operating parameters, and switch to a higher level temporarily only when they must maintain the device.

When an administrator must leave for a while or ask someone else to manage the device temporarily, they can switch to a lower privilege level before they leave to restrict the operation by others.

Configuring the authentication parameters for user privilege level switching

A user can switch to a privilege level equal to or lower than the current one unconditionally and is not required to enter a password (if any).

For security, a user is required to enter a password (if any) to switch to a higher privilege level. The authentication falls into one of the following categories:

Keywords	Authentication mode	Description
local	Local password authentication only (local-only)	The device authenticates a user by using the privilege level switching password entered by the user. To use this mode, you must set the password for privilege level switching by using the super password command.
scheme	Remote AAA authentication through HWTACACS or RADIUS	The device sends the username and password for privilege level switching to the HWTACACS or RADIUS server for remote authentication. To use this mode, you must perform the following configuration tasks: <ul style="list-style-type: none">• Configure the required HWTACACS or RADIUS schemes and configure the ISP domain to use the schemes for users. For more information, see <i>Security Configuration Guide</i>.• Add user accounts and specify the user passwords on the HWTACACS or RADIUS server.
local scheme	Local password authentication first and then remote AAA authentication	The device authenticates a user by using the local password first, and if no password for privilege level switching is set, for the user logged in to the AUX user interface, the privilege level is switched directly; for VTY users, AAA authentication is performed.
scheme local	Remote AAA authentication first and then local password authentication	AAA authentication is performed first, and if the remote HWTACACS or RADIUS server does not respond or AAA configuration on the device is invalid, the local password authentication is performed.

To configure the authentication parameters for a user privilege level:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the authentication mode for user privilege level switching.	super authentication-mode { local scheme } *	Optional. By default, local-only authentication is used.
3. Configure the password for a user privilege level.	super password [level <i>user-level</i>] { cipher simple } <i>password</i>	Required for local authentication. By default, a privilege level has no password. If no user privilege level is specified when you configure the command, the user privilege level defaults to 3.

If local-only authentication is used, an AUX user interface user (a user logged in through the console port) can switch to a higher privilege level even if the privilege level has not been assigned a password.

Switching to a higher user privilege level

Before you switch to a higher user privilege level, obtain the required authentication data as described in Table 8.

The privilege level switching fails after three consecutive unsuccessful password attempts.

To switch the user privilege level, perform the following task in user view:

Task	Command	Remarks
Switch the user privilege level.	super [<i>level</i>]	When logging in to the device, a user has a user privilege level, which depends on user interface or authentication user level.

Table 8 Information required for user privilege level switching

User interface authentication mode	User privilege level switching authentication mode	Information required for the first authentication mode	Information required for the second authentication mode
none/password	local	Password configured on the device with the super password command for the privilege level	N/A
	local scheme	Password configured on the device with the super password command for the privilege level	Username and password configured on the AAA server for the privilege level
	scheme	Username and password for the privilege level	N/A
	scheme local	Username and password for the privilege level	Local user privilege level switching password

User interface authentication mode	User privilege level switching authentication mode	Information required for the first authentication mode	Information required for the second authentication mode
scheme	local	Password configured on the device with the super password command for the privilege level	N/A
	local scheme	Password configured on the device with the super password command for the privilege level	Password for privilege level switching (configured on the AAA server). The system uses the username used for logging in as the privilege level switching username.
	scheme	Password for privilege level switching (configured on the AAA server). The system uses the username used for logging in as the privilege level switching username.	N/A
	scheme local	Password for privilege level switching (configured on the AAA server). The system uses the username used for logging in as the privilege level switching username.	Password configured on the device with the super password command for the privilege level

Changing the level of a command

Every command in a view has a default command level. The default command level scheme is sufficient for the security and ease of maintenance requirements of most networks. If you want to change the level of a command, make sure the change does not result in any security risk or maintenance problem.

To change the level of a command:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Change the level of a command in a specific view.	command-privilege level level view view command	See Table 7 for the default settings.

Saving the running configuration

You can use the **save** command in any view to save all submitted and executed commands into the configuration file. Commands saved in the configuration file can survive a reboot. The **save** command does not take effect on one-time commands, including **display** and **reset** commands. One-time commands are never saved.

Displaying and maintaining CLI

Task	Command	Remarks
Display the command keyword alias configuration.	display command-alias [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display data in the clipboard.	display clipboard [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Login overview

This chapter describes the available CLI login methods and their configuration procedures.

Login methods at a glance

You can access the device only through the console port at the first login, locally or remotely by using a pair of modems. After you log in to the device, you can configure other login methods, including Telnet and SSH, for remote access.

Table 9 Login methods

Login method	Default setting and configuration requirements
Logging in to the CLI:	
<ul style="list-style-type: none">Logging in through the console port for the first time	By default, login through the console port is enabled, no username or password is required, and the user privilege level is 3.
<ul style="list-style-type: none">Logging in through Telnet	By default, Telnet service is enabled. To use Telnet service, complete the following configuration tasks: <ul style="list-style-type: none">Enable the Telnet server.Assign an IP address to a Layer 3 interface and make sure the interface and the Telnet client can reach each other.Configure the authentication mode for VTY login users (password by default).Configure the user privilege level of VTY login users (0 by default).
<ul style="list-style-type: none">Logging in through SSH	By default, SSH service is disabled. To use SSH service, complete the following configuration tasks: <ul style="list-style-type: none">Enable the SSH function and configure SSH attributes.Assign an IP address to a Layer 3 interface and make sure the interface and the SSH client can reach each other.Enable scheme authentication for VTY login users.Configure the user privilege level of VTY login users (0 by default).
<ul style="list-style-type: none">Modem dial-in through the console port	By default, modem dial-in is enabled, no username or password is required, and the user privilege level is 3.
Logging in to the Web interface	
	By default, Web login is disabled. To use Web service, complete the following configuration tasks: <ul style="list-style-type: none">Assign an IP address to a Layer 3 interface.Configure a local user account for Web login, and assign a user privilege level and the Web service to the account.
Logging in through NMS	
	By default, SNMP login is disabled. To use SNMP service, complete the following configuration tasks: <ul style="list-style-type: none">Assign an IP address to a Layer 3 interface, and make sure the interface and the NMS can reach each other.Configure SNMP basic parameters.

User interfaces

The device uses user interfaces (also called "lines") to control CLI logins and monitor CLI sessions. You can configure access control settings, including authentication, user privilege, and login redirect on user interfaces. After users are logged in, their actions must be compliant with the settings on the user interfaces assigned to them.

Users are assigned different user interfaces, depending on their login methods, as shown in Table 10.

Table 10 CLI login method and user interface matrix

User interface	Login method
AUX user interface	Console port (EIA/TIA-232 DCE), locally or remotely by using modems
Virtual type terminal (VTY) user interface	Telnet or SSH

User interface assignment

The device automatically assigns user interfaces to CLI login users, depending on their login methods. Each user interface can be assigned to only one user at a time. If no user interface is available, a CLI login attempt will be rejected.

The device provides one AUX user interfaces and 16 VTY user interfaces. For a CLI login, the device always picks the lowest numbered user interface from the idle user interfaces available for the type of login.

For example, four VTY user interfaces (0 to 3) are configured, of which VTY 0 and VTY 3 are idle. When a user Telnets to the device, the device assigns VTY 0 to the user and uses the settings on VTY 0 to authenticate and manage the user.

User interface numbering

User interfaces are numbered by using absolute numbering or relative numbering.

Absolute numbering

An absolute number uniquely identifies a user interface among all user interfaces. The user interfaces are numbered starting from 0 and incrementing by 1 and in the sequence of AUX and VTY user interfaces. You can use the **display user-interface** command without any parameters to view supported user interfaces and their absolute numbers.

Relative numbering

A relative number uniquely identifies a user interface among all user interfaces that are the same type. The number format is *user interface type + number*. All the types of user interfaces are numbered starting from 0 and incrementing by 1. For example, the first AUX user interface is AUX 0.

A relative number uniquely identifies a user interface among all user interfaces that are the same type. The number format is *user interface type + number*. The user interfaces are numbered starting from 0 and incrementing by 1. For example, the first AUX user interface is AUX 0, and the second AUX user interface is AUX 1.

Logging in to the CLI

By default, the first time you access the CLI you must log in through the console port, locally or remotely by using a pair of modems. At the CLI, you can configure Telnet or SSH for remote access.

Logging in through the console port for the first time

To log in through the console port, make sure the console terminal has a terminal emulation program (for example, HyperTerminal in Windows XP). In addition, the port settings of the terminal emulation program must be the same as the default settings of the console port in Table 11.

Table 11 Default console port properties

Parameter	Default
Bits per second	9600 bps
Flow control	None
Parity	None
Stop bits	1
Data bits	8

To log in through the console port from a console terminal (for example, a PC):

1. Plug the DB-9 female connector of the console cable to the serial port of the PC.
2. Plug the RJ-45 connector of the console cable to the console port of the device.

NOTE:

- Identify the mark on the console port and make sure you are connecting to the correct port.
- The serial ports on PCs do not support hot swapping. If the switch has been powered on, always connect the console cable to the PC before connecting to the switch, and when you disconnect the cable, first disconnect it from the switch.

Figure 4 Connecting a terminal to the console port

3. If the PC is off, turn on the PC.

Launch the terminal emulation program and configure the communication properties on the PC. Figure 5 through Figure 7 show the configuration procedure on Windows XP HyperTerminal. Make sure the port settings are the same as listed in Table 11.

NOTE:

On Windows Server 2003, add the HyperTerminal program first, and then log in to and manage the device as described in this document. On Windows Server 2008, Windows 7, Windows Vista, or some other operating system, obtain a third-party terminal control program first, and then follow the user guide or online help to log in to the device.

Figure 5 Connection description

Figure 6 Specifying the serial port used to establish the connection

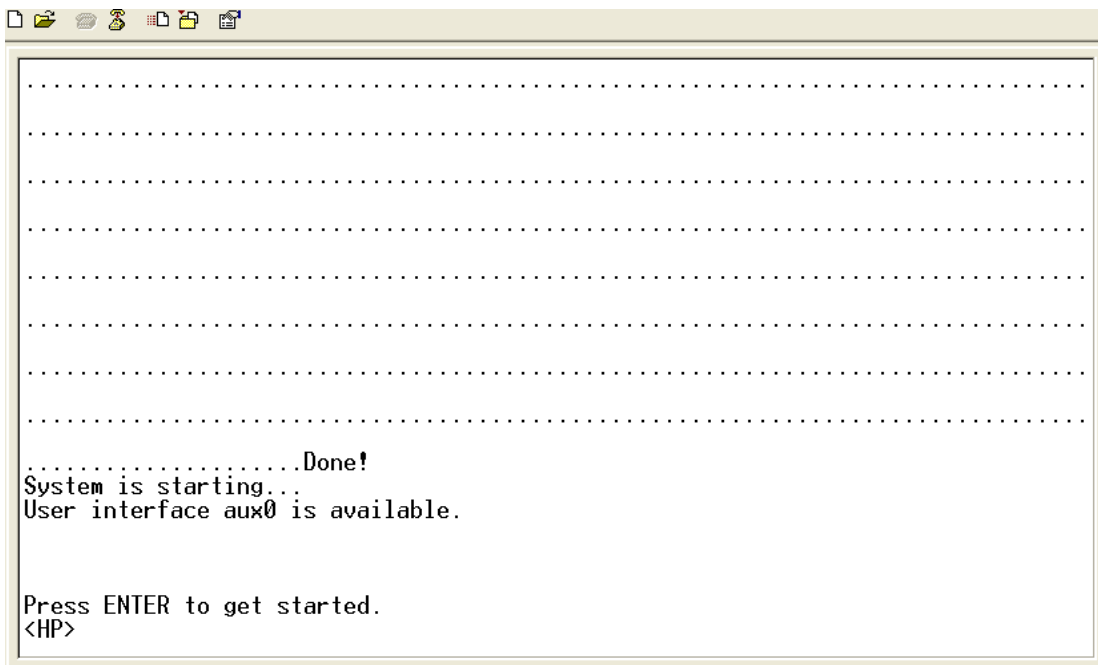

Figure 7 Setting the properties of the serial port

4. Power on the device and press **Enter** at the prompt.

Figure 8 CLI

5. At the default user view prompt <HP>, enter commands to configure the device or view the running status of the device. To get help, enter ?.

Configuring console login control settings

The following authentication modes are available for controlling console logins:

- **None**—Requires no authentication. This mode is insecure.
- **Password**—Requires password authentication. If your password was lost, see *HP Series Ethernet Switches Login Password Recovery Manual* for password recovery.
- **Scheme**—Uses the AAA module to provide local or remote console login authentication. You must provide a username and password for accessing the CLI. If the password configured in the local user database was lost, see *HP Series Ethernet Switches Login Password Recovery Manual* for password recovery. If the username or password configured on a remote server was lost, contact the server administrator for help.

By default, console login does not require authentication. Any user can log in through the console port without authentication and have user privilege level 3. To improve device security, configure the password or scheme authentication mode immediately after you log in to the device for the first time.

Table 12 Configuration required for different console login authentication modes

Authentication mode	Configuration tasks	Reference
None	Set the authentication mode to none for the AUX user interface.	"Configuring none authentication for console login"
Password	Enable password authentication on the AUX user interface. Set a password.	"Configuring password authentication for console login"
Scheme	Enable scheme authentication on the AUX user interface. Configure local or remote authentication settings. To configure local authentication: <ol style="list-style-type: none"> 3. Configure a local user and specify the password. 4. Configure the device to use local authentication. To configure remote authentication: <ol style="list-style-type: none"> 5. Configure the RADIUS or HWTACACS scheme on the device. Configure the username and password on the AAA server. 6. Configure the device to use the scheme for user authentication. 	"Configuring scheme authentication for console login"

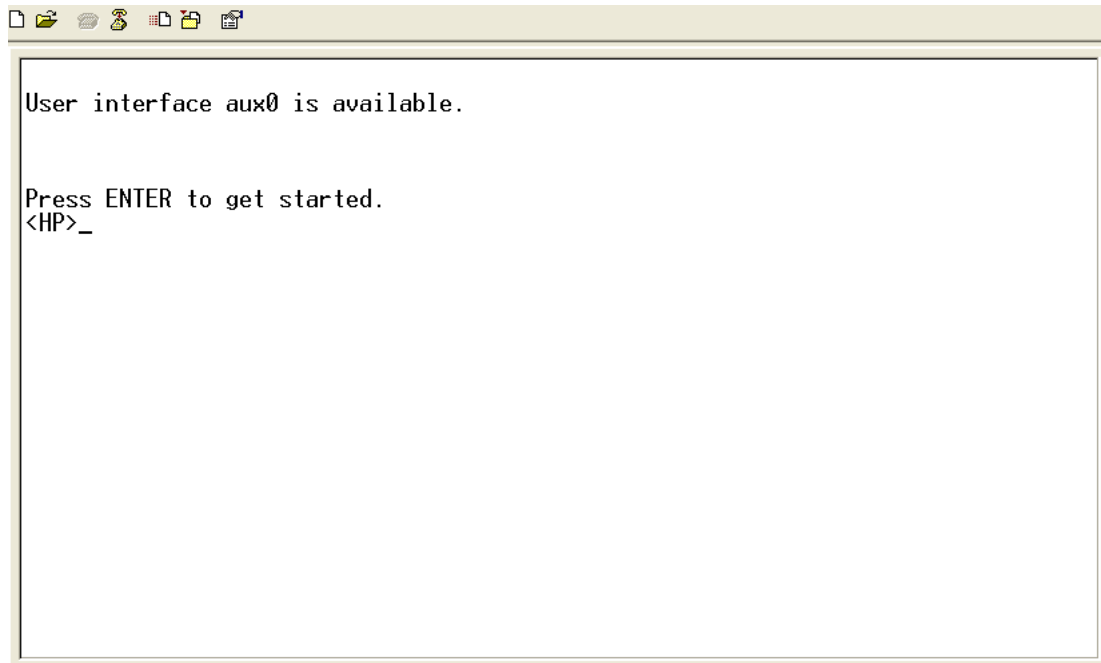

Configuring none authentication for console login

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter AUX user interface view.	user-interface aux <i>first-number</i> [<i>last-number</i>]	N/A
3. Enable the none authentication mode.	authentication-mode none	By default, you can log in to the device through the console port without authentication and have user privilege level 3.

Step	Command	Remarks
4.	Configure common settings for console login.	See "Configuring common console login settings (optional)." Optional.

The next time you attempt to log in through the console port, you do not need to provide any username or password, as shown in [Figure 9](#).

Figure 9 Accessing the CLI through the console port without authentication

Configuring password authentication for console login

Step	Command	Remarks
1.	Enter system view.	system-view N/A
2.	Enter AUX user interface view.	user-interface aux <i>first-number</i> [<i>last-number</i>] N/A
3.	Enable password authentication.	authentication-mode password By default, you can log in to the device through the console port without authentication and have user privilege level 3 after login.
4.	Set a password.	set authentication password { cipher simple } <i>password</i> By default, no password is set.
5.	Configure common settings for console login.	See "Configuring common console login settings (optional)." Optional.

The next time you attempt to log in through the console port, you must provide the configured login password, as shown in [Figure 10](#).

Figure 10 Password authentication interface for console login

Configuring scheme authentication for console login

Follow these guidelines when you configure scheme authentication for console login:

- To make the command authorization or command accounting function take effect, apply an HWTACACS scheme to the intended ISP domain. This scheme must specify the IP address of the authorization server and other authorization parameters.
- If the local authentication scheme is used, use the **authorization-attribute level** *level* command in local user view to set the user privilege level on the device.
- If a RADIUS or HWTACACS authentication scheme is used, set the user privilege level on the RADIUS or HWTACACS server.

To configure scheme authentication for console login:

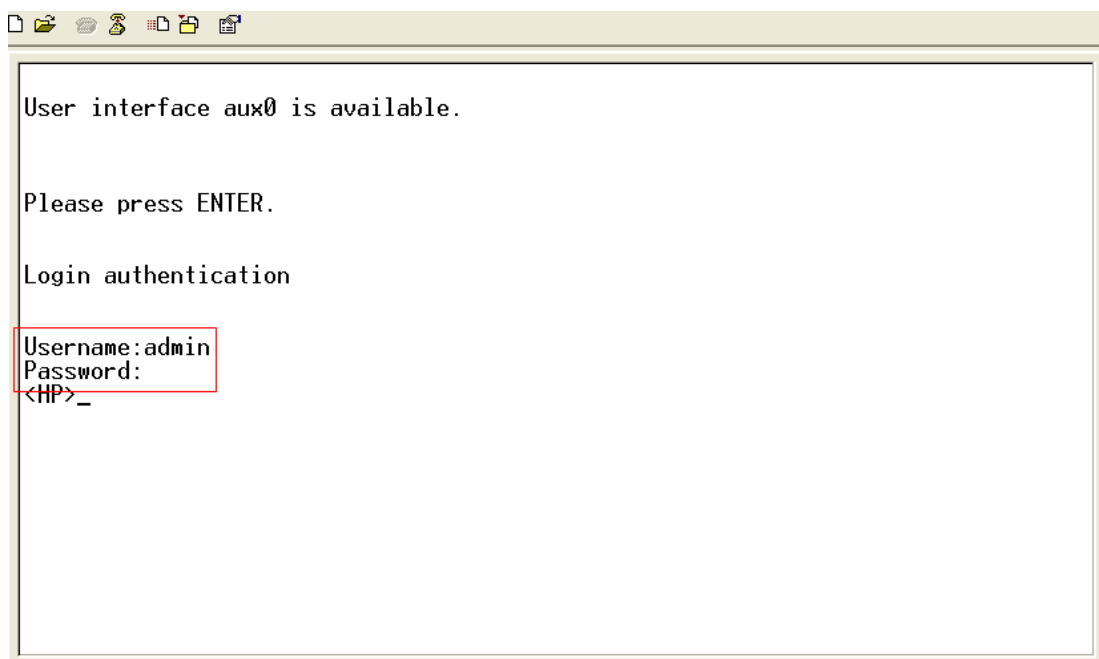

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter AUX user interface view.	user-interface aux <i>first-number</i> [<i>last-number</i>]	N/A
3. Enable scheme authentication.	authentication-mode scheme	Whether local, RADIUS, or HWTACACS authentication is adopted depends on the configured AAA scheme. By default, console log users are not authenticated.

Step	Command	Remarks
4. Enable command authorization.	command authorization	Optional. By default, command authorization is disabled. The commands available for a user only depend on the user privilege level. If command authorization is enabled, a command is available only if the user has the commensurate user privilege level and is authorized to use the command by the AAA scheme.
5. Enable command accounting.	command accounting	Optional. By default, command accounting is disabled. The accounting server does not record the commands executed by users. Command accounting allows the HWTACACS server to record all commands executed by users, regardless of command execution results. This function helps control and monitor user behaviors on the device. If command accounting is enabled and command authorization is not enabled, every executed command is recorded on the HWTACACS server. If both command accounting and command authorization are enabled, only the authorized and executed commands are recorded on the HWTACACS server.
6. Exit to system view.	quit	N/A
7. Apply an AAA authentication scheme to the intended domain.	<p>8. Enter ISP domain view: domain <i>domain-name</i></p> <p>9. Apply an AAA scheme to the domain: authentication default { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] }</p> <p>10. Exit to system view: quit</p>	Optional. By default, local authentication is used. For local authentication, configure local user accounts. For RADIUS or HWTACACS authentication, configure the RADIUS or HWTACACS scheme on the device and configure authentication settings (including the username and password) on the server. For more information about AAA configuration, see <i>Security Configuration Guide</i> .
11. Create a local user and enter local user view.	local-user <i>user-name</i>	By default, no local user exists.

Step	Command	Remarks
12. Set an authentication password for the local user.	password { cipher simple } <i>password</i>	By default, no password is set.
13. Specifies a command level of the local user.	authorization-attribute level <i>level</i>	Optional. By default, the command level is 0.
14. Specify terminal service for the local user.	service-type terminal	By default, no service type is specified.
15. Configure common settings for console login.	See " Configuring common console login settings (optional) ."	Optional.

The next time you attempt to log in through the console port, you must provide the configured login username and password, as shown in [Figure 11](#).

Figure 11 Scheme authentication interface for console login

Configuring common console login settings (optional)

Some common settings configured for an AUX user interface take effect immediately and can interrupt the console login session. To save you the trouble of repeated re-logins, use a login method different from console login to log in to the device before you change console login settings.

After the configuration is complete, change the terminal settings on the configuration terminal and make sure they are the same as the settings on the device.

To configure common settings for an AUX user interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable copyright information display.	copyright-info enable	By default, copyright information display is enabled.

Step	Command	Remarks
3. Enter AUX user interface view.	user-interface aux <i>first-number</i> [<i>last-number</i>]	N/A
4. Configure the baud rate.	speed <i>speed-value</i>	By default, the transmission rate is 9600 bps.
5. Configure the parity check mode.	parity { even none odd }	The default setting is none , namely, no parity check.
6. Configure the number of stop bits.	stopbits { 1 1.5 2 }	The default is 1. Stop bits indicate the end of a character. The more the stop bits, the slower the transmission.
7. Configure the number of data bits in a character.	databits { 7 8 }	By default, the number of data bits in each character is 8. The setting depends on the character coding type. For example, you can set it to 7 if standard ASCII characters are to be sent, and set it to 8 if extended ASCII characters are to be sent.
8. Define a shortcut key for enabling a terminal session.	activation-key <i>character</i>	By default, press Enter to enable a terminal session.
9. Define a shortcut key for terminating tasks.	escape-key { default <i>character</i> }	By default, press Ctrl+C to terminate a task.
10. Configure the flow control mode.	flow-control { hardware none software }	By default, the flow control mode is none . The device supports only the none mode.
11. Specify the terminal display.	terminal type { ansi vt100 }	By default, the terminal display type is ANSI. The device supports two terminal display types: ANSI and VT100. HP recommends setting the display type to VT100 for both the device and the client. If the device and the client use different display types or both use the ANSI display type, when the total number of characters of a command line exceeds 80, the screen display on the terminal might be abnormal. For example, the cursor might be displayed at a wrong place.
12. Configure the user privilege level for login users.	user privilege level <i>level</i>	By default, the default command level is 3 for AUX user interfaces.
13. Set the maximum number of lines to be displayed on a screen.	screen-length <i>screen-length</i>	By default, a screen displays 24 lines at most. A value of 0 disables pausing between screens of output.

Step	Command	Remarks
14. Set the size of command history buffer.	history-command max-size <i>value</i>	By default, the buffer saves 10 history commands at most.
15. Set the idle-timeout timer.	idle-timeout <i>minutes</i> [<i>seconds</i>]	The default idle-timeout is 10 minutes. The system automatically terminates the user's connection if there is no information interaction between the device and the user within the idle-timeout time. Setting idle-timeout to 0 disables the timer.

Logging in through Telnet

You can Telnet to the device through a VTY user interface for remote management, or use the device as a Telnet client to Telnet to other devices, as shown in [Figure 12](#).

Figure 12 Telnet login

Table 13 shows the Telnet server and client configuration required for a successful Telnet login.

Table 13 Telnet server and Telnet client configuration requirements

Object	Requirements
Telnet server	Enable Telnet server Assign an IP address to a Layer 3 interface, and make sure the Telnet server and client can reach each other. Configure the authentication mode and other settings.
Telnet client	Run the Telnet client program. Obtain the IP address of the Layer 3 interface on the server.

To control Telnet access to the device working as a Telnet server, configure authentication and user privilege for Telnet users.

By default, password authentication applies to Telnet login, but no login password is configured. To allow Telnet access to the device after you enable the Telnet server, you must configure a password.

The following are authentication modes available for controlling Telnet logins:

- **None**—Requires no authentication and is insecure.
- **Password**—Requires a password for accessing the CLI. If your password was lost, log in to the device through the console port to modify the password.
- **Scheme**—Uses the AAA module to provide local or remote authentication. You must provide a username and password for accessing the CLI. If the password configured in the local user database was lost, see *HP Series Ethernet Switches Login Password Recovery Manual* for password

recovery. If the username or password configured on a remote server was lost, contact the server administrator for help.

Table 14 Configuration required for different Telnet login authentication modes

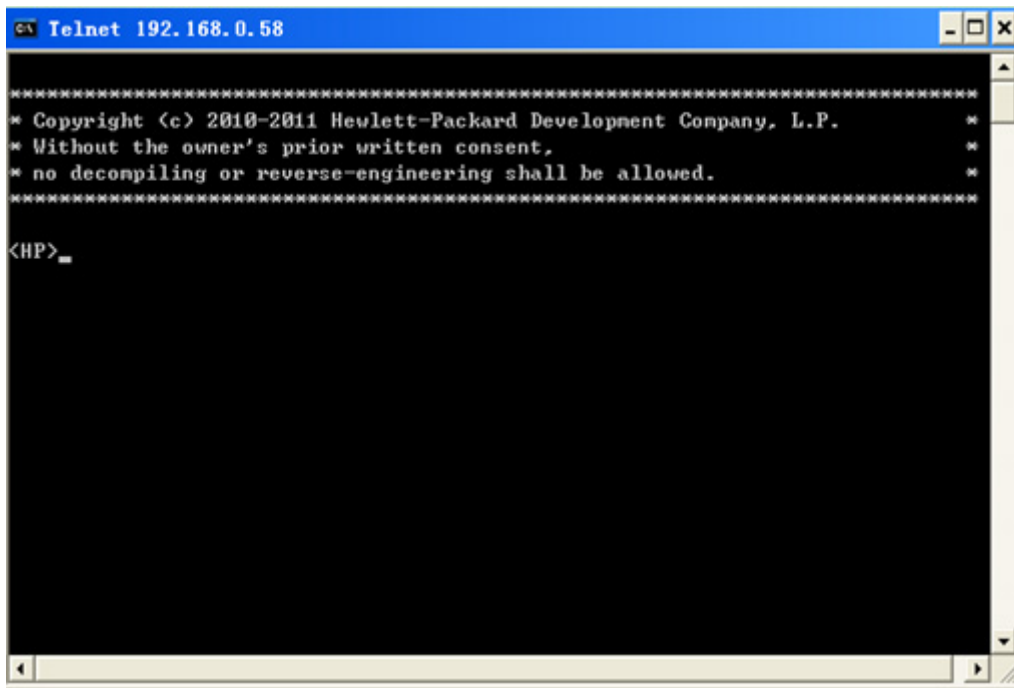

Authentication mode	Configuration tasks	Reference
None	Set the authentication mode to none for the VTY user interface.	"Configuring none authentication for Telnet login"
Password	Enable password authentication on the VTY user interface. Set a password.	"Configuring password authentication for Telnet login"
AAA	Enable scheme authentication on the VTY user interface. Configure local or remote authentication settings. To configure local authentication: <ol style="list-style-type: none"> 1. Configure a local user and specify the password. 2. Configure the device to use local authentication. To configure remote authentication: <ol style="list-style-type: none"> 3. Configure the RADIUS or HWTACACS scheme on the device. 4. Configure the username and password on the AAA server. 5. Configure the device to use the scheme for user authentication. 	"Configuring scheme authentication for Telnet login"

Configuring none authentication for Telnet login

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable Telnet server.	telnet server enable	By default, the Telnet server is disabled.
3. Enter one or multiple VTY user interface views.	user-interface vty <i>first-number</i> [<i>last-number</i>]	N/A
4. Enable the none authentication mode.	authentication-mode none	By default, authentication mode for VTY user interfaces is password .
5. Configure the command level for login users on the current user interfaces.	user privilege level <i>level</i>	By default, the default command level is 0 for VTY user interfaces.
6. Configure common settings for the VTY user interfaces.	See "Configuring common settings for VTY user interfaces (optional)."	Optional.

The next time you attempt to Telnet to the device, you do not need to provide any username or password, as shown in [Figure 13](#). If the maximum number of login users has been reached, your login attempt fails and the message "All user interfaces are used, please try later!" appears.

Figure 13 Telnetting to the device without authentication

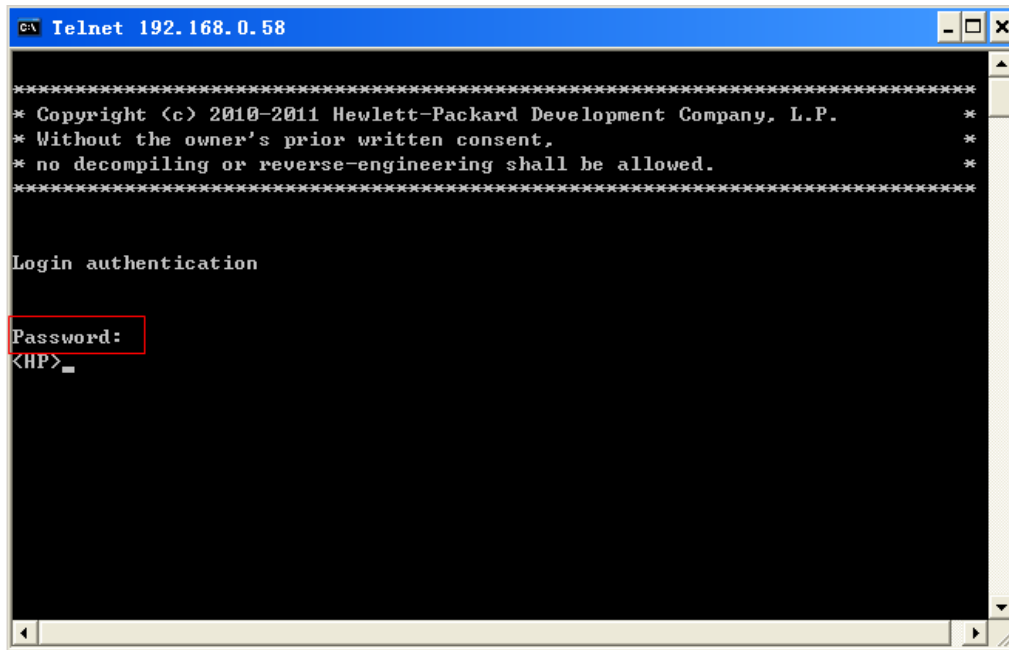

Configuring password authentication for Telnet login

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable Telnet.	telnet server enable	By default, the Telnet service is disabled.
3. Enter one or multiple VTY user interface views.	user-interface vty <i>first-number</i> [<i>last-number</i>]	N/A
4. Enable password authentication.	authentication-mode password	By default, password authentication is enabled for VTY user interfaces.
5. Set a password.	set authentication password { cipher simple } <i>password</i>	By default, no password is set.
6. Configure the user privilege level for login users.	user privilege level <i>level</i>	The default level is 0.
7. Configure common settings for VTY user interfaces.	See " Configuring common settings for VTY user interfaces (optional) ."	Optional.

The next time you attempt to Telnet to the device, you must provide the configured login password, as shown in [Figure 14](#). If the maximum number of login users has been reached, your login attempt fails and the message "All user interfaces are used, please try later!" appears.

Figure 14 Password authentication interface for Telnet login

Configuring scheme authentication for Telnet login

Follow these guidelines when you configure scheme authentication for Telnet login:

- To make the command authorization or command accounting function take effect, apply an HWTACACS scheme to the intended ISP domain. This scheme must specify the IP address of the authorization server and other authorization parameters.
- If the local authentication scheme is used, use the **authorization-attribute level** *level* command in local user view to set the user privilege level on the device.
- If a RADIUS or HWTACACS authentication scheme is used, set the user privilege level on the RADIUS or HWTACACS server.

To configure scheme authentication for Telnet login:

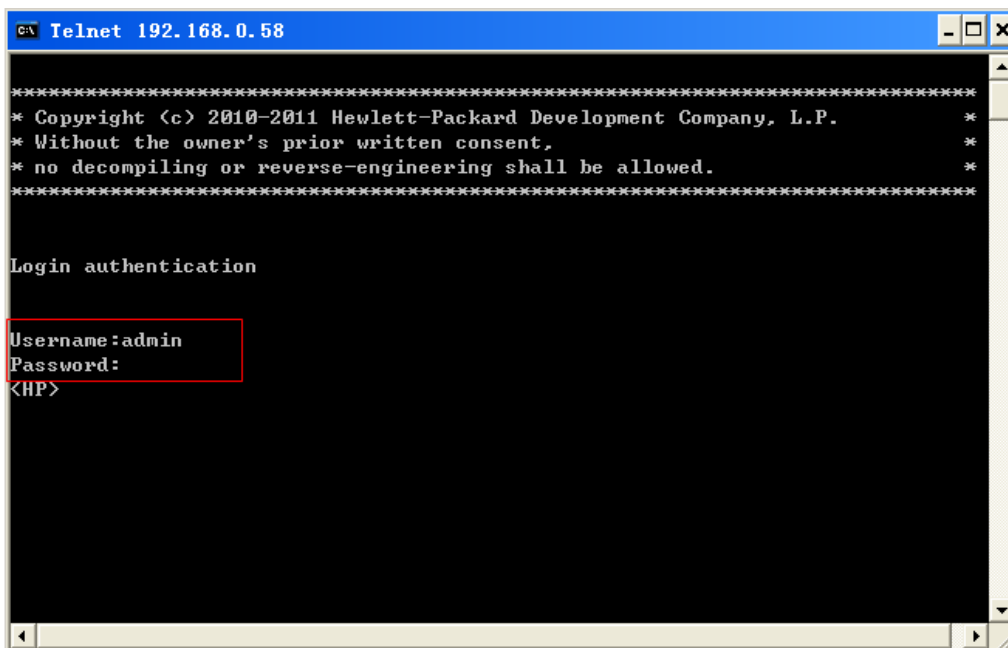

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable Telnet.	telnet server enable	By default, the Telnet service is disabled.
3. Enter one or multiple VTY user interface views.	user-interface vty <i>first-number</i> [<i>last-number</i>]	N/A
4. Enable scheme authentication.	authentication-mode scheme	Whether local, RADIUS, or HWTACACS authentication is adopted depends on the configured AAA scheme. By default, local authentication is adopted.

Step	Command	Remarks
5. Enable command authorization.	command authorization	<p>Optional.</p> <p>By default, command authorization is disabled. The commands available for a user only depend on the user privilege level.</p> <p>If command authorization is enabled, a command is available only if the user has the commensurate user privilege level and is authorized to use the command by the AAA scheme.</p>
6. Enable command accounting.	command accounting	<p>Optional.</p> <p>By default, command accounting is disabled. The accounting server does not record the commands executed by users.</p> <p>Command accounting allows the HWTACACS server to record all executed commands that are supported by the device, regardless of the command execution result. This function helps control and monitor user behaviors on the device. If command accounting is enabled and command authorization is not enabled, every executed command is recorded on the HWTACACS server. If both command accounting and command authorization are enabled, only the authorized and executed commands are recorded on the HWTACACS server.</p>
7. Exit to system view.	quit	N/A
8. Apply an AAA authentication scheme to the intended domain.	<ol style="list-style-type: none"> 1. Enter ISP domain view: domain <i>domain-name</i> 2. Apply an AAA scheme to the domain: authentication default { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] } 3. Exit to system view: quit 	<p>Optional.</p> <p>By default, local authentication is used.</p> <p>For local authentication, configure local user accounts.</p> <p>For RADIUS or HWTACACS authentication, configure the RADIUS or HWTACACS scheme on the device and configure authentication settings (including the username and password) on the server.</p> <p>For more information about AAA configuration, see <i>Security Configuration Guide</i>.</p>

Step	Command	Remarks
9. Create a local user and enter local user view.	local-user <i>user-name</i>	By default, no local user exists.
10. Set a password.	password { cipher simple } <i>password</i>	By default, no password is set.
11. Specify the command level of the local user.	authorization-attribute level <i>level</i>	Optional. By default, the command level is 0.
12. Specify Telnet service for the local user.	service-type telnet	By default, no service type is specified.
13. Exit to system view.	quit	N/A
14. Configure common settings for VTY user interfaces.	See " Configuring common settings for VTY user interfaces (optional) ."	Optional.

The next time you attempt to Telnet to the CLI, you must provide the configured login username and password, as shown in [Figure 15](#). If you are required to pass a second authentication, you must also provide the correct password to access the CLI. If the maximum number of login users has been reached, your login attempt fails and the message "All user interfaces are used, please try later!" appears.

Figure 15 Scheme authentication interface for Telnet login

Configuring common settings for VTY user interfaces (optional)

You might be unable to access the CLI through a VTY user interface after configuring the **auto-execute command** command on it. Before you configure the command and save the configuration, make sure you can access the CLI through a different user interface.

To configure common settings for VTY user interfaces:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable copyright information display.	copyright-info enable	By default, copyright information display is enabled.
3. Enter one or multiple VTY user interface views.	user-interface vty <i>first-number</i> [<i>last-number</i>]	N/A
4. Enable the terminal service.	shell	Optional. By default, terminal service is enabled.
5. Enable the user interfaces to support Telnet, SSH, or both of them.	protocol inbound { all ssh telnet }	Optional. By default, both Telnet and SSH are supported. The configuration takes effect the next time you log in.
6. Define a shortcut key for terminating tasks.	escape-key { default <i>character</i> }	Optional. By default, press Ctrl+C to terminate a task.
7. Configure the type of terminal display.	terminal type { ansi vt100 }	Optional. By default, the terminal display type is ANSI.
8. Set the maximum number of lines to be displayed on a screen.	screen-length <i>screen-length</i>	Optional. By default, a screen displays 24 lines. A value of 0 disables the function.
9. Set the size of command history buffer.	history-command max-size <i>value</i>	Optional. By default, the buffer saves 10 history commands.
10. Set the idle-timeout timer.	idle-timeout <i>minutes</i> [<i>seconds</i>]	Optional. The default idle-timeout is 10 minutes for all user interfaces. The system automatically terminates the user's connection if there is no information interaction between the device and the user within the timeout time. Setting idle-timeout to 0 disables the timer.

Step	Command	Remarks
11. Specify a command to be automatically executed when a user logs in to the user interfaces.	auto-execute command <i>command</i>	Optional. By default, no automatically executed command is specified. The command auto-execute function is typically used for redirecting a Telnet user to a specific host. After executing the specified command and performing the incurred task, the system automatically disconnect the Telnet session.

Using the device to log in to a Telnet server

You can use the device as a Telnet client to log in to a Telnet server. If the server is located in a different subnet than the device, make sure the two devices have routes to reach each other.

Figure 16 Telnetting from the device to a Telnet server

To use the device to log in to a Telnet server:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify a source IPv4 address or source interface for outgoing Telnet packets.	telnet client source { interface <i>interface-type interface-number</i> ip <i>ip-address</i> }	Optional. By default, no source IPv4 address or source interface is specified. The IP address of the outbound interface is used as the source IPv4 address.
3. Exit to user view.	quit	N/A
4. Use the device to log in to a Telnet server.	<ul style="list-style-type: none"> Log in to an IPv4 Telnet server: telnet <i>remote-host</i> [<i>service-port</i>] [[vpn-instance <i>vpn-instance-name</i>] [source { interface <i>interface-type</i> <i>interface-number</i> ip <i>ip-address</i> }]] Log in to an IPv6 Telnet server: telnet ipv6 <i>remote-host</i> [-i <i>interface-type</i> <i>interface-number</i>] [<i>port-number</i>] [vpn-instance <i>vpn-instance-name</i>] 	Use either command. The vpn-instance <i>vpn-instance-name</i> option is only available on the HP 5500-EI switches.

Setting the DSCP value for IP to use for outgoing Telnet packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for IP to use for outgoing Telnet packets.	<ul style="list-style-type: none"> On a Telnet client running IPv4: telnet client dscp dscp-value On a Telnet client running IPv6: telnet client ipv6 dscp dscp-value On a Telnet server running IPv4: telnet server dscp dscp-value On a Telnet server running IPv6: telnet server ipv6 dscp dscp-value 	<p>The default is as follows:</p> <ul style="list-style-type: none"> 16 for a Telnet client running IPv4. 0 for a Telnet client running IPv6. 48 for a Telnet server running IPv4. 0 for a Telnet server running IPv6.

Logging in through SSH

SSH offers a secure approach to remote login. By providing encryption and strong authentication, it protects devices against attacks such as IP spoofing and plaintext password interception. You can log in to the device working as an SSH server for remote management, as shown in Figure 17. You can also use the device as an SSH client to log in to an SSH server.

Figure 17 SSH login diagram

Table 15 shows the SSH server and client configuration required for a successful SSH login.

Table 15 SSH server and client requirements

Device role	Requirements
SSH server	<p>Assign an IP address to a Layer 3 interface, and make sure the interface and the client can reach each other.</p> <p>Configure the authentication mode and other settings.</p>
SSH client	<p>If the host operates as an SSH client, run the SSH client program on the host.</p> <p>Obtain the IP address of the Layer 3 interface on the server.</p>

To control SSH access to the device working as an SSH server, configure authentication and user privilege level for SSH users.

By default, password authentication is adopted for SSH login, but no login password is configured. To allow SSH access to the device after you enable the SSH server, you must configure a password.

Configuring the SSH server on the device

Follow these guidelines when you configure the SSH server:

- To make the command authorization or command accounting function take effect, apply an HWTACACS scheme to the intended ISP domain. This scheme must specify the IP address of the authorization server and other authorization parameters.
- If the local authentication scheme is used, use the **authorization-attribute level** *level* command in local user view to set the user privilege level on the device.
- If a RADIUS or HWTACACS authentication scheme is used, set the user privilege level on the RADIUS or HWTACACS server.

The SSH client authentication method is password in this configuration procedure. For more information about SSH and publickey authentication, see *Security Configuration Guide*.

To configure the SSH server on the device:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create local key pairs.	public-key local create { dsa rsa }	By default, no local key pairs are created.
3. Enable SSH server.	ssh server enable	By default, SSH server is disabled.
4. Enter one or more VTY user interface views.	user-interface vty <i>first-number</i> [<i>last-number</i>]	N/A
5. Enable scheme authentication.	authentication-mode scheme	By default, password authentication is enabled on VTY user interfaces.
6. Enable the user interfaces to support Telnet, SSH, or both of them.	protocol inbound { all ssh Telnet }	Optional. By default, both Telnet and SSH are supported.
7. Enable command authorization.	command authorization	Optional. By default, command authorization is disabled. The commands available for a user only depend on the user privilege level. If command authorization is enabled, a command is available only if the user has the commensurate user privilege level and is authorized to use the command by the AAA scheme.

Step	Command	Remarks
8. Enable command accounting.	command accounting	Optional. By default, command accounting is disabled. The accounting server does not record the commands executed by users. Command accounting allows the HWTACACS server to record all executed commands that are supported by the device, regardless of the command execution result. This function helps control and monitor user behaviors on the device. If command accounting is enabled and command authorization is not enabled, every executed command is recorded on the HWTACACS server. If both command accounting and command authorization are enabled, only the authorized and executed commands are recorded on the HWTACACS server.
9. Exit to system view.	quit	N/A
10. Apply an AAA authentication scheme to the intended domain.	<ol style="list-style-type: none"> Enter the ISP domain view: domain <i>domain-name</i> Apply the specified AAA scheme to the domain: authentication default { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] } Exit to system view: quit 	Optional. For local authentication, configure local user accounts. For RADIUS or HWTACACS authentication, configure the RADIUS or HWTACACS scheme on the device and configure authentication settings (including the username and password) on the server. For more information about AAA configuration, see <i>Security Configuration Guide</i> .
11. Create a local user and enter local user view.	local-user <i>user-name</i>	By default, no local user exists.
12. Set a password for the local user.	password { cipher simple } <i>password</i>	By default, no password is set.
13. Specify the command level of the user.	authorization-attribute level <i>level</i>	Optional. By default, the command level is 0.
14. Specify SSH service for the user.	service-type <i>ssh</i>	By default, no service type is specified.
15. Exit to system view.	quit	N/A

Step	Command	Remarks
16. Create an SSH user, and specify the authentication mode for the SSH user.	ssh user <i>username</i> service-type stelnet authentication-type { password { any password-publickey publickey } assign publickey <i>keyname</i> }	N/A By default, no SSH user is created.
17. Configure common settings for VTY user interfaces.	See " Configuring common settings for VTY user interfaces (optional) ."	Optional.

Using the device as an SSH client to log in to the SSH server

You can use the device as an SSH client to log in to an SSH server. If the server is located in a different subnet than the device, make sure the two devices have routes to reach each other.

Figure 18 Logging in to an SSH server from the device

To use the device as an SSH client to log in to an SSH server, perform the following tasks in user view:

Task	Command	Remarks
Log in to an IPv4 SSH server.	ssh2 server	The <i>server</i> argument represents the IPv4 address or host name of the server.
Log in to an IPv6 SSH server.	ssh2 ipv6 server	The <i>server</i> argument represents the IPv6 address or host name of the server.

To work with the SSH server, you might need to configure the SSH client. For information about configuring the SSH client, see *Security Configuration Guide*.

Modem dial-in through the console port

You can use a pair of modems to remotely connect to a device through its console port over the PSTN when the IP network connection is broken. To do so, make sure the dial-in connection, the device, and the modems are correctly set up.

By default, you can log in to the device through modems without authentication, and have user privilege level 3. To improve device security, configure AUX login authentication.

The following are authentication modes available for modem dial-in through the console port:

- **None**—Requires no authentication and is insecure.
- **Password**—Requires a password for accessing the CLI. If your password was lost, log in to the device through the console port or modify the password.
- **Scheme**—Uses the AAA module to provide local or remote authentication. If your username or password was lost, log in to the device through the console port to modify the setting. If the username or password configured on a remote server was lost, contact the server administrator for help.

Table 16 Configuration required for different modem login authentication modes

Authentication mode	Configuration task	Reference
None	Set the authentication mode to none for the AUX user interface.	"Configuring none authentication for modem dial-in"
Password	Enable password authentication on the AUX user interface. Set a password.	"Configuring password authentication for modem dial-in"
Scheme	Enable scheme authentication on the AUX user interface. Configure local or remote authentication settings. To configure local authentication: <ol style="list-style-type: none"> 1. Configure a local user and specify the password. 2. Configure the device to use local authentication. To configure remote authentication: <ol style="list-style-type: none"> 3. Configure the RADIUS or HWTACACS scheme on the device. 4. Configure the username and password on the AAA server. 5. Configure the device to use the scheme for user authentication. 	"Configuring scheme authentication for modem dial-in"

Setting up the configuration environment

Set up a configuration environment as shown in Figure 19:

1. Connect the serial port of the PC to a modem and the console port of the device to a modem.
2. Connect each modem to the PSTN through a telephone cable.
3. Obtain the telephone number of the modem connected to the device.

Figure 19 Connecting the PC to the device through modems

4. Perform the following configurations on the modem directly connected to the device:
 - **AT&F**—Restores the factory default.
 - **ATS0=1**—Configures auto-answer on first ring.
 - **AT&D**—Ignores data Terminal Ready signals.
 - **AT&K0**—Disables local flow control.
 - **AT&R1**—Ignores Data Flow Control signals.
 - **AT&S0**—Forces **DSR** to remain on.
 - **ATEQ1&W**—Disables the modem from returning command responses and execution results.
 To verify your configuration, enter **AT&V** to display the configuration results.

NOTE:

The configuration commands and output vary by modem. For more information, see the modem user guide.

5. To avoid data loss, verify that the speed of the console port is lower than the transmission rate of the modem, and the default parity check, stop bits, and data bits settings are used.
6. Launch the terminal emulation program and create a connection by using the telephone number of the modem connected to the device.

Figure 20 to Figure 23 shows the configuration procedure in Windows XP HyperTerminal.

Figure 20 Creating a connection

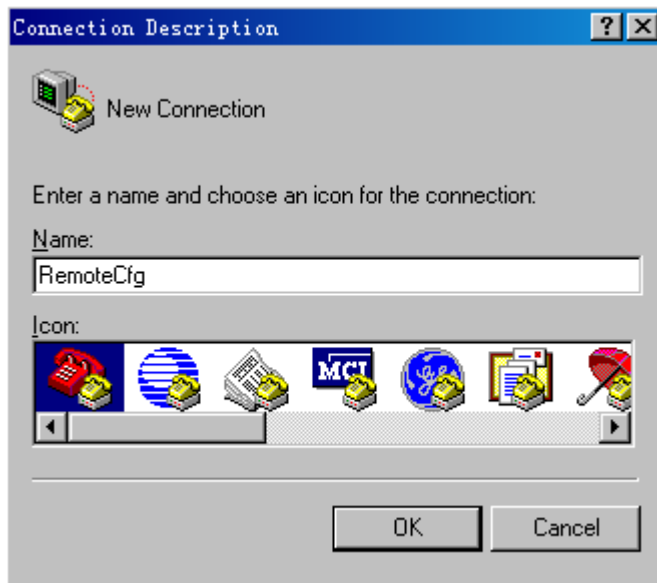

Figure 21 Configuring the dialing parameters

NOTE:

On Windows Server 2003, you must add the HyperTerminal program first, and then log in to and manage the device as described in this document. On Windows Server 2008, Windows 7, Windows Vista, or some other operating system, obtain a third-party terminal control program first, and follow the user guide or online help of that program to log in to the device.

7. Dial the telephone number to establish a connection to the device.

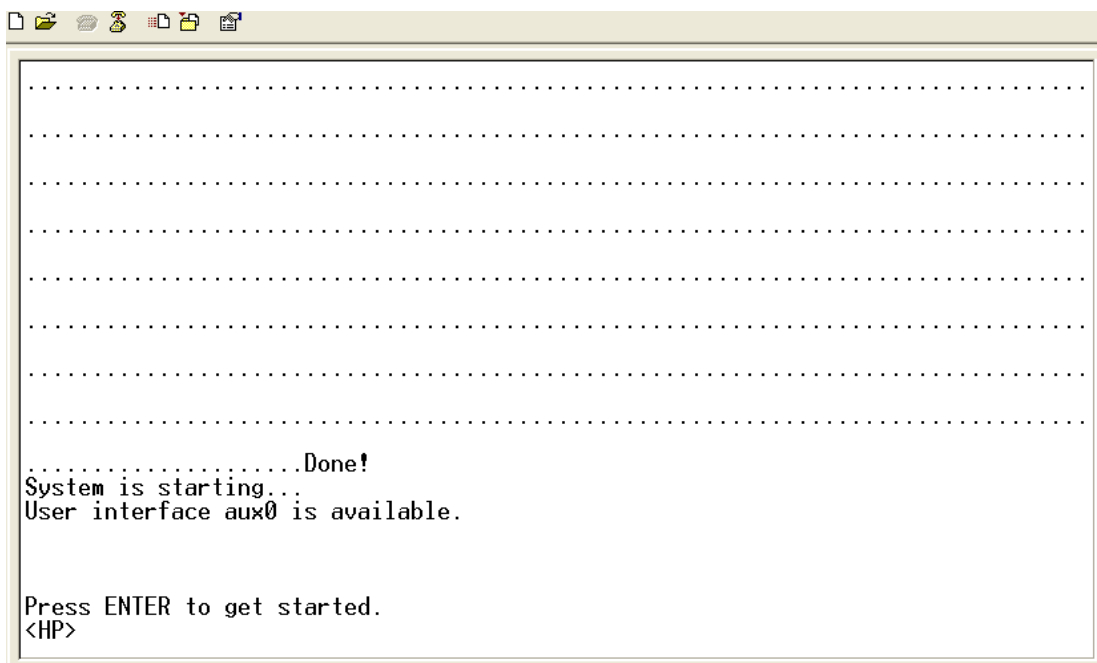

Figure 22 Dialing the number

Character string CONNECT9600 is displayed on the terminal.

8. Press **Enter** as prompted.

Figure 23 Configuration page

9. At the default user view prompt <HP>, enter commands to configure the device or view the running status of the device. To get help, enter ?.

To disconnect the PC from the device, execute the **ATH** command in the HyperTerminal. If the command cannot be entered, type AT+ + + and then press **Enter**. When the word "OK" appears, execute the **ATH** command. The connection is terminated if "OK" is displayed. You can also terminate the connection by clicking  in the HyperTerminal window.

! **IMPORTANT:**

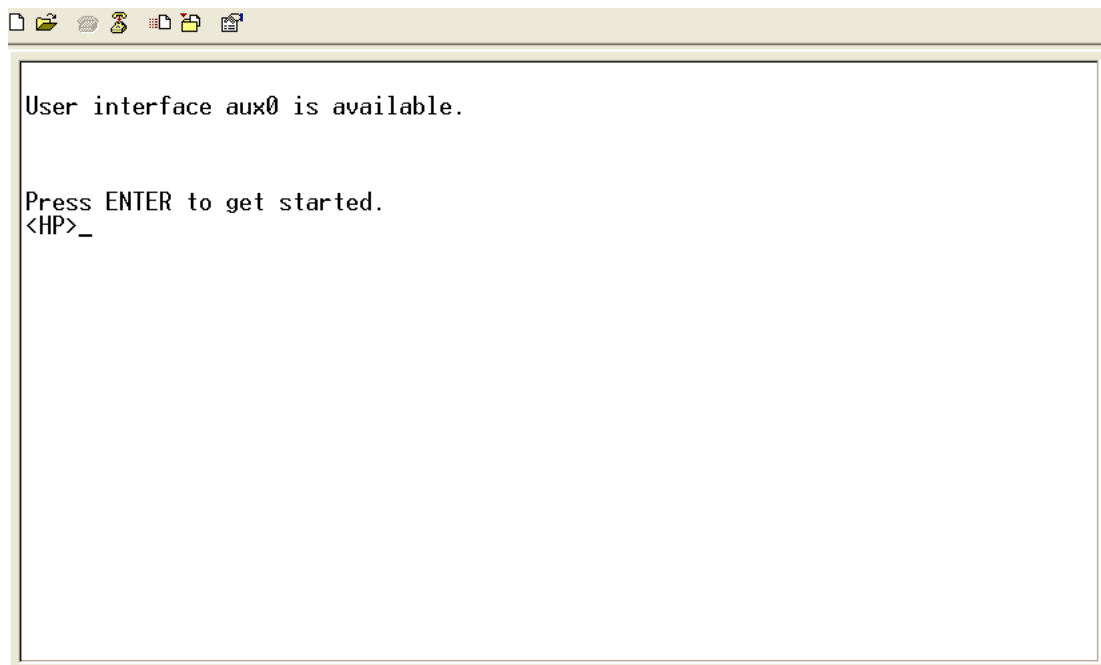

Do not directly close the HyperTerminal. Doing so can cause some modems to stay in use, and your subsequent dial-in attempts will always fail.

Configuring none authentication for modem dial-in

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter one or more AUX user interface views.	user-interface aux <i>first-number</i> [<i>last-number</i>]	N/A
3. Enable the none authentication mode.	authentication-mode none	By default, modem users can dial in to the device without authentication.
4. Configure common settings for the AUX user interfaces.	See " Configuring common settings for modem dial-in (optional) ."	Optional.

The next time you attempt to dial in to the device, you do not need to provide any username or password, as shown in [Figure 24](#).

Figure 24 Dialing in to the device without any authentication

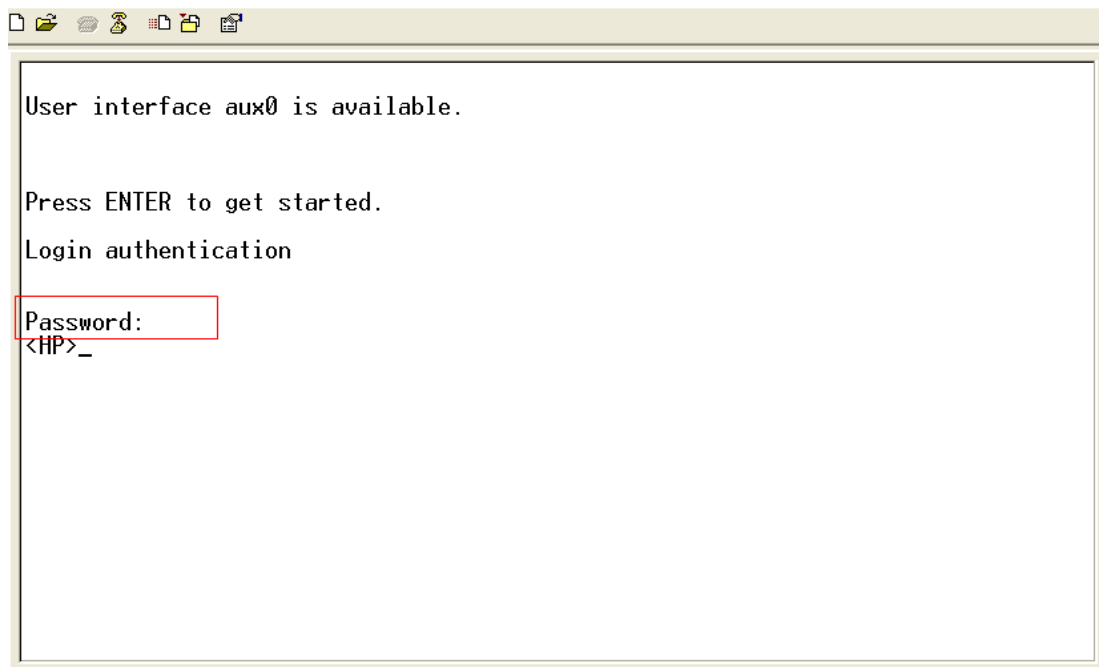

Configuring password authentication for modem dial-in

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter one or more AUX user interface views.	user-interface aux <i>first-number</i> [<i>last-number</i>]	N/A
3. Enable password authentication.	authentication-mode password	By default, no authentication is performed for modem dial-in users.
4. Set a password.	set authentication password { cipher simple } <i>password</i>	By default, no is set.
5. Configure common settings for the AUX user interfaces.	For more information, see " Configuring common settings for modem dial-in (optional) ."	Optional.

The next time you attempt to dial in to the device, you must provide the configured login password, as shown in [Figure 25](#).

Figure 25 Password authentication interface for modem dial-in users

Configuring scheme authentication for modem dial-in

Follow these guidelines when you configure scheme authentication for AUX login:

- To make the command authorization or command accounting function take effect, apply an HWTACACS scheme to the intended ISP domain. This scheme must specify the IP address of the authorization server and other authorization parameters.
- If the local authentication scheme is used, use the **authorization-attribute level** *level* command in local user view to set the user privilege level on the device.
- If a RADIUS or HWTACACS authentication scheme is used, set the user privilege level on the RADIUS or HWTACACS server.

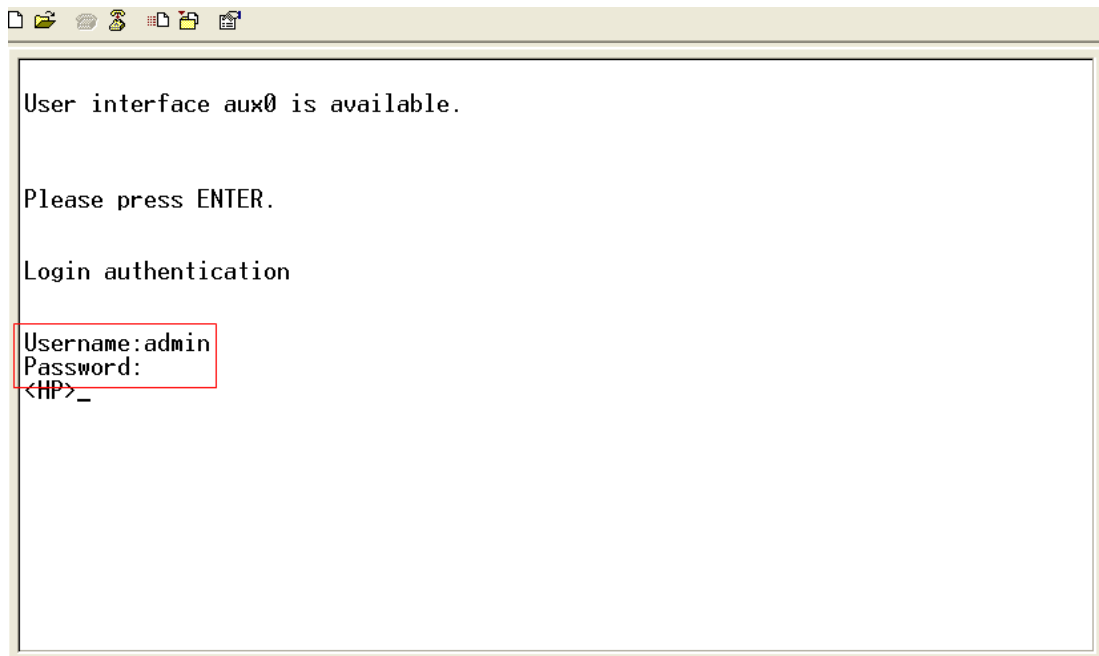

To configure scheme authentication for modem dial-in users:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter AUX user interface view.	user-interface aux <i>first-number</i> [<i>last-number</i>]	N/A
3. Enable scheme authentication.	authentication-mode scheme	Whether local, RADIUS, or HWTACACS authentication is adopted depends on the configured AAA scheme. By default, no authentication is performed for modem dial-in users.
4. Enable command authorization.	command authorization	Optional. By default, command authorization is disabled. The commands available for a user only depend on the user privilege level. If command authorization is enabled, a command is available only if the user has the commensurate user privilege level and is authorized to use the command by the AAA scheme.
5. Enable command accounting.	command accounting	Optional. By default, command accounting is disabled. The accounting server does not record the commands executed by users. Command accounting allows the HWTACACS server to record all executed commands that are supported by the device, regardless of the command execution result. This function helps control and monitor user behaviors on the device. If command accounting is enabled and command authorization is not enabled, every executed command is recorded on the HWTACACS server. If both command accounting and command authorization are enabled, only the authorized and executed commands are recorded on the HWTACACS server.
6. Exit to system view.	quit	N/A

Step	Command	Remarks
7. Apply an AAA authentication scheme to the intended domain.	<ol style="list-style-type: none"> 1. Enter the ISP domain view: domain <i>domain-name</i> 2. Apply the specified AAA scheme to the domain: authentication default { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] } 3. Exit to system view: quit 	<p>Optional.</p> <p>By default, local authentication is used.</p> <p>For local authentication, configure local user accounts.</p> <p>For RADIUS or HWTACACS authentication, configure the RADIUS or HWTACACS scheme on the device and configure authentication settings (including the username and password) on the server.</p> <p>For more information about AAA configuration, see <i>Security Configuration Guide</i>.</p>
8. Create a local user and enter local user view.	local-user <i>user-name</i>	By default, no local user exists.
9. Set a password for the local user.	password { cipher simple } <i>password</i>	By default, no password is set.
10. Specify the command level of the local user.	authorization-attribute level <i>level</i>	Optional. By default, the command level is 0.
11. Specify terminal service for the local user.	service-type terminal	By default, no service type is specified.
12. Configure common settings for the AUX user interfaces.	See " Configuring common settings for modem dial-in (optional) ."	Optional.

The next time you attempt to dial in to the device, you must provide the configured username and password, as shown in [Figure 26](#).

Figure 26 Scheme authentication interface for modem dial-in users

Configuring common settings for modem dial-in (optional)

⚠ CAUTION:

To avoid packet loss, make sure the speed of the console port is lower than the transmission rate of the modem.

Some common settings configured for an AUX user interface take effect immediately and can interrupt the login session. To save you the trouble of repeated re-logins, use a login method different from AUX login to log in to the device before you change AUX user interface settings.

After the configuration is complete, change the terminal settings on the configuration terminal and make sure they are the same as the settings on the device.

To configure common AUX user interface settings for modem dial-in accesses:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable copyright information display.	copyright-info enable	By default, copyright information display is enabled.
3. Enter one or more AUX user interface views.	user-interface aux <i>first-number</i> [<i>last-number</i>]	N/A
4. Configure the baud rate.	speed <i>speed-value</i>	By default, the baud rate is 9600 bps.
5. Configure the parity check mode.	parity { even none odd }	The default setting is none , namely, no parity check.

Step	Command	Remarks
6. Configure the number of stop bits.	stopbits { 1 1.5 2 }	The default is 1. Stop bits indicate the end of a character. The more the bits, the slower the transmission.
7. Configure the number of data bits in each character.	 databits { 7 8 }	By default, the number of data bits in each character is 8. The setting depends on the character coding type. For example, you can set it to 7 if standard ASCII characters are to be sent, and set it to 8 if extended ASCII characters are to be sent.
8. Define a shortcut key for starting a session.	activation-key <i>character</i>	By default, press Enter to start a session.
9. Define a shortcut key for terminating tasks.	escape-key { default <i>character</i> }	By default, press Ctrl+C to terminate a task.
10. Configure the flow control mode.	flow-control { hardware none software }	By default, the flow control mode is none . The device supports only the none mode.
11. Specify the terminal display type.	terminal type { ansi vt100 }	By default, the terminal display type is ANSI. The device supports two terminal display types: ANSI and VT100. HP recommends setting the display type to VT100 for both the device and the client. If the device and the client use different display types or both use the ANSI display type, when the total number of characters of a command line exceeds 80, the screen display on the terminal might be abnormal. For example, the cursor might be displayed at a wrong place.
12. Configure the user privilege level for login users.	user privilege level <i>level</i>	3 by default.
13. Set the maximum number of lines to be displayed on a screen.	screen-length <i>screen-length</i>	By default, a screen displays 24 lines at most. A value of 0 disables the function.
14. Set the size of the command history buffer.	history-command max-size <i>value</i>	By default, the buffer saves 10 history commands at most.

Step	Command	Remarks
15. Set the idle-timeout timer.	idle-timeout <i>minutes</i> [<i>seconds</i>]	The default idle-timeout is 10 minutes. The system automatically terminates the user's connection if there is no information interaction between the device and the user within the idle-timeout time. Setting idle-timeout to 0 disables the timer.

Displaying and maintaining CLI login

Task	Command	Remarks
Display information about the user interfaces that are being used.	display users [{ begin exclude include } <i>regular-expression</i>]	Available in any view.
Display information about all user interfaces the device supports.	display users all [{ begin exclude include } <i>regular-expression</i>]	Available in any view.
Display user interface information.	display user-interface [<i>num1</i> { aux vty } <i>num2</i>] [summary] [{ begin exclude include } <i>regular-expression</i>]	Available in any view.
Display the configuration of the device when it serves as a Telnet client.	display telnet client configuration [{ begin exclude include } <i>regular-expression</i>]	Available in any view.
Release a user interface.	free user-interface { <i>num1</i> { aux vty } <i>num2</i> }	Available in user view. Multiple users can log in to the system to simultaneously configure the device. You can execute the command to release the connections established on the specified user interfaces. You cannot use this command to release the connection you are using.
Lock the current user interface.	lock	Available in user view. By default, the current user interface is not locked.
Send messages to the specified user interfaces.	send { all <i>num1</i> { aux vty } <i>num2</i> }	Available in user view.

Logging in to the Web interface

The device provides a built-in Web server for you to configure the device through a Web browser. Web login is by default disabled.

To enable Web login, log in via the console port, and perform the following configuration tasks:

- Enable HTTP or HTTPS service.
- Configure the IP address of a Layer 3 interface, and make sure the interface and the configuration terminal can reach each other.
- Configure a local user account for Web login.

The device supports HTTP 1.0 and HTTPS for transferring webpage data across the Internet.

HTTPS uses SSL to encrypt data between the client and the server for data integrity and security, and is more secure than HTTP. You can define a certificate attribute-based access control policy to allow only legal clients to access the device.

HTTP login and HTTPS login are separate login methods. To use HTTPS login, you do not need to configure HTTP login.

Table 17 shows the basic Web login configuration requirements.

Table 17 Basic web login configuration requirements

Object	Requirements
Device	Configure an IP address for a Layer 3 interface. Configuring routes to make sure the interface and the PC can reach each other. Perform either or both of the following task: <ul style="list-style-type: none">• Configuring HTTP login• Configuring HTTPS login
PC	Install a Web browser. Obtain the IP address of the device's Layer 3 interface.

Configuring HTTP login

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the HTTP service.	ip http enable	By default, HTTP service is enabled.
3. Configure the HTTP service port number.	ip http port <i>port-number</i>	Optional. The default HTTP service port is 80. If you execute the command multiple times, the last one takes effect.

Step	Command	Remarks
4. Associate the HTTP service with an ACL.	ip http acl <i>acl-number</i>	Optional. By default, the HTTP service is not associated with any ACL. Associating the HTTP service with an ACL enables the device to allow only clients permitted by the ACL to access the device.
5. Create a local user and enter local user view.	local-user <i>user-name</i>	By default, no local user is configured.
6. Configure a password for the local user.	password { cipher simple } <i>password</i>	By default, no password is configured for the local user.
7. Specify the command level of the local user.	authorization-attribute level <i>level</i>	No command level is configured for the local user.
8. Specify the Telnet service type for the local user.	service-type web	By default, no service type is configured for the local user.
9. Exit to system view.	quit	N/A
10. Set the DSCP value for IP to use for HTTP packets.	<ul style="list-style-type: none"> For IPv4: ip http dscp <i>dscp-value</i> For IPv6: ipv6 http dscp <i>dscp-value</i> 	Optional. The default is as follows: <ul style="list-style-type: none"> 16 for IPv4. 0 for IPv6.
11. Create a VLAN interface and enter its view.	interface vlan-interface <i>vlan-interface-id</i>	If the VLAN interface already exists, the command enters its view.
12. Assign an IP address and subnet mask to the interface.	ip address <i>ip-address</i> { <i>mask</i> <i>mask-length</i> }	By default, no IP address is assigned to the interface.

Configuring HTTPS login

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Associate the HTTPS service with an SSL server policy.	ip https ssl-server-policy <i>policy-name</i>	<p>By default, the HTTPS service is not associated with any SSL server policy, and the device uses a self-signed certificate for authentication.</p> <p>If you disable the HTTPS service, the system automatically de-associates the HTTPS service from the SSL service policy. Before re-enabling the HTTPS service, associate the HTTPS service with an SSL server policy first.</p> <p>If the HTTPS service has been enabled, any changes to the SSL server policy associated with the HTTP service that is enabled do not take effect.</p>

Step	Command	Remarks
3. Enable the HTTPS service.	ip https enable	<p>By default, HTTPS is disabled.</p> <p>Enabling the HTTPS service triggers an SSL handshake negotiation process. During the process, if the local certificate of the device exists, the SSL negotiation succeeds, and the HTTPS service can be started properly. If no local certificate exists, a certificate application process will be triggered by the SSL negotiation. Because the application process takes much time, the SSL negotiation often fails and the HTTPS service cannot be started normally. In that case, execute the ip https enable command multiple times to start the HTTPS service.</p>
4. Associate the HTTPS service with a certificate attribute-based access control policy.	ip https certificate access-control-policy <i>policy-name</i>	<p>Optional.</p> <p>By default, the HTTPS service is not associated with any certificate-based attribute access control policy.</p> <p>Associating the HTTPS service with a certificate-based attribute access control policy enables the device to control the access rights of clients.</p> <p>You must configure the client-verify enable command in the associated SSL server policy. If not, no clients can log in to the device.</p> <p>The associated SSL server policy must contain at least one permit rule. Otherwise, no clients can log in to the device.</p> <p>For more information about certificate attribute-based access control policies, see <i>Security Configuration Guide</i>.</p>
5. Specify the HTTPS service port number.	ip https port <i>port-number</i>	<p>Optional.</p> <p>The default HTTPS service port is 443.</p>
6. Associate the HTTPS service with an ACL.	ip https acl <i>acl-number</i>	<p>By default, the HTTPS service is not associated with any ACL.</p> <p>Associating the HTTPS service with an ACL enables the device to allow only clients permitted by the ACL to access the device.</p>
7. Create a local user and enter local user view.	local-user <i>user-name</i>	By default, no local user is configured.
8. Configure a password for the local user.	password { cipher simple } <i>password</i>	By default, no password is configured for the local user.
9. Specify the command level of the local user.	authorization-attribute level <i>level</i>	By default, no command level is configured for the local user.

Step	Command	Remarks
10. Specify the Web service type for the local user.	service-type web	By default, no service type is configured for the local user.
11. Exit to system view.	quit	N/A
12. Create a VLAN interface and enter its view.	interface vlan-interface <i>vlan-interface-id</i>	If the VLAN interface already exists, the command enters its view. You could replace this VLAN interface with any other Layer 3 interface as appropriate.
13. Assign an IP address and subnet mask to the interface.	ip address <i>ip-address</i> { <i>mask</i> <i>mask-length</i> }	By default, no IP address is assigned to the interface.

For more information about SSL and PKI, see *Security Configuration Guide*.

Displaying and maintaining Web login

Task	Command	Remarks
Display information about Web users.	display web users [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display HTTP state information.	display ip http [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display HTTPS state information.	display ip https [{ begin exclude include } <i>regular-expression</i>]	Available in any view

HTTP login configuration example

Network requirements

As shown in [Figure 27](#), configure the device to allow the PC to log in over the IP network by using HTTP.

Figure 27 Network diagram

Configuration procedure

1. Configure the device:

```
# Create VLAN 999, and add GigabitEthernet 1/0/1 (the interface connected to the PC) to VLAN 999.
<Sysname> system-view
```

```

[Sysname] vlan 999
[Sysname-vlan999] port GigabitEthernet 1/0/1
[Sysname-vlan999] quit

# Assign the IP address 192.168.0.58 and the subnet mask 255.255.255.0 to VLAN-interface 999.

[Sysname] interface vlan-interface 999
[Sysname-VLAN-interface999] ip address 192.168.0.58 255.255.255.0
[Sysname-VLAN-interface999] quit

# Create a local user named admin, and set the password to admin for the user. Specify the Web service type for the local user, and set the command level to 3 for this user.

[Sysname] local-user admin
[Sysname-luser-admin] service-type web
[Sysname-luser-admin] authorization-attribute level 3
[Sysname-luser-admin] password simple admin

```

2. Verify the configuration:

On the PC, run the Web browser. Enter the IP address of the device in the address bar. The Web login page appears, as shown in [Figure 28](#).

Figure 28 Web login page

Enter the user name, password, verify code, select **English**, and click **Login**. The homepage appears. After login, you can configure device settings through the Web interface.

HTTPS login configuration example

Network requirements

As shown in [Figure 29](#), to prevent unauthorized users from accessing the device, configure the device as the HTTPS server and the host as the HTTPS client, and request a certificate for each of them.

Figure 29 Network diagram

Configuration procedure

This example assumes that the CA is named **new-ca**, runs Windows Server, and is installed with the Simple Certificate Enrollment Protocol (SCEP) add-on. This example also assumes that the device, host, and CA can reach one other.

1. Configure the device (HTTPS server):

Configure a PKI entity, configure the common name of the entity as **http-server1**, and the FQDN of the entity as **ssl.security.com**.

```
<Device> system-view
[Device] pki entity en
[Device-pki-entity-en] common-name http-server1
[Device-pki-entity-en] fqdn ssl.security.com
[Device-pki-entity-en] quit
```

Create a PKI domain, specify the trusted CA as **new-ca**, the URL of the server for certificate request as **http://10.1.2.2/certsrv/mscep/mscep.dll**, authority for certificate request as **RA**, and the entity for certificate request as **en**.

```
[Device] pki domain 1
[Device-pki-domain-1] ca identifier new-ca
[Device-pki-domain-1] certificate request url
http://10.1.2.2/certsrv/mscep/mscep.dll
[Device-pki-domain-1] certificate request from ra
[Device-pki-domain-1] certificate request entity en
[Device-pki-domain-1] quit
```

Create RSA local key pairs.

```
[Device] public-key local create rsa
```

Retrieve the CA certificate from the certificate issuing server.

```
[Device] pki retrieval-certificate ca domain 1
```

Request a local certificate from a CA through SCEP for the device.

```
[Device] pki request-certificate domain 1
```

Create an SSL server policy **myssl**, specify PKI domain 1 for the SSL server policy, and enable certificate-based SSL client authentication.

```
[Device] ssl server-policy myssl
[Device-ssl-server-policy-myssl] pki-domain 1
[Device-ssl-server-policy-myssl] client-verify enable
[Device-ssl-server-policy-myssl] quit
```

Create a certificate attribute group **mygroup1**, and configure a certificate attribute rule, specifying that the distinguished name (DN) in the subject name includes the string of **new-ca**.

```
[Device] pki certificate attribute-group mygroup1
[Device-pki-cert-attribute-group-mygroup1] attribute 1 issuer-name dn ctn new-ca
[Device-pki-cert-attribute-group-mygroup1] quit
```

Create a certificate attribute-based access control policy **myacp**. Configure a certificate attribute-based access control rule, specifying that a certificate is considered valid when it matches an attribute rule in certificate attribute group **myacp**.

```
[Device] pki certificate access-control-policy myacp
[Device-pki-cert-acp-myacp] rule 1 permit mygroup1
[Device-pki-cert-acp-myacp] quit
```

Associate the HTTPS service with SSL server policy **myssl**.

```
[Device] ip https ssl-server-policy myssl
```

Associate the HTTPS service with certificate attribute-based access control policy **myacp**.

```
[Device] ip https certificate access-control-policy myacp
```

Enable the HTTPS service.

```
[Device] ip https enable
```

Create a local user named **usera**, set the password to **123**, specify the Web service type, and specify the user privilege level 3. A level-3 user can perform all operations supported by the device.

```
[Device] local-user usera
[Device-luser-usera] password simple 123
[Device-luser-usera] service-type web
[Device-luser-usera] authorization-attribute level 3
```

2. Configure the host (HTTPS client):

On the host, run the IE browser, and then enter **http://10.1.2.2/certsrv** in the address bar and request a certificate for the host as prompted.

3. Verify the configuration:

Enter **https://10.1.1.1** in the address bar, and select the certificate issued by **new-ca**. When the Web login page of the device appears, enter the username **usera** and password **123** to log in to the Web management page.

For more information about PKI configuration commands, SSL configuration commands, and the **public-key local create rsa** command, see *Security Command Reference*.

Logging in through NMS

You can use an NMS to access the device MIB and perform GET and SET operations to manage and monitor the device. The device supports SNMPv1, SNMPv2c, and SNMPv3, and can work with various network management software products, including IMC. For more information about SNMP, see *Network Management and Monitoring Configuration Guide*.

By default, SNMP access is disabled. To enable SNMP access, log in to the device via any other method.

Configuring SNMP login

Connect the PC (the NMS) and the device to the network, making sure they can reach each other, as shown in Figure 30.

Figure 30 Network diagram

! IMPORTANT:

This document describes only the basic SNMP configuration procedures on the device. To make SNMP work correctly, make sure the SNMP settings (including the SNMP version) on the NMS are consistent with those on the device.

Prerequisites

- Assign an IP address to a Layer 3 interface on the device.
- Configure routes to make sure the NMS and the Layer 3 interface can reach each other.

Configuring SNMPv3 settings

Step	Command	Remarks
1. Enter system view.	<code>system-view</code>	N/A
2. Enable the SNMP agent.	<code>snmp-agent</code>	Optional. By default, the SNMP agent is disabled. You can enable SNMP agent with this command or any command that begins with <code>snmp-agent</code> .

Step	Command	Remarks
3. Configure an SNMP group and specify its access right.	snmp-agent group v3 <i>group-name</i> [authentication privacy] [read-view <i>read-view</i>] [write-view <i>write-view</i>] [notify-view <i>notify-view</i>] [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] *	By default, no SNMP group is configured.
4. Add a user to the SNMP group.	snmp-agent usm-user v3 <i>user-name</i> <i>group-name</i> [[cipher] authentication-mode { md5 sha } <i>auth-password</i> [privacy-mode { 3des aes128 des56 } <i>priv-password</i>]] [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] *	N/A

Configuring SNMPv1 or SNMPv2c settings

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the SNMP agent.	snmp-agent	Optional. By default, the SNMP agent is disabled. You can enable SNMP agent with this command or any command that begins with snmp-agent .
3. Create or update MIB view information.	snmp-agent mib-view { excluded included } <i>view-name</i> <i>oid-tree</i> [mask <i>mask-value</i>]	Optional. By default, the MIB view name is ViewDefault and OID is 1.
4. Configure SNMP NMS access right.	<ul style="list-style-type: none"> (Approach 1) Specify the SNMP NMS access right directly by configuring an SNMP community: snmp-agent community { read write } <i>community-name</i> [mib-view <i>view-name</i>] [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] * (Approach 2) Configure an SNMP group and add a user to the SNMP group: <ul style="list-style-type: none"> a. snmp-agent group { v1 v2c } <i>group-name</i> [read-view <i>read-view</i>] [write-view <i>write-view</i>] [notify-view <i>notify-view</i>] [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] * b. snmp-agent usm-user { v1 v2c } <i>user-name</i> <i>group-name</i> [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] * 	Use either approach. The direct configuration approach is for SNMPv1 or SNMPv2c. The community name configured on the NMS should be consistent with the username configured on the agent. The indirect configuration approach is for SNMPv3.

NMS login example

Network requirements

Configure the device and network management station so you can remotely manage the device through SNMPv3.

Figure 31 Network diagram

Configuration procedure

1. Configure the device:

Assign an IP address to the device. Make sure the device and the NMS can reach each other. (Details not shown.)

Enter system view.

```
<Sysname> system-view
```

Enable the SNMP agent.

```
[Sysname] snmp-agent
```

Configure an SNMP group.

```
[Sysname] snmp-agent group v3 managev3group
```

Add a user to the SNMP group.

```
[Sysname] snmp-agent usm-user v3 managev3user managev3group
```

2. Configure the NMS:

Make sure the NMS has the same SNMP settings, including the username as the device. If not, the device cannot be discovered or managed by the NMS.

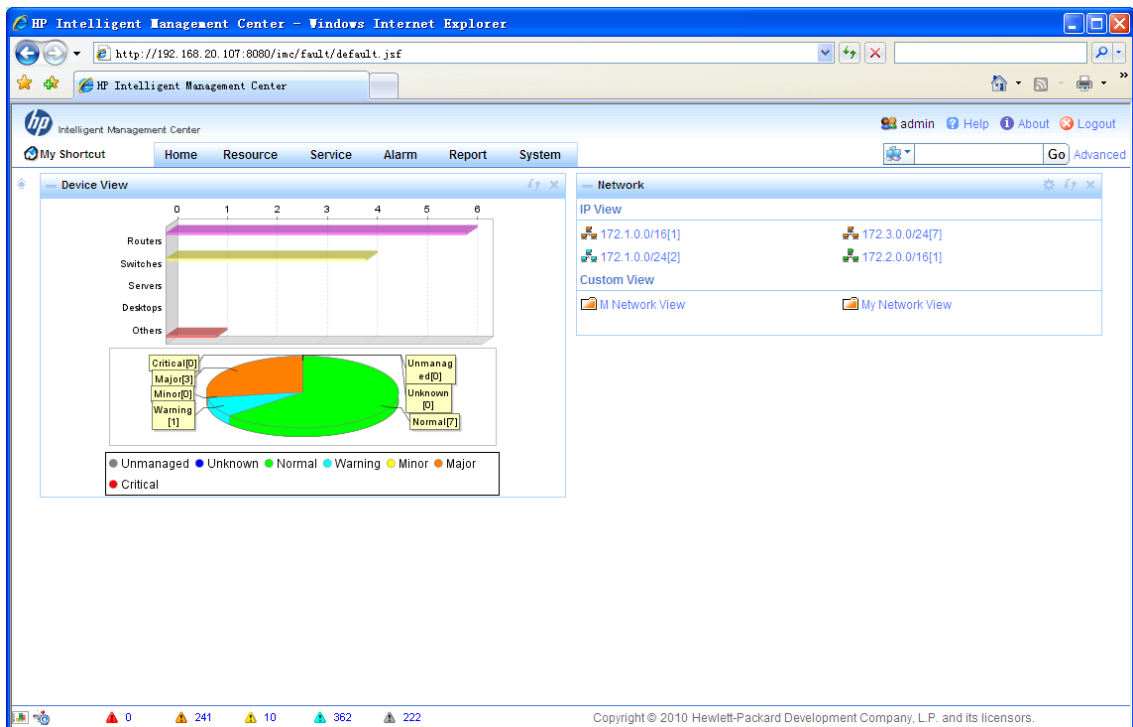

- a. On the PC, launch the browser, and enter **http://192.168.3.104:8080/imc** in the address bar (suppose that the IP address of IMC is 192.168.3.104).

Figure 32 IMC login page

- b. Enter the username and password, and then click **Login**.
The IMC homepage appears.

Figure 33 IMC homepage

- c. Log in to IMC and configure SNMP settings for IMC to find the switch.
- d. After the switch is found, you can manage and maintain the switch through IMC. For example, query switch information or configure switch parameters.

Controlling user logins

To harden device security, use ACLs to prevent unauthorized logins. For more information about ACLs, see *ACL and QoS Configuration Guide*.

Controlling Telnet logins

Use a basic ACL (2000 to 2999) to filter Telnet traffic by source IP address. Use an advanced ACL (3000 to 3999) to filter Telnet traffic by source and/or destination IP address. Use an Ethernet frame header ACL (4000 to 4999) to filter Telnet traffic by source MAC address.

To access the device, a Telnet user must match a permit statement in the ACL applied to the user interface.

Configuring source IP-based Telnet login control

Step	Command	Remarks
1. Enter system view.	<code>system-view</code>	N/A
2. Create a basic ACL and enter its view, or enter the view of an existing basic ACL.	<code>acl [ipv6] number acl-number [match-order { config auto }]</code>	By default, no basic ACL exists.
3. Configure an ACL rule.	<code>rule [rule-id] { permit deny } [source { sour-addr sour-wildcard any } time-range time-name fragment logging]*</code>	By default, a basic ACL does not contain any rule.
4. Exit the basic ACL view.	<code>quit</code>	N/A
5. Enter user interface view.	<code>user-interface [type] first-number [last-number]</code>	N/A
6. Use the ACL to control user logins by source IP address.	<code>acl [ipv6] acl-number { inbound outbound }</code>	<ul style="list-style-type: none">• inbound: Filters incoming packets.• outbound: Filters outgoing packets.

Configuring source/destination IP-based Telnet login control

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an advanced ACL and enter its view, or enter the view of an existing advanced ACL.	acl [ipv6] number <i>acl-number</i> [match-order { config auto }]	By default, no advanced ACL exists.
3. Configure an ACL rule.	rule [<i>rule-id</i>] { permit deny } <i>rule-string</i>	N/A
4. Exit advanced ACL view.	quit	N/A
5. Enter user interface view.	user-interface [<i>type</i>] <i>first-number</i> [<i>last-number</i>]	N/A
6. Use the ACL to control user logins by source and destination IP addresses.	acl [ipv6] <i>acl-number</i> { inbound outbound }	<ul style="list-style-type: none"> • inbound: Filters incoming packets. • outbound: Filters outgoing packets.

Configuring source MAC-based Telnet login control

Ethernet frame header ACLs apply to Telnet traffic only if the Telnet client and server are located in the same subnet.

To configure source MAC-based Telnet login control:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an Ethernet frame header ACL and enter its view.	acl number <i>acl-number</i> [match-order { config auto }]	By default, no Ethernet frame header ACL exists.
3. Configure an ACL rule.	rule [<i>rule-id</i>] { permit deny } <i>rule-string</i>	N/A
4. Exit Ethernet frame header ACL view.	quit	N/A
5. Enter user interface view.	user-interface [<i>type</i>] <i>first-number</i> [<i>last-number</i>]	N/A
6. Use the ACL to control user logins by source MAC address.	acl <i>acl-number</i> inbound	inbound: Filters incoming packets.

Telnet login control configuration example

Network requirements

As shown in [Figure 34](#), configure an ACL on the device to permit only incoming Telnet packets sourced from Host A and Host B.

Figure 34 Network diagram

Configuration procedure

Configure basic ACL 2000, and configure rule 1 to permit packets sourced from Host B, and rule 2 to permit packets sourced from Host A.

```
<Sysname> system-view
[Sysname] acl number 2000 match-order config
[Sysname-acl-basic-2000] rule 1 permit source 10.110.100.52 0
[Sysname-acl-basic-2000] rule 2 permit source 10.110.100.46 0
[Sysname-acl-basic-2000] quit
```

Reference ACL 2000 in user interface view to allow Telnet users from Host A and Host B to access the Device.

```
[Sysname] user-interface vty 0 15
[Sysname-ui-vty0-15] acl 2000 inbound
```

Configuring source IP-based SNMP login control

Use a basic ACL (2000 to 2999) to control SNMP logins by source IP address. To access the requested MIB view, an NMS must use a source IP address permitted by the ACL.

Configuration procedure

To configure source IP-based SNMP login control:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a basic ACL and enter its view, or enter the view of an existing basic ACL.	acl [ipv6] number <i>acl-number</i> [match-order { config auto }]	By default, no basic ACL exists.
3. Create an ACL rule.	rule [<i>rule-id</i>] { permit deny } [source { <i>sour-addr</i> <i>sour-wildcard</i> any } time-range <i>time-name</i> fragment logging]*	N/A
4. Exit the basic ACL view.	quit	N/A

Step	Command	Remarks
5. Apply the ACL to an SNMP community, group or user.	<ul style="list-style-type: none"> SNMPv1/v2c community: snmp-agent community { read write } <i>community-name</i> [mib-view <i>view-name</i>] [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] * SNMPv1/v2c group: snmp-agent group { v1 v2c } <i>group-name</i> [read-view <i>read-view</i>] [write-view <i>write-view</i>] [notify-view <i>notify-view</i>] [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] * SNMPv3 group: snmp-agent group v3 <i>group-name</i> [authentication privacy] [read-view <i>read-view</i>] [write-view <i>write-view</i>] [notify-view <i>notify-view</i>] [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] * SNMPv1/v2c user: snmp-agent usm-user { v1 v2c } <i>user-name</i> <i>group-name</i> [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] * SNMPv3 user: snmp-agent usm-user v3 <i>user-name</i> <i>group-name</i> [[cipher] authentication-mode { md5 sha } <i>auth-password</i> [privacy-mode { 3des aes128 des56 } <i>priv-password</i>]] [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] * 	For more information about SNMP, see <i>Network Management and Monitoring Configuration Guide</i> .

SNMP login control configuration example

Network requirements

As shown in Figure 35, configure the device to allow only NMS users from Host A and Host B to access.

Figure 35 Network diagram

Configuration procedure

Create ACL 2000, and configure rule 1 to permit packets sourced from Host B, and rule 2 to permit packets sourced from Host A.

```
<Sysname> system-view
[Sysname] acl number 2000 match-order config
[Sysname-acl-basic-2000] rule 1 permit source 10.110.100.52 0
[Sysname-acl-basic-2000] rule 2 permit source 10.110.100.46 0
[Sysname-acl-basic-2000] quit
```

Associate the ACL with the SNMP community and the SNMP group.

```
[Sysname] snmp-agent community read aaa acl 2000
[Sysname] snmp-agent group v2c groupa acl 2000
[Sysname] snmp-agent usm-user v2c usera groupa acl 2000
```

Configuring Web login control

Use a basic ACL (2000 to 2999) to filter HTTP traffic by source IP address for Web login control. To access the device, a Web user must use an IP address permitted by the ACL.

You can also log off suspicious Web users who have been logged in.

Configuring source IP-based Web login control

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a basic ACL and enter its view, or enter the view of an existing basic ACL.	acl [ipv6] number <i>acl-number</i> [match-order { config auto }]	By default, no basic ACL exists.
3. Create rules for this ACL.	rule [<i>rule-id</i>] { permit deny } [source { <i>sour-addr</i> <i>sour-wildcard</i> any } time-range <i>time-name</i> fragment logging]*	N/A
4. Exit the basic ACL view.	quit	N/A
5. Associate the HTTP service with the ACL.	ip http acl <i>acl-number</i>	N/A

Logging off online Web users

Task	Command	Remarks
Log off online Web users.	free web-users { all user-id <i>user-id</i> user-name <i>user-name</i> }	Available in user interface view

Web login control configuration example

Network requirements

As shown in [Figure 36](#), configure the device to allow only Web users from Host B to access.

Figure 36 Network diagram

Configuration procedure

Create ACL 2000, and configure rule 1 to permit packets sourced from Host B.

```
<Sysname> system-view
```

```
[Sysname] acl number 2030 match-order config
```

```
[Sysname-acl-basic-2030] rule 1 permit source 10.110.100.52 0
```

Associate the ACL with the HTTP service so only Web users from Host B are allowed to access the device.

```
[Sysname] ip http acl 2030
```

Configuring FTP

File Transfer Protocol (FTP) is an application layer protocol based on the client/server model. It is used to transfer files from one host to another over a TCP/IP network.

FTP server uses TCP port 20 to transfer data and TCP port 21 to transfer control commands. For more information about FTP, see RFC 959.

FTP supports the following transfer modes:

- **Binary mode**—Used to transfer image files, such as **.app** and **.bin** files.
- **ASCII mode**—Used to transfer text files, such as **.txt**, **.bat**, and **.cfg** files.

FTP can operate in either of the following modes:

- **Active mode (PORT)**—The FTP server initiates the TCP connection. This mode is not suitable when the FTP client is behind a firewall (for example, the FTP client resides in a private network).
- **Passive mode (PASV)**—The FTP client initiates the TCP connection. This mode is not suitable when the server does not allow the client to use a random unprivileged port greater than 1024.

The FTP operation mode varies depending on the FTP client program.

The device can act as the FTP client or FTP server:

Figure 37 FTP application scenario

Using the device as an FTP client

To connect to an FTP server or enter FTP client view, make sure the following requirements are met:

- You have level-3 (Manage) user privileges on the device. In FTP client view, whether a directory or file management command can be successfully executed depends on the authorization set on the FTP server.
- The device and the FTP server can reach each other.
- You have a user account (including the username, password, and authorization) on the FTP server. If the FTP server supports anonymous FTP, you can directly access the FTP server without a username and password.

Establishing an FTP connection

To access an FTP server, use the **ftp** command in user view or use the **open** command in FTP client view to establish a connection to the FTP server.

You can use the **ftp client source** command to specify a source IP address or source interface for the FTP packets sent by the device. If a source interface (typically a loopback interface) is specified, its primary IP address is used as the source IP address for the FTP packets sent by the device. The source interface setting and the source IP address setting overwrite each other.

The **ftp client source** command setting applies to all FTP sessions. When you set up an FTP session by using the **ftp** or **ftp ipv6** command, you can also specify a different source IP address for the FTP session.

! **IMPORTANT:**

To avoid FTP connection failures, when you specify a source interface for FTP packets, make sure that the interface has been assigned a primary IP address.

To establish an IPv4 FTP connection:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify a source IP address for outgoing FTP packets.	ftp client source { interface <i>interface-type interface-number</i> ip <i>source-ip-address</i> }	Optional. By default, the primary IP address of the output interface is used as the source IP address.
3. Return to user view.	quit	N/A
4. Log in to the FTP server.	<ul style="list-style-type: none"> • (Approach 1) Log in to the FTP server in user view: ftp [<i>server-address</i> [<i>service-port</i>] [vpn-instance <i>vpn-instance-name</i>] [source { interface <i>interface-type interface-number</i> ip <i>source-ip-address</i> }]] • (Approach 2) Log in to the FTP server in FTP client view: <ol style="list-style-type: none"> a. ftp b. open <i>server-address</i> [<i>service-port</i>] 	Use either approach. Only HP 5500-EI switches support the vpn-instance <i>vpn-instance-name</i> option.

To establish an IPv6 FTP connection, perform one of the following tasks:

Task	Command	Remarks
Log in to the FTP server from user view.	ftp ipv6 [<i>server-address</i> [<i>service-port</i>] [vpn-instance <i>vpn-instance-name</i>] [source ipv6 <i>source-ipv6-address</i>] [-i <i>interface-type interface-number</i>]]	Only HP 5500-EI switches support the vpn-instance <i>vpn-instance-name</i> option.
Log in to the FTP server from FTP client view.	<ol style="list-style-type: none"> 1. ftp ipv6 2. open ipv6 <i>server-address</i> [<i>service-port</i>] [-i <i>interface-type interface-number</i>] 	

Setting the DSCP value for IP to use for outgoing FTP packets

You can set the DSCP value for IPv4 or IPv6 to use for outgoing FTP packets on an FTP client, so that outgoing FTP packets are forwarded based on their priority on transit devices.

To set the DSCP value for IP to use for outgoing FTP packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for IP to use for outgoing FTP packets.	<ul style="list-style-type: none"> For IPv4: ftp client dscp <i>dscp-value</i> For IPv6: ftp client ipv6 dscp <i>dscp-value</i> 	The default is 0, whether the FTP client is running IPv4 or IPv6.

Managing directories on the FTP server

After the device establishes a connection to an FTP server, you can create or delete folders in the authorized directory on the FTP server.

To manage the directories on the FTP server:

Task	Command
Display detailed information about files and directories under the current directory on the FTP server.	dir [<i>remotefile</i> [<i>localfile</i>]]
Query a directory or file on the FTP server.	ls [<i>remotefile</i> [<i>localfile</i>]]
Change the working directory on the FTP server.	cd { <i>directory</i> .. / }
Return to the upper level directory on the FTP server.	cdup
Display the current directory on the FTP server.	pwd
Create a directory on the FTP server.	mkdir <i>directory</i>
Remove the specified working directory on the FTP server.	rmdir <i>directory</i>

Working with the files on the FTP server

After you log in to the server, you can upload a file to or download a file from the authorized directory by following these steps:

1. Use the **dir** or **ls** command to display the directory and the location of the file on the FTP server.
2. Delete unused files to get more free storage space.
3. Set the file transfer mode. FTP transmits files in two modes: ASCII and binary. Use ASCII mode to transfer text files. Use binary mode to transfer image files.
4. Use the **lcd** command to display the local working directory of the FTP client. You can upload the file or save the downloaded file in this directory.
5. Upload or download the file.

To work with the files on the FTP server:

Task	Command	Remarks
Display detailed information about a directory or file on the FTP server.	dir [<i>remotefile</i> [<i>localfile</i>]]	The ls command displays the name of a directory or file only, while the dir command displays detailed information such as the file size and creation time.

Task	Command	Remarks
Query a directory or file on the FTP server.	ls [<i>remotefile</i> [<i>localfile</i>]]	The ls command displays the name of a directory or file only, while the dir command displays detailed information such as the file size and creation time.
Delete the specified file on the FTP server permanently.	delete <i>remotefile</i>	N/A
Set the file transfer mode to ASCII.	ascii	By default, ASCII mode is used.
Set the file transfer mode to binary.	binary	By default, ASCII mode is used.
Set the FTP operation mode to passive.	passive	By default, passive mode is used
Display the local working directory of the FTP client.	lcd	N/A
Upload a file to the FTP server.	put <i>localfile</i> [<i>remotefile</i>]	N/A
Download a file from the FTP server.	get <i>remotefile</i> [<i>localfile</i>]	N/A

Switching to another user account

After you log in to the FTP server with one user account, you can switch to another user account to get a different privilege without reestablishing the FTP connection. You must correctly enter the new username and password. A wrong username or password can cause the FTP connection to disconnect.

To switch to another user account:

Task	Command
Change the username after FTP login.	user <i>username</i> [<i>password</i>]

Maintaining and troubleshooting the FTP connection

Task	Command	Remarks
Display the help information of FTP-related commands on the FTP server.	remotehelp [<i>protocol-command</i>]	N/A
Enable displaying detailed prompt information received from the server.	verbose	Enabled by default
Enable FTP related debugging when the device acts as the FTP client.	debugging	Disabled by default

Terminating the FTP connection

To terminate an FTP connection, perform one of the following tasks:

Task	Command	Remarks
Terminate the FTP connection without exiting FTP client view.	<ul style="list-style-type: none"> • disconnect • close 	Use either command in FTP client view.
Terminate the FTP connection and return to user view.	<ul style="list-style-type: none"> • bye • quit 	Use either command in FTP client view.

FTP client configuration example

Network requirements

As shown in Figure 38, the IRF fabric that comprises two member devices acts as the FTP client and the PC acts as the FTP server. The IRF fabric and the PC can reach each other. An account with the username **abc** and password **abc** is already configured on the FTP server.

Log in to the FTP server from the FTP client, download the file **newest.bin** from the FTP server to the FTP client, and upload the configuration file **config.cfg** from the FTP client to the FTP server for backup.

Figure 38 Network diagram

Note: The orange line represents an IRF link.

Configuration procedure

Examine the storage medium of the device for insufficiency or impairment. If no sufficient free space is available, use the **delete/unreserved file-url** command to delete unused files. (Details not shown.)

Log in to the server at 10.1.1.1 through FTP.

```
<Sysname> ftp 10.1.1.1
Trying 10.1.1.1 ...
Connected to 10.1.1.1.
220 WFTPD 2.0 service (by Texas Imperial Software) ready for new user
User(10.1.1.1:(none)):abc
331 Give me your password, please
Password:
230 Logged in successfully
```

Set the file transfer mode to binary.

```
[ftp] binary
200 Type set to I.
```

Download the system software image file **newest.bin** from the PC to the IRF fabric.

- Download the file **newest.bin** from the PC to the Flash root directory of the master device.

```
[ftp] get newest.bin
```

- Download the file **newest.bin** from the PC to the Flash root directory of the subordinate device (with member ID of 2).

```
[ftp] get newest.bin slot2#flash:/newest.bin
```

Set the transfer mode to ASCII and upload the configuration file **config.cfg** from the IRF fabric to the PC for backup.

```
[ftp] ascii
[ftp] put config.cfg back-config.cfg
227 Entering Passive Mode (10,1,1,1,4,2).
125 ASCII mode data connection already open, transfer starting for /config.cfg.
226 Transfer complete.
FTP: 3494 byte(s) sent in 5.646 second(s), 618.00 byte(s)/sec.
[ftp] bye
221 Server closing.
```

Specify **newest.bin** as the main system software image file for the next startup of all member devices.

```
<Sysname> boot-loader file newest.bin slot all main
This command will set the boot file of the specified board. Continue? [Y/N]:y
The specified file will be used as the main boot file at the next reboot on slot 1!
The specified file will be used as the main boot file at the next reboot on slot 2!
```

! **IMPORTANT:**

The system software image file used for the next startup must be saved in the Flash root directory. You can copy or move a file to the Flash root directory.

Reboot the device, and the system software image file is updated at the system reboot.

```
<Sysname> reboot
```

Using the device as an FTP server

If the device is operating as an FTP server, make sure the following requirements are met to ensure successful FTP operations:

- The device and the FTP server can reach each other.
- Configure a user account (including the username, password, and authorization) on the device or a remote authentication server for an FTP user. This task is required because the device does not support anonymous FTP for security reasons. By default, authenticated users can access the root directory of the device.
- The FTP user provides the correct username and password.

NOTE:

When you use the Internet Explorer browser to log in to the device operating as an FTP server, some FTP functions are not available. This is because multiple connections are required during the login process but the device supports only one connection at a time.

Configuring basic parameters

The FTP server uses one of the following modes to update a file when you upload the file (use the **put** command) to the FTP server:

- **Fast mode**—The FTP server starts writing data to the Flash after a file is transferred to the memory. This prevents the existing file on the FTP server from being corrupted in the event that anomaly, such as a power failure, occurs during a file transfer.
- **Normal mode**—The FTP server writes data to the Flash while receiving data. This means that any anomaly, such as a power failure, during file transfer might result in file corruption on the FTP server. This mode, however, consumes less memory space than the fast mode.

To configure basic parameters for the FTP server:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the FTP server.	ftp server enable	By default, the FTP server is disabled.
3. Set the DSCP value for IPv4 to use for outgoing FTP packets.	ftp server dscp <i>dscp-value</i>	Optional. The default is 0.
4. Use an ACL to control FTP access.	ftp server acl <i>acl-number</i>	Optional. By default, no ACL is used for access control.
5. Configure the idle-timeout timer.	ftp timeout <i>minutes</i>	Optional. The default idle-timeout timer is 30 minutes. If no data is transferred within the idle-timeout time, the connection is terminated.
6. Set the file update mode for the FTP server.	ftp update { fast normal }	Optional. By default, normal update is used.
7. Return to user view.	quit	N/A
8. Release the FTP connection established by a specific user.	free ftp user <i>username</i>	Optional.

Configuring authentication and authorization

Perform this task on the FTP server to authenticate FTP clients and specify the directories that authenticated clients can access.

The following authentication modes are available:

- **Local authentication**—The device looks up the client's username and password in the local user account database. If a match is found, authentication succeeds.
- **Remote authentication**—The device sends the client's username and password to a remote authentication server for authentication. If this approach is used, the user account is configured on the remote authentication server rather than the device.

To assign an FTP user write access (including upload, delete, and create) to the device, assign level-3 (Manage) user privileges to the user. For read-only access to the file system, any user privilege level is OK.

For more information, see *Security Configuration Guide*.

To configure authentication and authorization for the FTP server:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a local user account and enter its view.	local-user <i>user-name</i>	By default, no local user account exists, and the system does not support FTP anonymous user access.
3. Set a password for the user account.	password { simple cipher } <i>password</i>	N/A
4. Assign FTP service to the user account	service-type ftp	By default, no service type is specified. If the FTP service is specified, the root directory of the device is by default used.
5. Configure authorization attributes.	authorization-attribute { acl <i>acl-number</i> callback-number <i>callback-number</i> idle-cut <i>minute</i> level <i>level</i> user-profile <i>profile-name</i> user-role { guest guest-manager security-audit } vlan <i>vlan-id</i> work-directory <i>directory-name</i> } *	Optional. By default, the FTP/SFTP users can access the root directory of the device, and the user level is 0. You can change the default configuration by using this command.

For more information about the **local-user**, **password**, **service-type ftp**, and **authorization-attribute** commands, see *Security Command Reference*.

FTP server configuration example

Network requirements

Create a local user account with username **abc** and password **abc** and enable FTP server on the IRF fabric in Figure 39. Use the user account to log in to the FTP server from the FTP client, upload the file **newest.bin** from the FTP client to the FTP server, and download the configuration file **config.cfg** from the FTP server to the FTP client for backup.

Figure 39 Network diagram

Note: The orange line represents an IRF link.

Configuration procedure

- Configure the FTP server:
 - # Examine the storage medium of the device for insufficiency or impairment. If no sufficient free space is available, use the **delete/unreserved file-url** command to delete unused files. (Details not shown.)

Create a local user account **abc**, set its password to **abc** and the user privilege level to level 3 (the manage level), specify the Flash root directory of the master device as the authorized directory, and specify the service type as FTP.

```
<Sysname> system-view
[Sysname] local-user abc
[Sysname-luser-abc] password simple abc
[Sysname-luser-abc] authorization-attribute level 3
[Sysname-luser-abc] authorization-attribute work-directory flash:/
[Sysname-luser-abc] service-type ftp
[Sysname-luser-abc] quit
```

To access the Flash root directory of the subordinate device (with the member ID 2), replace **flash:/** in the command **authorization-attribute work-directory flash:/** with **slot2#flash:/**.

Enable the FTP server.

```
[Sysname] ftp server enable
[Sysname] quit
```

2. Perform FTP operations from the FTP client:

Log in to the FTP server at 1.1.1.1 by using the username **abc** and password **abc**.

```
c:\> ftp 1.1.1.1
Connected to 1.1.1.1.
220 FTP service ready.
User(1.1.1.1:(none)):abc
331 Password required for abc.
Password:
230 User logged in.
```

Download the configuration file **config.cfg** from the FTP server to the PC for backup.

```
ftp> get config.cfg back-config.cfg
```

Upload the file **newest.bin** to the Flash root directory of the master.

```
ftp> put newest.bin
ftp> bye
```

This FTP procedure also applies to upgrading configuration files.

After you finish upgrading the Boot ROM image through FTP, execute the **bootrom update** command to upgrade Boot ROM.

3. Upgrade the FTP server:

Copy the system software image file **newest.bin** to the Flash root directory of the subordinate device (with the member ID 2).

```
<Sysname> copy newest.bin slot2#flash:/
```

Specify **newest.bin** as the main system software image file for the next startup of all member devices.

```
<Sysname> boot-loader file newest.bin slot all main
This command will set the boot file of the specified board. Continue? [Y/N]:y
The specified file will be used as the main boot file at the next reboot on slot
1!
The specified file will be used as the main boot file at the next reboot on slot
2!
```

! **IMPORTANT:**

The system software image file used for the next startup and the startup configuration file must be saved in the Flash root directory. You can copy or move a file to the Flash root directory.

```
# Reboot the IRF fabric and the system software image file is updated at the system reboot.  
<Sysname> reboot
```

Displaying and maintaining FTP

Task	Command	Remarks
Display the source IP address configuration of the FTP client.	display ftp client configuration [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the FTP server configuration.	display ftp-server [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display online FTP user information.	display ftp-user [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Configuring TFTP

Trivial File Transfer Protocol (TFTP) is a simplified version of FTP for file transfer over secure reliable networks. TFTP uses UDP port 69 for data transmission. In contrast to TCP-based FTP, TFTP requires no authentication or complex message exchanges, and is easier to deploy.

TFTP supports the following transfer modes:

- **Binary mode**—Used to transfer image files, such as **.app** and **.bin .btm** files.
- **ASCII mode**—Used to transfer text files, such as **.txt**, **.bat**, and **.cfg** files.

The device can operate only as a TFTP client (see Figure 40) to upload or download files.

Figure 40 TFTP application scenario

Prerequisites

Run a TFTP server program on the file host and set a TFTP working directory.

Configure IP addresses and routes to make sure that the device and the TFTP server can reach each other.

Using the device as a TFTP client

The device provides the following modes for downloading a new file from a TFTP server:

- **Normal download**—The new file is written directly to Flash and overwrites the old file that has the same name as it. If file download is interrupted, both old and new files are lost.
- **Secure download**—The new file is downloaded to memory and will not be written to Flash until the whole file is obtained. A download failure does not affect the old file that has the same name as the old file.

To avoid undesired file loss, use the secure download mode. If you use the normal download mode because of insufficient memory, assign the new file a file name unique in Flash.

You can use the **fttp client source** command to specify a source IP address or source interface for the TFTP packets sent by the device. If a source interface (typically, a loopback interface) is specified, its primary IP address is used as the source IP address for the TFTP packets. The source interface setting and the source IP address setting overwrite each other.

The **fttp client source** command setting applies to all TFTP sessions. When you set up a TFTP session with the **fttp** command, you can also specify a different source IP address for the TFTP session.

! IMPORTANT:

To avoid TFTP connection failures, when you specify a source interface for TFTP packets, make sure the interface has a primary IP address.

To configure the TFTP client:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Use an ACL to control the client's access to TFTP servers.	tftp-server [ipv6] acl acl-number	Optional. By default, no ACL is used for access control.
3. Specify a source IP address for outgoing TFTP packets.	tftp client source { interface interface-type interface-number ip source-ip-address }	Optional. By default, the primary IP address of the output interface is used as the source IP address.
4. Set the DSCP value for IP to use for outgoing TFTP packets.	<ul style="list-style-type: none"> For IPv4: tftp client dscp dscp-value For IPv6: tftp client ipv6 dscp dscp-value 	Optional The default is 0, whether the TFTP client is running IPv4 or IPv6.
5. Return to user view.	quit	N/A
6. Download or upload a file.	<ul style="list-style-type: none"> For IPv4: tftp server-address { get put sget } source-filename [destination-filename] [vpn-instance vpn-instance-name] [source { interface interface-type interface-number ip source-ip-address }] For IPv6: tftp ipv6 tftp-ipv6-server [-i interface-type interface-number] { get put } source-filename [destination-filename] [vpn-instance vpn-instance-name] 	Optional. Only HP 5500-EI switches support the vpn-instance vpn-instance-name option.

Displaying and maintaining the TFTP client

Task	Command	Remarks
Display the source IP address configuration of the TFTP client.	display tftp client configuration [{ begin exclude include } regular-expression]	Available in any view

TFTP client configuration example

Network requirements

Configure the PC in [Figure 41](#) as a TFTP server, and use TFTP to download the system software image file **newest.bin** from the TFTP server to the client and upload the configuration file **config.cfg** from the TFTP client to the server for backup.

Figure 41 Network diagram

Configuration procedure

This configuration procedure assumes that the PC and the IRF fabric can reach each other.

1. Configure the PC (TFTP server):

- Enable the TFTP server. (Details not shown.)
- Configure a TFTP working directory. (Details not shown.)

2. Configure the IRF fabric (TFTP client):

Examine the storage medium of the device for insufficiency or impairment. If no sufficient free space is available, use the **delete/unreserved file-url** command to delete unused files. (Details not shown.)

Download system software image file **newest.bin** from the PC to the master and subordinate devices.

- Download system software image file **newest.bin** from the PC to the root directory of the Flash on the master.

```
<Sysname> tftp 1.2.1.1 get newest.bin
```

- Download system software image file **newest.bin** from the PC to the root directory of the Flash on a subordinate device (with the member ID 2).

```
<Sysname> tftp 1.2.1.1 get newest.bin slot2#flash:/newest.bin
```

Upload a configuration file **config.cfg** to the TFTP server.

```
<Sysname> tftp 1.2.1.1 put config.cfg configback.cfg
```

Specify **newest.bin** as the main system software image file for the next startup for all member devices.

```
<Sysname> boot-loader file newest.bin slot all main
```

```
This command will set the boot file of the specified board. Continue? [Y/N]:y
```

```
The specified file will be used as the main boot file at the next reboot on slot 1!
```

```
The specified file will be used as the main boot file at the next reboot on slot 2!
```

! **IMPORTANT:**

The system software image file used for the next startup must be saved in the Flash root directory. You can copy or move a file to the Flash root directory.

Reboot the IRF fabric and the software is upgraded.

```
<Sysname> reboot
```

Managing the file system

This chapter describes how to manage the device's file system, including the storage media, directories and files.

Managing files

△ CAUTION:

To avoid file system corruption, do not plug or unplug storage media or perform active/standby switchover while the system is processing a file operation.

You can display directory or file information; display file contents; rename, copy, move, remove, restore, and delete files.

The copy operation enables you to create a file. You can also create a file by performing the download operation or using the **save** command.

When you specify a file, enter the file name in one of the formats shown in, Table 18.

Table 18 File name formats

Format	Description	Length	Example
<i>file-name</i>	Specifies a file in the current working directory.	1 to 91 characters	a.cfg indicates a file named a.cfg in the current working directory. This working directory might be on the master device or a subordinate device.
<i>path/file-name</i>	Specifies a file in a specific folder in the current working directory. The <i>path</i> argument represents the path to the file. If the file is in a single-level folder, specify the folder name for the argument. If the file is in a nested folder, separate each folder name by a forward slash (/).	1 to 135 characters	test/a.cfg indicates a file named a.cfg in the test folder in the current working directory.

Format	Description	Length	Example
<i>drive:/[path]/file-name</i>	<p>Specifies a file in a specific storage medium on the device.</p> <p>The <i>drive</i> argument represents the storage medium name.</p> <p>The storage medium on the master is typically flash.</p> <p>The storage medium on a subordinate device is typically slotX#flash, where X represents the member ID of the subordinate device, for example, slot2#flash.</p> <p>To view the correspondence between a device and its member ID, use the display irf command.</p>	1 to 135 characters	<p>flash:/test/a.cfg indicates a file named a.cfg in the test folder in the root directory of the Flash memory on the master.</p> <p>To access the file a.cfg in the root directory of the Flash on the subordinate device with member ID 2, enter slot2#flash:/a.cfg for the file name.</p>

Displaying file information

Perform this task in user view.

Task	Command
Display file or directory information.	dir [/all] [<i>file-url</i> /all-filestems]

Displaying file contents

Perform this task in user view.

Task	Command	Remarks
Display the contents of a file.	more <i>file-url</i>	Only text files can be displayed.

Renaming a file

Perform this task in user view.

Task	Command
Rename a file.	rename <i>fileurl-source fileurl-dest</i>

Copying a file

Perform this task in user view.

Task	Command
Copy a file.	copy <i>fileurl-source fileurl-dest</i>

Moving a file

Perform this task in user view.

Task	Command
Move a file.	move <i>fileurl-source fileurl-dest</i>

Deleting/restoring a file

You can delete a file permanently or just move it to the recycle bin. A file moved to the recycle bin can be restored, but a file permanently deleted cannot.

A file in the recycle bin occupies storage space. To release the occupied space, execute the **reset recycle-bin** command in the directory that holds the file. To save storage space, periodically empty the recycle bin with the **reset recycle-bin** command.

Perform the following tasks in user view:

Task	Command
Delete a file by moving it to the recycle bin.	delete <i>file-url</i>
Restore a file from the recycle bin.	undelete <i>file-url</i>
Delete a file permanently.	delete /unreserved <i>file-url</i>

Emptying the recycle bin

Step	Command	Remarks
1. Enter the original working directory of the file to be deleted in user view.	cd { <i>directory</i> <i>..</i> <i>/</i> }	Skip this step if the original directory of the file to be deleted is the current working directory.
2. Empty the recycle bin.	reset recycle-bin [<i>/force</i>]	N/A

Managing directories

You can create or remove a directory, display or change the current working directory, and display a specific directory.

Displaying directory information

Perform this task in user view.

Task	Command
Display directory or file information.	dir [<i>/all</i>] [<i>file-url</i> <i>/all-filestems</i>]

Displaying the current working directory

Perform this task in user view.

Task	Command
Display the current working directory.	<code>pwd</code>

Changing the current working directory

Perform this task in user view.

Task	Command
Change the current working directory.	<code>cd { <i>directory</i> .. / }</code>

Creating a directory

Perform this task in user view.

Task	Command
Create a directory.	<code>mkdir <i>directory</i></code>

Removing a directory

Before you remove a directory, you must delete all files and subdirectories in this directory. To delete a file, use the **delete** command; to delete a subdirectory, use the **rmdir** command.

The **rmdir** command automatically deletes the files in the recycle bin in the current directory.

Perform this task in user view.

Task	Command
Remove a directory.	<code>rmdir <i>directory</i></code>

Managing storage media

Storage media management includes space assignment. A storage medium is named based on the following rules:

If a storage medium is the only storage medium of its type on the device, it is named by its type. For example, if the device has only one Flash, the name of the Flash is **flash**.

Managing storage medium space

When the space of a storage medium becomes inaccessible, you can use the **fixdisk** command to examine the medium for damage and repair any damage.

The **format** command formats the storage medium, and all data on the storage medium is deleted.

△ CAUTION:

After a storage medium is formatted, all files on it are erased and cannot be restored. If a startup configuration file exists on the storage medium, formatting the storage medium results in loss of the startup configuration file.

To manage the space of a storage medium, perform the following tasks in user view:

Task	Command	Remarks
Repair a storage medium.	fixdisk <i>device</i>	N/A
Format a storage medium.	format <i>device</i>	N/A

Performing batch operations

A batch file comprises a set of executable commands. Executing a batch file is the same as executing the commands one by one. However, execution of a batch file does not guarantee successful execution of every command in the batch file. If a command has error settings or the conditions for executing the command are not satisfied, the system skips this command.

You can edit a batch file on your PC, and then upload or download it to the device. If the extension of the file is not **.bat**, use the **rename** command to change it to **.bat**.

To execute a batch file:

Step	Command
1. Enter system view.	system-view
2. Execute a batch file.	execute <i>filename</i>

Setting the file system operation mode

The file systems support the following operation modes:

- **alert**—The system warns you about operations that might cause problems such as file corruption and data loss. To prevent incorrect operations, use the **alert** mode.
- **quiet**—The system does not prompt for any operation confirmation.

To set the file system operation mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the file system operation mode.	file prompt { alert quiet }	Optional. The default is alert .

File system management examples

```
# Display the files and the subdirectories in the current directory.  
<Sysname> dir
```

```
Directory of flash:/
 0  -rw- 13308645 Mar 22 2011 11:34:07  main.bin
 1  -rw-   7380 Mar 25 2011 10:47:36  patch-package.bin
 2  -rw-   228 Mar 25 2011 10:50:39  patchstate
 3  -rw-   3921 Apr 01 2011 17:56:30  startup.cfg
 4  -rw-   151 Apr 01 2011 17:56:24  system.xml
15240 KB total (2521 KB free)

# Create new folder mytest in the test directory.
<Sysname> cd test
<Sysname> mkdir mytest
%Created dir flash:/test/mytest.

# Display the current working directory.
<Sysname> pwd
flash:/test

# Display the files and the subdirectories in the test directory.
<Sysname> dir
Directory of flash:/test/
 0  drw-      - Apr 01 2011 18:28:14  mytest
15240 KB total (2519 KB free)

# Return to the upper directory.
<Sysname> cd ..

# Display the current working directory.
<Sysname> pwd
flash:
```

Managing configuration files

You can manage configuration files at the CLI or by using the Boot menu of the device. This chapter describes the CLI approach.

Overview

A configuration file saves a configuration as a set of text commands. You can save the running configuration to a configuration file so the configuration takes effect after you reboot the device. You can also back up the configuration file to a host and download the file to the device as needed.

Configuration types

The device maintains the following types of configurations: factory defaults, startup configuration, and running configuration.

Factory defaults

The device is shipped with some basic settings called "factory defaults." These default settings make sure the device can start up and run normally when it has no configuration file or the configuration file is corrupted.

To view the factory defaults, use the **display default-configuration** command.

NOTE:

Factory defaults vary with device models and might differ from the default settings of commands.

Startup configuration

The device uses startup configuration to configure software features during startup. After the device starts up, you can specify a different configuration file for the next startup. This configuration file is called the "next-startup configuration file."

If no next-startup configuration file exists, the device boots with the factory defaults.

To view the current startup configuration, use either of the following ways:

- Execute the **display startup** command. To view detailed file contents, use the **more** command.
- After the device reboots, execute the **display current-configuration** command before making any configuration.

Running configuration

The running configuration includes the startup settings that have not been changed and the new settings you have made.

The running configuration is stored in a volatile storage medium. To make the settings you made to survive a reboot, save them to the startup configuration file.

To view the running configuration, use the **display current-configuration** command.

Configuration file format and content

A configuration file is saved as a text file according to the following rules:

- Commands are saved in their complete form.
- The commands are listed in sections by view, typically in this order: system view, interface view, protocol views, and user interface view.
- Sections are separated with one or more blank lines or comment lines that start with a pound sign (#).
- A configuration file ends with a return.

Coexistence of multiple configuration files

The device can save multiple configuration files on its storage media. You can save the configurations used for different networking environments to different configuration files. When the device moves between networking environments, you can quickly adapt the device to the environments by loading the intended configuration file onto the device.

You can specify one main startup configuration file and one backup startup configuration file for the device. At startup, the device first tries to start up with the main startup configuration file. If the main startup configuration file is corrupted or lost, the device tries to start up with the backup startup configuration file. For reliability, do not specify a configuration file as both the main and backup startup configuration files. If a configuration file is not assigned the main or backup attribute, its file attribute is NULL.

You can specify a main or backup startup configuration file directly (see "[Specifying a configuration file](#)") or when saving the running configuration (see "[Saving the running configuration](#)").

Startup with a configuration file

The device selects the configuration file to load at startup, as follows:

1. If the specified main startup configuration file exists, the device starts up with this configuration file.
2. If the specified main startup configuration file does not exist but the backup startup configuration file exists, the device starts up with the backup startup configuration file.
3. If neither the main nor the backup startup configuration file exists, the device starts up with the factory defaults.

Saving the running configuration

To make configuration changes take effect at the next startup of the device, save the running configuration to the startup configuration file to be used at the next startup before the device reboots.

Complete these tasks to save the current configuration:

Task	Remarks
Enabling configuration file auto-update	Optional Perform this task to ensure configuration consistency across member devices.
Saving running configuration in fast mode or safe mode	Required

Enabling configuration file auto-update

The configuration auto-update function enables all subordinate switches to automatically save the running configuration as the master does when you execute the **save** [**safely**] [**backup** | **main**] [**force**] command or the **save filename all** command. If this function is disabled, only the master saves the configuration.

To ensure configuration consistency, HP recommends enabling the function.

To enable configuration auto-update:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable configuration file auto-update.	slave auto-update config	By default, this function is enabled.

Saving running configuration in fast mode or safe mode

You can save the running configuration to a configuration file in one of the following modes:

- **Fast mode**—Use the **save** command without the **safely** keyword. The file is saved more quickly but is likely to be lost if the device reboots or power failure occurs during the process. If the startup configuration file for the next startup is lost, the device will use the factory defaults the next time it reboots, and you must re-specify a new startup configuration file for the device (see "Specifying a configuration file for the next startup").
- **Safe mode**—Use the **save** command with the **safely** keyword. The file is saved slowly, but the system retains the configuration file even if the device reboots or a power failure occurs during the process.

The fast saving mode is suitable for environments where a reliable power source is used. The safe mode is preferred in environments where the power source is not reliable or remote maintenance is involved.

The configuration file name extension must be **.cfg**.

To save the running configuration, perform either of the following tasks in any view:

Task	Command	Remarks
Save the running configuration to a configuration file without specifying the file as the startup configuration file for the next startup.	save file-url [all slot slot-number]	The save command executed with only the <i>file-url</i> argument saves the running configuration only to the specified path, regardless of whether the configuration auto-update function has been enabled.

Task	Command	Remarks
Save the running configuration to a configuration file and specify the file as the startup configuration file for the next startup.	save [safely] [backup main] [force]	By default, the running configuration is saved to the current startup configuration file. You can choose to save the configuration to a different file as instructed by the system. If you execute the save [safely] command without specifying any other keyword, the command saves the configuration to the main startup configuration file.

If configuration auto-update is enabled, the **save file-url all** command and the **save** [**safely**] [**backup** | **main**] [**force**] command save the configuration to the master device and all member devices. If the function is disabled, the commands save the configuration only to the master device.

Configuring configuration rollback

To replace the running configuration with the configuration in a configuration file without rebooting the device, use the configuration rollback function. This function helps you revert to a previous configuration state or adapt the running configuration to different network environments.

The configuration rollback function compares the running configuration against the specified replacement configuration file and handles configuration differences as follows:

- If a command in the running configuration is not in the replacement file, executes its **undo** form.
- If a command in the replacement file is not in the running configuration, adds it to the running configuration.
- If a command has different settings in the running configuration and the configuration file, replaces its running configuration with the setting in the configuration file.

To facilitate configuration rollback, the configuration archive function is developed. This function enables the system to automatically save the running configuration at regular intervals as checkpoint references.

Configuration task list

Task	Remarks
Configuring configuration archive parameters	Required.
<ul style="list-style-type: none"> • Enabling automatic configuration archiving • Manually archiving running configuration 	Required. Use either approach.
Performing configuration rollback	Required.

Configuring configuration archive parameters

Before archiving the running configuration, either manually or automatically, you must configure a file directory and file name prefix for configuration archives.

Configuration archives are saved with the file name format *prefix_serial number.cfg*, for example, **20080620archive_1.cfg** and **20080620archive_2.cfg**. The serial number is automatically assigned from 1 to 1000, increasing by 1. After the serial number reaches 1000, it restarts from 1.

After you change the file directory or file name prefix, or reboot the device, the old configuration archives are regarded as common configuration files, the configuration archive counter resets, and the **display archive configuration** command does not display them. The serial number for new configuration archives starts from 1.

After the maximum number of configuration archives is reached, the system deletes the oldest archive for the new archive.

Configuration guidelines

In an IRF fabric, the configuration archive function saves running configuration only on the master device. To make sure the system can archive running configuration after a master/subordinate switchover, create the directory on all IRF members.

Configuration procedure

To configure configuration archive parameters:

Step	Command	Remarks
1. Create the configuration archive directory.	See "Managing the file system."	In an IRF fabric, create the directory at least on the master. HP recommends creating the directory on all member devices.
2. Enter system view.	system-view	N/A
3. Configure the directory and file name prefix for archiving the running configuration.	archive configuration location <i>directory filename-prefix</i> <i>filename-prefix</i>	Do not include member ID information in the directory name. By default, no path or file name prefix is set for configuration archives, and the system does not regularly save configuration. ! IMPORTANT: The undo form of this command disables both manual and automatic configuration archiving, restores the default settings for the archive configuration interval and archive configuration max commands, and deletes all saved configuration archives.
4. Set the maximum number of configuration archives.	archive configuration max <i>file-number</i>	Optional. The default number is 10. Change the setting depending on the available storage space.

Enabling automatic configuration archiving

To avoid decreasing system performance, follow these guidelines when you configure automatic configuration archiving:

- If the device configuration does not change frequently, manually archive the running configuration as needed.
- If a low-speed storage media (such as a Flash) is used, archive the running configuration manually, or configure automatic archiving with an interval longer than 1440 minutes (24 hours).

Make sure you have set an archive path and file name prefix before performing this task.

To enable automatic configuration archiving:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable automatic configuration archiving and set the archiving interval.	archive configuration interval <i>minutes</i>	By default, this function is disabled. To view configuration archive names and their archiving time, use the display archive configuration command.

Manually archiving running configuration

To save system resources, disable automatic configuration archiving and manually archive configuration if the configuration will not be changed very often. You can also manually archive configuration before performing complicated configuration tasks so you can use the archive for configuration recovery after the configuration attempt fails.

Make sure you have set an archive path and file name prefix before performing this task.

Perform the following task in user view:

Task	Command
Manually archive the running configuration.	archive configuration

Performing configuration rollback

To avoid rollback failure, follow these guidelines:

- Do not reboot member devices while the system is executing the **configuration replace file** command. Make sure the replacement configuration file is created by using the configuration archive function or the **save** command on the current device.
- If the configuration file is not created on the current device, make sure the configuration file content format is fully compatible with the current device.
- The replacement configuration file is not encrypted.

To perform configuration rollback:

Step	Command
1. Enter system view.	system-view
2. Perform configuration rollback.	configuration replace file filename

The configuration rollback function might fail to reconfigure some commands in the running configuration for one of the following reasons:

- A command cannot be undone because the **undo** form designed for the command does not include a keyword or argument configured in the command. For example, if the **undo** form designed for the **A [B] C** command is **undo A C**, the configuration rollback function cannot undo the **A B C** command, because the system does not recognize the **undo A B C** command.
- A command (for example, a hardware-dependent command) cannot be deleted, overwritten, or undone due to system restrictions.
- The commands in different views are dependent on each other.
- Commands or command settings not supported on the current device cannot be added to the running configuration.

Specifying a configuration file for the next startup

You can specify a configuration file as the main startup configuration file to be used at the next startup when you use the **save** command to save the running configuration to it.

Alternatively, perform the following task in user view to specify a startup configuration file for the next startup:

Task	Command	Remarks
Specify a startup configuration file of all member switches.	startup saved-configuration <i>cfgfile</i> [backup main]	The configuration file must use the .cfg extension and be saved in the root directory of storage media.

Backing up the next-startup configuration file to a TFTP server

Before performing this task, make sure the server is reachable and enabled with TFTP service, and you have read and write permissions.

This task backs up only the main next-startup configuration file.

To back up the startup configuration file to be used at the next startup:

Step	Command	Remarks
1. Verify that a next-startup configuration file has been specified in user view.	display startup	Optional. If no next-startup configuration file has been specified, the back operation will fail.

Step	Command	Remarks
2. Back up the next-startup configuration file to a TFTP server in user view.	backup startup-configuration to <i>dest-addr</i> [<i>dest-filename</i>]	N/A

Deleting the next-startup configuration file

⚠ CAUTION:

This task permanently deletes the next-startup configuration file from all member devices. Before performing this task, back up the file as needed.

You can delete the main, the backup, or both. If the device has only one next-startup configuration file, the system sets the attribute of the configuration file to NULL instead of deleting the file.

You may need to delete the next-startup configuration file for one of the following reasons:

- After you upgrade system software, the file does not match the new system software.
- The file has been corrupted or is not fully compatible with the device.

After the file is deleted, the device uses factory defaults at the next startup.

Perform the following task in user view:

Task	Command
Delete the next-startup configuration file.	reset saved-configuration [backup main]

Restoring the next-startup configuration file from a TFTP server

To download a configuration file from a TFTP server to the root directory of each member' storage medium, and specify the file as the configuration file for the next startup, perform the task in this section.

This task restores only the main next-startup configuration file.

Before restoring the next-startup configuration file, make sure the server is reachable, the server is enabled with TFTP service, and you have read and write permissions.

To restore the next-startup configuration file from a TFTP server:

Step	Command	Remarks
1. Restore the main next-startup configuration file from a TFTP server in user view.	restore startup-configuration from <i>src-addr</i> <i>src-filename</i>	N/A
2. Verify that the specified configuration file has been set as the main next-startup configuration file.	display startup	Optional

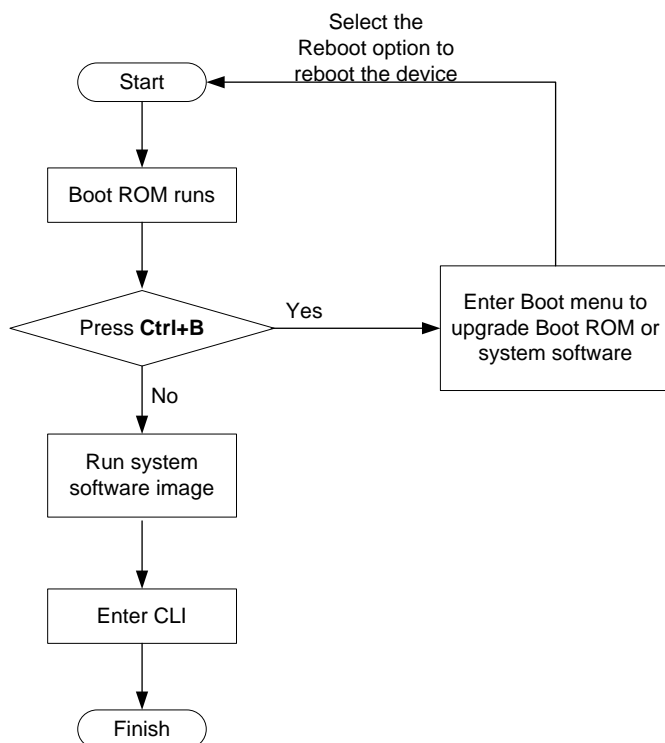

Displaying and maintaining a configuration file

Task	Command	Remarks
Display information about configuration rollback.	display archive configuration [{ begin exclude include } <i>regular-expression</i>]	Available in any view.
Display the running configuration.	display current-configuration [[configuration [<i>configuration</i>] interface [<i>interface-type</i>] [<i>interface-number</i>] exclude modules] [by-linenum] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view.
Display the factory defaults.	display default-configuration [{ begin exclude include } <i>regular-expression</i>]	Available in any view.
Display the running configuration file saved on the storage media of the device.	display saved-configuration [by-linenum] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view.
Display the configuration files used at this startup and the next startup.	display startup [[{ begin exclude include } <i>regular-expression</i>]	Available in any view.
Display the valid configuration under the current view.	display this [by-linenum] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view.

Upgrading software

Upgrading software includes upgrading the Boot ROM and system software. Each time the switch is powered on, it runs the Boot ROM image to initialize hardware and display hardware information, and then runs the system software image (also called the "boot file") so you can access the software features, as shown in Figure 42.

Figure 42 Relationship between the Boot ROM and the system software images

Software upgrade methods

You can upgrade both Boot ROM and system software at the Boot menu or at the CLI. The following sections describe the CLI approach. For instructions about how to upgrade them at the Boot menu, see the release notes of your switch.

The CLI approach provides the following upgrading methods:

Upgrade method	Upgrade object	Description
Upgrading software through a system reboot	Boot ROM and system software	A switch reboot is required during the upgrade, causing service interruption.
Upgrading software by installing hotfixes	System software	Hotfixes repair software defects without rebooting the switch and interrupting the running services of the switch. The patch files must match the switch model and software version. Otherwise, the hotfixing operation fails.

Upgrade method	Upgrade object	Description
In-Service Software Upgrade (ISSU)	System software	ISSU enables software upgrade and ensures continues packet forwarding. For more information, see "Performing ISSU." The ISSU feature is available only on the HP 5500-EI switch.

Upgrading software through a system reboot

Upgrading software by rebooting the switch interrupts the ongoing services. If any other method is possible, do not use this method.

Upgrading Boot ROM through a system reboot

1. Transfer the Boot ROM image to the root directory of the switch's storage media, for example, by using FTP or TFTP.

ⓘ IMPORTANT:

- To successfully upgrade the Boot ROM of a member switch, make sure the Boot ROM image is stored in the root directory of the member switch's storage media.

2. Upgrade the Boot ROM from the CLI, as follows:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable Boot ROM image validity check.	bootrom-update security-check enable	Optional By default, the validity check function is enabled. This feature examines the upgrade Boot ROM image for version and hardware incompatibility to ensure a successful upgrade.
3. Return to user view.	quit	N/A
4. Upgrade Boot ROM on member switches.	bootrom update file file-url slot slot-number-list	Available in user view.

3. Reboot the switch.

Upgrading system software through system reboot (method 1)

1. Transfer the system software image to the root directory of the master switch's storage media, for example, by using FTP or TFTP.

ⓘ IMPORTANT:

The image file must be saved in the root directory for a successful upgrade.

2. Copy the new system software image to the root directory of each subordinate switch's storage media.

❗ **IMPORTANT:**

You can assign different names to the image files for different member switches, but must make sure the image versions are the same.

3. Use the **boot-loader file** *file-url slot* { **all** | *slot-number* } { **main** | **backup** } command in user view to specify the system software image to be used at the next startup for each member switch.
4. Reboot all member switches.

Upgrading system software through system reboot (method 2)

This method simplifies the software upgrade procedure described in "Upgrading system software through system reboot (method 1)" for a multiple-MPU context by using one command to complete copying a system software image to an MPU and specifying the file as the system software image to be used at the next startup.

To use this method to upgrade system software:

1. Transfer the system software image to the root directory of the master switch's storage media, for example, by using FTP or TFTP.
2. Use the **boot-loader update file** *file-url slot* { *slot-number* | **all** } { **main** | **backup** } command in user view to specify the system software image as the file to be used at the next startup for each member switch.
3. Reboot all member switches.

Upgrading software by installing hotfixes

Hotfixes can repair software defects without rebooting the switch.

Basic concepts

- Patch and patch file

A patch fixes certain software defects. Patches might be released as patch files. A patch file might contain one or more patches. After being loaded from the storage media to the memory patch area, each patch is assigned a unique number, which starts from 1, for identification, management and operation. For example, if a patch file has three patches, they are numbered as 1, 2, and 3.
- Incremental patch

Incremental patches are dependent on previous patches and cannot separately run. For example, if a patch file has three patches, patch 3 can be running only after patch 1 and 2 take effect. You cannot run patch 3 separately.

Patches that have been released are all incremental patches.
- Common patch and temporary patch

There are common and temporary patches:

 - Common patches are formally released through the version release flow.
 - Temporary patches are not formally released through the version release flow, but temporarily provided to solve the emergent problems.

Common patches always include the functions of the previous temporary patches. The patch type only affects the patch loading process. The system deletes all of the temporary patches before it loads the common patch.

- Patch package file

A patch package file typically contains multiple patch files. A patch package file enables you to fix bugs for multiple components by executing a single command.

Using patch files is more troublesome. Patch file names are strictly defined and cannot be changed. To fix software bugs for a component, you must download the specific patch file, and rename the file to that pre-defined for the hardware. If the file name is unqualified, the upgrade fails. If there are multiple components, repeat this operation multiple times.

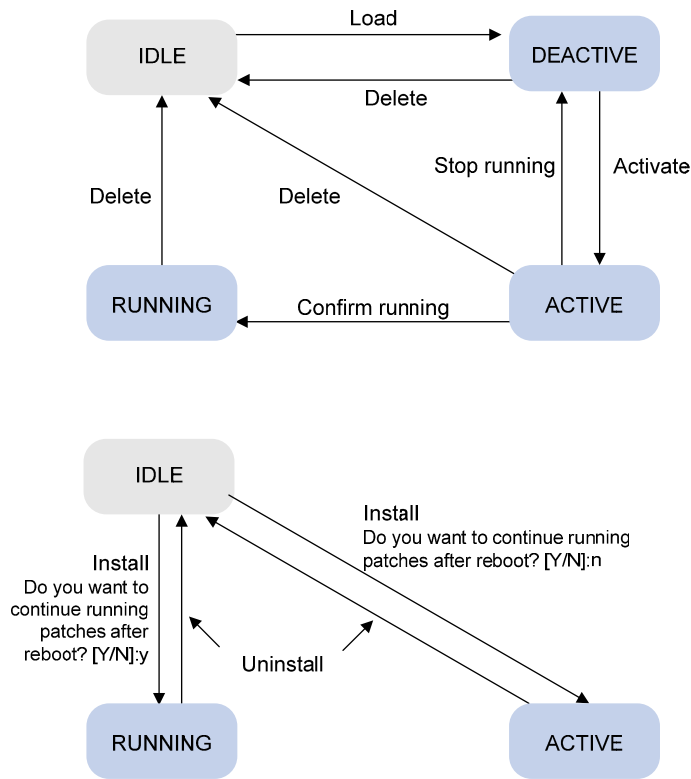

Patch state

Each patch has a state, which can be switched only by commands. The relationship between patch state changes and command actions is shown in Figure 43. The patch can be in IDLE, DEACTIVE, ACTIVE, or RUNNING state. Load, run temporarily, confirm running, stop running, delete, install, and uninstall are operations and they correspond to the following commands: **patch load**, **patch active**, **patch run**, **patch deactivate**, **patch delete**, **patch install**, and **undo patch install**. For example, if you execute the **patch active** command for the patches in DEACTIVE state, the patches switch to the ACTIVE state.

❗ **IMPORTANT:**

Patch state information is saved in Flash memory in the file **patchstate**. To make sure that the switch can correctly find the patches, do not edit, delete, move the file, or change the file name.

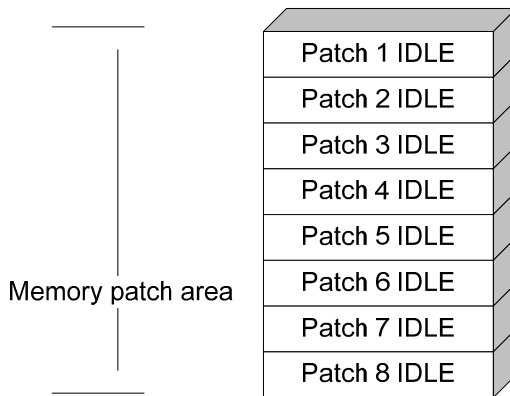

Figure 43 Relationship between patch state changes and command actions

IDLE state

Patches in IDLE state are not loaded. You cannot install or run the patches, as shown in [Figure 44](#). In this example, the memory patch area can load up to eight patches.

Figure 44 Patches are not loaded to the memory patch area

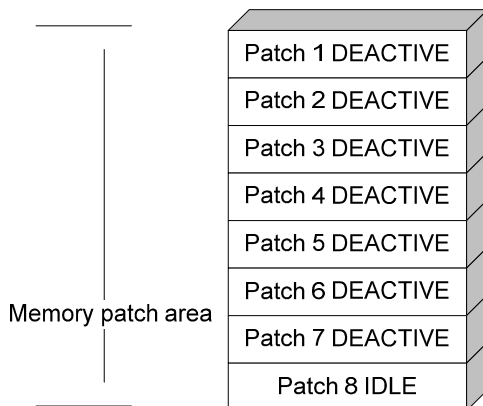

The memory patch area supports up to 200 patches.

DEACTIVE state

Patches in DEACTIVE state have been loaded to the memory patch area but have not yet run in the system. Suppose that there are seven patches in the patch file to be loaded. After the seven patches successfully pass the version check and CRC check, they are loaded to the memory patch area and are in DEACTIVE state. At this time, the patch states in the system are as shown in [Figure 45](#).

Figure 45 A patch file is loaded to the memory patch area

ACTIVE state

Patches in ACTIVE state have run temporarily in the system and become DEACTIVE after system reboot. For the seven patches in [Figure 45](#), if you activate the first five patches, their states change from DEACTIVE to ACTIVE. The patch states in the system are as shown in [Figure 46](#).

The patches that are in ACTIVE state are in DEACTIVE state after system reboot.

Figure 46 Patches are activated

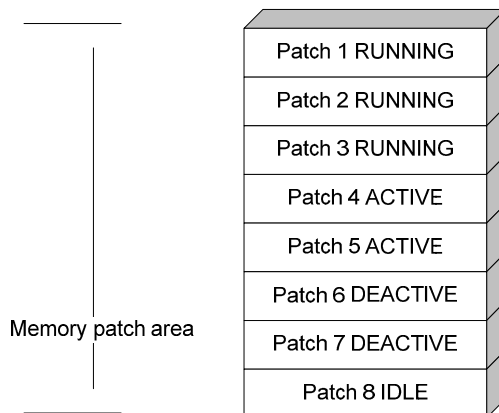

RUNNING state

After you confirm the ACTIVE patches are running, the state of the patches changes to RUNNING and the patches are in RUNNING state after system reboot. If you confirm the first three patches are running, for the five patches in [Figure 46](#), their states change from ACTIVE to RUNNING. The patch states of the system are shown in [Figure 47](#).

The patches that are in RUNNING state are still in RUNNING state after system reboot.

Figure 47 Patches are running

Hotfix configuration task list

Task	Remarks
Installing patches: <ul style="list-style-type: none">• Installing a patch in one step• Installing a patch step-by-step	Use either approach. The step-by-step patch installation allows you to control the patch status.
Uninstalling a patch step-by-step	Optional.

Installation prerequisites

Patches are released per switch model. To ensure a successful hotfix operation and normal switch operation after the hotfix operation:

- Make sure each patch file you are installing matches the switch model and software version.
- The loading and installation are performed on all member switches of an IRF fabric. Before these operations, save the same patch files to the storage media's root directory of each member switch.
- Name a patch file properly. Otherwise, the system cannot locate the patch file and the hotfixing operation fails. The name is in the format of "patch_PATCH-FLAG suffix.bin". The PATCH-FLAG is pre-defined. The value of the version field (using the **display patch information** command) represents the PATCH-FLAG suffix. The system searches the root directory of the storage media (Flash by default) for patch files based on the PATCH-FLAG. If there is a match, the system loads patches to or install them on the memory patch area. The default name of a patch file is patch_xxx.bin.

Installing a patch in one step

To install patches in one step, use the **patch install** command and specify either the directory where the patch file locates or the filename of the patch package.

After you execute the command, the system displays the message "Do you want to continue running patches after reboot? [Y/N]:"

- Entering **y** or **Y**: All the specified patches are installed, and turn to RUNNING state from IDLE. This equals executing commands **patch location**, **patch load**, **patch active**, and **patch run**. The patches remain RUNNING after system reboot.
- Entering **n** or **N**: All the specified patches are installed and turn to ACTIVE state from IDLE. This equals executing commands **patch location**, **patch load** and **patch active**. The patches turn to DEACTIVE state after system reboot.

To install the patches in one step:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Install the patches in one step.	patch install { <i>patch-location</i> file <i>patch-package</i> }	<ul style="list-style-type: none">• <i>patch-location</i>: Specifies the directory where the patch file locates. Provide this argument when you install a patch file which is not packaged in a patch package file.• file <i>patch-location</i>: Specifies the name of the patch package file. Provide this option when you install a patch package file.

If you execute the **patch install** *patch-location* command, the directory specified for the *patch-location* argument will replace the directory specified with the **patch location** command after the upgrade is complete.

If you execute the **patch install file** *patch-package* command, the directory specified with the **patch location** command does not change.

To uninstall all patches in one operation, use the **undo patch install** command, which is the same as performing [Uninstalling a patch step-by-step](#).

Installing a patch step-by-step

Step-by-step patch installation enables you to control the patch status during the patch installation process.

Step-by-step patch installation task list

Task	Remarks
Configuring the patch file location	Optional. To install a patch package, skip this step.
Loading a patch file	Required.
Activating patches	Required.
Confirming running patches	Optional.

Configuring the patch file location

HP recommends that you save the patch file to the root directory of the Flash. If you save the patch files to a storage medium other than the Flash, you must specify the directory that saves patch files so the system can locate them.

Make sure the specified directory exist on each member switch in the IRF fabric.

If the switch has only one storage medium, you do not need to perform this task.

To configure the patch file location:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the patch file location.	patch location <i>patch-location</i>	Optional. flash: by default.

NOTE:

After you execute the **patch install** *patch-location* command, the directory specified for the *patch-location* argument will replace the directory specified with the **patch location** command after the upgrade is complete.

Loading a patch file

Loading the correct patch files is the basis of other hotfix operations.

If you install a patch from a patch file, the system loads a patch file from the Flash by default.

If you install a patch from a patch package, the system finds the correct patch file in the patch package file and loads the patch file.

IMPORTANT:

Set the file transfer mode to binary mode before using FTP or TFTP to upload or download patch files to or from the Flash of the switch. Otherwise, patch file cannot be parsed properly.

To load a patch file:

Step	Command
1. Enter system view.	system-view
2. Load the patch file on from the storage media (the Flash) to the specified memory patch area.	patch load slot <i>slot-number</i> [file <i>patch-package</i>]

Activating patches

After you activate a patch, the patch takes effect and is in the test-run stage. After the switch is reset or rebooted, the patch becomes invalid.

If you find that an ACTIVE patch causes an error, reboot the switch to deactivate the patch, so as to avoid a series of running faults resulting from patch error.

To activate patches:

Step	Command
1. Enter system view.	system-view
2. Activate patches.	patch active [<i>patch-number</i>] slot <i>slot-number</i>

Confirming running patches

This operation is applicable only to patches in ACTIVE state.

After you confirm that the installed patch is running, the patch state changes to RUNNING, and the patch is in the normal running stage. After the switch is reset or rebooted, the patch is still valid.

To confirm the running of patches:

Step	Command
1. Enter system view.	system-view
2. Confirm the running of patches.	patch run [<i>patch-number</i>] [slot <i>slot-number</i>]

Uninstalling a patch step-by-step

This section describes the procedure of uninstalling patches.

Step-by-step patch uninstallation task list

Task	Remarks
Stopping running patches	Required
Deleting patches	Required

Stopping running patches

When you stop running a patch, the patch state becomes DEACTIVE, and the system runs the way it did before it was installed with the patch.

To stop running patches:

Step	Command
1. Enter system view.	system-view
2. Stop running patches.	patch deactivate [<i>patch-number</i>] slot <i>slot-number</i>

Deleting patches

Deleting patches only removes the patches from the memory patch area, and does not delete them from the storage media. The patches turn to IDLE state after this operation. After a patch is deleted, the system runs the way it did before it was installed with the patch.

In an IRF fabric, HP recommends that you uninstall all patches by using the **undo patch install** command in one operation.

To delete patches:

Step	Command
1. Enter system view.	system-view
2. Delete patches from the memory patch area.	patch delete [<i>patch-number</i>] slot <i>slot-number</i>

Displaying and maintaining software upgrade

Task	Command	Remarks
Display information about system software	display boot-loader [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the patch package.	display patch [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the patch information.	display patch information [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Software upgrade examples

Immediate upgrade configuration example

Network requirement

The IRF fabric in [Figure 48](#) comprises two member switches, the master use the member ID 1 and the subordinate switch uses the member ID 2. The current software version of the IRF fabric is **soft-version1**. The latest system software image **soft-version2.bin** and the latest configuration file **new-config.cfg** are both saved on the TFTP server. The TFTP server and IRF fabric can reach each other.

Upgrade the software version of the IRF fabric to **soft-version2** and the configuration file to **new-config**.

Figure 48 Network diagram

Configuration procedure

1. Configure the TFTP server (the configuration varies with server vendors):
Obtain the system software image and configuration file through legitimate channels, such as the official website of HP, agents, and technical staff. Save these files under the TFTP server's working path for the access of the TFTP clients.
2. Configure the members of the IRF fabric:

Download file **new-config.cfg** on the TFTP server to the master.

```
<IRF> tftp 2.2.2.2 get new-config.cfg
..
File will be transferred in binary mode
Downloading file from remote TFTP server, please wait.....
TFTP: 917 bytes received in 1 second(s)
File downloaded successfully.
```

Download file **new-config.cfg** to the subordinate switch with the member ID of 2.

```
<IRF> tftp 2.2.2.2 get new-config.cfg slot2#flash:/new-config.cfg
```

Download file **soft-version2.bin** on the TFTP server to the master and subordinate switch.

```
<IRF> tftp 2.2.2.2 get soft-version2.bin
...
File will be transferred in binary mode
Downloading file from remote TFTP server, please wait.....
TFTP: 10058752 bytes received in 141 second(s)
File downloaded successfully.
```

```
<IRF> tftp 2.2.2.2 get soft-version2.bin slot2#flash:/soft-version2.bin
```

Specify file **new-config.cfg** as the startup configuration file for all members of the IRF fabric.

```
<IRF> startup saved-configuration new-config.cfg main
Please wait ...
Setting the master board ...
... Done!
Setting the slave board ...
Slot 2:
Set next configuration file successfully
```

Specify file **soft-version2.bin** as the system software image to be used at the next boot of all members of the IRF fabric.

```

<IRF> boot-loader file soft-version2.bin slot all main
  This command will set the boot file of the specified board. Continue? [Y/N]:y
  The specified file will be used as the main boot file at the next reboot on slot
  1!
  The specified file will be used as the main boot file at the next reboot on slot
  2!
# Reboot the switch. The software version is upgraded now.
<IRF> reboot

```

3. Verify the configuration:

Use the **display version** command to check if the upgrade is successful. (Details not shown.)

Hotfix configuration example

Network requirements

The IRF fabric in Figure 49 comprises two member switches, the master and subordinate switch. The software running on the member switches has a bug. The patch files **patch_mpu.bin** and **patch_lpu.bin** are saved on the TFTP server. The IRF fabric and TFTP server can reach each other.

From the IRF fabric, use TFTP to download the patch files and then hotfix the software on the fabric.

Figure 49 Network diagram

Note: The orange line represents the IRF link.

Configuration procedure

1. Configure the TFTP server (the configuration varies with server vendors):

- Enable the TFTP server function. (Details not shown.)
- Save the patch files **patch_mpu.bin** and **patch_lpu.bin** to the directory of TFTP server. (Details not shown.)

2. Configure the IRF fabric:

Before upgrading the software, use the **save** command to save the current system configuration. (Details not shown.)

Examine the free space of the Flash on the switch. If the free space is not sufficient for the patch files, delete unused files to release enough space. (Details not shown.)

Load the patch files **patch_mpu.bin** and **patch_lpu.bin** from the TFTP server to the root directory of the master's storage media.

```

<IRF> tftp 2.2.2.2 get patch_mpu.bin
<IRF> tftp 2.2.2.2 get patch_lpu.bin

```

Load the patch files **patch_mpu.bin** and **patch_lpu.bin** from the TFTP server to the root directory of the subordinate switch's storage media.

```

<IRF> tftp 2.2.2.2 get patch_mpu.bin slot2#flash:/patch_mpu.bin
<IRF> tftp 2.2.2.2 get patch_lpu.bin slot2#flash:/patch_lpu.bin

```

Install the patch.

```
<IRF> system-view
```

```
[IRF] patch install flash:
```

```
Patches will be installed. Continue? [Y/N]:y
```

```
Do you want to continue running patches after reboot? [Y/N]:y
```

```
Installing patches.....
```

3. Verify the configuration:

After the installation is complete, use the **display patch information** command to verify whether the patches are installed successfully. (Details not shown.)

Performing ISSU

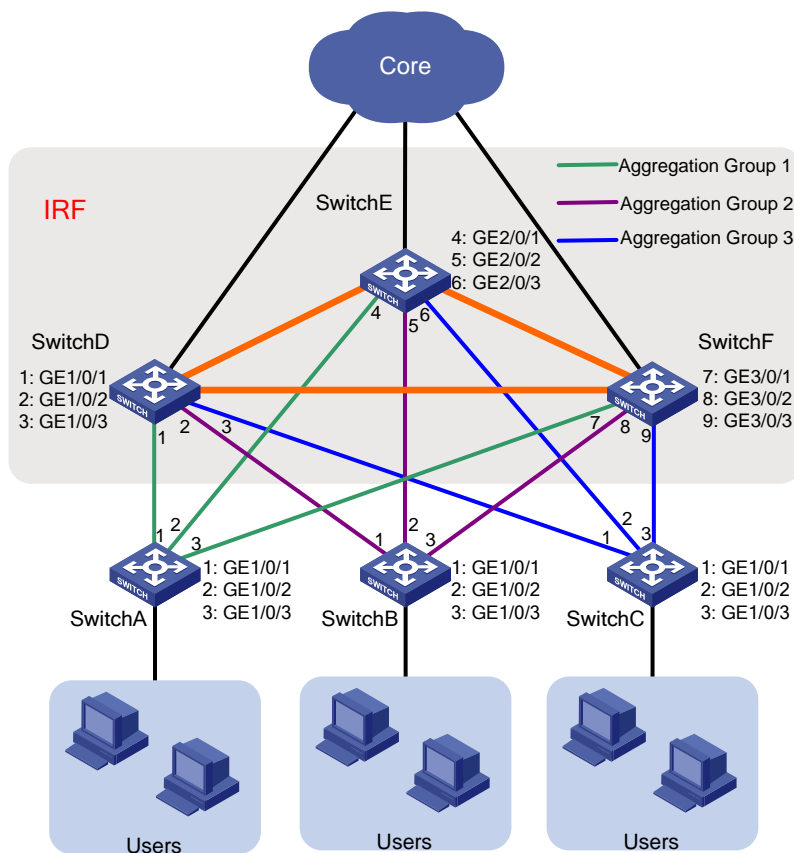

This chapter describes how to use the In-Service Software Upgrade (ISSU) feature to upgrade software. The ISSU feature is available only on the HP 5500-EI switch.

ISSU overview

ISSU enables software upgrade and ensures continuous packet forwarding.

As shown in Figure 50, to ensure high availability for user networks, cross-device link aggregation is configured on the IRF member switches at the distribution layer so that every three physical links with the same color between the IRF member switches and access switches are aggregated as one logical link. In this scenario, you can use ISSU to upgrade system software of each IRF member switch to ensure non-stop forwarding or reduce down time for users connected to Switch A, Switch B, and Switch C.

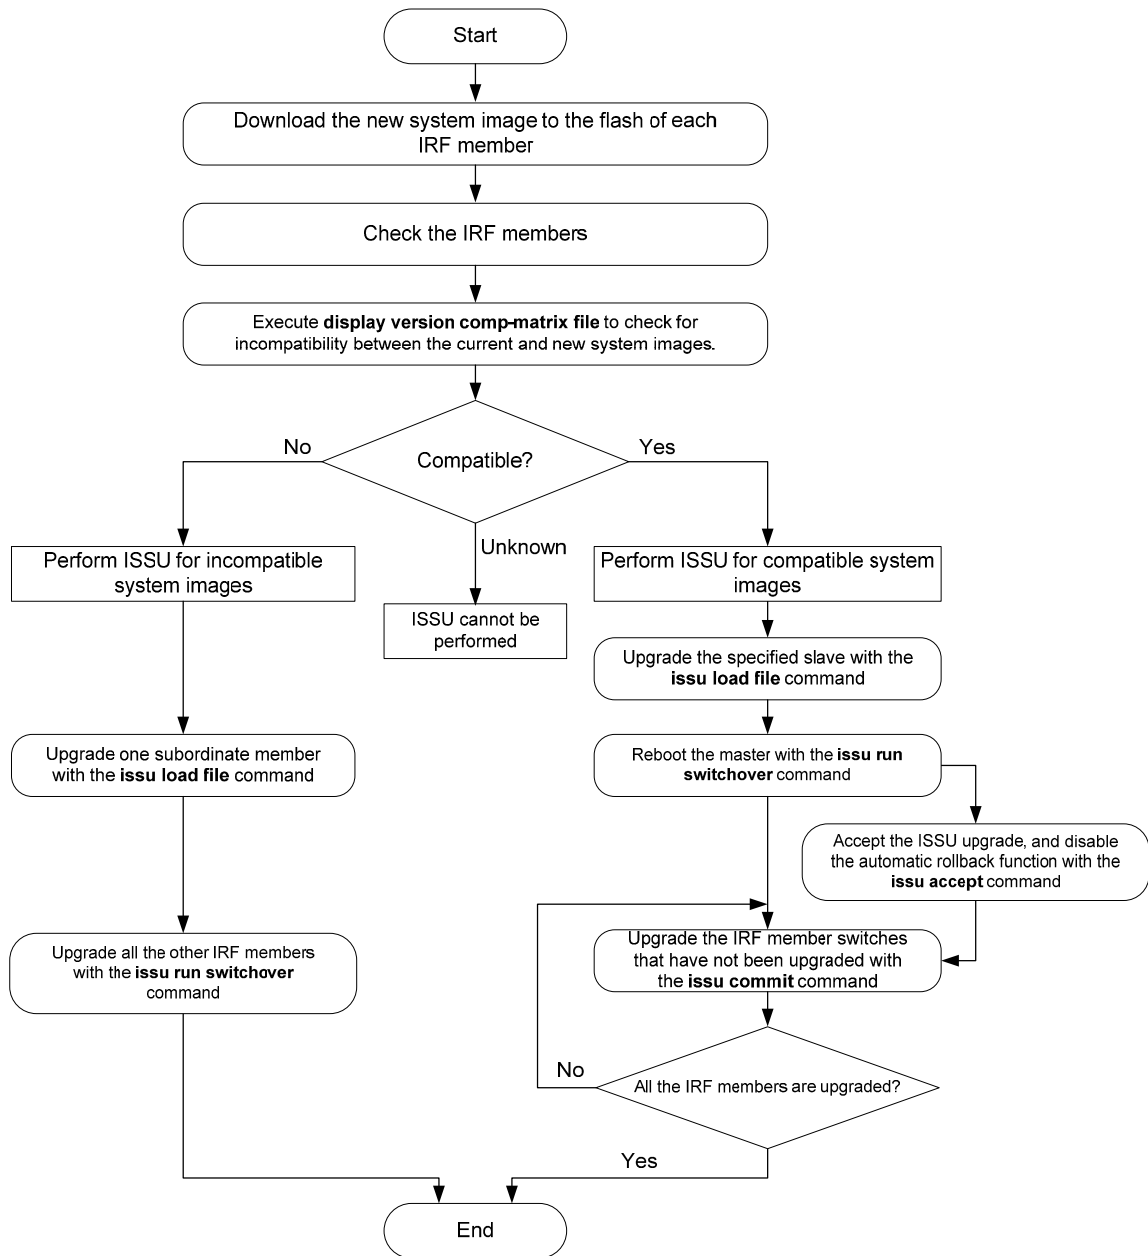

Figure 50 IRF network diagram

ISSU upgrade procedure

ISSU follows a strict procedure, as shown in Figure 51.

Figure 51 ISSU flow chart

IMPORTANT:

- Do not modify the current configuration, plug or unplug cables connected to IRF ports, or delete or modify the system software image during ISSU. Otherwise, the upgrade might fail.
- To upgrade system software of IRF member switches through ISSU, make sure the member switches form a ring topology.

ISSU states

During the ISSU process, you can use the **display issu state** command to display the ISSU state of the IRF fabric, including whether the new system software image is compatible with the current system software image, and the adopted ISSU method.

Table 19 ISSU state description

State	Remarks
Init (Initial state)	No ISSU starts or an ISSU upgrade has completed.
Load	A subordinate switch is being upgraded or has been upgraded. To stop the loading process, perform a manual or automatic roll back to revert system software to its original version.
Switchover	The master is being rebooted to trigger a new master election.
Accept	The ISSU has been accepted. To stop the loading process, you have to perform a manual roll back to revert system software to its original version. The automatic roll back function is not available in this state.
Commit	At least one member switch has not been upgraded to the new version. In this state, neither manual nor automatic rollback can be performed.

System software version rollback

The HP 5500-EI switch series supports version rollback during ISSU. When ISSU fails to proceed on an IRF member switch (for example, the new system software image file is broken), you can use this feature to revert system software to the previous version.

The HP 5500-EI switches support the following version rollback methods.

Automatic rollback

When you reboot the specified subordinate switch with the **issu load** command, the system automatically creates a configurable version rollback timer.

During ISSU for a compatible version, if you do not execute the **issu accept** command on the specified subordinate switch or the **issu commit** command on any other member switch before the rollback timer expires, the system automatically stops the upgrade and rolls back the system software image of the upgraded IRF member switches to the previous version.

During ISSU for an incompatible version, if you do not execute the **issu run switchover** command to upgrade all the IRF member switches that have not been upgraded in one operation before the rollback timer expires, the system automatically rolls back the system software image of all the upgraded IRF member switches to the previous version.

For information about compatible and incompatible ISSU methods, see "[Displaying version compatibility](#)."

Manual rollback

You can use the **issu rollback** command to roll back the system software image of an IRF member switch to the previous version. Whether manual rollback can be performed depends on the ISSU state. For more information, see [Table 19](#).

Performing an ISSU

This section describes how to perform an ISSU.

ISSU upgrade task list

Task	Remarks
Downloading the new system software image to the Flash of all the IRF member switches	Required.
ISSU upgrade prerequisites	Required.
Displaying version compatibility	Required.
Performing an ISSU for a compatible version	Required.
Performing an ISSU for an incompatible version	Use either approach.
<p>If you do not execute the issu run switchover command before the rollback timer expires, the ISSU upgrade ends automatically, the software reverts to the previous version, and the MPUs resume their former roles.</p> <p>The issu run switchover command deletes the rollback timer. After this command is executed, no manual or automatic rollback can be performed for the upgrade.</p>	Optional.
Setting the ISSU version rollback timer	
Performing a manual version rollback	Optional.
Displaying and maintaining ISSU	Optional.

ISSU upgrade prerequisites

Task	Command	Remarks
Save the current configuration.	save	Before performing ISSU, make sure that the current configuration of the IRF fabric has been saved to the configuration file.
Display the running status of each IRF member switch.	display device	Before performing ISSU, make sure that all the member switches of the IRF fabric are in normal state.
Display the information about system software.	display boot-loader	Before performing an ISSU upgrade, make sure that the system software image of all the IRF member switches is identical, which means the version, name, and directory of the system software image are the same.
Display the roles of IRF member switches.	display irf	N/A
Display information about the files in the Flash.	dir	Before performing an ISSU upgrade, make sure that the new and current system software images exist in the Flash of each IRF member switch, and they are saved in the same directory.

Displaying version compatibility

Before performing an ISSU upgrade, check the version compatibility between the new and current system software images, to determine whether ISSU can be performed, and which ISSU method is adopted.

After downloading and saving the new system software image, select an ISSU upgrade method according to one of the following version compatibility check results:

- **Compatible**—The running system software image is compatible with the new system software image. You can use the compatible ISSU method to upgrade system software of the IRF fabric. For more information, see ".".
- **Incompatible**—The current running system software image is incompatible with the new system software image. You can use the incompatible ISSU method to upgrade system software of the IRF fabric. For more information, see "[Performing an ISSU for an incompatible version.](#)"
- **Unknown**—The current and new system software images have big differences, or the current system software image does not support ISSU. You cannot upgrade system software through ISSU.

To display version compatibility:

Step	Command
1. Enters system view.	system-view
2. Check whether the new system software image is compatible with the current system software image.	display version comp-matrix file <i>upgrading-filename</i>

Performing an ISSU for a compatible version

Use the **display version comp-matrix file** *upgrading-filename* command to view the versions of the new and current system software images. If the new system software image is compatible with the current system software image, use this task for ISSU.

ⓘ IMPORTANT:

Before performing compatible ISSU, make sure that the priorities of the current master switch and the specified subordinate switch are higher than other IRF member switches so that the specified subordinate switch can be elected as the new master after the master is rebooted. Otherwise, modify the priorities of the current master switch and the specified subordinate switch with the **irf member** *member-id* **priority** *priority* command.

To perform an ISSU for a compatible version:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Upgrade the specified subordinate switch (the new master after the upgrade).	issu load file <i>upgrading-filename</i> slot <i>slot-number</i>	<i>slot-number</i> is the member ID of the subordinate switch. The specified subordinate switch reboots with the new system software image when this command is executed. Perform the next operation after the subordinate switch is rebooted.

Step	Command	Remarks
3. Reboot the master current manually.	issu run switchover slot <i>slot-number</i>	<p>With this command executed:</p> <ul style="list-style-type: none"> The master reboots with the current system software image, and becomes a subordinate switch after reboot. The subordinate switches of the IRF fabric perform master election. The winner (the subordinate switch specified with the issu load command) becomes the new master. <p>The <i>slot-number</i> provided in this command must be the same as that specified in the issu load command.</p> <p>Perform the next operation after the reboot process is completed.</p>
4. Accept the ISSU.	issu accept slot <i>slot-number</i>	<p>Optional</p> <p>By default, the rollback timer is 45 minutes. If you do not execute the issu accept command on the specified subordinate switch or you do not execute the issu commit command on any other member switch before the rollback timer expires, the system automatically stops the ISSU process and reverts to the previous software version.</p> <p>The <i>slot-number</i> argument provided in this command must be the same as that specified in the issu load command.</p> <p>When this command is executed, the rollback timer becomes invalid and system software cannot be automatically rolled back.</p>
5. Upgrade an IRF member switch that has not been upgraded.	issu commit slot <i>slot-number</i>	<p>This command upgrades one IRF member switch at a time. If the IRF fabric has three or more than three member switches, repeat this command to upgrade them one by one.</p> <p>When all the IRF member switches reboot with the new system software image, the ISSU process completes.</p>

The roles of some IRF member switches change after an ISSU upgrade.

If you do not execute the **issu accept** or **issu commit** command on the specified IRF member switch before the specified rollback timer expires, the system automatically stops the ISSU process and reverts to the previous software version.

After executing the **issu commit** command, you cannot perform version rollback with the **issu rollback** command.

Performing an ISSU for an incompatible version

Use the **display version comp-matrix file** *upgrading-filename* command to view the versions of the new and current system software images. If they are incompatible, use this task for ISSU.

! **IMPORTANT:**

To upgrade system software of the IRF fabric through ISSU when the new and current system software image versions are incompatible, make sure that the multi-active detection (MAD) function has been configured for the IRF fabric. Otherwise, duplicate IRF fabrics will coexist after the new master (the subordinate switch specified with the **issu load** command) is rebooted, causing network faults.

To perform an ISSU for an incompatible version:

Step	Command	Remarks
1. Enters system view.	system-view	N/A
2. Upgrade the specified subordinate switch (the new master after the upgrade).	issu load file <i>upgrading-filename</i> slot <i>slot-number</i> force	<i>slot-number</i> is the member ID of the subordinate switch. After this command is executed, the specified subordinate switch (the new master after the upgrade) reboots with the new system software image, and stays in the Recover state after reboot. Perform the next operation after the reboot process completes.
3. Upgrade all the IRF member switches that have not been upgraded in one operation.	issu run switchover slot <i>slot-number</i>	The <i>slot-number</i> argument provided in this command must be the same as that specified in the issu load command. When this command is executed, all the IRF member switches except the specified subordinate switch (the new master) are upgraded to the new version, and the ISSU process completes after reboot.

If you do not execute the **issu run switchover** command before the rollback timer expires, the ISSU upgrade ends automatically, the software reverts to the previous version, and the MPUs resume their former roles.

The **issu run switchover** command deletes the rollback timer. After this command is executed, no manual or automatic rollback can be performed for the upgrade.

Setting the ISSU version rollback timer

Step	Command	Remarks
1. Enters system view.	system-view	N/A
2. Set the rollback timer.	issu rollback-timer <i>minutes</i>	Optional. By default, the rollback timer is 45 minutes.

During an ISSU upgrade process, if you modify the rollback timer after executing the **issu load** command, the new rollback timer does not take effect for this ISSU process.

Performing a manual version rollback

Step	Command	Remarks
1. Enters system view.	system-view	N/A
2. Perform a manual version rollback.	issu rollback slot <i>slot-number</i>	Optional By default, automatic rollback is performed to revert to the previous version. The <i>slot-number</i> argument provided in this command must be the same as that specified in the issu load command.

Displaying and maintaining ISSU

Task	Command	Remarks
Display information about the rollback timer.	display issu rollback-timer [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the ISSU state.	display issu state	Available in any view
Display version compatibility information.	display version comp-matrix [file <i>upgrading-filename</i>]	Available in any view

ISSU upgrade example

Network status

As shown in [Figure 52](#), access layer switches Switch A, Switch B, and Switch C connect to user networks. Distribution layer switches Switch D, Switch E, and Switch form an IRF fabric. The member ID of the master is 1, and those of the subordinate switches are 2 and 3 respectively.

To ensure high availability, configure cross-device link aggregation using the following guidelines so that every three physical links with the same color between the IRF member switches and access switches are aggregated as one logical link:

- On the IRF fabric, create three dynamic aggregation groups. Ports in aggregation group 1 connect to Switch A, ports in aggregation group 2 connect to Switch B, and ports in aggregation group 3 connect to Switch C.
- On Switch A, create aggregation group 1 that corresponds to aggregation group 1 on the IRF fabric.
- On Switch B, create aggregation group 2 that corresponds to aggregation group 2 on the IRF fabric.
- On Switch C, create aggregation group 3 that corresponds to aggregation group 3 on the IRF fabric.

Network requirements

The current system software image on each IRF member switch is **soft-version1.bin**. The new system software image **soft-version2.bin** is saved on the TFTP server. The IP address of the IRF fabric is 1.1.1.1/24, and that of the TFTP server is 2.2.2.2/24. The IRF fabric and the TFTP server can reach each other.

Use ISSU to upgrade system software of the IRF member switches to avoid traffic interruption.

Figure 52 Network diagram

Upgrade procedure

Configuring link aggregation

1. Configure the IRF fabric:

Create three dynamic aggregation groups 1, 2, and 3.

```
<IRF> system-view
[IRF] interface bridge-aggregation 1
[IRF-Bridge-Aggregation1] link-aggregation mode dynamic
[IRF-Bridge-Aggregation1] quit
[IRF] interface bridge-aggregation 2
[IRF-Bridge-Aggregation2] link-aggregation mode dynamic
[IRF-Bridge-Aggregation2] quit
[IRF] interface bridge-aggregation 3
[IRF-Bridge-Aggregation3] link-aggregation mode dynamic
[IRF-Bridge-Aggregation3] quit
```

Add ports GigabitEthernet 1/0/1, GigabitEthernet 2/0/1, and GigabitEthernet 3/0/1 that connect to Switch A to aggregation group 1.

```
[IRF] interface GigabitEthernet 1/0/1
[IRF-GigabitEthernet1/0/1] port link-aggregation group 1
[IRF-GigabitEthernet1/0/1] quit
```

```
[IRF] interface GigabitEthernet 2/0/1
[IRF-GigabitEthernet2/0/1] port link-aggregation group 1
[IRF-GigabitEthernet2/0/1] quit
[IRF] interface GigabitEthernet 3/0/1
[IRF-GigabitEthernet3/0/1] port link-aggregation group 1
[IRF-GigabitEthernet3/0/1] quit
```

Add ports GigabitEthernet 1/0/2, GigabitEthernet 2/0/2, and GigabitEthernet 3/0/2 that connect to Switch B to aggregation group 2.

```
[IRF] interface GigabitEthernet 1/0/2
[IRF-GigabitEthernet1/0/2] port link-aggregation group 2
[IRF-GigabitEthernet1/0/2] quit
[IRF] interface GigabitEthernet 2/0/2
[IRF-GigabitEthernet2/0/2] port link-aggregation group 2
[IRF-GigabitEthernet2/0/2] quit
[IRF] interface GigabitEthernet 3/0/2
[IRF-GigabitEthernet3/0/2] port link-aggregation group 2
[IRF-GigabitEthernet3/0/2] quit
```

Add ports GigabitEthernet 1/0/3, GigabitEthernet 2/0/3, and GigabitEthernet 3/0/3 that connect to Switch C to aggregation group 3.

```
[IRF] interface GigabitEthernet 1/0/3
[IRF-GigabitEthernet1/0/3] port link-aggregation group 3
[IRF-GigabitEthernet1/0/3] quit
[IRF] interface GigabitEthernet 2/0/3
[IRF-GigabitEthernet2/0/3] port link-aggregation group 3
[IRF-GigabitEthernet2/0/3] quit
[IRF] interface GigabitEthernet 3/0/3
[IRF-GigabitEthernet3/0/3] port link-aggregation group 3
[IRF-GigabitEthernet3/0/3] quit
```

2. Configure Switch A:

Create dynamic aggregate interface 1.

```
<SwitchA> system-view
[SwitchA] interface bridge-aggregation 1
[SwitchA-Bridge-Aggregation1] link-aggregation mode dynamic
[SwitchA-Bridge-Aggregation1] quit
```

#Add ports GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 that connect to IRF member switches to aggregation group 1 (corresponding to aggregate interface 1).

```
[SwitchA] interface GigabitEthernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port link-aggregation group 1
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface GigabitEthernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] port link-aggregation group 1
[SwitchA-GigabitEthernet1/0/2] quit
[SwitchA] interface GigabitEthernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] port link-aggregation group 1
[SwitchA-GigabitEthernet1/0/3] quit
```

3. Configure Switch B:

Create dynamic aggregate interface 2.

```

<SwitchB> system-view
[SwitchB] interface bridge-aggregation 2
[SwitchB-Bridge-Aggregation2] link-aggregation mode dynamic
[SwitchB-Bridge-Aggregation2] quit

```

#Add ports GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 that connect to IRF member switches to aggregation group 2 (corresponding to aggregate interface 2).

```

[SwitchB] interface GigabitEthernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port link-aggregation group 2
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface GigabitEthernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port link-aggregation group 2
[SwitchB-GigabitEthernet1/0/2] quit
[SwitchB] interface GigabitEthernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] port link-aggregation group 2
[SwitchB-GigabitEthernet1/0/3] quit

```

4. Configure Switch C:

Create dynamic aggregate interface 3.

```

<SwitchC> system-view
[SwitchC] interface bridge-aggregation 3
[SwitchC-Bridge-Aggregation3] link-aggregation mode dynamic
[SwitchB-Bridge-Aggregation3] quit

```

Add ports GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 that connect to IRF member switches to aggregation group 3 (corresponding to aggregate interface 3).

```

[SwitchC] interface GigabitEthernet 1/0/1
[SwitchC-GigabitEthernet1/0/1] port link-aggregation group 3
[SwitchC-GigabitEthernet1/0/1] quit
[SwitchC] interface GigabitEthernet 1/0/2
[SwitchC-GigabitEthernet1/0/2] port link-aggregation group 3
[SwitchC-GigabitEthernet1/0/2] quit
[SwitchC] interface GigabitEthernet 1/0/3
[SwitchC-GigabitEthernet1/0/3] port link-aggregation group 3
[SwitchC-GigabitEthernet1/0/3] quit

```

Configuring the TFTP server

Obtain the new system software image through a legal channel, and save the file to the working directory of the TFTP server so that the TFTP client can access the file. The working directory varies with TFTP server models.

Downloading the new system software image

Download system software image soft-version2.bin to the root directory of the Flash of each IRF member switch.

```

<IRF> tftp 2.2.2.2 get soft-version2.bin
File will be transferred in binary mode
Downloading file from remote TFTP server, please wait.....
TFTP: 10058752 bytes received in 141 second(s)
File downloaded successfully.

```

```
<IRF> copy soft-version2.bin slot2#flash:/
<IRF> copy soft-version2.bin slot3#flash:/
```

Checking all IRF member switches before the ISSU upgrade

1. Check the running status of all IRF member switches. If the running state of a member switch is abnormal, the ISSU upgrade cannot be performed.

```
<IRF> display device
Slot 1
SubSNo PortNum PCBVer FPGAVer CPLDVer BootRomVer AddrLM Type State
0 28 REV.C NULL 002 CC1 IVL MAIN Normal
1 2 REV.A NULL NULL NULL IVL 2*10GE Normal
Slot 2
SubSNo PortNum PCBVer FPGAVer CPLDVer BootRomVer AddrLM Type State
0 28 REV.C NULL 002 CC1 IVL MAIN Normal
2 2 REV.A NULL NULL NULL IVL 2*10GE Normal
Slot 3
SubSNo PortNum PCBVer FPGAVer CPLDVer BootRomVer AddrLM Type State
0 28 REV.C NULL 002 CC1 IVL MAIN Normal
3 2 REV.A NULL NULL NULL IVL 2*10GE Normal
```

The output shows that all IRF member switches are in normal state.

2. Check whether the current system software images on IRF member switches are the same. If not, the ISSU upgrade cannot be performed.

```
<IRF> display boot-loader
Slot 1
The current boot app is: flash:/soft-version1.bin
The main boot app is: flash:/soft-version1.bin
The backup boot app is: flash:/
Slot 2
The current boot app is: flash:/soft-version1.bin
The main boot app is: flash:/soft-version1.bin
The backup boot app is: flash:/
Slot 3
The current boot app is: flash:/soft-version1.bin
The main boot app is: flash:/soft-version1.bin
The backup boot app is: flash:/
```

The output shows that the current system software image file on each IRF member switch is **soft-version1.bin**.

3. View the role of each IRF member switch.

```
<IRF> display irf
Switch Role Priority CPU-Mac Description
*+1 Master 10 0023-8927-ad54 -----
2 Slave 9 0023-8927-afdc -----
3 Slave 1 0023-89d9-3223 -----
-----
```

* indicates the device is the master.

+ indicates the device through which the user logs in.

```
The Bridge MAC of the IRF is: 0023-8927-ad53
Auto upgrade           : yes
Mac persistent        : 6 min
Domain ID             : 0
```

The output shows the following information:

- The member ID and the priority of the master is 1 and 10 respectively
- The member ID and the priority of one subordinate switch is 2 and 9 respectively
- The member ID and the priority of the other subordinate switch is 3 and 1 respectively

During the ISSU upgrade process, you must select subordinate switch 2 as the specified subordinate switch.

Before performing compatible ISSU, make sure the priorities of the master switch and the specified subordinate switch are higher than other IRF member switches so that the specified subordinate switch can be elected as the new master after the master is rebooted. Otherwise, modify the priorities of the master switch and the specified subordinate switch with the **irf member member-id priority priority** command.

4. Check whether the new system software image has been saved in the Flash of each IRF member switch. If not, the ISSU upgrade cannot be performed.

Verify whether the new system software image **soft-version2.bin** has been saved to the Flash of the master.

```
<IRF> dir
```

```
Directory of flash:/
```

0	-rw-	6085	May 29 2010 11:38:45	config.cfg
1	-rw-	10518	Apr 26 2011 12:45:05	logfile.log
2	-rw-	12397691	Apr 26 2011 14:24:11	soft-version1.bin
3	-rw-	13308645	Apr 26 2011 14:13:46	soft-version2.bin
4	drw-	-	Apr 26 2011 12:00:33	seclog
5	-rw-	287	Apr 26 2011 12:19:52	system.xml

```
31496 KB total (5981 KB free)
```

The output shows that the new system software image has been saved to the Flash of the master.

Verify whether the new system software image **soft-version2.bin** has been saved to the Flash of subordinate switch 2.

```
<IRF> dir slot2#flash:/
```

```
Directory of slot2#flash:/
```

0	-rw-	6085	May 29 2010 11:38:45	config.cfg
1	-rw-	10518	Apr 26 2011 12:45:05	logfile.log
2	-rw-	12397691	Apr 26 2011 14:24:11	soft-version1.bin
3	-rw-	13308645	Apr 26 2011 14:13:46	soft-version2.bin
4	drw-	-	Apr 26 2011 12:00:33	seclog
5	-rw-	287	Apr 26 2011 12:19:52	system.xml

```
31496 KB total (5981 KB free)
```

The output shows that the new system software image has been saved to the Flash of subordinate switch 2.

Verify whether the new system software image **soft-version2.bin** has been saved to the Flash of subordinate switch 3.

```
<IRF> dir slot3#flash:/
Directory of slot3#flash:/

 0  -rw-     6085  May 29 2010 11:38:45  config.cfg
 1  -rw-    10518  Apr 26 2011 12:45:05  logfile.log
 2  -rw- 12397691  Apr 26 2011 14:24:11  soft-version1.bin
 3  -rw- 13308645  Apr 26 2011 14:13:46  soft-version2.bin
 4  drw-      -   Apr 26 2011 12:00:33  seclog
 5  -rw-     287  Apr 26 2011 12:19:52  system.xml
```

31496 KB total (5981 KB free)

The output shows that the new system software image has been saved to the Flash of subordinate switch 3.

5. Save the current configuration.

```
<IRF> save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/config.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/config.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait....
Saved the current configuration to mainboard device successfully.
Slot 2:
Save next configuration file successfully.
Slot 3:
Save next configuration file successfully.
Configuration is saved to device successfully.
```

The output shows that the current configuration has been saved to the configuration file of each IRF member switch.

Viewing the version compatibility

Check whether the current and new system software images are compatible.

```
<IRF> display version comp-matrix file soft-version2.bin
```

- If they are compatible, the output is like the following:

```
Number of Matrices in Table = 1
Matrix for HP 5500-EI
```

```
Running Version: version1
Version Compatibility List:
version2 (Compatible)
```

The output shows that the new and current versions are fully compatible. You can use the compatible ISSU upgrade method. For more information, see "[Performing compatible ISSU upgrade.](#)"

- If the two versions are incompatible, the output is like the following:

```
Number of Matrices in Table = 1
```

Matrix for HP 5500-EI

```
Running Version: version1
Version Compatibility List:
version2 (Incompatible)
```

The output shows that the two versions are incompatible. You must use the incompatible ISSU method. For more information, see "[Performing incompatible ISSU upgrade.](#)"

Performing compatible ISSU upgrade

Upgrade the specified subordinate switch (the new master after the upgrade), which is subordinate switch 2 in this example.

```
<IRF> system-view
```

```
[IRF] issu load file soft-version2.bin slot 2
```

This command will begin ISSU, and the specified board will reboot and be upgraded. Please save the current running configuration first; otherwise, the configuration may be lost. Continue? [Y/N]:y

After the reboot of subordinate switch 2, check whether the system software image of slave switch 2 is **soft-version2.bin**.

```
[IRF] display boot-loader
```

```
Slot 1
```

```
The current boot app is: flash:/soft-version1.bin
```

```
The main boot app is: flash:/soft-version1.bin
```

```
The backup boot app is: flash:/
```

```
Slot 2
```

```
The current boot app is: flash:/soft-version2.bin
```

```
The main boot app is: flash:/soft-version2.bin
```

```
The backup boot app is: flash:/
```

```
Slot 3
```

```
The current boot app is: flash:/soft-version1.bin
```

```
The main boot app is: flash:/soft-version1.bin
```

```
The backup boot app is: flash:/
```

The output shows that the system software image of subordinate switch 2 is soft-version2.bin.

Reboot the master manually.

```
[IRF] issu run switchover slot 2
```

Master will reboot, switch the specified board to master and update the line card. Continue? [Y/N]:y

In this example, the member ID of the master is 1. After reboot, the master becomes a subordinate switch in the IRF fabric. Then the subordinate switches perform a role election, and slave 2 becomes the new master because the priority of subordinate switch 2 is higher than that of subordinate switch 3.

Accept the ISSU upgrade and delete the rollback timer.

```
[IRF] issu accept slot 2
```

Upgrade switch 1 and switch 3.

```
[IRF] issu commit slot 1
```

The specified board will reboot and be upgraded. Continue? [Y/N]:y

```
[IRF] issu commit slot 3
```

The specified board will reboot and be upgraded. Continue? [Y/N]:y

Then the ISSU upgrade process completes and the system software images of all IRF member switches have been upgraded to the new version.

Verify whether the current system software images on the IRF member switches are **soft-version2.bin**.

```
[IRF] display boot-loader
```

```
Slot 1
```

```
The current boot app is: flash:/soft-version2.bin
```

```
The main boot app is: flash:/soft-version2.bin
```

```
The backup boot app is: flash:/
```

```
Slot 2
```

```
The current boot app is: flash:/soft-version2.bin
```

```
The main boot app is: flash:/soft-version2.bin
```

```
The backup boot app is: flash:/
```

```
Slot 3
```

```
The current boot app is: flash:/soft-version2.bin
```

```
The main boot app is: flash:/soft-version2.bin
```

```
The backup boot app is: flash:/
```

Performing incompatible ISSU upgrade

IMPORTANT:

To upgrade system software of the IRF fabric through ISSU when the new and current system software image versions are incompatible, make sure that the multi-active detection (MAD) function has been configured for the IRF fabric. Otherwise, duplicate IRF fabrics will coexist after the new master (the subordinate switch specified with the **issu load** command) is rebooted, causing network faults.

Upgrade the specified subordinate switch (the new master after the upgrade), which is subordinate switch 2 in this example.

```
<IRF> system-view
```

```
[IRF] issu load file soft-version2.bin slot 2
```

```
This command will begin ISSU, and the specified board will reboot and be upgraded. Please save the current running configuration first; otherwise, the configuration may be lost.Continue? [Y/N]: y
```

After the reboot of subordinate switch 2, reboot and upgrade all IRF member switches that have not been upgraded.

```
[IRF] issu run switchover slot 2
```

```
Master will reboot, switch the specified board to master and update the line card. Continue? [Y/N]:y
```

Then, the ISSU upgrade process completes and the system software images of all IRF member switches have been upgraded to the new version.

Verify whether the current system software images on the IRF member switches are **soft-version2.bin**.

```
[IRF] display boot-loader
```

```
Slot 1
```

```
The current boot app is: flash:/soft-version2.bin
```

```
The main boot app is: flash:/soft-version2.bin
```

```
The backup boot app is: flash:/
```

```
Slot 2
```

```
The current boot app is: flash:/soft-version2.bin
```

```
The main boot app is:    flash:/soft-version2.bin
The backup boot app is: flash:/
Slot 3
The current boot app is: flash:/soft-version2.bin
The main boot app is:    flash:/soft-version2.bin
The backup boot app is:  flash:/
```

Managing the device

Device management includes monitoring the operating status of devices and configuring their running parameters.

The configuration tasks in this document are order independent. You can perform these tasks in any order.

Configuring the device name

A device name identifies a device in a network and works as the user view prompt at the CLI. For example, if the device name is **Sysname**, the user view prompt is <Sysname>.

To configure the device name:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the device name.	sysname <i>sysname</i>	Optional. The default device name is HP .

Changing the system time

You must synchronize your device with a trusted time source by using NTP or changing the system time before you run it on the network. Network management depends on an accurate system time setting, because the timestamps of system messages and logs use the system time.

In a small-sized network, you can manually set the system time of each device.

Configuration guidelines

You can change the system time by configuring the relative time, time zone, and daylight saving time. The configuration result depends on their configuration order (see [Table 20](#)). In the first column of this table, 1 represents the **clock datetime** command, 2 represents the **clock timezone** command, and 3 represents the **clock summer-time** command. To verify the system time setting, use the **display clock** command. This table assumes that the original system time is 2005/1/1 1:00:00.

Table 20 System time configuration results

Command	Effective system time	Configuration example	System time
1	<i>date-time</i>	<code>clock datetime 1:00 2007/1/1</code>	01:00:00 UTC Mon 01/01/2007.
2	Original system time ± <i>zone-offset</i>	<code>clock timezone zone-time add 1</code>	02:00:00 zone-time Sat 01/01/2005.
1, 2	<i>date-time</i> ± <i>zone-offset</i>	<code>clock datetime 2:00 2007/2/2</code> <code>clock timezone zone-time add 1</code>	03:00:00 zone-time Fri 02/02/2007.

Command	Effective system time	Configuration example	System time
2, 1	<i>date-time</i>	clock timezone zone-time add 1 clock datetime 3:00 2007/3/3	03:00:00 zone-time Sat 03/03/2007.
	The original system time outside the daylight saving time range: The system time does not change until it falls into the daylight saving time range.	clock summer-time ss one-off 1:00 2006/1/1 1:00 2006/8/8 2	01:00:00 UTC Sat 01/01/2005.
3	The original system time in the daylight saving time range: The system time increases by <i>summer-offset</i> .	clock summer-time ss one-off 00:30 2005/1/1 1:00 2005/8/8 2	03:00:00 ss Sat 01/01/2005. NOTE: If the original system time plus <i>summer-offset</i> is beyond the daylight saving time range, the original system time does not change. After you disable the daylight saving setting, the system time automatically decreases by <i>summer-offset</i> .
	<i>date-time</i> outside the daylight saving time range: <i>date-time</i>	clock datetime 1:00 2007/1/1 clock summer-time ss one-off 1:00 2006/1/1 1:00 2006/8/8 2	01:00:00 UTC Mon 01/01/2007.
1, 3	<i>date-time</i> in the daylight saving time range: <i>date-time</i> + <i>summer-offset</i>	clock datetime 8:00 2007/1/1 clock summer-time ss one-off 1:00 2007/1/1 1:00 2007/8/8 2	10:00:00 ss Mon 01/01/2007. NOTE: If the <i>date-time</i> plus <i>summer-offset</i> is outside the daylight saving time range, the system time equals <i>date-time</i> . After you disable the daylight saving setting, the system time automatically decreases by <i>summer-offset</i> .
3, 1 (<i>date-time</i> outside the daylight saving time range)	<i>date-time</i>	clock summer-time ss one-off 1:00 2007/1/1 1:00 2007/8/8 2 clock datetime 1:00 2008/1/1	01:00:00 UTC Tue 01/01/2008.

Command	Effective system time	Configuration example	System time
3, 1 (<i>date-time</i> in the daylight saving time range)	<i>date-time</i> – <i>summer-offset</i> outside the daylight saving time range:	clock summer-time ss one-off 1:00 2007/1/1 1:00 2007/8/8 2	23:30:00 UTC Sun 12/31/2006.
	<i>date-time</i> – <i>summer-offset</i>	clock datetime 1:30 2007/1/1	
	<i>date-time</i> – <i>summer-offset</i> in the daylight saving time range:	clock summer-time ss one-off 1:00 2007/1/1 1:00 2007/8/8 2	03:00:00 ss Mon 01/01/2007.
	<i>date-time</i>	clock datetime 3:00 2007/1/1	
2, 3 or 3, 2	Original system clock ± <i>zone-offset</i> outside the daylight saving time range:	clock timezone zone-time add 1 clock summer-time ss one-off 1:00 2007/1/1 1:00 2007/8/8 2	02:00:00 zone-time Sat 01/01/2005.
	Original system clock ± <i>zone-offset</i>		
	Original system clock ± <i>zone-offset</i> outside the daylight saving time range:	clock timezone zone-time add 1 clock summer-time ss one-off 1:00 2005/1/1 1:00 2005/8/8 2	System clock configured: 04:00:00 ss Sat 01/01/2005.
	Original system clock ± <i>zone-offset</i> + <i>summer-offset</i>		
1, 2, 3 or 1, 3, 2	<i>date-time</i> ± <i>zone-offset</i> outside the daylight saving time range:	clock datetime 1:00 2007/1/1 clock timezone zone-time add 1 clock summer-time ss one-off 1:00 2008/1/1 1:00 2008/8/8 2	02:00:00 zone-time Mon 01/01/2007.
	<i>date-time</i> ± <i>zone-offset</i>	clock datetime 1:00 2007/1/1	
	<i>date-time</i> ± <i>zone-offset</i> outside the daylight saving time range:	clock timezone zone-time add 1 clock summer-time ss one-off 1:00 2007/1/1 1:00 2007/8/8 2	04:00:00 ss Mon 01/01/2007.
	<i>date-time</i> ± <i>zone-offset</i> + <i>summer-offset</i>		
2, 3, 1 or 3, 2, 1	<i>date-time</i> outside the daylight saving time range:	clock timezone zone-time add 1 clock summer-time ss one-off 1:00 2008/1/1 1:00 2008/8/8 2	01:00:00 zone-time Mon 01/01/2007.
	<i>date-time</i>	clock datetime 1:00 2007/1/1	

Command	Effective system time	Configuration example	System time
	<i>date-time</i> in the daylight saving time range, but <i>date-time – summer-offset</i> outside the summer-time range:	<pre>clock timezone zone-time add 1 clock summer-time ss one-off 1:00 2008/1/1 1:00 2008/8/8 2</pre>	23:30:00 zone-time Mon 12/31/2007.
	<i>date-time – summer-offset</i>	<pre>clock datetime 1:30 2008/1/1</pre>	
	Both <i>date-time</i> and <i>date-time – summer-offset</i> in the daylight saving time range:	<pre>clock timezone zone-time add 1 clock summer-time ss one-off 1:00 2008/1/1 1:00 2008/8/8 2</pre>	03:00:00 ss Tue 01/01/2008.
	<i>date-time</i>	<pre>clock datetime 3:00 2008/1/1</pre>	

Configuration procedure

To change the system time:

Step	Command	Remarks
1. Set the system time and date.	clock datetime <i>time date</i>	Optional. Available in user view.
2. Enter system view.	system-view	N/A
3. Set the time zone.	clock timezone <i>zone-name</i> { add minus } <i>zone-offset</i>	Optional. Universal time coordinated (UTC) time zone by default.
4. Set a daylight saving time scheme.	<ul style="list-style-type: none"> Set a non-recurring scheme: clock summer-time <i>zone-name one-off start-time start-date end-time end-date add-time</i> Set a recurring scheme: clock summer-time <i>zone-name repeating start-time start-date end-time end-date add-time</i> 	Optional. Use either command. By default, daylight saving time is disabled, and the UTC time zone applies.

Enabling displaying the copyright statement

The device by default displays the copyright statement when a Telnet or SSH user logs in, or when a console user quits user view. You can disable or enable the function as needed. The following is a sample copyright statement:

```
*****
* Copyright (c) 2010-2011 Hewlett-Packard Development Company, L.P.          *
* Without the owner's prior written consent,                                *
* no decompiling or reverse-engineering shall be allowed.                  *
*****
```

To enable displaying the copyright statement:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable displaying the copyright statement.	copyright-info enable	Optional Enabled by default.

Changing the brand name

An IRF fabric using HP, H3C, and 3Com member switches together might cause network management problems. For example, if an IRF fabric uses an HP switch as the master member switch and uses an H3C switch as a subordinate member switch, the network management software identifies the switch as an HP IRF fabric. Then, if the IRF fabric is rebooted and the H3C switch is elected as the master, the network management software identifies the IRF fabric as a new IRF fabric. To avoid this problem, perform this task to change the brand names of all member switches to the same.

Table 21 lists the model matrix for HP, H3C, and 3Com switches. You can change brand names among them, except the models marked N/A. Before you change the brand name, you must get clear of the matrix for proper operation of the switches.

Table 21 Brand matrix

HP switch model	H3C switch model	3COM switch model
HP 5500-24G EI Switch with 2 Interface Slots	S5500-28C-EI	Switch 4800G 24-Port
HP 5500-48G EI Switch with 2 Interface Slots	S5500-52C-EI	Switch 4800G 48-Port
HP 5500-24G-SFP EI Switch with 2 Interface Slots	S5500-28F-EI	Switch 4800G 24-Port SFP
HP 5500-24G-PoE+ EI Switch with 2 Interface Slots	S5500-28C-PWR-EI	Switch 4800G PWR 24-Port
HP 5500-48G-PoE+ EI Switch with 2 Interface Slots	S5500-52C-PWR-EI	Switch 4800G PWR 48-Port
HP 5500-24G SI Switch with 2 Interface Slots	S5500-28C-SI	N/A
HP 5500-48G SI Switch with 2 Interface Slots	S5500-52C-SI	N/A
HP 5500-24G-PoE+ SI Switch with 2 Interface Slots	S5500-28C-PWR-SI	N/A
HP 5500-48G-PoE+ SI Switch with 2 Interface Slots	S5500-52C-PWR-SI	N/A

Configuration preparation

Before you change the brand name for an HP, H3C, or 3Com switch, prepare the proper Boot ROM and system software image file according to the model matrix as listed in Table 21. The following describes

the procedure for changing the brand name of an H3C or 3Com switch to HP. The procedure is the same for changing the brand names among HP, H3C, and 3Com switches.

1. Load the proper HP Boot ROM to the flash memory of the H3C or 3Com switch and use the HP Boot ROM to upgrade the Boot ROM of the switch.
2. Load the proper HP system software image file to the flash memory of the H3C or 3Com switch, specify the file as the main system software image file, and reboot the switch.
3. Execute the **brand** command and reboot the switch.

NOTE:

For HP 5500 EI and HP 5500SI use the **bootrom update** command to upgrade the Boot ROM.

Configuration guidelines

- After you change the brand name of a 3Com switch to HP or H3C, the default baudrate of the console port changes from 19200 to 9600.
- The port numbering rule for 3Com switches is different from that for HP and H3C switches. After you change the brand name for a 3Com switch, the port numbers become inconsistent with the silkscreen marks. Configure the port (if necessary) according to the numbering rules for the models in the model matrix in Table 21.
- The default settings for some features on 3Com switches are different from those on HP and H3C switches. After you change the brand name for a switch, the default settings for those features become the default settings of the target brand.

Configuration procedure

You can use the **display brand** command to display the brand names of the member switches. If any consistent brand names exist in the IRF fabric, change them to the same.

To change brand name for a member switch:

Step	Command
1. Change the brand name for a member switch.	brand { hp h3c 3com } [slot slot-number]
2. Reboot the member switch.	reboot slot slot-number

After you change the brand name for a member switch, the switch can use the later software versions for the new brand.

NOTE:

The default settings vary with different brands. Changing the brand name might affect the running configuration. After you change the brand name of a member switch, verify the configuration and re-configure the switch if necessary.

Configuring banners

Banners are messages that the system displays during user login.

The system supports the following banners:

- **Legal banner**—Appears after the copyright or license statement. To continue login, the user must enter **Y** or press **Enter**. To quit the process, the user must enter **N**. **Y** and **N** are case-insensitive.
- **Message of the Day (MOTD) banner**—Appears after the legal banner and before the login banner.
- **Login banner**—Appears only when password or scheme authentication has been configured.
- **Incoming banner**—Appears for Modem users.
- **Shell banner**—Appears for non-Modem users.

Banner message input modes

You can configure a banner in one of the following ways:

- Single-line input

Input the entire banner in the same line as the command. The start and end delimiters for the banner must be the same but can be any visible character. The input text, including the command keywords and the delimiters cannot exceed 510 characters. In this mode, do not press **Enter** before you input the end delimiter. For example, you can configure the shell banner “Have a nice day.” as follows:

```
<System> system-view
[System] header shell %Have a nice day.%
```

- Multiple-line input

Input message text in multiple lines. In this approach, the message text can be up to 2000 characters. Use one of the following methods to implement multi-line input mode:

- **Method 1**—Press **Enter** after the last command keyword. At the system prompt, enter the banner message and end with the delimiter character **%**. For example, you can configure the banner “Have a nice day. Please input the password.” as follows:

```
<System> system-view
[System] header shell
Please input banner content, and quit with the character '%'.--System prompt
Have a nice day.
Please input the password.%
```

- **Method 2**—After you type the last command keyword, type any character as the start delimiter for the banner message and press **Enter**. At the system prompt, type the banner message and end the last line with a delimiter that is the same as the start delimiter. For example, you can configure the banner “Have a nice day. Please input the password.” as follows:

```
<System> system-view
[System] header shell A
Please input banner content, and quit with the character 'A'.--System prompt
Have a nice day.
Please input the password.A
```

- **Method 3**—After you type the last keyword, type the start delimiter and part of the banner message and press **Enter**. At the system prompt, enter the rest of the banner and end the last line with a delimiter that is the same as the start delimiter. In this approach, you can use any character as the start and end delimiters but must make sure that it is not the same as the end character of the message text in the first line. For example, you can configure the banner “Have a nice day. Please input the password.” as follows:

```
<System> system-view
[System] header shell AHave a nice day.
```

```
Please input banner content, and quit with the character 'A'.--System prompt
Please input the password.A
```

Configuration procedure

To configure a banner:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the incoming banner.	header incoming <i>text</i>	Optional
3. Configure the login banner.	header login <i>text</i>	Optional
4. Configure the legal banner.	header legal <i>text</i>	Optional
5. Configure the shell banner.	header shell <i>text</i>	Optional
6. Configure the MOTD banner.	header motd <i>text</i>	Optional

Configuring the exception handling method

You can configure the device to handle system exceptions in one of the following methods:

- **reboot**—The device automatically reboots to recover from the error condition.
- **maintain**—The device stays in the error condition so you can collect complete data, including error messages, for diagnosis. In this approach, you must manually reboot the device.

To configure the exception handling method:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the exception handling method.	system-failure { maintain reboot }	Optional. By default, the system reboots when an exception occurs.

NOTE:

In an IRF fabric, the exception handling method applies to all member switches, but the member switches handle system exceptions independently without affecting one another.

Rebooting the device

△ CAUTION:

- A reboot can interrupt network services.
 - To avoid data loss, use the **save** command to save the current configuration before a reboot.
 - Use the **display startup** and **display boot-loader** commands to verify that you have correctly set the startup configuration file and the main system software image file. If the main system software image file has been corrupted or does not exist, the device cannot reboot. You must re-specify a main system software image file, or power off the device and then power it on so the system can reboot with the backup system software image file.
-

You can reboot the device in one of the following ways to recover from an error condition:

- Reboot the device immediately at the CLI.
- At the CLI, schedule a reboot to occur at a specific time and date or after a delay.
- Power off and then power on the device. This method might cause data loss and hardware damage, and is the least preferred method.
- Reboot at the CLI enables easy remote device maintenance.

Rebooting devices immediately at the CLI

To reboot a device, perform the following task in user view:

Task	Command	Remarks
Reboot a switch or all IRF member switches immediately.	reboot [<i>slot slot-number</i>]	If you do not specify any IRF member ID for the <i>slot-number</i> argument, all IRF member switches reboot.

Scheduling a device reboot

The switch supports only one device reboot schedule. If you configure the **schedule reboot delay** command multiple times, the last configuration takes effect.

The **schedule reboot at** command and the **schedule reboot delay** command overwrite each other, and whichever is configured last takes effect.

For data security, if you are performing file operations at the reboot time, the system does not reboot.

To schedule a device reboot, perform the following task in user view:

Task	Command	Remarks
Schedule a reboot.	<ul style="list-style-type: none">• Schedule a reboot to occur at a specific time and date: schedule reboot at <i>hh:mm</i> [<i>date</i>]• Schedule a reboot to occur after a delay: schedule reboot delay { <i>hh:mm</i> <i>mm</i> }	<p>Use either command.</p> <p>The scheduled reboot function is disabled by default.</p> <p>Changing any clock setting can cancel the reboot schedule.</p>

Scheduling jobs

You can schedule a job to automatically run a command or a set of commands without administrative interference. The commands in a job are polled every minute. When the scheduled time for a command is reached, the job automatically executes the command. If a confirmation is required while the command is running, the system automatically inputs **Y** or **Yes**. If characters are required, the system automatically inputs a default character string, or inputs an empty character string when there is no default character string.

Job configuration approaches

You can configure jobs in a non-modular or modular approach. Use the non-modular approach for a one-time command execution and use non-modular approach for complex maintenance work.

Table 22 A comparison of non-modular and modular approaches

Comparison item	Scheduling a job in the non-modular approach	Scheduling a job in the modular approach
Configuration method	Configure all elements in one command	Separate job, view, and time settings.
Can multiple jobs be configured?	No	Yes
Can a job have multiple commands?	No If you use the schedule job command repeatedly, only the last configuration takes effect.	Yes You can use the time command in job view to configure commands to be executed at different time points.
Supported views	User view and system view. In the schedule job command, shell represents user view, and system represents system view.	All views. In the time command, monitor represents user view.
Supported commands	Commands in user view and system view	Commands in all views.
Can a job be repeatedly executed?	No	Yes
Can a job be saved to the configuration file?	No	Yes

Configuration guidelines

- To have a job successfully run a command, check that the specified view and command are valid. The system does not verify their validity.
- The configuration interface, view, and user status that you have before job execution restores even if the job has run a command that changes the user interface (for example, **telnet**, **ftp**, and **ssh2**), the view (for example, **system-view** and **quit**), or the user status (for example, **super**).
- The jobs run in the background without displaying any messages except log, trap and debugging messages.
- In the modular approach:
 - Every job can have only one view and up to 10 commands. If you specify multiple views, the one specified the last takes effect.

- Input a view name in its complete form. Most commonly used view names include **monitor** for user view, **system** for system view, **GigabitEthernetx/x/x**, and **Ten-GigabitEthernetx/x/x** for Ethernet interface view, and **Vlan-interfacex** for VLAN interface view.
- The time ID (*time-id*) must be unique in a job. If two time and command bindings have the same time ID, the one configured last takes effect.

Scheduling a job in the non-modular approach

Perform one of the following commands in user view to schedule a job:

Step	Command	Remarks
Schedule a job.	<ul style="list-style-type: none"> • Schedule a job to run a command at a specific time: schedule job at time [date] view view command • Schedule a job to run a command after a delay: schedule job delay time view view command 	Use either command. NOTE: <ul style="list-style-type: none"> • If you execute the schedule job command repeatedly, the last configuration takes effect. • Changing any clock setting can cancel the job set by using the schedule job command.

Scheduling a job in the modular approach

To configure a scheduled job:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a job and enter job view.	job job-name	N/A
3. Specify the view in which the commands in the job run.	view view-name	You can specify only one view for a job. The job executes all commands in the specified view.
4. Add commands to the job.	<ul style="list-style-type: none"> • Configure a command to run at a specific time and date: time time-id at time date command command • Configure a command to run at a specific time: time time-id { one-off repeating } at time [month-date month-day week-day week-daylist] command command • Configure a command to run after a delay: time time-id { one-off repeating } delay time command command 	Use any of the commands. NOTE: Changing a clock setting does not affect the schedule set by using the time at or time delay command.

Disabling Boot ROM access

By default, anyone can press **Ctrl+B** during startup to enter the Boot menu and configure the Boot ROM. To protect the system, you can disable Boot ROM access so the users can access only the CLI.

You can also set a Boot ROM password the first time you access the Boot menu to protect the Boot ROM.

To view Boot ROM accessibility status, use the **display startup** command. For more information about the **display startup** command, see *Fundamentals Command Reference*.

Follow the step below to disable Boot ROM access:

Task	Command	Remarks
Disable Boot ROM access.	undo startup bootrom-access enable	By default, Boot ROM access is enabled. Available in user view.

Configuring the port status detection timer

Some protocols might shut down ports under specific circumstances. For example, MSTP shuts down a BPDU guard enabled port when the port receives a BPDU. Then, the device starts the detection timer. If the port is still down when the detection timer expires, the port quits the shutdown status and resumes its actual physical status.

To configure the port status detection timer:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the port status detection timer.	shutdown-interval time	Optional. The detection timer is 30 seconds by default.

Configuring temperature thresholds for a device

You can set the temperature thresholds to monitor the temperature of a device.

The temperature thresholds include lower threshold and warning threshold.

When the device temperature drops below the lower threshold or reaches the warning threshold, the device logs the event and outputs a log message and a trap.

When the device temperature reaches the alarming threshold, the device logs the event and outputs a log message and a trap repeatedly.

When the device temperature reaches the shut-down threshold, the device logs the event, outputs a log message and a trap, and automatically shuts down.

To configure temperature thresholds for an IRF member device:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure temperature thresholds for an IRF member device.	temperature-limit slot <i>slot-number</i> hotspot <i>sensor-number</i> lowerlimit <i>warninglimit</i>	Optional. By default, the lower threshold is -5°C (23°F), and the warning threshold is 55°C (131°F). The warning threshold must be higher than the lower threshold.

Clearing unused 16-bit interface indexes

The device must maintain persistent 16-bit interface indexes and keep one interface index match one interface name for network management. After deleting a logical interface, the device retains its 16-bit interface index so the same index can be assigned to the interface at interface re-creation.

To avoid index depletion causing interface creation failures, you can clear all 16-bit indexes that have been assigned but not in use. The operation does not affect the interface indexes of the interfaces that have been created but the indexes assigned to re-created interfaces might change.

! IMPORTANT:

A confirmation is required when you execute this command. The command will not run if you fail to make a confirmation within 30 seconds or enter **N** to cancel the operation.

To clear unused 16-bit interface indexes, perform the following task in user view:

Task	Command	Remarks
Clear unused 16-bit interface indexes.	reset unused porttag	In an IRF fabric, the command applies to all member switches.

Verifying and diagnosing transceiver modules

You can verify the genuineness of a transceiver module in the following ways:

- Display the key parameters of a transceiver module, including its transceiver type, connector type, central wavelength of the transmit laser, transfer distance and vendor name.
- Display its electronic label. The electronic label is a profile of the transceiver module and contains the permanent configuration including the serial number, manufacturing date, and vendor name. The data is written to the storage component during debugging or testing.

To verify transceiver modules, perform the following tasks in any view:

Task	Command
Display key parameters of transceiver modules.	display transceiver interface [<i>interface-type</i> <i>interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]

Task	Command
Display electronic label data for transceiver modules.	display transceiver manuinfo interface [<i>interface-type</i> <i>interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]

Diagnosing transceiver modules

The device provides the alarm function and digital diagnosis function for transceiver modules. When a transceiver module fails or inappropriately operates, you can check for alarms present on the transceiver module to identify the fault source or examine the key parameters monitored by the digital diagnosis function, including the temperature, voltage, laser bias current, TX power, and RX power.

To diagnose transceiver modules, perform the following tasks in any view:

Task	Command
Display alarms present on transceiver modules.	display transceiver alarm interface [<i>interface-type</i> <i>interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]
Display the present measured values of the digital diagnosis parameters for pluggable transceivers.	display transceiver diagnosis interface [<i>interface-type</i> <i>interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]

Displaying and maintaining device management

For diagnosis or troubleshooting, you can use separate **display** commands to collect running status data module by module, or use the **display diagnostic-information** command to bulk collect running data for multiple modules. The **display diagnostic-information** command equals this set of commands: **display clock**, **display version**, **display device**, and **display current-configuration**.

Task	Command	Remarks
Display system version information.	display version [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the system time and date.	display clock [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display or save operating statistics for multiple feature modules.	display diagnostic-information [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display alarm information.	display alarm [<i>slot slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display CPU usage statistics.	display cpu-usage [slot slot-number [cpu cpu-number]] [{ begin exclude include } regular-expression] display cpu-usage entry-number [offset] [verbose] [slot slot-number] [cpu cpu-number] [{ begin exclude include } regular-expression]	Available in any view
Display historical CPU usage statistics in a chart.	display cpu-usage history [task task-id] [slot slot-number [cpu cpu-number]] [{ begin exclude include } regular-expression]	Available in any view
Display hardware information.	display device [[slot slot-number] verbose] [{ begin exclude include } regular-expression]	Available in any view
Display the electronic label data for the device.	display device manuinfo [slot slot-number] [{ begin exclude include } regular-expression]	Available in any view
Display device temperature statistics.	display environment [slot slot-number] [{ begin exclude include } regular-expression]	Available in any view
Display the operating states of fan trays.	display fan [slot slot-number [fan-id]] [{ begin exclude include } regular-expression]	Available in any view
Display memory usage statistics.	display memory [slot slot-number [cpu cpu-number]] [{ begin exclude include } regular-expression]	Available in any view
Display power supply information.	display power [slot slot-number [power-id]] [{ begin exclude include } regular-expression]	Available in any view
Display the mode of the last reboot.	display reboot-type [slot slot-number] [{ begin exclude include } regular-expression]	Available in any view
Display RPS status information.	display rps [slot slot-number [rps-id]] [{ begin exclude include } regular-expression]	Available in any view
Display the configuration of the job configured by using the schedule job command.	display schedule job [{ begin exclude include } regular-expression]	Available in any view
Display the device reboot setting.	display schedule reboot [{ begin exclude include } regular-expression]	Available in any view
Display the configuration of jobs configured by using the job command.	display job [job-name] [{ begin exclude include } regular-expression]	Available in any view
Display the exception handling method.	display system-failure [{ begin exclude include } regular-expression]	Available in any view

Automatic configuration introduction

Automatic configuration enables a device without any configuration file to automatically obtain and execute a configuration file during startup. Automatic configuration simplifies network configuration, facilitates centralized management, and reduces maintenance workload.

To implement automatic configuration, the network administrator saves configuration files on a server and a device automatically obtains and executes a specific configuration file.

Typical application scenario

Figure 53 Network diagram

As shown in [Figure 53](#), the device implements automatic configuration with the cooperation of the following servers:

- **DHCP server**—Assigns an IP address and other configuration parameters such as the configuration file name, TFTP server IP address, and DNS server IP address to the device.
- **TFTP server**—Saves files needed in automatic configuration. The device gets the files needed from the TFTP server, such as the host name file that saves mappings between host IP addresses and host names, and the configuration file.
- **DNS server**—Resolves between IP addresses and host names. In some cases, the device resolves its IP address to the corresponding host name through the DNS server, and then uses the host name to request the configuration file with the same name (**hostname.cfg**) from the TFTP server. If the device gets the domain name of the TFTP server from the DHCP response, the device can also resolve the domain name of the TFTP server to the IP address of the TFTP server through the DNS server.

If the DHCP server, TFTP server, DNS server, and the device are not in the same network segment, you need to configure the DHCP relay agent on the gateway, and configure routing protocols to enable each server and the device to reach one another.

How automatic configuration works

Automatic configuration works in the following manner:

1. During startup, the device sets the first up interface (if up Layer 2 Ethernet ports exist, the VLAN interface of the default VLAN of the Ethernet ports is selected as the first up interface. Otherwise, the up Layer 3 Ethernet interface with the smallest interface number is selected as the first up interface) as the DHCP client to request parameters from the DHCP server, such as an IP address and name of a TFTP server, IP address of a DNS server, and the configuration file name.
2. After getting related parameters, the device sends a TFTP request to obtain the configuration file from the specified TFTP server and executes the configuration file. If the client cannot get such parameters, it uses the factory defaults.

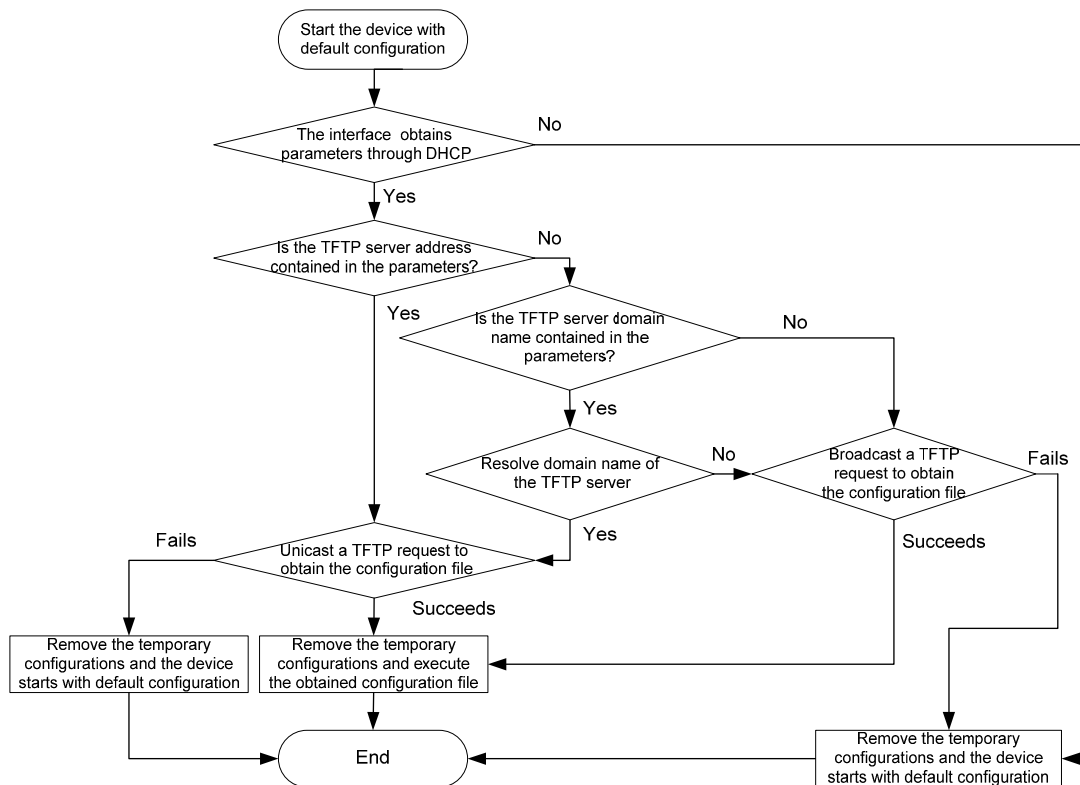

To implement automatic configuration, you must configure the DHCP server, DNS server, and TFTP server, but you do not need to perform any configuration on the device that performs automatic configuration.

Before starting the device, connect only the interface needed in automatic configuration to the network.

Automatic configuration work flow

Figure 54 shows the work flow of automatic configuration.

Figure 54 Automatic configuration work flow

Using DHCP to obtain an IP address and other configuration information

Address acquisition process

As previously mentioned, a device sets the first up interface as the DHCP client during startup. The DHCP client broadcasts a DHCP request, where the Option 55 field specifies the information that the client wants to obtain from the DHCP server such as the configuration file name, domain name and IP address of the TFTP server, and DNS server IP address.

After receiving the DHCP response from the DHCP server, the device obtains the IP address and resolves the following fields in the DHCP response:

- Option 67 or the file field—Obtains the configuration file name. The device resolves Option 67 first. If Option 67 contains the configuration file name, the device does not resolve the file field. If not, the device resolves the file field.
- Option 66—Obtains the TFTP server domain name
- Option 150—Obtains the TFTP server IP address
- Option 6—Obtains the DNS server IP address.

If no response is received from the DHCP server, the device removes the temporary configuration and starts up with the factory defaults.

The temporary configuration contains two parts: the configuration made on the interface through which automatic configuration is performed, and the **ip host** command in the host name file (For more information about the **ip host** command, see *Layer 3—IP Services Command Reference*.). The temporary configuration is removed by executing the corresponding **undo** commands.

For more information about DHCP, see *Layer 3—IP Services Configuration Guide*.

Principles for selecting an address pool on the DHCP server

The DHCP server selects IP addresses and other network configuration parameters from an address pool for clients. DHCP supports the following types of address pools:

- **Dynamic address pool**—A dynamic address pool contains a range of IP addresses and other parameters that the DHCP server dynamically assigns to clients.
- **Static address pool**—A static address pool contains the binding of an IP address and a MAC address (or a client ID). The DHCP server assigns the IP address of the binding and specific configuration parameters to a requesting client whose MAC address or ID is contained in the binding. In this way, the client can get a fixed IP address.

Select address pools by using one of the following methods:

- If devices use the same configuration file, you can configure a dynamic address pool on the DHCP server to assign IP addresses and the same configuration parameters (for example, configuration file name) to the devices. In this case, the configuration file can only contain common configurations of the devices, and the specific configurations of each device need to be performed in other ways. For example, the configuration file can enable Telnet and create a local user on devices so that the administrator can Telnet to each device to perform specific configurations (for example, configure the IP address of each interface).
- If devices use different configuration files, you need to configure static address pools to make sure each device can get a fixed IP address and a specific configuration file. With this method, no more configuration is required for the devices.

To configure static address pools, you must obtain corresponding client IDs. To obtain a device's client ID, use the **display dhcp server ip-in-use** command to display address binding information on the DHCP server after the device obtains its IP address through DHCP.

Obtaining the configuration file from the TFTP server

A device can obtain the following files from the TFTP server during automatic configuration:

- The configuration file specified by the Option 67 or file field in the DHCP response.
- The host name file named `network.cfg` that stores mappings between IP addresses and host names.

For example, the host name file can include the following:

```
ip host host1 101.101.101.101
ip host host2 101.101.101.102
ip host client1 101.101.101.103
ip host client2 101.101.101.104
```

IMPORTANT:

- There must be a space before the keyword **ip host**.
 - The host name of a device saved in the host name file must be the same as the configuration file name of the device, and can be identical with or different from that saved in the DNS server.
-
- The configuration file for the device, which is named `hostname.cfg` (*hostname* is the host name of the device). For example, if the host name of a device is **aaa**, the configuration file for the device is named **aaa.cfg**.
 - The default configuration file named **device.cfg**.

Obtaining the configuration file

Figure 55 Obtaining the configuration file

A device obtains its configuration file by using the following workflow:

- If the DHCP response contains the configuration file name, the device requests the specified configuration file from the TFTP server.
- If not, the device tries to get its host name from the host name file obtained from the TFTP server. If it fails, the device resolves its IP address to the host name through DNS server. Once the device gets its host name, it requests the configuration file with the same name from the TFTP server.
- If all the above operations fail, the device requests the default configuration file from the TFTP server.

TFTP request sending mode

The device chooses whether to unicast or broadcast a TFTP request as follows:

- If a legitimate TFTP server IP address is contained in the DHCP response, the device unicasts a TFTP request to the TFTP server.
- If not, the device resolves the TFTP server domain name contained in the DHCP response to the corresponding IP address through the DNS server. If successful, the device unicasts a TFTP request to the TFTP server; if not, the device broadcasts a TFTP request.

- If the IP address and the domain name of the TFTP server are not contained in the DHCP response or they are illegitimate, the device broadcasts a TFTP request.

After broadcasting a TFTP request, the device selects the TFTP server that responds first to obtain the configuration file. If the requested configuration file does not exist on the TFTP server, the request operation fails, and the device removes the temporary configuration and starts up with the factory defaults.

If the device and the TFTP server reside in different subnets, you must configure the UDP Helper function for the gateway to change the broadcast TFTP request from the device to a unicast packet and forward the unicast packet to the specified TFTP server. For more information about UDP Helper, see *Layer 3—IP Services Configuration Guide*.

Executing the configuration file

After obtaining the configuration file, the device removes the temporary configuration and executes the configuration file. If no configuration file is obtained, the device removes the temporary configuration and starts up with the factory defaults.

NOTE:

If the configuration file contains any IRF configuration, the device does not execute the IRF configuration when executing the configuration file.

The configuration file is deleted after executed. Save the configuration by using the **save** command. Otherwise, the device has to perform automatic configuration again after reboot. For more information about the **save** command, see *Fundamentals Command Reference*.

IRF overview

The HP Intelligent Resilient Framework (IRF) technology creates a large IRF fabric from multiple switches to provide data center class availability and scalability. IRF virtualization technology offers processing power, interaction, unified management, and uninterrupted maintenance of multiple switches.

This book describes IRF concepts and guides you through the IRF setup procedure.

Hardware compatibility

5500 switches in an IRF fabric must be the same sub-series. For example, a 5500 EI and a 5500 SI cannot form an IRF fabric.

To use IRF on these switches, you must purchase at least one 10-GE interface card listed in "[IRF physical port restrictions and cabling requirements](#)."

IRF benefits

IRF delivers the following benefits:

- **Simplified topology and easy management**—An IRF fabric appears as one node and is accessible at a single IP address on the network. You can use this IP address to log in at any member device to manage all the members of the IRF fabric. In addition, you do not need to run the spanning tree feature among the IRF members.
- **1:N redundancy**—In an IRF fabric, one member works as the master to manage and control the entire IRF fabric, and all the other members process services while backing up the master. When the master fails, all the other member devices elect a new master from among them to take over without interrupting services.
- **IRF link aggregation**—You can assign several physical links between neighboring members to their IRF ports to create a load-balanced aggregate IRF connection with redundancy.
- **Multiple-chassis link aggregation**—You can use the Ethernet link aggregation feature to aggregate the physical links between the IRF fabric and its upstream or downstream devices across the IRF members.
- **Network scalability and resiliency**—Processing capacity of an IRF fabric equals the total processing capacities of all the members. You can increase ports, network bandwidth, and processing capacity of an IRF fabric simply by adding member devices without changing the network topology.

Application scenario

[Figure 1](#) shows an IRF fabric that comprises two switches, which appear as a single node to the upper and lower layer devices.

Figure 1 IRF application scenario

Basic concepts

This section describes the basic concepts that you might encounter when working with IRF.

IRF member roles

IRF uses two member roles: master and slave (called "subordinate" throughout the documentation).

When switches form an IRF fabric, they elect a master to manage the IRF fabric, and all other switches back up the master. When the master switch fails, the other switches automatically elect a new master from among them to take over. For more information about master election, see "[Master election](#)."

IRF member ID

An IRF fabric uses member IDs to uniquely identify and manage its members. This member ID information is included as the first part of interface numbers and file paths to uniquely identify interfaces and files in an IRF fabric. For more information about interface and file path naming, see "[Interface naming conventions](#)" and "[File system naming conventions](#)."

If two switches have the same IRF member ID, they cannot form an IRF fabric.

IRF port

An IRF port is a logical interface for the connection between IRF member devices. Every IRF-capable device supports two IRF ports. The IRF ports are named IRF-port $n/1$ and IRF-port $n/2$, where n is the member ID of the switch. The two IRF ports are referred to as "IRF-port 1" and "IRF-port 2" in this book for simplicity.

To use an IRF port, you must bind at least one physical port to it. The physical ports assigned to an IRF port automatically form an aggregate IRF link. An IRF port goes down only if all its physical IRF ports are down.

Physical IRF port

Physical IRF ports connect IRF member devices and must be bound to an IRF port. They forward IRF protocol packets between IRF member devices and data packets that must travel across IRF member devices.

For more information about physical ports that can be used for IRF links, see "[General restrictions and configuration guidelines](#)."

IRF domain ID

One IRF fabric forms one IRF domain. IRF uses IRF domain IDs to uniquely identify IRF fabrics and prevent IRF fabrics from interfering with one another.

As shown in [Figure 2](#), Switch A and Switch B form IRF fabric 1, and Switch C and Switch D form IRF fabric 2. The fabrics have LACP MAD detection links between them. When a member switch in one IRF fabric receives an extended LACP packet for MAD detection, it looks at the domain ID in the packet to see whether the packet is from the local IRF fabric or from a different IRF fabric. Then, the switch can handle the packet correctly.

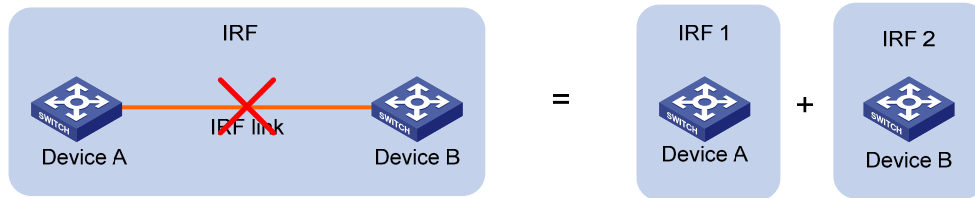

Figure 2 A network that comprises two IRF domains

IRF split

IRF split occurs when an IRF fabric breaks up into two or more IRF fabrics because of IRF link failures, as shown in [Figure 3](#). The split IRF fabrics operate with the same IP address and cause routing and forwarding problems on the network. To quickly detect a multi-active collision, configure at least one MAD mechanisms (see "[IRF multi-active detection](#)").

Figure 3 IRF split

IRF merge

IRF merge occurs when two split IRF fabrics re-unite or when you configure and connect two independent IRF fabrics to be one IRF fabric, as shown in Figure 4.

Figure 4 IRF merge

Member priority

Member priority determines the possibility of a member device to be elected the master. A member with higher priority is more likely to be elected the master.

The default member priority is 1. You can change the member priority of a member device to affect the master election result.

Interface naming conventions

An interface is named in the format of *member-id/slot-number/port-index*, where:

- *member-id*—If the switch is standalone, the member ID defaults to 1. If the standalone switch was once an IRF member switch, it uses the same member ID as it was in the IRF fabric.
- *slot-number*—Represents the slot number of the interface card. This argument takes 0 for the fixed ports on the front panel, and takes 1 and 2 for the two interface cards (from left to right) on the rear panel.
- *port-index*—Port index depends on the number of ports available on the switch. To identify the index of a port, look at its port index mark on the chassis.

For one example, on the standalone switch Sysname, GigabitEthernet 1/0/1 represents the first fixed port on the front panel. Set its link type to trunk, as follows:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port link-type trunk
```

For another example, on the IRF fabric Master, GigabitEthernet 3/0/1 represents the first fixed port on the front panel of member switch 3. Set its link type to trunk, as follows:

```
<Sysname> system-view
```

```
[Sysname] interface gigabitethernet 3/0/1
[Sysname-GigabitEthernet3/0/1] port link-type trunk
```

File system naming conventions

On a standalone switch, you can use the name of storage device to access its file system. For more information about storage device naming conventions, see *Fundamentals Configuration Guide*.

On an IRF fabric, you can use the name of storage device to access the file system of the master. To access the file system of any other member switch, use the name in the **slotmember-ID#storage-device-name** format. For example:

To access the **test** folder under the root directory of the Flash on the master switch:

```
<Master> mkdir test
...
%Created dir flash:/test.
<Master> dir
Directory of flash:/
  0   -rw-  10105088  Apr 26 2000 13:44:57  test.bin
  1   -rw-    2445    Apr 26 2000 15:18:19  config.cfg
  2   drw-      -    Jul 14 2008 15:20:35  test
30861 KB total (20961 KB free)
```

To create and access the **test** folder under the root directory of the Flash on member switch 3:

```
<Master> mkdir slot3#flash:/test
%Created dir slot3#flash:/test.
<Master> cd slot3#flash:/test
<Master> pwd
slot3#flash:/test
```

Or:

```
<Master> cd slot3#flash:/
<Master> mkdir test
%Created dir slot3#flash:/test.
```

To copy the file **test.bin** on the master to the root directory of the Flash on member switch 3:

Display the current working path. In this example, the current working path is the root directory of the Flash on member switch 3.

```
<Master> pwd
slot3#flash:
```

Change the current working path to the root directory of the Flash on the master switch:

```
<Master> cd flash:/
<Master> pwd
flash:
```

Copy the file to member switch 3.

```
<Master> copy test.bin slot3#flash:/
Copy flash:/test.bin to slot3#flash:/test.bin?[Y/N]:y
%Copy file flash:/test.bin to slot3#flash:/test.bin...Done.
```

Configuration synchronization mechanism

IRF uses a strict running-configuration synchronization mechanism so all chassis in an IRF fabric can work as a single node, and after the master fails, other members can operate normally.

In an IRF fabric, all chassis get and run the running configuration of the master. Any configuration you have made is propagated to all members.

When you execute the **save [safely] [backup | main] [force]** command or the **save file-url all** command, the system saves the running configuration, as follows:

- If the configuration auto-update function (the **slave auto-update config** command) is enabled, saves the configuration as the startup configuration on all member switches for the next startup.
- If the configuration auto-update function is disabled, saves the configuration as the startup configuration on the master for the next startup.

For more information about configuration management, see *Fundamentals Configuration Guide*.

Master election

Master election is held each time the IRF fabric topology changes, for example, when the IRF fabric is established, a new member device is plugged in, the master device fails or is removed, the IRF fabric splits, or IRF fabrics merge.

Master election uses the following rules in descending order:

1. Current master, even if a new member has higher priority.
When an IRF fabric is being formed, all member switches consider themselves as the master, and this rule is skipped
2. Member with higher priority.
3. Member with the longest system uptime.
4. Member with the lowest bridge MAC address.

The IRF fabric is formed on election of the master.

During an IRF merge, the switches of the IRF fabric that fails the master election reboot automatically to re-join the IRF fabric that wins the election.

After a master election, all subordinate switches initialize and reboot with the configuration on the master. Their original configuration, even if has been saved, does not take effect.

IRF multi-active detection

An IRF link failure causes an IRF fabric to split in two IRF fabrics operating with the same Layer 3 configurations, including the same IP address. To avoid IP address collision and network problems, IRF uses multi-active detection (MAD) mechanisms to detect the presence of multiple identical IRF fabrics, handle collisions, and recover from faults.

Multi-active handling procedure

The multi-active handling procedure includes detection, collision handling and failure recovery.

Detection

The MAD implementation of this switch series detects active IRF fabrics with the same Layer 3 global configuration by extending the LACP, BFD, or gratuitous ARP protocol.

These MAD mechanisms identify each IRF fabric with a domain ID and an active ID (the member ID of the master). If multiple active IDs are detected in a domain, MAD determines that an IRF collision or split has occurred.

You can use at least one of these mechanisms in an IRF fabric, depending on your network topology. For a comparison of these MAD mechanisms, see "[Configuring MAD](#)."

Collision handling

When multiple identical active IRF fabrics are detected, MAD compares the member IDs of their masters. If the master in one IRF fabric has the lowest member ID among all the masters, the members in the fabric continue to operate in Active state and forward traffic. MAD sets all the other IRF fabrics in Recovery (disabled) state and shuts down all their physical ports but the console ports, physical IRF ports, and any ports you have specified with the **mad exclude interface** command.

Failure recovery

To merge two split IRF fabrics, first repair the failed IRF link and remove the IRF link failure.

If the IRF fabric in Recovery state fails before the failure is recovered, repair the failed IRF fabric and the failed IRF link.

If the IRF fabric in Active state fails before the failure is recovered, first enable the IRF fabric in Recovery state to take over the active IRF fabric and protect the services from being affected. After that, recover the MAD failure.

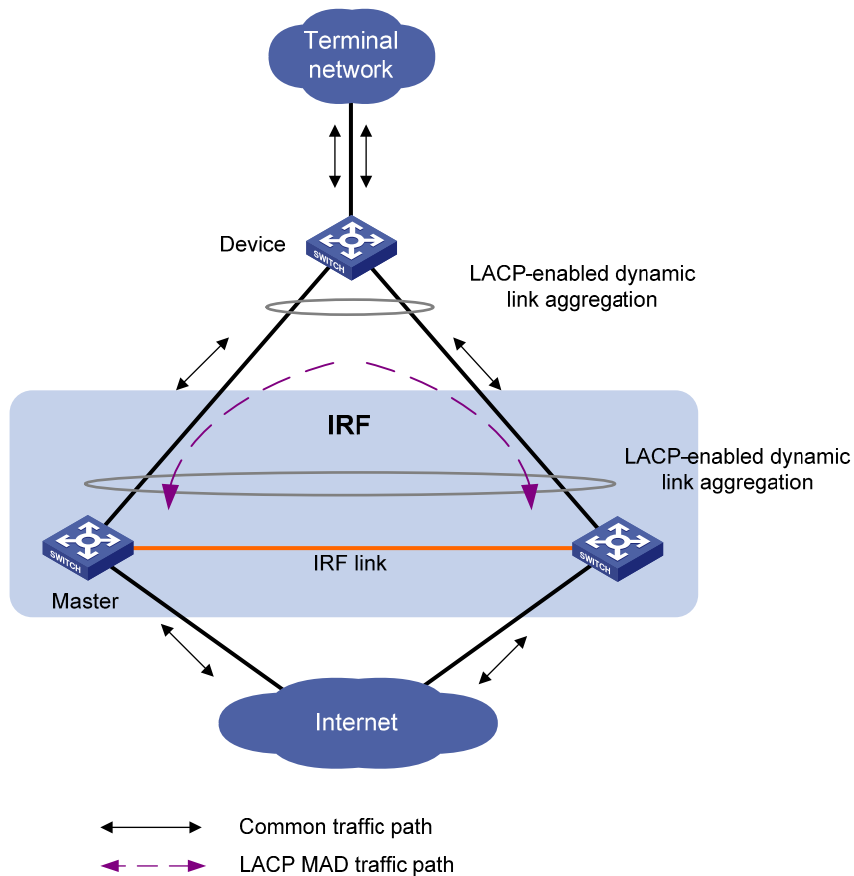

LACP MAD

LACP MAD requires that every IRF member have a link with an intermediate device, and all these links form a dynamic link aggregation group, as shown in [Figure 5](#). In addition, the intermediate device must be an HP device that supports extended LACP for MAD.

The IRF member switches send extended LACPDU s with TLVs that convey the domain ID and the active ID of the IRF fabric. The intermediate device transparently forwards the extended LACPDU s received from one member switch to all the other member switches:

- If the domain IDs and the active IDs in the extended LACPDU s sent by all the member devices are the same, the IRF fabric is integrated.
- If the extended LACPDU s convey the same domain ID but different active IDs, a split has occurred. To handle this situation, LACP MAD sets the IRF fabric with higher active ID in Recovery state, and shuts down all its physical ports but the console port, IRF ports, and any ports you have specified with the **mad exclude interface** command. The IRF fabric with lower active ID is still in Active state and forwards traffic.

Figure 5 LACP MAD application scenario

BFD MAD

BFD MAD can work with or without intermediate devices. Figure 6 shows a typical BFD MAD application scenario.

To use BFD MAD:

- Set up dedicated BFD MAD link between each pair of IRF members or between each IRF member and the intermediate device. Do not use the BFD MAD links for any other purpose.
- Assign the ports connected by BFD MAD links to the same VLAN, create a VLAN interface for the VLAN, and assign a MAD IP address to each member on the VLAN interface.

The MAD addresses identify the member switches and must belong to the same subnet.

With BFD MAD, the master tries to establish BFD sessions with other member switches by using its MAD IP address as the source IP address:

- If the IRF fabric is integrated, only the MAD IP address of the master is effective, and the master cannot establish a BFD session with any other member. If you execute the **display bfd session** command, the state of the BFD sessions is **Down**.
- When the IRF fabric splits, the IP addresses of the masters in the split IRF fabrics take effect, and the two masters can establish a BFD session. If you execute the **display bfd session** command, the state of the BFD session between the two devices is **Up**.

Figure 6 BFD MAD application scenario

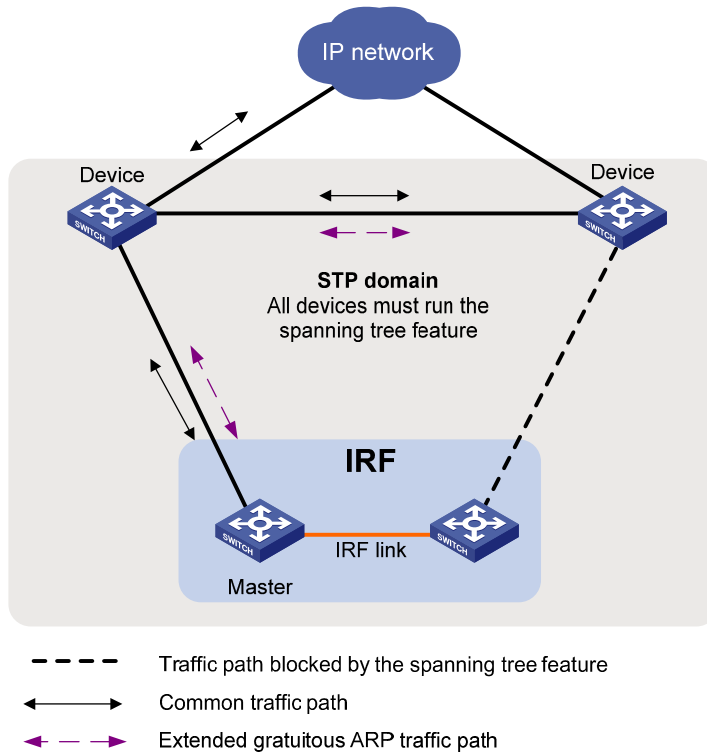

ARP MAD

ARP MAD detects multi-active collisions by using extended gratuitous ARP packets that convey the IRF domain ID and the active ID.

You can set up ARP MAD links between neighbor IRF member devices, or more commonly, between each IRF member device and an intermediate device (see [Figure 7](#)). If an intermediate device is used, you must also run the spanning tree feature between the IRF fabric and the intermediate device.

Figure 7 ARP MAD application scenario

Each IRF member compares the domain ID and the active ID in incoming extended gratuitous ARP packets with its domain ID and active ID:

- If the domain IDs are different, the extended gratuitous ARP packet is from a different IRF fabric, and the device does not continue to process the packet with the MAD mechanism.
- If the domain IDs are the same, the device compares the active IDs:
 - If the active IDs are different, the IRF fabric has split.
 - If the active IDs are the same, the IRF fabric is integrated.

Configuring IRF

Read the configuration restrictions and guidelines carefully when you connect and set up an IRF fabric.

General restrictions and configuration guidelines

This section describes the restrictions and configuration guidelines you must follow.

Software requirements

All IRF member switches must run the same system software image version.

IRF physical port restrictions and cabling requirements

Candidate IRF physical ports include 10-GE ports on expansion interface cards. To use IRF, purchase at least one interface card. The following are the interface cards available for IRF connections:

- LSPM1XP1P (JD361B)
- LSPM1XP2P (JD359B)
- LSPM1CX2P (JD360B)
- LSPM2SP2P (JD368B)

For long-distance IRF connections, use XFP or SFP+ transceiver modules and fibers. For short-distance IRF connections, use CX4 or SFP+ cables. For more information about transceiver modules available for an interface card, see the interface card user guide.

For more information about transceiver modules, see *HP A-Series Switches Transceiver Modules User Guide*.

The SFP+ modules and SFP+ cables available for this switch series are subject to change over time. For the most up-to-date list of SFP+ modules and cables, contact HP technical support or marketing staff.

IRF link redundancy

This switch series supports up to two physical ports to one IRF port. These two ports must be located on the same interface card.

MAD

- Configure at least one MAD mechanism for prompt IRF split detection and IRF fabric recovery.
- If LACP MAD or ARP MAD runs between two IRF fabrics, assign each fabric a unique IRF domain ID. For BFD MAD, this task is optional.
- BFD MAD is available only on 5500 EI switches.
- To exclude a port from the shutdown action performed when an IRF fabric to the Recovery state, use the **mad exclude interface** command. To bring up a port after the IRF fabric transits to the Recovery state, you must use the **mad restore** command to activate the entire IRF fabric, rather than using the **undo shutdown** command.

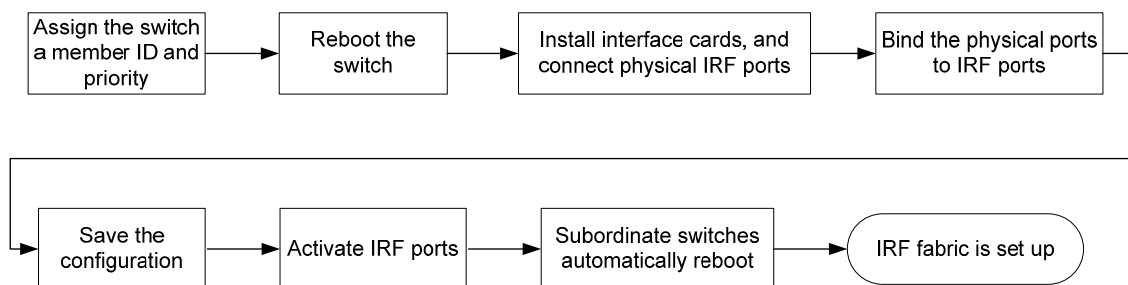

Other configuration guidelines

- Strictly follow the IRF fabric setup procedure described in "[Setup and configuration task list](#)" to plan the IRF fabric, identify IRF physical ports, connect IRF member switches, and configure basic settings.
- Assign each member a unique IRF member ID to make sure they can merge. You must reboot the members to validate the IRF member ID settings.
- Assign the highest member priority to the device you want to use as the master.
- Before removing an interface card that has physical IRF ports in an IRF fabric, remove the IRF connection cables, or use the **shutdown** command to shut down the IRF physical ports.
- If a subordinate switch uses the same next-startup configuration file name as the master switch, the file might be overwritten depending on your configuration file management settings. To continue to use the configuration file after removing the switch from the IRF fabric, back up the file before setting up the IRF fabric.
- Save any configuration you have made to the startup configuration file before rebooting the IRF member devices.
- The Layer 3 Ethernet port in this book refers to an Ethernet port that can perform IP routing and inter-VLAN routing. You can set an Ethernet port as a Layer 3 Ethernet interface by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).
- You can configure an Ethernet port as a Layer 3 Ethernet port only on the 5500 EI switch.

Setup and configuration task list

HP recommends the configuration procedure in [Figure 8](#).

Figure 8 IRF setup and configuration flow chart

HP recommends the following IRF fabric setup and configuration procedure:

Task	Remarks
1. Planning the IRF fabric setup	Required.
2. Assigning a member ID to each IRF member switch	Required. Perform this task on each member switch.
3. Specifying a priority for each member switch	Required. Perform this task on each member switch.
4. Connecting physical IRF ports	Required.

Task	Remarks
5. Binding physical ports to IRF ports	Required. Perform this task on each member switch.
6. Accessing the IRF fabric: <ul style="list-style-type: none"> o Accessing the CLI of the master switch o Accessing the CLI of a subordinate switch 	Login to the master's CLI is required. You configure all member switches at the master's CLI. From the master's CLI, you can log in to any other member switch's CLI to execute a limited set of maintenance commands.
7. Assigning an IRF domain ID to the IRF fabric	This task is required for ARP MAD and LACP MAD.
8. Configuring a member switch description	Optional.
9. Configuring IRF link load sharing mode: <ul style="list-style-type: none"> o Configuring the global load sharing mode o Configuring port-specific load sharing criteria 	Optional.
10. Configuring IRF bridge MAC persistence	Optional.
11. Enabling software auto-update for system software image synchronization	Optional. HP recommends enabling software auto-update to make sure system software image synchronization
12. Setting the IRF link down report delay	Optional.
13. Configuring MAD: <ul style="list-style-type: none"> o Configuring LACP MAD o Configuring BFD MAD o Configuring ARP MAD o Excluding a port from the shutdown action upon detection of multi-active collision o Recovering an IRF fabric 	Required. MAD mechanisms are independent of one another. You can configure at least one MAD mechanism for an IRF fabric.

Planning the IRF fabric setup

Consider the following items when you plan an IRF fabric:

- Hardware compatibility and restrictions
- IRF fabric size
- Master switch
- IRF physical ports
- Member ID and priority assignment scheme
- Fabric topology and cabling scheme

For more information about hardware and cabling, see the installation guide for the device.

Assigning a member ID to each IRF member switch

CAUTION:

In an IRF fabric, changing IRF member IDs might cause undesirable configuration changes and even data loss. Before you do that, back up the configuration and make sure you fully understand the impact on your network. For example, all member switches in an IRF fabric are the same model. If you swapped the IDs of any two members, their interface settings would also be swapped.

By default, the member IDs of all switches are 1. To create an IRF fabric, you must assign a unique IRF member ID to each switch.

Perform this task before the IRF fabric is formed. To prevent any undesirable configuration change or data loss, avoid changing member IDs after the IRF fabric is formed.

The new member ID takes effect at a reboot. After the switch reboots, the settings on all member-ID related physical resources (including common physical network ports) are removed and require reconfiguration, regardless of whether you have saved the configuration.

To set a member ID for a switch:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Assign an IRF member ID to the switch.	irf member <i>member-id</i> renumber <i>new-member-id</i>	The default IRF member ID is 1. Optional.
3. Save the configuration.	save [safely] [backup main] [force]	If you have bound physical ports to IRF ports or assigned member priority, save the configuration before rebooting the switch so these settings can continue to take effect after the reboot.
4. Reboot the switch.	reboot [slot <i>slot-number</i>]	N/A

Specifying a priority for each member switch

IRF member priority represents the possibility for a device to be elected the master in an IRF fabric. The higher the priority, the higher the possibility.

A member priority change affects the election result at the next master election, but does not cause immediate master re-election.

To specify a priority for the switch:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify a priority for the switch.	irf priority <i>priority</i>	The default IRF member priority is 1.

Connecting physical IRF ports

When you connect two neighboring IRF members, connect the physical ports of IRF-port 1 on one member to the physical ports of IRF-port 2 on the other, as shown in [Figure 9](#).

! **IMPORTANT:**

No intermediate devices are allowed between neighboring members.

Figure 9 Connecting IRF physical ports

Connection restrictions

The switches support up to two physical IRF ports for an IRF port.

Note the following IRF link binding restrictions when you connect physical IRF ports:

- Facing the rear panel, make sure the physical ports bound to IRF port 1 is on the left of the physical ports bound to IRF port 2.
- Physical ports of an IRF port must be on the same interface card

IRF fabric topology

Connect the switches into a daisy chain topology or more reliably, a ring topology (see [Figure 10](#)). In ring topology, the failure of one IRF link does not cause the IRF fabric to split as in daisy chain topology. Rather, the IRF fabric changes to a daisy chain topology without interrupting network services.

To use the ring topology, you must have at least three member switches.

Figure 10 Daisy chain topology vs. ring topology

Binding physical ports to IRF ports

When you bind physical ports to IRF ports, follow the restrictions in "[Connection restrictions](#)."

On a physical port that has been bound to an IRF port, you can only use the **bfd**, **default**, **shutdown**, **description**, and **flow-interval** commands. For more information about these commands, see *Layer 2—LAN Switching Command Reference*.

To bind physical ports to IRF ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter physical IRF port view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Shut down the port.	shutdown	Always shut down a physical port before binding it to an IRF port or removing the binding. Start the shutdown operation on the master and then the switch that has the fewest number of hops from the master.
4. Return to system view.	quit	N/A
5. Create an IRF port and enter IRF port view.	irf-port <i>member-id/port-number</i>	N/A
6. Bind the physical port to the IRF port.	port group interface <i>interface-type</i> <i>interface-number</i> [mode { enhanced normal }]	By default, no physical port is bound to any IRF port. The switch does not support the enhanced keyword. Make sure the two ends of an IRF link use the same binding mode.

Step	Command	Remarks
7. Return to system view.	quit	N/A
8. Enter physical IRF port view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
9. Bring up the port.	undo shutdown	N/A
10. Return to system view.	quit	N/A
11. Save the running configuration.	save	N/A
12. Activate the IRF port configuration.	irf-port-configuration active	<p>After this step is performed, the state of the IRF port changes to UP, the member switches automatically elects a master, and the subordinate switch automatically reboots.</p> <p>After the IRF fabric is formed, you can add more physical ports to an IRF port (in UP state) without performing this step.</p>

Accessing the IRF fabric

The IRF fabric appears as one device after it is formed. You configure and manage all IRF members at the CLI of the master. All settings you made are automatically propagated to the IRF members.

When you log in to an IRF fabric, you are placed at the CLI of the master, regardless of at which member switch you are logged in. After that, you can access the CLI of a subordinate switch to execute a limited set of maintenance commands.

The IRF fabric supports up to 16 concurrent VTY users. The maximum number of concurrent console users equals the total number of member switches in the IRF fabric.

Accessing the CLI of the master switch

Access an IRF fabric in one of the following ways:

- **Local login**—Log in through the console port of any member switch.
- **Remote login**—Remotely log in at a Layer 3 interface on any member switch through Telnet, SNMP, or Web.

For more information, see the chapter on login in *Fundamentals Configuration Guide*.

Accessing the CLI of a subordinate switch

You can log in to the CLI of a subordinate switch for maintenance or debugging. At the CLI of a subordinate switch, you are placed in user view, and the command prompt changes to `<Sysname-Slave#member-ID/slot-number>`, for example, `<Sysname-Slave#2>`. You can use the following commands at a subordinate switch's CLI:

- **display**
- **quit**
- **return**

- **system-view**
- **debugging**
- **terminal debugging**
- **terminal logging**
- **terminal monitor**
- **terminal trapping**

Perform the following task in user view:

Task	Command	Remarks
Log in to a subordinate switch.	irf switch-to <i>member-id</i>	By default, you are placed at the master's CLI.

To return to the master's CLI, use the **quit** command.

Assigning an IRF domain ID to the IRF fabric

This task is required for running LACP MAD or ARP MAD between two IRF fabrics. For BFD MAD, this task is optional.

One IRF fabric forms one IRF domain. IRF domain IDs prevent IRF fabrics from interfering with one another.

In [Figure 11](#), Switch A and Switch B form IRF fabric 1, and Switch C and Switch D form IRF fabric 2. These fabrics have LACP MAD links between them. When a member switch in one IRF fabric receives an LACP MAD packet, it looks at the domain ID in the packet to see whether the packet is from the local IRF fabric or from a different IRF fabric. Then, the switch can handle the packet correctly.

Figure 11 A network that comprises two IRF domains

To assign a domain ID to an IRF fabric:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Assign a domain ID to the IRF fabric.	irf domain <i>domain-id</i>	By default, the domain ID of an IRF fabric is 0.

Configuring a member switch description

You can configure a description for a member switch to identify its physical location, or for any other management purpose.

To configure a description for a member switch:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the description of a member.	irf member <i>member-id</i> description <i>text</i>	By default, no member switch description is configured.

Configuring IRF link load sharing mode

On an IRF port that has multiple links, traffic is balanced across its physical links. You can configure the IRF port to distribute traffic based on certain criteria, including source IP address, destination IP address,

source MAC address, destination MAC address, or a combination of them. If a criteria combination is not supported, the system displays an error message.

Configure the IRF link load sharing mode for IRF links in system view or IRF port view.

- In system view, the configuration is global and takes effect on all IRF ports.
- In IRF port view, the configuration is port specific and takes effect only on the specific IRF port.

An IRF port preferentially uses the port-specific load sharing mode. If no port-specific load sharing mode is available, it uses the global load sharing mode.

Configuring the global load sharing mode

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the global IRF link load sharing mode.	irf-port load-sharing mode { destination-ip destination-mac source-ip source-mac } *	By default, the switch uses source and destination MAC addresses for packets that have no IP header, and uses source and destination IP addresses for IP packets.

Configuring port-specific load sharing criteria

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IRF port view.	irf-port <i>member-id/port-number</i>	N/A
3. Configure the port-specific load sharing mode.	irf-port load-sharing mode { destination-ip destination-mac source-ip source-mac } *	By default, the switch uses source and destination MAC addresses for packets that have no IP header, and uses source and destination IP addresses for IP packets.

Configuring IRF bridge MAC persistence

An IRF fabric by default uses the bridge MAC address of the master switch as its bridge MAC address. This bridge MAC address is used by Layer 2 protocols, for example, LACP, to identify the IRF fabric, and must be unique on a switched LAN for proper communication.

To avoid duplicate bridge MAC addresses, an IRF fabric can automatically change its bridge MAC address after its master leaves, but the change can cause transient traffic interruption.

Depending on your network condition, enable the IRF fabric to preserve or change its bridge MAC address after the master leaves. Available options include:

- **irf mac-address persistent timer**—Bridge MAC address of the IRF fabric persists for six minutes after the master leaves. If the master does not come back before the timer expires, the IRF fabric uses the bridge MAC address of the new master as its bridge MAC address. This option avoids unnecessary

bridge MAC address change due to a device reboot, transient link failure, or purposeful link disconnection.

- **irf mac-address persistent always**—Bridge MAC address of the IRF fabric does not change after the master leaves.
- **undo irf mac-address persistent**—Bridge MAC address of the new master replaces the original one as soon as the old master leaves.

IMPORTANT:

If ARP MAD is used, configure the **undo irf mac-address persistent** command to enable immediate bridge MAC address change after a master leaves.

If two IRF fabrics have the same bridge MAC address, they cannot merge.

To configure the IRF bridge MAC persistence setting:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure IRF bridge MAC persistence.	<ul style="list-style-type: none">• Keep the bridge MAC address unchanged even if the master has changed: irf mac-address persistent always• Preserve the bridge MAC address for six minutes after the master leaves: irf mac-address persistent timer• Change the bridge MAC address as soon as the master leaves: undo irf mac-address persistent	By default, the IRF fabric's bridge MAC address persists permanently even after the master leaves.

Enabling software auto-update for system software image synchronization

To join an IRF fabric, a switch must use the same system software image as the master in the fabric.

The software auto-update function automatically propagates the system software image of the master to all members in the IRF fabric. If software auto-update is disabled, you must manually update the switch with the system software image of the master.

When you add a switch to the IRF fabric, the software auto-update function compares the system software versions of the switch and the IRF master. If the versions are different, the switch automatically downloads the system software image from the master, sets the downloaded image as the system software for the next startup, and automatically reboots with the new system software image to re-join the IRF fabric.

Before you use the software auto-update function, make sure:

- The switch you are adding to the IRF fabric is compatible with the software version running on the master. If not, the automatic system software upgrading function cannot correctly work.
- The switch you are adding to the IRF fabric has sufficient space for the new system software image.

To enable the IRF fabric to automatically synchronize the system software of the master to the switch you are adding to the IRF fabric:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the software auto-update function.	irf auto-update enable	By default, this function is disabled.

In an IRF fabric enabled with software auto-update, if a software upgrade requires upgrading the Boot ROM image, use the following upgrading procedure:

1. Download the new system software image to the master device.
2. Use the **bootrom update** command to upgrade the Boot ROM image on the master.
This step guarantees that the master can complete startup prior to other member switches.
3. Use the **boot-loader file** *file-url slot slot-number main* command to specify the system software image as the startup image for the master.
4. Reboot the entire IRF fabric to complete upgrading software.

For the system software image and Boot ROM compatibility, see the release notes for the new software release.

Setting the IRF link down report delay

You can avoid IRF link flapping causing frequent IRF splits and merges during a short time by configuring the IRF ports to delay reporting link down events. An IRF port works as follows:

- When the IRF link changes from up to down, the port does not immediately report the change to the IRF fabric. If the IRF link state is still down when the delay time is reached, the port reports the change to the IRF fabric.
- When the IRF link changes from down to up, the link layer immediately reports the event to the IRF fabric.

To set the IRF link down report delay:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the IRF link down report delay.	irf link-delay <i>interval</i>	The default IRF link down report delay is 4 seconds. The recommended value range is 200 to 500 milliseconds. The greater the interval, the slower the service recovery.

Configuring MAD

You have the following MAD mechanisms for detecting multi-active collisions in different network scenarios:

- LACP MAD
- BFD MAD
- ARP MAD

These MAD detection mechanisms operate independently. You can configure all of them for an IRF fabric.

Table 1 provides a reference for you to make a MAD mechanism selection decision.

Table 1 A comparison of the MAD mechanisms

MAD mechanism	Advantages	Disadvantages	Application scenario
LACP MAD	<ul style="list-style-type: none"> Detection speed is fast. Requires no MAD-dedicated physical ports or interfaces. 	Requires an intermediate HP device that supports LACP MAD packets.	<p>Link aggregation is used between the IRF fabric and its upstream or downstream device.</p> <p>For information about LACP, see <i>Layer 2—LAN Switching Configuration Guide</i>.</p>
BFD MAD	<ul style="list-style-type: none"> Detection speed is fast. No intermediate device is required. Intermediate device, if used, can come from any vendor. 	<ul style="list-style-type: none"> Requires MAD dedicated physical ports and Layer 3 interfaces, which cannot be used for transmitting user traffic. If no intermediate device is used, the IRF members must be fully meshed. If an intermediate device is used, every IRF member must connect to the intermediate device. 	<ul style="list-style-type: none"> Suitable for various network scenarios. If no intermediate device is used, this mechanism is only suitable for IRF fabrics that have a small number of members that are geographically close to one another. <p>For information about BFD, see <i>High Availability Configuration Guide</i>.</p>
ARP MAD	<ul style="list-style-type: none"> No intermediate device is required. Intermediate device, if used, can come from any vendor. Requires no MAD dedicated ports. 	<ul style="list-style-type: none"> Detection speed is slower than BFD MAD and LACP MAD. MSTP must be enabled. 	<p>MSTP-enabled non-link aggregation IPv4 network scenario.</p> <p>For information about ARP, see <i>Layer 3—IP Services Configuration Guide</i>.</p>

Configuring LACP MAD

When you use LACP MAD, follow these guidelines:

- The intermediate device must be an HP device that support extended LACP for MAD.
- If the intermediate device is in an IRF fabric, assign this fabric a different domain ID than the LACP MAD-enabled fabric to avoid false detection of IRF partition.
- Use dynamic link aggregation mode. MAD is LACP dependent. Even though LACP MAD can be configured on both static and dynamic aggregate interfaces, it takes effect only on dynamic aggregate interfaces.
- Configure link aggregation settings also on the intermediate device.

To configure LACP MAD:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Assign a domain ID to the IRF fabric.	irf domain <i>domain-id</i>	The default IRF domain ID is 0.
3. Create an aggregate interface and enter aggregate interface view.	<ul style="list-style-type: none"> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter Layer 3 aggregate interface view: interface route-aggregation <i>interface-number</i> 	<p>Use either command.</p> <p>Perform this step also on the intermediate device.</p> <p>The 5500 SI switch series does not support Layer 3 aggregate interfaces.</p>
4. Configure the aggregation group to work in dynamic aggregation mode.	link-aggregation mode dynamic	<p>By default, an aggregation group operates in static aggregation mode.</p> <p>Perform this step also on the intermediate device.</p>
5. Enable LACP MAD.	mad enable	By default, LACP MAD is disabled.
6. Return to system view.	quit	N/A
7. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
8. Assign the Ethernet interface to the specified aggregation group.	port link-aggregation group <i>number</i>	Perform this step also on the intermediate device.

Configuring BFD MAD

When you configure BFD MAD, follow these guidelines:

- You cannot enable BFD MAD detection on VLAN-interface 1.
- Do not use the BFD MAD VLAN for any other purpose. No Layer 2 or Layer 3 features, including ARP and LACP, can work on the BFD MAD-enabled VLAN interface or any port in the VLAN. If you configure any other feature on the VLAN, neither the configured feature nor the BFD MAD function can work correctly.
- Do not enable the spanning tree function on any port in a BFD MAD VLAN. The MAD function is mutually exclusive with the spanning tree function.
- Do not bind a BFD MAD-enabled VLAN interface to any VPN. The MAD function is mutually exclusive with VPN.
- To avoid anomalies, do not assign the BFD MAD-enabled VLAN interface a common IP address, for example, an IP address configured with the **ip address** command or a VRRP virtual IP address.
- If an intermediate device is used, you must assign the ports of the BFD MAD links to the BFD MAD VLAN on the device.

To configure BFD MAD:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VLAN dedicated to BFD MAD.	vlan <i>vlan-id</i>	The default VLAN on the switch is VLAN 1.
3. Return to system view.	quit	N/A
4. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
5. Assign the port to the BFD MAD VLAN.	<ul style="list-style-type: none"> Assign the port to the VLAN as an access port: port access vlan <i>vlan-id</i> Assign the port to the VLAN as a trunk port: port trunk permit vlan <i>vlan-id</i> Assign the port to the VLAN as a hybrid port: port hybrid vlan <i>vlan-id</i> { tagged untagged } 	<p>Choose one command depending on the port type.</p> <p>BFD MAD detection has no requirement for the link type of the detection port.</p> <p>The default link type of a port is access.</p>
6. Return to system view.	quit	N/A
7. Enter VLAN interface view.	interface vlan-interface <i>interface-number</i>	N/A
8. Enable BFD MAD.	mad bfd enable	By default, BFD MAD is disabled.
9. Configure a MAD IP address for the specified member on the VLAN interface.	mad ip address <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } member <i>member-id</i>	<p>By default, no MAD IP address is configured on any VLAN interface.</p> <p>The MAD IP address must not on the same subnet as any IP address configured on any member device.</p>

NOTE:

After a BFD MAD-enabled IRF fabric splits, route conflict messages (for example, %May 5 16:15:47:733 2010 ARP/3/ROUTECONFLICT: Slot=5;Route conflict found, IP:192.168.2.1, VrfIndex:0) might appear on the fabric part that does not have the original master, because this fabric part still keeps the forwarding entries with the original master as the destination. This message does not affect forwarding. The system stops generating it after the forwarding entries are aged out.

Configuring ARP MAD

When you configure ARP MAD, follow these guidelines:

- If an intermediate device is used, you can use common data links as ARP MAD links. If no intermediate device is used, set up dedicated ARP MAD links between IRF member devices.
- Use a VLAN dedicated to ARP MAD.
- If an intermediate device is used, do the following:
 - Run the spanning tree feature between the IRF fabric and the intermediate device.

- Enable the IRF fabric to change its bridge MAC address as soon as the master leaves.
- Create the ARP MAD VLAN and assign the ports on the ARP MAD links to the VLAN.
- If the intermediate device is in an IRF fabric, assign this fabric a different domain ID than the ARP MAD-enabled fabric to avoid false detection of IRF partition.

To configure ARP MAD:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Assign a domain ID to the IRF fabric.	irf domain <i>domain-id</i>	The default IRF domain ID is 0.
3. Create a VLAN dedicated to ARP MAD.	vlan <i>vlan-id</i>	The default VLAN on the device is VLAN 1.
4. Return to system view.	quit	N/A
5. Enter Layer 2 Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Assign the port to the ARP MAD VLAN.	<ul style="list-style-type: none"> • Assign the port to the VLAN as an access port: port access vlan <i>vlan-id</i> • Assign the port to the VLAN as a trunk port: port trunk permit vlan <i>vlan-id</i> • Assign the port to the VLAN as a hybrid port: port hybrid vlan <i>vlan-id</i> { tagged untagged } 	<p>Choose one command depending on the port type.</p> <p>ARP MAD detection has no requirement for the link type.</p> <p>The default link type of a port is access.</p>
7. Return to system view.	quit	N/A
8. Enter VLAN interface view.	interface <i>vlan-interface</i> <i>vlan-interface-id</i>	N/A
9. Assign the interface an IP address.	ip address <i>ip-address</i> { <i>mask</i> <i>mask-length</i> }	By default, no IP address is assigned to any VLAN interface.
10. Enable ARP MAD.	mad arp enable	By default, ARP MAD is disabled.

Excluding a port from the shutdown action upon detection of multi-active collision

When the IRF fabric transits to the Recovery state, all ports but the console and physical IRF ports by default automatically shut down.

You can exclude a port from the shutdown action for management or other special purposes. For example:

- Exclude a port from the shutdown action, so you can telnet to the port for managing the switch.
- Exclude a VLAN interface and its Layer 2 ports from the shutdown action, so you can log in through the VLAN interface.

CAUTION:

Excluding a VLAN interface and its Layer 2 ports from the shutdown action introduces IP collision risks because the VLAN interface might be active on both the IRF fabric in Active state and the IRF fabric in Recovery state.

To configure a port to not shut down when the IRF fabric transits to the recovery state:

Step	Command	Remarks
1. Enter system view.	<code>system-view</code>	N/A
2. Configure a port to not shut down when the IRF fabric transits to the Recovery state.	<code>mad exclude interface interface-type interface-number</code>	By default, when an IRF fabric transits to the Recovery state, all its network ports except the IRF physical ports and console port are shut down.

Recovering an IRF fabric

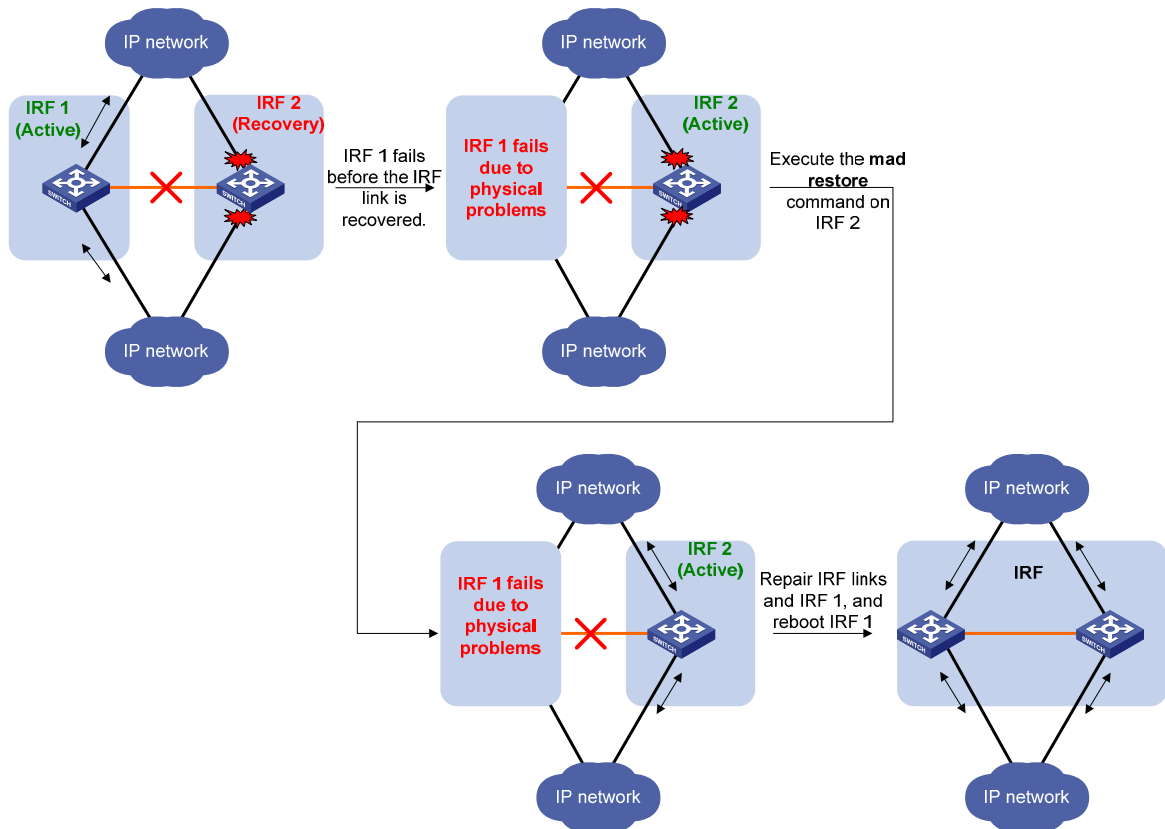

After the failed IRF link between two split IRF fabrics is recovered, log in to the Recovery-state IRF fabric, and use the **reboot** command to reboot all its members. After these member switches join the Active-state IRF fabric as subordinates, IRF merge is complete, as shown in Figure 12.

Figure 12 Recovering the IRF fabric

If the Active-state fabric has failed, for example, because of device or link failures, before the IRF link is recovered (see Figure 13), use the **mad restore** command on the Recovery-state fabric to change its state to Active for forwarding traffic. After you repair the IRF link, the two parts merge into a unified IRF fabric.

Figure 13 Active-state IRF fabric fails before the IRF link is recovered

To manually recover an IRF fabric in Recovery state:

Step	Command
1. Enter system view.	system-view
2. Change the state of the IRF fabric from Recovery to Active.	mad restore

After the IRF fabric is recovered, all ports that have been shut down by MAD automatically come up.

Displaying and maintaining an IRF fabric

Task	Command	Remarks
Display information about all IRF members.	display irf [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the IRF fabric topology.	display irf topology [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the IRF settings that take effect at the next startup.	display irf configuration [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display the load sharing mode for IRF links.	<code>display irf-port load-sharing mode</code> [<code>irf-port</code> [<code>member-id/port-number</code>]] [{ <code>begin</code> <code>exclude</code> <code>include</code> } <code>regular-expression</code>]	Available in any view
Display the master/subordinate switchover state of IRF members.	<code>display switchover state</code> [<code>slot</code> <code>member-id</code>] [{ <code>begin</code> <code>exclude</code> <code>include</code> } <code>regular-expression</code>]	Available in any view
Display MAD configuration.	<code>display mad</code> [<code>verbose</code>] [{ <code>begin</code> <code>exclude</code> <code>include</code> } <code>regular-expression</code>]	Available in any view

Configuration examples

This section provides IRF configuration examples for IRF fabrics that use different MAD mechanisms.

LACP MAD-enabled IRF configuration example

Network requirements

Set up a two-member IRF fabric at the access layer of the enterprise network in Figure 14. Configure LACP MAD in the IRF fabric, because the IRF fabric has a multi-chassis aggregate link to Device C, an HP device that supports extended LACP.

Figure 14 Network diagram

Configuration procedure

This example assumes that the system names of Device A, Device B and Device C are **DeviceA**, **DeviceB**, and **DeviceC** respectively before the IRF fabric is formed.

1. Assign member IDs:
Keep the default member ID of Device A unchanged.

Change the member ID of Device B to 2.

```
<DeviceB> system-view
[DeviceB] irf member 1 renumber 2
Warning: Renumbering the switch number may result in configuration change or loss.
Continue? [Y/N]:y
[DeviceB]
```

2. Power off the devices, connect IRF links as shown in [Figure 14](#), and power on the two devices.
3. Configure IRF port bindings:

Create IRF port 2 on Device A, bind Ten-GigabitEthernet 1/1/2 to the IRF port, and save the configuration.

```
<DeviceA> system-view
[DeviceA] interface ten-gigabitethernet 1/1/2
[DeviceA-Ten-GigabitEthernet1/1/2] shutdown
[DeviceA] irf-port 1/2
[DeviceA-irf-port1/2] port group interface ten-gigabitethernet 1/1/2
[DeviceA-irf-port1/2] quit
[DeviceA] interface ten-gigabitethernet 1/1/2
[DeviceA-Ten-GigabitEthernet1/1/2] undo shutdown
[DeviceA-Ten-GigabitEthernet1/1/2] save
```

Create IRF port 1 on Device B, bind Ten-GigabitEthernet 2/1/1 to the IRF port, and save the configuration.

```
<DeviceB> system-view
[DeviceB] interface ten-gigabitethernet 2/1/1
[DeviceB-Ten-GigabitEthernet2/1/1] shutdown
[DeviceB] irf-port 2/1
[DeviceB-irf-port2/1] port group interface ten-gigabitethernet 2/1/1
[DeviceB-irf-port2/1] quit
[DeviceB] interface ten-gigabitethernet 2/1/1
[DeviceB-Ten-GigabitEthernet2/1/1] undo shutdown
[DeviceB-Ten-GigabitEthernet2/1/1] save
```

Activate IRF port configuration on Device A.

```
[DeviceA-Ten-GigabitEthernet1/1/2] quit
[DeviceA] irf-port-configuration active
```

Activate IRF port configuration on Device B.

```
[DeviceB-Ten-GigabitEthernet2/1/1] quit
[DeviceB] irf-port-configuration active
```

After the IRF port configuration is activated, the two devices automatically elect a master. In this example, Device A is the master. Device B automatically reboots and joins the Device A as a subordinate switch to form an IRF fabric. The system name of the IRF fabric is **DevicieA**.

4. Configure LACP MAD:

Create a dynamic aggregation interface and enable LACP MAD. Because LACP MAD is not run between IRF domains, you can use the default value 0.

```
<DeviceA> system-view
[DeviceA] interface bridge-aggregation 2
[DeviceA-Bridge-Aggregation2] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation2] mad enable
You need to assign a domain ID (range: 0-4294967295)
```

```

[Current domain is: 0]:
The assigned domain ID is: 0
Info: MAD LACP only enable on dynamic aggregation interface.
# Add GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1 to the aggregation interface.
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 2
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 2/0/1
[DeviceA-GigabitEthernet2/0/1] port link-aggregation group 2

```

5. Configure Device C as the intermediate device:

```

# Create a dynamic aggregation interface.
<DeviceC> system-view
[DeviceC] interface bridge-aggregation 2
[DeviceC-Bridge-Aggregation2] link-aggregation mode dynamic
[DeviceC-Bridge-Aggregation2] quit
# Add GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to the aggregation interface.
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] port link-aggregation group 2
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] port link-aggregation group 2

```

BFD MAD-enabled IRF configuration example

This configuration example applies only to the 5500 EI switches.

Network requirements

Set up an IRF fabric at the distribution layer of the network in [Figure 15](#). Configure BFD MAD in the IRF fabric and set up BFD MAD links between the member devices. Disable the spanning tree function on the ports used for BFD MAD, because the two features conflict with each other.

Assign the highest member priority to Device A so it can be elected as the master.

Figure 15 Network diagram

Configuration procedure

This example assumes that the system names of Device A and Device B are **DeviceA** and **DeviceB** respectively before the IRF fabric is formed.

1. Assign member IDs:

Keep the default member ID of Device A unchanged.

Change the member ID of Device B to 2.

```
<DeviceB> system-view
[DeviceB] irf member 1 renumber 2
Warning: Renumbering the switch number may result in configuration change or loss.
Continue? [Y/N]:y
[DeviceB]
```

2. Power off the member devices, connect IRF links as shown in Figure 15, and power on the two devices.

3. Configure IRF port bindings:

Create IRF port 2 on Device A, bind Ten-GigabitEthernet 1/1/2 to the IRF port, and save the configuration.

```
<DeviceA> system-view
[DeviceA] interface ten-gigabitethernet 1/1/2
[DeviceA-Ten-GigabitEthernet1/1/2] shutdown
[DeviceA] irf-port 1/2
[DeviceA-irf-port1/2] port group interface ten-gigabitethernet 1/1/2
[DeviceA-irf-port1/2] quit
[DeviceA] interface ten-gigabitethernet 1/1/2
[DeviceA-Ten-GigabitEthernet1/1/2] undo shutdown
[DeviceA-Ten-GigabitEthernet1/1/2] save
```

Create IRF port 1 on Device B, bind Ten-GigabitEthernet 2/1/1 to the IRF port, and save the configuration.

```
<DeviceB> system-view
[DeviceB] interface ten-gigabitethernet 2/1/1
[DeviceB-Ten-GigabitEthernet2/1/1] shutdown
[DeviceB] irf-port 2/1
[DeviceB-irf-port2/1] port group interface ten-gigabitethernet 2/1/1
[DeviceB-irf-port2/1] quit
[DeviceB] interface ten-gigabitethernet 2/1/1
[DeviceB-Ten-GigabitEthernet2/1/1] undo shutdown
[DeviceB-Ten-GigabitEthernet2/1/1] save
```

Activate IRF port configuration on Device A.

```
[DeviceA-Ten-GigabitEthernet1/1/2] quit
[DeviceA] irf-port-configuration active
```

Activate IRF port configuration on Device B.

```
[DeviceB-Ten-GigabitEthernet2/1/1] quit
[DeviceB] irf-port-configuration active
```

After the IRF port configuration is activated, the two devices automatically elect a master. In this example, Device A is the master. Device B automatically reboots and joins the Device A as a subordinate switch to form an IRF fabric. The system name of the IRF fabric is **DevicieA**.

4. Configure BFD MAD:

Create VLAN 3, and add port GigabitEthernet 1/0/1 on Device A (member ID 1) and port GigabitEthernet 2/0/1 on Device B (member ID 2) to VLAN 3.

```
<DeviceA> system-view
[DeviceA] vlan 3
[DeviceA-vlan3] port gigabitethernet 1/0/1 gigabitethernet 2/0/1
[DeviceA-vlan3] quit
```

Create VLAN-interface 3 and configure a MAD IP address for each member device on the interface.

```
[DeviceA] interface vlan-interface 3
[DeviceA-Vlan-interface3] mad bfd enable
[DeviceA-Vlan-interface3] mad ip address 192.168.2.1 24 member 1
[DeviceA-Vlan-interface3] mad ip address 192.168.2.2 24 member 2
[DeviceA-Vlan-interface3] quit
```

Connect the BFD MAD links as shown in [Figure 15](#).

Disable the spanning tree function on GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-Gigabitethernet1/0/1] undo stp enable
[DeviceA-Gigabitethernet1/0/1] quit
[DeviceA] interface gigabitethernet 2/0/1
[DeviceA-Gigabitethernet2/0/1] undo stp enable
```

ARP MAD-enabled IRF configuration example

Network requirements

Set up an IRF fabric in the enterprise network in Figure 16. Configure ARP MAD in the IRF fabric and use the links connected to Device C for transmitting ARP MAD packets. To prevent loops, run the spanning tree function between Device C and the IRF fabric.

Figure 16 Network diagram

Configuration procedure

This example assumes that the system names of Device A, Device B and Device C are **DeviceA**, **DeviceB**, and **DeviceC**, respectively, before the IRF fabric is formed.

1. Assign member IDs:

Keep the default member ID of Device A unchanged.

Change the member ID of Device B to 2.

```
<DeviceB> system-view
```

```
[DeviceB] irf member 1 renumber 2
```

Warning: Renumbering the switch number may result in configuration change or loss.

Continue? [Y/N]:y

```
[DeviceB]
```

2. Power off the member devices, connect IRF links as shown in Figure 16, and power on the two devices.

3. Configure IRF port bindings:

Create IRF port 2 on Device A, and bind Ten-GigabitEthernet 1/1/2 to the IRF port, and save the configuration.

```
<DeviceA> system-view
```

```
[DeviceA] interface ten-gigabitethernet 1/1/2
```

```
[DeviceA-Ten-GigabitEthernet1/1/2] shutdown
```

```
[DeviceA] irf-port 1/2
```

```
[DeviceA-irf-port1/2] port group interface ten-gigabitethernet 1/1/2
```

```
[DeviceA-irf-port1/2] quit
```

```
[DeviceA] interface ten-gigabitethernet 1/1/2
```

```
[DeviceA-Ten-GigabitEthernet1/1/2] undo shutdown
```

```
[DeviceA-Ten-GigabitEthernet1/1/2] save
```

Create IRF port 1 on Device B, bind Ten-GigabitEthernet 2/1/1 to the IRF port, and save the configuration.

```
<DeviceB> system-view
```

```
[DeviceB] interface ten-gigabitethernet 2/1/1
```

```
[DeviceB-Ten-GigabitEthernet2/1/1] shutdown
```

```
[DeviceB] irf-port 2/1
```

```
[DeviceB-irf-port2/1] port group interface ten-gigabitethernet 2/1/1
```

```
[DeviceB-irf-port2/1] quit
```

```
[DeviceB] interface ten-gigabitethernet 2/1/1
```

```
[DeviceB-Ten-GigabitEthernet2/1/1] undo shutdown
```

```
[DeviceB-Ten-GigabitEthernet2/1/1] save
```

Activate IRF port configuration on Device A.

```
[DeviceA-Ten-GigabitEthernet1/1/2] quit
```

```
[DeviceA] irf-port-configuration active
```

Activate IRF port configuration on Device B.

```
[DeviceB-Ten-GigabitEthernet2/1/1] quit
```

```
[DeviceB] irf-port-configuration active
```

After the IRF port configuration is activated, the two devices automatically elect a master. In this example, Device A is the master. Device B automatically reboots and joins the Device A as a subordinate switch to form an IRF fabric. The system name of the IRF fabric is **DevicieA**.

4. Configure ARP MAD:

Enable MSTP globally on the IRF fabric to prevent loops.

```
<DeviceA> system-view
```

```
[DeviceA] stp enable
```

Connect the ARP MAD links as shown in [Figure 16](#).

Configure the IRF fabric to change its bridge MAC address as soon as the master leaves.

```
[DeviceA] undo irf mac-address persistent
```

Create VLAN 3, and add port GigabitEthernet 1/0/1 (on Device A) and port GigabitEthernet 2/0/1 (on Device B) to VLAN 3.

```
[DeviceA] vlan 3
```

```
[DeviceA-vlan3] port gigabitethernet 1/0/1 gigabitethernet 2/0/1
```

```
[DeviceA-vlan3] quit
```

Create VLAN-interface 3, assign it an IP address, and enable ARP MAD on the interface. Because ARP MAD is not run between IRF domains, you can use the default value 0.

```
[DeviceA] interface vlan-interface 3
```

```
[DeviceA-Vlan-interface3] ip address 192.168.2.1 24
```

```
[DeviceA-Vlan-interface3] mad arp enable
```

```
You need to assign a domain ID (range: 0-4294967295)
```

```
[Current domain is: 0]:
```

```
The assigned domain ID is: 0
```

5. Configure Device C:

Enable MSTP globally on Device C to prevent loops.

```
<DeviceC> system-view
```

```
[DeviceC] stp enable
```

```
# Create VLAN 3, and add GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to VLAN 3.  
[DeviceC] vlan 3  
[DeviceC-vlan3] port gigabitethernet 1/0/1 gigabitethernet 1/0/2  
[DeviceC-vlan3] quit
```

Configuring Ethernet interfaces

Ethernet interface naming conventions

The GE and 10-GE interfaces on the switches are named in the format of *interface-type A/B/C*, where the following definitions apply:

- **A**—Represents the ID of the switch in an IRF fabric. If the switch is not assigned to any IRF fabric, A uses 1.
- **B**—Represents a slot number on the switch. It uses 0 for fixed interfaces, 1 for interfaces on interface expansion card 1, and 2 for interfaces on interface expansion card 2.
- **C**—Represents the number of an interface on a slot.

NOTE:

The GE ports of the GE interface expansion card are displayed as 10-GE ports on the switch where the expansion card is installed.

For more information about the expansion cards, see *HP 5500 EI Switch Series Installation Guide* and *HP 5500 SI Switch Series Installation Guide*.

Performing general configurations

This section describes the attributes and configurations common to Layer 2 and Layer 3 Ethernet interfaces.

- For more information about the attributes and configuration of Layer 2 Ethernet interfaces, see "[Configuring a Layer 2 Ethernet interface](#)."
- For more information about the attributes and configuration of Layer 3 Ethernet interfaces, see "[Setting the MTU for a Layer 3 Ethernet interface](#)."

Configuring a combo interface

A combo interface is a logical interface that comprises one optical (fiber) port and one electrical (copper) port. The two ports share one forwarding interface, so they cannot work simultaneously. When you enable one port, the other is automatically disabled.

The fiber combo port and copper combo port are Layer 2 Ethernet interfaces. They have their own separate interface views, in which you can activate the fiber or copper combo port and configure other port attributes such as the interface rate and duplex mode.

Configuration prerequisites

Before you configure a combo interface, complete the following tasks:

- Use the **display port combo** command to identify the combo interfaces on your switch and identify the two physical ports that compose each combo interface.
- Use the **display interface** command to determine, of the two physical ports that compose a combo interface, which is the fiber combo port and which is the copper combo port. If the current port is the copper port, the output will include "Media type is twisted pair, Port hardware type is

1000_BASE_T". If the current port is the fiber port, the output will not include the information mentioned above.

Changing the active port of a combo interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Activate the current interface.	undo shutdown	Optional. By default, of the two ports that compose a combo interface, the one with a smaller port ID is active.

Configuring basic settings of an Ethernet interface

You can set an Ethernet interface to operate in one of the following duplex modes:

- **Full-duplex mode (full)**—Interfaces that operate in this mode can send and receive packets simultaneously.
- **Half-duplex mode (half)**—Interfaces that operate in this mode cannot send and receive packets simultaneously.
- **Auto-negotiation mode (auto)**—Interfaces that operate in this mode negotiate a duplex mode with their peers.

You can set the speed of an Ethernet interface or enable it to automatically negotiate a speed with its peer. For a 100-Mbps or 1000-Mbps Layer 2 Ethernet interface, you can also set speed options for auto negotiation. The two ends can select a speed only from the available options. For more information, see "[Setting speed options for auto negotiation on an Ethernet interface.](#)"

To configure an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Set the interface description.	description <i>text</i>	Optional. By default, the description of an interface is in the format of <i>interface-name</i> Interface . For example, GigabitEthernet1/0/1 Interface .

Step	Command	Remarks
4. Set the duplex mode of the interface.	duplex { auto full half }	Optional. By default, the duplex mode is auto for Ethernet interfaces. The half keyword is not applicable to Ethernet copper ports that are configured with a 1000-Mbps port speed and fiber ports.
5. Set the port speed.	speed { 10 100 1000 auto }	Optional. By default, an Ethernet interface automatically negotiates a speed with the peer. A Gigabit fiber port does not support the 10 or 100 keyword, A 10-Gigabit fiber port does not support this command
6. Restore the default settings for the interface.	default	Optional.

Shutting down an Ethernet interface

△ CAUTION:

Use this feature with caution. After you manually shut down an Ethernet interface, the Ethernet interface cannot forward packets even if it is physically connected.

You might need to shut down and then bring up an Ethernet interface to activate some configuration changes, for example, the speed or duplex mode changes.

To shut down an Ethernet interface or a group of Ethernet interfaces:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none"> Enter Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use any command. To shut down an Ethernet interface, enter Ethernet interface. To shut down all Ethernet interfaces in a port group, enter port group view.
3. Shut down the Ethernet interface or interfaces.	shutdown	By default, Ethernet interfaces are up.

Configuring flow control on an Ethernet interface

To avoid packet drops on a link, you can enable flow control at both ends of the link. When traffic congestion occurs at the receiving end, the receiving end sends a flow control (Pause) frame to ask the sending end to suspend sending packets

- With the **flow-control** command configured, an interface can both send and receive flow control frames: When congested, the interface sends a flow control frame to its peer. Upon receiving a flow control frame from the peer, the interface suspends sending packets.
- With the **flow-control receive enable** command configured, an interface can receive, but not send flow control frames. When the interface receives a flow control frame from its peer, it suspends sending packets to the peer. When congested, the interface cannot send flow control frames to the peer.

To handle unidirectional traffic congestion on a link, configure the **flow-control receive enable** command at one end, and the **flow-control** command at the other. To enable both ends of the link to handle traffic congestion, configure the **flow-control** command at both ends.

To enable flow control on an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable flow control.	<ul style="list-style-type: none"> • Enable TxRx flow control: flow-control • Enable Rx flow control: flow-control receive enable 	<p>Use either command.</p> <p>By default, Rx flow control is disabled on an Ethernet interface.</p>

Configuring link state change suppression on an Ethernet interface

An Ethernet interface has two physical link states: up and down. Each time the physical link of an interface goes up or comes down, the physical layer reports the change to the upper layers, and the upper layers handle the change, resulting in increased overhead.

To prevent physical link flapping from affecting system performance, configure link change suppression to delay the reporting of physical link state changes. When the delay expires, the interface reports any detected change.

Link change suppression does not suppress administrative up or down events. When you shut down or bring up an interface by using the **shutdown** or **undo shutdown** command, the interface reports the event to the upper layers immediately.

Link-down event suppression enables an interface to suppress link-down events and start a delay timer each time the physical link goes down. During this delay, the interface does not report the link-down event, and the **display interface brief** or **display interface** command displays the interface state as UP. If the physical link is still down when the timer expires, the interface reports the link-down event to the upper layers.

Link-up event suppression enables an interface to suppress link-up events and start a delay timer each time the physical link goes up. During this delay, the interface does not report the link-up event, and the **display interface brief** or **display interface** command displays the interface state as DOWN. If the physical link is still up when the timer expires, the interface reports the link-up event to the upper layers.

Configuring link-down event suppression

To enable an Ethernet interface to suppress link-down events:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Set a link-down event suppression interval.	link-delay <i>delay-time</i>	Link-down event suppression is disabled by default.

Configuring link-up event suppression

To configure link-up event suppression on an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Set a link-up event suppression interval.	link-delay <i>delay-time</i> mode up	Link-up event suppression is disabled by default.

NOTE:

The **link-delay mode up** command and the **link-delay** command supersedes each other, and whichever is configured last takes effect.

Configuring loopback testing on an Ethernet interface

If an Ethernet interface does not work normally, you can enable loopback testing on it to identify the problem. Loopback testing has the following types:

- **Internal loopback testing**—Tests all on-chip functions related to Ethernet interfaces.
- **External loopback testing**—Tests hardware of Ethernet interfaces. To perform external loopback testing on an Ethernet interface, connect a loopback plug to the Ethernet interface. The switch sends test packets out of the interface, which are expected to loop over the plug and back to the interface. If the interface fails to receive any test packet, the hardware of the interface is faulty.

An Ethernet interface in a loopback test does not forward data traffic.

Configuration restrictions and guidelines

- On an interface that is physically down, you can only perform internal loopback testing. On an interface administratively shut down, you can perform neither internal nor external loopback testing.
- During loopback testing, the Ethernet interface operates in full duplex mode. When you disable loopback testing, the interface returns to its duplex setting.
- Loopback testing is a one-time operation, and is not recorded in the configuration file.

Configuration procedure

To enable loopback testing on an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable loopback testing.	loopback { external internal }	Optional. Disabled by default.

Configuring the link mode of an Ethernet interface (available only on the 5500 EI)

⚠ CAUTION:

- After you change the link mode of an Ethernet interface, all the settings of the Ethernet interface are restored to their defaults under the new link mode.
- The link mode configuration for an Ethernet interface in system view and in interface view supersedes each other.

An Ethernet interface operates either in Layer 2 (bridge) or Layer 3 (route) mode. To meet networking requirements, you can use a command to set the link mode of an Ethernet interface to bridge or route.

To change the link mode of an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Change the link mode of Ethernet interfaces.	<ul style="list-style-type: none"> • In system view: port link-mode { bridge route } <i>interface-list</i> • In Ethernet interface view: a. interface <i>interface-type</i> <i>interface-number</i> b. port link-mode { bridge route } 	Use either approach.

Configuring jumbo frame support

An Ethernet interface might receive some frames larger than the standard Ethernet frame size (called "jumbo frames") during high-throughput data exchanges such as file transfers. Usually, an Ethernet interface discards jumbo frames. With jumbo frame support enabled, the interface can process frames larger than the standard Ethernet frame size yet within the specified range.

In interface configuration mode (Ethernet interface view or port group view), you can set the length of jumbo frames that are allowed to pass through the Ethernet interface.

- If you execute the command in Ethernet interface view, the configuration takes effect only on the interface.
- If you execute the command in port group view, the configuration takes effect on all ports in the port group.

To configure jumbo frame support in interface view or port group view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure jumbo frame support.	jumboframe enable [<i>value</i>]	By default, the switch allows jumbo frames within 9216 bytes to pass through Ethernet interfaces. If you set the <i>value</i> argument multiple times, the latest configuration takes effect.

Enabling the auto power-down function on an Ethernet interface

To save power, enable the auto power-down function on Ethernet interfaces. An interface enters the power save mode if it has not received any packet for a certain period of time (this interval depends on the specifications of the chip, and is not configurable). When a packet arrives later, the interface enters its normal state.

To enable auto power-down on an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable auto power-down on an Ethernet interface.	port auto-power-down	Disabled by default.

NOTE:

When you connect an interface enabled with auto power-down to a device, if the link cannot go up properly, disable auto power-down on the interface and try again.

Configuring a Layer 2 Ethernet interface

Layer 2 Ethernet interface configuration task list

Task	Remarks
Configuring a port group	Optional Applicable to Layer 2 Ethernet interfaces
Configuring a MAC Address for an Ethernet port (available only on the 5500 S1)	Optional Applicable to Layer 2 Ethernet interfaces
Setting speed options for auto negotiation on an Ethernet interface	Optional Applicable to Layer 2 Ethernet interfaces

Task	Remarks
Configuring storm suppression	Optional Applicable to Layer 2 Ethernet interfaces
Setting the statistics polling interval	Optional Applicable to Layer 2 Ethernet interfaces
Enabling loopback detection on an Ethernet interface	Optional Applicable to Layer 2 Ethernet interfaces
Setting the MDI mode of an Ethernet interface	Optional Applicable to Layer 2 Ethernet interfaces
Enabling bridging on an Ethernet interface	Optional Applicable to Layer 2 Ethernet interfaces
Testing the cable connection of an Ethernet interface	Optional Applicable to Layer 2 Ethernet interfaces
Configuring storm control on an Ethernet interface	Optional Applicable to Layer 2 Ethernet interfaces

Configuring a port group

Some interfaces on your switch might use the same set of settings. To configure these interfaces in bulk rather than one by one, you can assign them to a port group.

You create port groups manually. All settings made for a port group apply to all the member ports of the group.

Even though the settings are made on the port group, they are saved on each interface basis rather than on a port group basis. You can only view the settings in the view of each interface by using the **display current-configuration** or **display this** command.

To configure a manual port group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a manual port group and enter manual port group view.	port-group manual <i>port-group-name</i>	N/A
3. Assign Ethernet interfaces to the manual port group.	group-member <i>interface-list</i>	N/A
4. Configure jumbo frame support.	jumboframe enable [<i>value</i>]	By default, the switch allows jumbo frames within 9216 bytes to pass through Ethernet interfaces. If you set the <i>value</i> argument multiple times, the latest configuration takes effect.
5. Enable auto power-down.	port auto-power-down	Disabled by default.

Configuring a MAC Address for an Ethernet port (available only on the 5500 SI)

You can use this function to manually configure a MAC address for an Ethernet port. After that, when the switch sends packets of Layer 2 protocols (including cluster, DLDAP, HABP, LACP, LLDP, MSTP, NDP, NTDP, and GVRP) out of this port, it can use the MAC address of this port as the source MAC address of these protocol packets.

Configuring a MAC address for an Ethernet port does not affect the normal forwarding of service packets.

To configure a MAC Address for an Ethernet port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet port view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure a MAC address for the current port.	mac-address <i>mac-address</i>	The default MAC address of an Ethernet port varies with device models.

Setting speed options for auto negotiation on an Ethernet interface

Speed auto negotiation enables an Ethernet interface to negotiate with its peer for the highest speed that both ends support by default. You can narrow down the speed option list for negotiation.

Figure 1 Speed auto negotiation application scenario

As shown in Figure 1, all ports on Switch A are operating in speed auto negotiation mode, with the highest speed of 1000 Mbps. If the transmission rate of each server in the server cluster is 1000 Mbps, their total transmission rate will exceed the capability of port GigabitEthernet 1/0/4, the port providing access to the Internet for the servers.

To avoid congestion on GigabitEthernet 1/0/4, set 100 Mbps as the only option available for speed negotiation on port GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3. As a result, the transmission rate on each port connected to a server is limited to 100 Mbps.

To set speed options for auto negotiation on an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type interface-number</i>	N/A
3. Set speed options for auto negotiation.	speed auto { 10 100 1000 } *	Optional.

NOTE:

- This function is available only for Layer 2 copper GE ports that support speed auto negotiation.
- The **speed** and **speed auto** commands supersede each other, and whichever is configured last takes effect.

Configuring storm suppression

You can use the storm suppression function to limit the size of a particular type of traffic (broadcast, multicast, or unknown unicast traffic) as a whole globally in system view or on a per-interface basis in Ethernet interface view or port group view.

In interface or port group view, you set the maximum size of broadcast, multicast or unknown unicast traffic allowed to pass through an interface or each interface in a port group. When the broadcast, multicast, or unknown unicast traffic on the interface exceeds this threshold, the system discards packets until the traffic drops below this threshold.

The storm suppression thresholds configured for an Ethernet interface might become invalid if you enable the storm control function for the interface. For information about the storm control function, see "[Configuring storm control on an Ethernet interface.](#)"

To set storm suppression thresholds on one or multiple Ethernet interfaces:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none"> • Enter Ethernet interface view: interface <i>interface-type interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	<p>Use either command.</p> <p>To configure storm suppression on an Ethernet interface, enter Ethernet interface view.</p> <p>To configure storm suppression on a group of Ethernet interfaces, enter port group view.</p>
3. Set the broadcast suppression threshold ratio.	broadcast-suppression { <i>ratio</i> pps <i>max-pps</i> kbps <i>max-kbps</i> }	<p>Optional.</p> <p>By default, all broadcast traffic is allowed to pass through.</p>
4. Set the multicast suppression threshold ratio.	multicast-suppression { <i>ratio</i> pps <i>max-pps</i> kbps <i>max-kbps</i> }	<p>Optional.</p> <p>By default, all multicast traffic is allowed to pass through.</p>

Step	Command	Remarks
5. Set the unknown unicast suppression threshold ratio.	unicast-suppression { <i>ratio</i> pps <i>max-pps</i> kbps <i>max-kbps</i> }	Optional. By default, all unknown unicast traffic is allowed to pass through.

NOTE:

For an Ethernet interface that belongs to a port group, if you set a traffic suppression threshold for the interface in both Ethernet interface view and port group view, the threshold configured last takes effect.

Setting the statistics polling interval

To set the statistics polling interval globally or on an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Set the statistics polling interval on the Ethernet interface.	flow-interval <i>interval</i>	Optional. The default interface statistics polling interval is 300 seconds.

To display the interface statistics collected in the last polling interval, use the **display interface** command.

To clear interface statistics, use the **reset counters interface** command.

Enabling loopback detection on an Ethernet interface

If a switch receives a packet that it sent, a loop has occurred to the switch. Loops might cause broadcast storms, which degrade network performance. You can use this feature to detect whether a loop has occurred.

Depending on whether the receiving interface is the same as the sending interface, loops fall into the following types:

- **Single-port loopback**—Occurs when an interface receives a packet that it sent out and the receiving interface is the same as the sending interface, as shown in [Figure 2](#).
- **Multi-port loopback**—Occurs when a switch receives a packet that it sent out but the receiving interface might not be the sending interface, as shown in [Figure 3](#).

Figure 2 Single-port loopback

Figure 3 Multi-port loopback

You can enable loopback detection to detect loops on an interface and, if the interface supports the **loopback-detection action** command, configure the protective action to take on the receiving interface when a loop is detected, for example, to shut down the interface. Depending on whether a protective action is configured, the switch takes the actions in [Table 1](#) to alleviate the impact of the loop condition.

Table 1 Actions to take upon detection of a loop condition

Port type	Actions	
	No protective action is configured	A protective action is configured
Access port	<ul style="list-style-type: none"> Place the receiving interface in controlled mode. The interface does not receive or send packets. Generate traps and log messages. Delete all MAC address entries of the interface. 	<ul style="list-style-type: none"> Perform the configured protective action. Generate traps and log messages. Delete all MAC address entries of the interface.
Hybrid or trunk port	<ul style="list-style-type: none"> Generate traps and log messages. If loopback detection control is enabled, place the receiving interface in controlled mode. The interface does not receive or send packets. Delete all MAC address entries of the interface. 	<ul style="list-style-type: none"> Generate traps and log messages. If loopback detection control is enabled, take the configured protective action on the interface. Delete all MAC address entries of the interface.

Configuration restrictions and guidelines

- To use loopback detection on an Ethernet interface, you must enable the function both globally and on the interface.
- To disable loopback detection on all interfaces, run the **undo loopback-detection enable** command in system view.
- To enable a hybrid or trunk port to take the administratively specified protective action, you must use the **loopback-detection control enable** command on the port.
- When you change the link type of an Ethernet interface by using the **port link-type** command, the switch removes the protective action configured on the interface. For more information about the **port link-type** command, see *Layer 2—LAN Switching Command Reference*.

Configuration procedure

To configure loopback detection:

Step	Command	Remarks
1.	Enter system view. system-view	N/A

Step	Command	Remarks
2. Enable global loopback detection.	loopback-detection enable	Disabled by default.
3. Enable multi-port loopback detection.	loopback-detection multi-port-mode enable	Optional. By default, multi-port loopback detection is disabled, and the switch can only detect single-port loopback.
4. Set the loopback detection interval.	loopback-detection interval-time <i>time</i>	Optional. 30 seconds by default.
5. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none"> Enter Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command. To configure loopback detection on one interface, enter Ethernet interface view. To configure loopback detection on a group of Ethernet interfaces, enter port group view.
6. Enable loopback detection on the interface.	loopback-detection enable	Disabled by default.
7. Enable loopback detection control on a trunk port or a hybrid port.	loopback-detection control enable	Optional. Disabled by default.
8. Enable loopback detection in all the VLANs on the trunk or hybrid port.	loopback-detection per-vlan enable	Optional. By default, a trunk or hybrid port performs loopback detection only in its port VLAN ID (PVID).
9. Set the protective action to take on the interface when a loop is detected.	loopback-detection action { no-learning semi-block shutdown }	Optional. By default, a looped interface does not receive or send packets; the system generates traps and log messages, and deletes all MAC address entries of the looped interface. With the shutdown keyword specified, the switch shuts down the looped ports and set their physical state to Loop down. When a looped port recovers, you must use the undo shutdown command to restore its forwarding capability.

Setting the MDI mode of an Ethernet interface

ⓘ IMPORTANT:

Fiber ports do not support the MDI mode setting.

You can use both crossover and straight-through Ethernet cables to connect copper Ethernet interfaces. To accommodate these types of cables, a copper Ethernet interface can operate in one of the following Medium Dependent Interface (MDI) modes:

- Across mode

- Normal mode
- Auto mode

A copper Ethernet interface uses an RJ-45 connector, which comprises eight pins, each of which plays a dedicated role. For example, pins 1 and 2 transmit signals, and pins 3 and 6 receive signals. The pin role varies by the MDI modes as follows:

- In normal mode, pins 1 and 2 are transmit pins, and pins 3 and 6 are receive pins.
- In across mode, pins 1 and 2 are receive pins, and pins 3 and 6 are transmit pins.
- In auto mode, the interface negotiates pin roles with its peer.

To enable the interface to communicate with its peer, make sure that its transmit pins are connected to the remote receive pins. If the interface can detect the connection cable type, set the interface in auto MDI mode. If not, set its MDI mode by using the following guidelines:

- When a straight-through cable is used, set the interface to operate in the MDI mode different than its peer.
- When a crossover cable is used, set the interface to operate in the same MDI mode as its peer, or set either end to operate in auto mode.

To set the MDI mode of an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Set the MDI mode of the Ethernet interface.	mdi { across auto normal }	Optional. By default, a copper Ethernet interface operates in auto mode to negotiate pin roles with its peer.

Enabling bridging on an Ethernet interface

When an incoming packet arrives, the device looks up the destination MAC address of the packet in the MAC address table. If an entry is found, but the outgoing interface is the same as the receiving interface, the device discards the packet.

To enable the device to forward such packets rather than drop them, enable the bridging function on the Ethernet interface.

To enable bridging on an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable bridging on the Ethernet interface.	port bridge enable	Disabled by default.

Testing the cable connection of an Ethernet interface

❗ **IMPORTANT:**

- Fiber ports do not support this feature.
 - If the link of an Ethernet port is up, testing its cable connection will cause the link to come down and then go up.
-

You can test the cable connection of an Ethernet interface for a short or open circuit. The switch displays cable test results within five seconds. If any fault is detected, the test results include the length of the faulty cable segment.

To test the cable connection of an Ethernet interface:

Step	Command
1. Enter system view.	system-view
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>
3. Test the cable connected to the Ethernet interface.	virtual-cable-test

Configuring storm control on an Ethernet interface

Storm control compares broadcast, multicast, and unknown unicast traffic regularly with their respective traffic thresholds on an Ethernet interface. For each type of traffic, storm control provides a lower threshold and a higher threshold.

For management purposes, you can configure the interface to send threshold event traps and log messages when monitored traffic exceeds the upper threshold or drops below the lower threshold from the upper threshold.

When a particular type of traffic exceeds its upper threshold, the interface does either of the following, depending on your configuration:

- Blocks this type of traffic, while forwarding other types of traffic. Even though the interface does not forward the blocked traffic, it still counts the traffic. When the blocked traffic drops below the lower threshold, the port begins to forward the traffic.
- Shuts down automatically. The interface shuts down automatically and stops forwarding any traffic. When the blocked traffic drops below the lower threshold, the port does not forward the traffic. To bring up the interface, use the **undo shutdown** command or disable the storm control function.

Alternatively, you can configure the storm suppression function to control a specific type of traffic. Do not enable them both on an Ethernet interface at the same time because the storm suppression and storm control functions are mutually exclusive. For example, with an unknown unicast suppression threshold set on an Ethernet interface, do not enable storm control for unknown unicast traffic on the interface. For more information about storm suppression, see "[Configuring storm suppression](#)."

Configuration restrictions and guidelines

- For network stability, use the default or set a higher traffic polling interval.
- Storm control uses a complete polling cycle to collect traffic data, and analyzes the data in the next cycle. It takes a port at least one polling interval and at most two polling intervals to take a storm control action.
- The storm control function allows you to set the upper and lower thresholds for all three types of packets respectively on the same interface.

Configuration procedure

To configure storm control on an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the traffic polling interval of the storm control module.	storm-constrain interval <i>seconds</i>	Optional. 10 seconds by default.
3. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable storm control, and set the lower and upper thresholds for broadcast, multicast, or unknown unicast traffic.	storm-constrain { broadcast multicast unicast } { pps kpps ratio } <i>max-pps-values</i> <i>min-pps-values</i>	Disabled by default.
5. Set the control action to take when monitored traffic exceeds the upper threshold.	storm-constrain control { block shutdown }	Optional. Disabled by default.
6. Enable the interface to send storm control threshold event traps..	storm-constrain enable trap	Optional. By default, the interface sends traps when monitored traffic exceeds the upper threshold or drops below the lower threshold from the upper threshold.
7. Enable the interface to log storm control threshold events..	storm-constrain enable log	Optional. By default, the interface outputs log messages when monitored traffic exceeds the upper threshold or drops below the lower threshold from the upper threshold.

Setting the MTU for a Layer 3 Ethernet interface (available only on the 5500 EI)

The maximum transmission unit (MTU) affects the fragmentation and re-assembly of IP packets.

To set the MTU for a Layer 3 Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Set the MTU.	mtu <i>size</i>	Optional. 1500 bytes by default.

Displaying and maintaining an Ethernet interface

Task	Command	Remarks
Display Ethernet interface information.	display interface [<i>interface-type</i>] brief [down] [{ begin exclude include } <i>regular-expression</i>] display interface <i>interface-type</i> <i>interface-number</i> [brief] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display traffic statistics for the specified interfaces.	display counters { inbound outbound } interface [<i>interface-type</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display traffic rate statistics over the last sampling interval.	display counters rate { inbound outbound } interface [<i>interface-type</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about discarded packets on the specified interfaces.	display packet-drop interface [<i>interface-type</i> [<i>interface-number</i>]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display summary information about discarded packets on all interfaces.	display packet-drop summary [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the combo interfaces and the fiber and copper combo ports.	display port combo [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about a manual port group or all manual port groups.	display port-group manual [all name <i>port-group-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the loopback function.	display loopback-detection [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear the interface statistics.	reset counters interface [<i>interface-type</i> [<i>interface-number</i>]]	Available in user view
Clear the statistics of discarded packets on the specified interfaces.	reset packet-drop interface [<i>interface-type</i> [<i>interface-number</i>]]	Available in user view

Configuring loopback and null interfaces

Configuring a loopback interface

Introduction to the loopback interface

A loopback interface is a software-only virtual interface. It delivers the following benefits:

- The physical layer state and link-layer protocols of a loopback interface are always up unless the loopback interface is manually shut down.
- To save IP address resources, you can assign an IP address with an all-F mask to a loopback interface. When you assign an IPv4 address whose mask is not 32-bit, the system automatically changes the mask into a 32-bit mask. When you assign an IPv6 address whose mask is not 128-bit, the system automatically changes the mask into a 128-bit mask.
- You can enable routing protocols on a loopback interface, and a loopback interface can send and receive routing protocol packets.

Because of the benefits mentioned above, loopback interfaces are widely used in the following scenarios:

- You can configure a loopback interface address as the source address of the IP packets that the device generates. Because loopback interface addresses are stable unicast addresses, they are usually used as device identifications. When you configure a rule on an authentication or security server to permit or deny packets generated by a device, you can simplify the rule by configuring it to permit or deny packets that carry the loopback interface address identifying the device. When you use a loopback interface address as the source address of IP packets, be sure to perform any necessary routing configuration to make sure that the route from the loopback interface to the peer is reachable. All data packets sent to the loopback interface are treated as packets sent to the device itself, so the device does not forward these packets.
- Because a loopback interface is always up, it can be used in dynamic routing protocols. For example, if you do not configure a router ID for a dynamic routing protocol, the highest loopback interface IP address is selected as the router ID. In BGP, to prevent physical port failure from interrupting BGP sessions, you can use a loopback interface as the source interface of BGP packets.

Configuration procedure

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a loopback interface and enter loopback interface view.	interface loopback <i>interface-number</i>	N/A
3. Set the interface description.	description <i>text</i>	Optional By default, the description of a loopback interface is <i>interface name</i> Interface.

Step	Command	Remarks
4. Shut down the loopback interface.	shutdown	Optional By default, a loopback interface is up.
5. Restore the default settings for the loopback interface.	default	Optional

NOTE:

You can configure settings such as IP addresses and IP routes on loopback interfaces. For more information, see *Layer 3—IP Services Configuration Guide* and *Layer 3—IP Routing Configuration Guide*.

Configuring a null interface

Introduction to the null interface

A null interface is a completely software-based logical interface, and is always up. However, you cannot use it to forward data packets or configure an IP address or link-layer protocol on it. With a null interface specified as the next hop of a static route to a specific network segment, any packets routed to the network segment are dropped. The null interface provides a simpler way to filter packets than ACL. You can filter uninteresting traffic by transmitting it to a null interface instead of applying an ACL.

For example, by executing the **ip route-static 92.101.0.0 255.255.0.0 null 0** command (which configures a static route that leads to null interface 0), you can have all the packets destined to the network segment 92.101.0.0/16 discarded.

Only one null interface, Null 0, is supported on your switch. You cannot remove or create a null interface.

Configuration procedure

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter null interface view.	interface null 0	The Null 0 interface is the default null interface on your switch. It cannot be manually created or removed.
3. Set the interface description.	description text	Optional By default, the description of a null interface is <i>interface name</i> Interface.
4. Restore the default settings for the null interface.	default	Optional

Displaying and maintaining loopback and null interfaces

Task	Command	Remarks
Display information about loopback interfaces.	display interface [loopback] [brief [down]] [{ begin exclude include } <i>regular-expression</i>] display interface loopback <i>interface-number</i> [brief] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the null interface.	display interface [null] [brief [down]] [{ begin exclude include } <i>regular-expression</i>] display interface null 0 [brief] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear the statistics on a loopback interface.	reset counters interface [loopback] [<i>interface-number</i>]	Available in user view
Clear the statistics on the null interface.	reset counters interface [null [0]]	Available in user view

Bulk configuring interfaces

You can enter interface range view to bulk configure multiple interfaces with the same feature instead of configuring them one by one. For example, you can perform the **shutdown** command in interface range view to shut down a range of interfaces.

Failure of applying a command on one member interface does not affect the application of the command on the other member interfaces. If applying a command on one member interface fails, the system displays an error message and continues with the next member interface.

Configuration guidelines

When you bulk configure interfaces in interface range view, follow these restrictions and guidelines:

- In interface range view, only the commands supported by the first interface are available.
- Do not assign an aggregate interface and any of its member interfaces to an interface range at the same time. Some commands, after being executed on both an aggregate interface and its member interfaces, can break up the aggregation.
- No limit is set on the maximum number of interfaces in an interface range. The more interfaces in an interface range, the longer the command execution time.

Configuration procedure

To bulk configure interfaces:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface range view.	Approach 1: interface range { <i>interface-type</i> <i>interface-number</i> [to <i>interface-type</i> <i>interface-number</i>] } &<1-5> Approach 2: interface range name <i>name</i> [interface { <i>interface-type</i> <i>interface-number</i> [to <i>interface-type</i> <i>interface-number</i>] } &<1-5>]	Use either approach. In approach 2, you assign a name to an interface range and can specify this name rather than the interface range to enter the interface range view.
3. Display commands available for the first interface in the interface range.	Enter ? at the interface range prompt.	Optional.
4. Perform available commands to configure the interfaces.	Available commands vary by interface.	N/A
5. Verify the configuration.	display this	Optional.

Configuring the MAC address table

This feature covers only the unicast MAC address table. For information about configuring static multicast MAC address table entries for IGMP snooping and MLD snooping, see *IP Multicast Configuration Guide*.

The MAC address table can contain only Layer 2 Ethernet ports and Layer 2 aggregate interfaces.

The MAC address table configuration tasks are all optional and can be performed in any order.

Overview

To reduce single-destination packet flooding in a switched LAN, an Ethernet device uses a MAC address table for forwarding frames through unicast instead of broadcast. This table describes from which port a MAC address (or host) can be reached. When forwarding a single-destination frame, the device first looks up the MAC address of the frame in the MAC address table for a match. If the switch finds an entry, it forwards the frame out of the outgoing port in the entry. If the switch does not find an entry, it floods the frame out of all but the incoming port.

How a MAC address table entry is created

The switch automatically obtains entries in the MAC address table, or you can add them manually.

MAC address learning

The device can automatically populate its MAC address table by obtaining the source MAC addresses (called "MAC address learning") of incoming frames on each port.

When a frame arrives at a port, Port A, for example, the device performs the following tasks:

1. Verifies the source MAC address (for example, MAC-SOURCE) of the frame.
2. Looks up the source MAC address in the MAC address table.
 - If an entry is found, the device updates the entry.
 - If no entry is found, the device adds an entry for MAC-SOURCE and Port A.
3. After obtaining this source MAC address, when the device receives a frame destined for MAC-SOURCE, the device finds the MAC-SOURCE entry in the MAC address table and forwards the frame out of Port A.

The device performs this learning process each time it receives a frame from an unknown source MAC address, until the MAC address table is fully populated.

Manually configuring MAC address entries

With dynamic MAC address learning, a device does not distinguish between illegitimate and legitimate frames, which can invite security hazards. For example, when a hacker sends frames with a forged source MAC address to a port different from the one to which the real MAC address is connected, the device creates an entry for the forged MAC address, and forwards frames destined for the legal user to the hacker instead.

To improve port security, you can bind specific user devices to the port by manually adding MAC address entries to the MAC address table of the switch.

Types of MAC address table entries

A MAC address table can contain the following types of entries:

- **Static entries**—Manually added and never age out.
- **Dynamic entries**—Manually added or dynamically obtained, and might age out.
- **Blackhole entries**—**Manually** configured and never age out. Blackhole entries are configured for filtering out frames with specific source or destination MAC addresses. For example, to block all packets destined for a specific user for security concerns, you can configure the MAC address of this user as a blackhole MAC address entry.

A static or blackhole MAC address entry can overwrite a dynamic MAC address entry, but not vice versa.

To adapt to network changes and prevent inactive entries from occupying table space, an aging mechanism is adopted for dynamic MAC address entries. Each time a dynamic MAC address entry is obtained or created, an aging time starts. If the entry has not updated when the aging timer expires, the device deletes the entry. If the entry has updated before the aging timer expires, the aging timer restarts.

MAC address table-based frame forwarding

When forwarding a frame, the device adopts the following forwarding modes based on the MAC address table:

- **Unicast mode:** If an entry is available for the destination MAC address, the device forwards the frame out of the outgoing interface indicated by the MAC address table entry.
- **Broadcast mode:** If the device receives a frame with the destination address as all-ones, or no entry is available for the destination MAC address, the device broadcasts the frame to all the interfaces except the receiving interface.

Configuring static, dynamic, and blackhole MAC address table entries

To prevent MAC address spoofing attacks and improve port security, you can manually add MAC address table entries to bind ports with MAC addresses. You can also configure blackhole MAC address entries to filter out packets with certain source or destination MAC addresses.

Adding or modifying a static, dynamic, or blackhole MAC address table entry in system view

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Add or modify a dynamic or static MAC address entry.	mac-address { dynamic static } <i>mac-address interface interface-type interface-number vlan vlan-id</i>	Use either command.
3. Add or modify a blackhole MAC address entry.	mac-address blackhole mac-address vlan <i>vlan-id</i>	Make sure that you have created the VLAN and assigned the interface to the VLAN.

Adding or modifying a static or dynamic MAC address table entry in interface view

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Add or modify a static or dynamic MAC address entry.	mac-address { dynamic static } <i>mac-address</i> vlan <i>vlan-id</i>	Make sure that you have created the VLAN and assigned the interface to the VLAN.

Disabling MAC address learning

Sometimes, you might need to disable MAC address learning to prevent the MAC address table from being saturated, for example, when your device is being attacked by a large amount of packets with different source MAC addresses.

When MAC address learning is disabled, the learned MAC addresses remain valid until they age out.

Disabling global MAC address learning

Disabling global MAC address learning disables the learning function on all ports.

To disable MAC address learning:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Disable global MAC address learning.	mac-address mac-learning disable	Enabled by default.

Disabling MAC address learning on ports

After enabling global MAC address learning, you can disable the function on a single port, or on all ports in a port group as needed.

To disable MAC address learning on an interface or a port group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable global MAC address learning.	undo mac-address mac-learning disable	Optional Enabled by default.

Step	Command	Remarks
3. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command. Settings in Layer 2 Ethernet interface view or Layer 2 aggregate interface view take effect on the interface only. Settings in port group view take effect on all member ports in the port group.
4. Disable MAC address learning on the interface or all ports in the port group.	mac-address mac-learning disable	Enabled by default. For more information about configuring a port group, see " Configuring Ethernet interfaces. "

Disabling MAC address learning on a VLAN (available only on the 5500 EI)

You can disable MAC address learning on a per-VLAN basis.

To disable MAC address learning on a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable global MAC address learning.	undo mac-address mac-learning disable	Optional Enabled by default.
3. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
4. Disable MAC address learning on the VLAN.	mac-address mac-learning disable	Enabled by default.

Configuring the aging timer for dynamic MAC address entries

The MAC address table uses an aging timer for dynamic MAC address entries for security and efficient use of table space. If a dynamic MAC address entry has failed to update before the aging timer expires, the device deletes that entry. This aging mechanism ensures that the MAC address table can quickly update to accommodate the latest network changes.

Set the aging timer appropriately. Too long an aging interval might cause the MAC address table to retain outdated entries, exhaust the MAC address table resources, and fail to update its entries to accommodate the latest network changes. Too short an interval might result in removal of valid entries, causing unnecessary flooding, which might affect device performance.

To configure the aging timer for dynamic MAC address entries:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Configure the aging timer for dynamic MAC address entries.	mac-address timer { aging <i>seconds</i> no-aging }	Optional 300 seconds by default. The no-aging keyword disables the aging timer.

You can reduce flooding on a stable network by disabling the aging timer to prevent dynamic entries from unnecessarily aging out. By reducing flooding, you improve not only network performance, but also security, because you reduce the chances that a data packet will reach unintended destinations.

Configuring the MAC learning limit on ports

To prevent the MAC address table from getting too large, you can limit the number of MAC addresses that a port can learn.

To configure the MAC learning limit on a Layer 2 Ethernet interface or all ports in a port group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command. Settings in Layer 2 Ethernet interface view take effect on the interface only. Settings in port group view take effect on all member ports in the port group.
3. Configure the MAC learning limit on the interface or port group.	mac-address max-mac-count <i>count</i>	No MAC learning limit is configured by default. Layer 2 aggregate interfaces do not support this command.

NOTE:

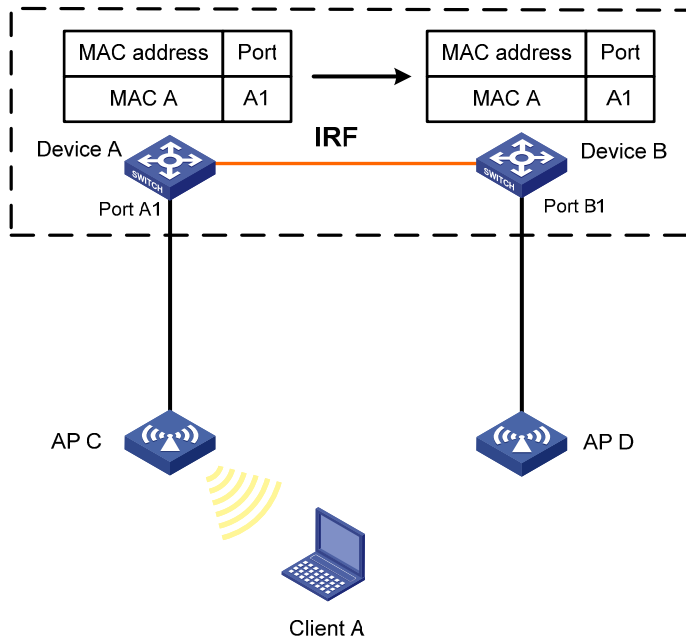

Do not configure the MAC learning limit on any member ports of an aggregation group. Otherwise, the member ports cannot be selected.

Enabling MAC address roaming

After you enable MAC address roaming on an IRF fabric, each member switch advertises learned MAC addresses to other member switches.

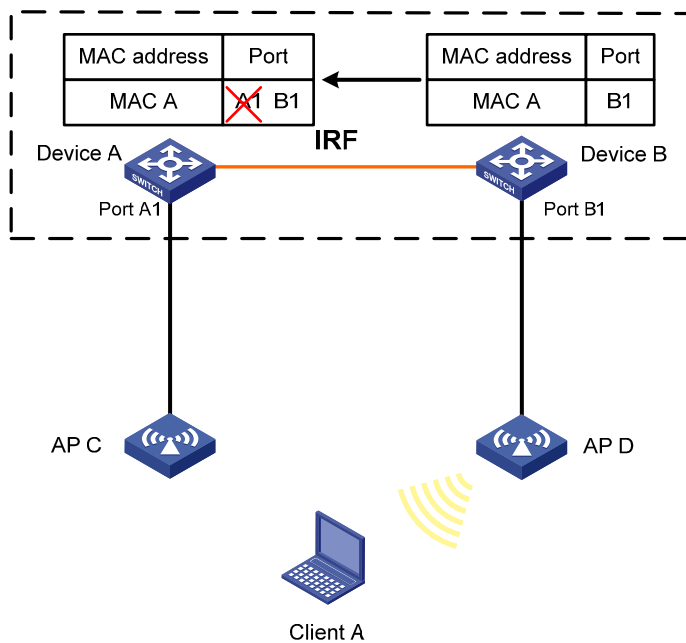

As shown in [Figure 4](#), Device A and Device B form an IRF fabric enabled with MAC address roaming. They connect to AP C and AP D, respectively. When Client A associates with AP C, Device A learns the MAC address of Client A and advertises it to the member switch Device B.

Figure 4 MAC address tables of devices when Client A associates with AP C

If Client A roams to AP D, Device B learns the MAC address of Client A and advertises it to Device A to ensure service continuity for Client A, as shown in Figure 5.

Figure 5 MAC address tables of devices when Client A roams to AP D

To enable MAC address roaming:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable MAC address roaming.	mac-address mac-roaming enable	Disabled by default.

Displaying and maintaining MAC address tables

Task	Command	Remarks
Display MAC address table information.	display mac-address [<i>mac-address</i> [vlan <i>vlan-id</i>]] [[dynamic static] [interface <i>interface-type</i> <i>interface-number</i>] blackhole] [vlan <i>vlan-id</i>] [count]] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the aging timer for dynamic MAC address entries.	display mac-address aging-time [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the system or interface MAC address learning state.	display mac-address mac-learning [<i>interface-type</i> <i>interface-number</i>] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MAC address statistics.	display mac-address statistics [[{ begin exclude include } <i>regular-expression</i>]	Available in any view

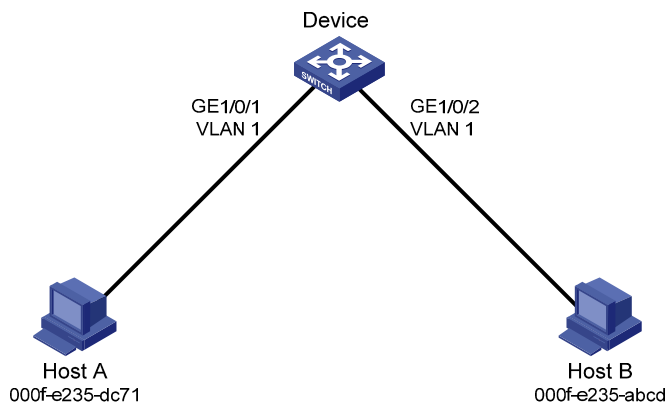

MAC address table configuration example

Network requirements

As shown in [Figure 6](#):

- The MAC address of Host A is 000f-e235-dc71 and belongs to VLAN 1. It is connected to GigabitEthernet 1/0/1 of the device. To prevent MAC address spoofing, add a static entry for the host in the MAC address table of the device.
- The MAC address of Host B is 000f-e235-abcd and belongs to VLAN 1. For security, because this host once behaved suspiciously on the network, add a blackhole MAC address entry for the host MAC address, so all packets destined for the host are dropped.
- Set the aging timer for dynamic MAC address entries to 500 seconds.

Figure 6 Network diagram

Configuration procedure

Add a static MAC address entry.

```
<Sysname> system-view
```

```
[Sysname] mac-address static 000f-e235-dc71 interface gigabitethernet 1/0/1 vlan 1
```

Add a blackhole MAC address entry.

```
[Sysname] mac-address blackhole 000f-e235-abcd vlan 1
```

Set the aging timer for dynamic MAC address entries to 500 seconds.

```
[Sysname] mac-address timer aging 500
```

Display the MAC address entry for port GigabitEthernet 1/0/1.

```
[Sysname] display mac-address interface gigabitethernet 1/0/1
```

MAC ADDR	VLAN ID	STATE	PORT INDEX	AGING TIME(s)
000f-e235-dc71	1	Config static	GigabitEthernet 1/0/1	NOAGED

```
--- 1 mac address(es) found ---
```

Display information about the blackhole MAC address table.

```
[Sysname] display mac-address blackhole
```

MAC ADDR	VLAN ID	STATE	PORT INDEX	AGING TIME(s)
000f-e235-abcd	1	Blackhole	N/A	NOAGED

```
--- 1 mac address(es) found ---
```

View the aging time of dynamic MAC address entries.

```
[Sysname] display mac-address aging-time
```

```
Mac address aging time: 500s
```

Configuring MAC Information

Overview

Introduction to MAC Information

To monitor a network, you must monitor users who are joining and leaving the network. Because a MAC address uniquely identifies a network user, you can monitor users who are joining and leaving a network by monitoring their MAC addresses.

With the MAC Information function, Layer 2 Ethernet ports send Syslog or trap messages to the monitor end in the network when they obtain or delete MAC addresses. By analyzing these messages, the monitor end can monitor users who are accessing the network.

How MAC Information works

When a new MAC address is obtained or an existing MAC address is deleted on a device, the device writes related information about the MAC address to the buffer area used to store user information. When the timer set for sending MAC address monitoring Syslog or trap messages expires, or when the buffer reaches capacity, the device sends the Syslog or trap messages to the monitor end.

The device writes information and sends messages only for the following MAC addresses: automatically learned source MAC addresses, MAC addresses that pass MAC authentication, MAC addresses that pass 802.1X authentication, MAC addresses matching OUI addresses in the voice VLAN feature, and secure MAC addresses. The device does not write information or send messages for blackhole MAC address, static MAC addresses, dynamic MAC addresses that are manually configured, multicast MAC addresses, and local MAC addresses.

For more information about MAC authentication, 802.1X, and secure MAC addresses in port security, see *Security Configuration Guide*. For more information about voice VLAN and OUI addresses, see "Configuring a voice VLAN."

Configuring MAC Information

Enabling MAC Information globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable MAC Information globally.	mac-address information enable	Disabled by default.

Enabling MAC Information on an interface

To enable MAC Information on an Ethernet interface, enable MAC Information globally first.

To enable MAC Information on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable MAC Information on the interface.	mac-address information enable { added deleted }	Disabled by default.

Configuring MAC Information mode

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure MAC Information mode.	mac-address information mode { syslog trap }	Optional trap by default.

Configuring the interval for sending Syslog or trap messages

To prevent Syslog or trap messages from being sent too frequently, change the interval for sending Syslog or trap messages.

To set the interval for sending Syslog or trap messages:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the interval for sending Syslog or trap messages.	mac-address information interval <i>interval-time</i>	Optional One second by default.

Configuring the MAC Information queue length

To avoid losing user MAC address information, when the buffer that stores user MAC address information reaches capacity, the user MAC address information in the buffer is sent to the monitor end in the network, even if the timer set for sending MAC address monitoring Syslog or trap messages has not expired yet.

To configure the MAC Information queue length:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the MAC Information queue length.	mac-address information queue-length <i>value</i>	Optional 50 by default.

MAC Information configuration example

Network requirements

As shown:

Enable MAC Information on GigabitEthernet 1/0/1 on Device in [Figure 7](#) to send MAC address changes in Syslog messages to Host B through GigabitEthernet 1/0/3. Host B analyzes and displays the Syslog messages.

Figure 7 Network diagram

Configuration procedure

1. Configure Device to send Syslog messages to Host B (see *Network Management and Monitoring Configuration Guide*).
2. Enable MAC Information.

Enable MAC Information on Device.

```
<Device> system-view
```

```
[Device] mac-address information enable
```

Configure MAC Information mode as Syslog.

```
[Device] mac-address information mode syslog
```

Enable MAC Information on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
```

```
[Device-GigabitEthernet1/0/1] mac-address information enable added
```

```
[Device-GigabitEthernet1/0/1] mac-address information enable deleted
```

```
[Device-GigabitEthernet1/0/1] quit
```

Set the MAC Information queue length to 100.

```
[Device] mac-address information queue-length 100
```

Set the interval for sending Syslog or trap messages to 20 seconds.

```
[Device] mac-address information interval 20
```

Configuring Ethernet link aggregation

The 5500 SI Switch Series does not support Layer 3 aggregate interfaces. The Layer 3 aggregate interface configurations in this document apply to only the 5500 EI Switch Series.

Overview

Ethernet link aggregation, or simply link aggregation, combines multiple physical Ethernet ports into one logical link, called an "aggregate link." Link aggregation delivers the following benefits:

- Increases bandwidth beyond the limits of any single link. In an aggregate link, traffic is distributed across the member ports.
- Improves link reliability. The member ports dynamically back up one another. When a member port fails, its traffic is automatically switched to other member ports.

As shown in [Figure 8](#), Device A and Device B are connected by three physical Ethernet links. These physical Ethernet links are combined into an aggregate link, Link Aggregation 1. The bandwidth of this aggregate link is as high as the total bandwidth of the three physical Ethernet links. At the same time, the three Ethernet links back up one another.

Figure 8 Ethernet link aggregation

Basic concepts

Aggregation group, member port, and aggregate interface

Link aggregation is implemented by combining Ethernet interfaces into a link aggregation group. Each link aggregation group has one logical aggregate interface. To an upper layer entity that uses the link aggregation service, a link aggregation group appears to be a single logical link and data traffic is transmitted through the aggregate interface. The rate of an aggregate interface equals the total rate of its member ports in the Selected state, and its duplex mode is the same as the selected member ports. For more information about the states of member ports in an aggregation group, see "[Aggregation states of member ports in an aggregation group](#)."

Aggregate interfaces are one of the following types:

Bridge-aggregation (BAGG) interfaces—Also called Layer 2 aggregate interfaces.

Route-aggregation (RAGG) interfaces—Also called Layer 3 aggregate interfaces.

When you create an aggregate interface, the switch automatically creates an aggregation group of the same type and number as the aggregate interface. For example, when you create interface Bridge-Aggregation 1, Layer 2 aggregation group 1 is automatically created.

You can assign Layer 2 Ethernet interfaces only to a Layer 2 aggregation group, and Layer 3 Ethernet interfaces only to a Layer 3 aggregation group.

Aggregation states of member ports in an aggregation group

A member port in an aggregation group can be in either of the following aggregation states:

- Selected: A Selected port can forward user traffic.
- Unselected: An Unselected port cannot forward user traffic.

Operational key

When aggregating ports, the system automatically assigns each port an operational key based on port information such as port rate and duplex mode. Any change to this information triggers a recalculation of the operational key.

In an aggregation group, all selected member ports are assigned the same operational key.

Configuration classes

Every configuration setting on a port might affect its aggregation state. Port configurations fall into the following classes:

- **Port attribute configurations**—Includes port rate, duplex mode, and link status (up/down). These are the most basic port configurations.
- **Class-two configurations**—A member port can be placed in Selected state only if it has the same class-two configurations as the aggregate interface. Class-two configurations made on an aggregate interface are automatically synchronized to all its member ports. These configurations are retained on the member ports even after the aggregate interface is removed.

Table 2 Class-two configurations

Feature	Considerations
Port isolation	Whether the port has joined an isolation group
QinQ	QinQ enable state (enable/disable), TPID for VLAN tags, outer VLAN tags to be added, inner-to-outer VLAN priority mappings, inner-to-outer VLAN tag mappings, inner VLAN ID substitution mappings
VLAN	Permitted VLAN IDs, PVID, link type (trunk, hybrid, or access), IP subnet-based VLAN configuration, protocol-based VLAN configuration, VLAN tagging mode
MAC address learning	MAC address learning capability

NOTE:

Any class-two configuration change might affect the aggregation state of link aggregation member ports and ongoing traffic. To be sure that you are aware of the risk, the system displays a warning message every time you attempt to change a class-two configuration setting on a member port.

- **Class-one configurations**—Include settings that do not affect the aggregation state of the member port even if they are different from those on the aggregate interface. GVRP and MSTP settings are examples of class-one configurations. The class-one configuration for a member port is effective only when the member port leaves the aggregation group.

Reference port

When setting the aggregation state of the ports in an aggregation group, the system automatically picks a member port as the reference port. A Selected port must have the same port attributes and class-two configurations as the reference port.

LACP

The IEEE 802.3ad Link Aggregation Control Protocol (LACP) enables dynamic aggregation of physical links. It uses link aggregation control protocol data units (LACPDU) for exchanging aggregation information between LACP-enabled devices.

1. LACP functions

The IEEE 802.3ad LACP offers basic LACP functions and extended LACP functions, as described in [Table 3](#).

Table 3 Basic and extended LACP functions

Category	Description
Basic LACP functions	Implemented through the basic LACPDU fields, including the system LACP priority, system MAC address, port aggregation priority, port number, and operational key. Each member port in a LACP-enabled aggregation group exchanges the preceding information with its peer. When a member port receives an LACPDU, it compares the received information with the information received on the other member ports. In this way, the two systems reach an agreement on which ports should be placed in the Selected state.
Extended LACP functions	Implemented by extending the LACPDU with new Type/Length/Value (TLV) fields. This is how the LACP multi-active detection (MAD) mechanism of the Intelligent Resilient Framework (IRF) feature is implemented. The 5500 EI[S] Switch Series can participate in LACP MAD as either an IRF member switch or an intermediate device.

For more information about IRF, member switches, intermediate devices, and the LACP MAD mechanism, see *IRF Configuration Guide*.

2. LACP priorities

LACP priorities have the following types: system LACP priority and port aggregation priority.

Table 4 LACP priorities

Type	Description	Remarks
System LACP priority	Used by two peer devices (or systems) to determine which one is superior in link aggregation. In dynamic link aggregation, the system that has higher system LACP priority sets the Selected state of member ports on its side first, and then the system that has lower priority sets the port state accordingly.	The smaller the priority value, the higher the priority.
Port aggregation priority	Determines the likelihood of a member port to be selected on a system. The higher the port aggregation priority, the higher the likelihood.	

3. LACP timeout interval

The LACP timeout interval specifies how long a member port waits to receive LACPDUs from the peer port. If a local member port fails to receive LACPDUs from the peer within three times the LACP timeout interval, the member port assumes that the peer port has failed. You can configure the LACP timeout interval as either the short timeout interval (1 second) or the long timeout interval (30 seconds).

Link aggregation modes

Link aggregation has the following modes: dynamic and static. Dynamic link aggregation uses LACP and static link aggregation does not. [Table 5](#) compares the two aggregation modes.

Table 5 A comparison between static and dynamic aggregation modes

Aggregation mode	LACP status on member ports	Pros	Cons
Static	Disabled	Aggregation is stable. Peers do not affect the aggregation state of the member ports.	The member ports do not adjust the aggregation state according to that of the peer ports. The administrator must manually maintain link aggregations.
Dynamic	Enabled	The administrator does not need to maintain link aggregations. The peer systems maintain the aggregation state of the member ports automatically.	Aggregation is unstable. The aggregation state of the member ports is susceptible to network changes.

The following points apply to a dynamic link aggregation group:

- A Selected port can receive and send LACPDUs.
- An Unselected port can receive and send LACPDUs only if it is up and has the same class-two configurations as the aggregate interface.

Aggregating links in static mode

LACP is disabled on the member ports in a static aggregation group. You must manually maintain the aggregation state of the member ports.

The static link aggregation process comprises:

- [Selecting a reference port](#)
- [Setting the aggregation state of each member port](#)

Selecting a reference port

The system selects a reference port from the member ports that are:

- Are in the up state and have
- Have the same class-two configurations as the aggregate interface.

The candidate ports are sorted by aggregation priority, duplex, and speed in the following order:

- Lowest aggregation priority value
- Full duplex/high speed
- Full duplex/low speed
- Half duplex/high speed
- Half duplex/low speed

The one at the top is selected as the reference port. If two ports have the same aggregation priority, duplex mode, and speed, the one with the lower port number wins.

Setting the aggregation state of each member port

After selecting the reference port, the static aggregation group sets the aggregation state of each member port, as shown in [Figure 9](#). After the static aggregation group has reached the limit on Selected ports, any port assigned to the group is placed in Unselected state to avoid traffic interruption on the current Selected ports.

Figure 9 Setting the aggregation state of a member port in a static aggregation group

Aggregating links in dynamic mode

LACP is automatically enabled on all member ports in a dynamic aggregation group. The protocol automatically maintains the aggregation state of ports.

The dynamic link aggregation process comprises:

- Selecting a reference port
- Setting the aggregation state of each member port

Selecting a reference port

The local system (the actor) and the remote system (the partner) negotiate a reference port using the following workflow:

1. The systems compare the system ID (which comprises the system LACP priority and the system MAC address). The system with the lower LACP priority value wins. If they are the same, the systems compare the system MAC addresses. The system with the lower MAC address wins.
2. The system with the smaller system ID selects the port with the smallest port ID as the reference port. A port ID comprises a port aggregation priority and a port number. The port with the lower aggregation priority value wins. If two ports have the same aggregation priority, the system compares their port numbers. The port with the smaller port number wins.

Setting the aggregation state of each member port

After the reference port is selected, the system with the lower system ID sets the state of each member port in the dynamic aggregation group on its side.

Figure 10 Setting the state of a member port in a dynamic aggregation group

Meanwhile, the system with the higher system ID, which has identified the aggregation state changes on the remote system, sets the aggregation state of local member ports as the same as their peer ports.

A dynamic link aggregation group preferably sets full-duplex ports as the Selected ports, and will set one, and only one, half-duplex port as a Selected port when none of the full-duplex ports can be selected or only half-duplex ports exist in the group.

When the aggregation state of a member port changes, the aggregation state of its peer port also changes.

After the Selected port limit has been reached, a port assigned to the dynamic aggregation group is placed in Selected state if it is more eligible for being selected than a current member port.

The port assigned to the dynamic aggregation group after the Selected port limit has been reached is placed in Selected state if it is more eligible for being selected than a current member port.

Load-sharing criteria for link aggregation groups

In a link aggregation group, traffic can be load-shared across the selected member ports based on a set of criteria, depending on your configuration.

You can choose one of the following criteria or any combination for load sharing:

- MAC addresses
- Service port numbers
- Ingress ports
- IP addresses

Alternatively, you can let the system automatically choose link-aggregation load-sharing criteria based on packet types (Layer 2, IPv4, or IPv6 for example)

Configuration restrictions and guidelines

Follow these guidelines when you configure a link aggregation group:

- To ensure stable aggregation state and service continuity, do not change port attributes or class-two configurations on any member port. If you must, make sure you understand its impact on the live network. Any port attribute or class-two configuration change might affect the aggregation state of link aggregation member ports and ongoing traffic.

Avoid assigning ports to a static aggregation group that has reached the limit on Selected ports. These ports will be placed in Unselected state to avoid traffic interruption on the current Selected ports. However, a device reboot can cause the aggregation state of member ports to change.

Ethernet link aggregation configuration task list

Complete the following tasks to configure Ethernet link aggregation:

Task	Remarks	
Configuring an aggregation group	Configuring a static aggregation group	
	Configuring a dynamic aggregation group	
Configuring an aggregate interface	Select either task	
	Configuring the description of an aggregate interface	Optional
	Configuring the MTU of a Layer 3 aggregate interface	Optional
	Enabling link state traps for an aggregate interface	Optional
	Limiting the number of Selected ports for an aggregation group	Optional
	Shutting down an aggregate interface	Optional
Configuring load sharing for link aggregation groups	Restoring the default settings for an aggregate interface	Optional
	Configuring load-sharing criteria for link aggregation groups	Optional
	Enabling local-first load sharing for link aggregation	Optional
Enabling link-aggregation traffic redirection	Optional	

Configuring an aggregation group

You can choose to create a Layer 2 or Layer 3 link aggregation group depending on the ports to be aggregated on the 5500 EI switch:

- To aggregate Layer 2 Ethernet interfaces, create a Layer 2 link aggregation group.

- To aggregate Layer 3 Ethernet interfaces, create a Layer 3 link aggregation group.

Configuration guidelines

- You cannot assign a port to a Layer 2 aggregation group if any of the features listed in [Table 6](#) is configured on the port.

Table 6 Features incompatible with Layer 2 aggregation groups

Feature	Reference
RRPP	RRPP in <i>High Availability Configuration Guide</i>
MAC authentication	MAC authentication in <i>Security Configuration Guide</i>
Port security	Port security in <i>Security Configuration Guide</i>
IP source guard	IP source guard in <i>Security Configuration Guide</i>
802.1X	802.1X in <i>Security Configuration Guide</i>
Ports specified as source interfaces in portal-free rules	Portal in <i>Security Configuration Guide</i>

- You cannot assign a port to a Layer 3 aggregation group if any of the features listed in [Table 7](#) is configured on the port.

Table 7 Interfaces that cannot be assigned to a Layer 3 aggregation group

Interface type	Reference
Interfaces configured with IP addresses	IP addressing in <i>Layer 3—IP Services Configuration Guide</i>
Interfaces configured as DHCP/BOOTP clients	DHCP in <i>Layer 3—IP Services Configuration Guide</i>
VRRP	VRRP in <i>High Availability Configuration Guide</i>
Portal	Portal in <i>Security Configuration Guide</i>

- Removing an aggregate interface also removes the corresponding aggregation group. At the same time, all member ports leave the aggregation group.

Configuring a static aggregation group

To guarantee a successful static aggregation, make sure that the ports at both ends of each link are in the same aggregation state.

Configuring a Layer 2 static aggregation group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a Layer 2 aggregate interface and enter Layer 2 aggregate interface view.	interface bridge-aggregation <i>interface-number</i>	When you create a Layer 2 aggregate interface, the system automatically creates a Layer 2 static aggregation group numbered the same.
3. Exit to system view.	quit	N/A

Step	Command	Remarks
4. Assign an Ethernet interface to the aggregation group.	<ul style="list-style-type: none"> a. Enter Layer 2 Ethernet interface view: interface <i>interface-type interface-number</i> b. Assign the Ethernet interface to the aggregation group: port link-aggregation group <i>number</i> 	Repeat this step to assign more Layer 2 Ethernet interfaces to the aggregation group.
5. Assign the port an aggregation priority.	link-aggregation port-priority <i>port-priority</i>	<p>Optional</p> <p>By default, the aggregation priority of a port is 32768.</p> <p>Changing the aggregation priority of a port might affect the aggregation state of the ports in the static aggregation group.</p>

Configuring a Layer 3 static aggregation group (available only on the 5500 EI)

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a Layer 3 aggregate interface and enter Layer 3 aggregate interface view.	interface route-aggregation <i>interface-number</i>	When you create a Layer 3 aggregate interface, the system automatically creates a Layer 3 static aggregation group numbered the same.
3. Exit to system view.	quit	N/A
4. Assign an Ethernet interface to the aggregation group.	<ul style="list-style-type: none"> a. Enter Layer 3 Ethernet interface view: interface <i>interface-type interface-number</i> b. Assign the Ethernet interface to the aggregation group: port link-aggregation group <i>number</i> 	Repeat this step to assign more Layer 3 Ethernet interfaces to the aggregation group.
5. Assign the port an aggregation priority.	link-aggregation port-priority <i>port-priority</i>	<p>Optional</p> <p>By default, the aggregation priority of a port is 32768.</p> <p>Changing the aggregation priority of a port might affect the aggregation state of the ports in the static aggregation group.</p>

Configuring a dynamic aggregation group

To guarantee a successful dynamic aggregation, be sure that the peer ports of the ports aggregated at one end are also aggregated. The two ends can automatically negotiate the aggregation state of each member port.

Configuring a Layer 2 dynamic aggregation group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the system LACP priority.	lacp system-priority <i>system-priority</i>	Optional By default, the system LACP priority is 32768. Changing the system LACP priority might affect the aggregation state of the ports in a dynamic aggregation group.
3. Create a Layer 2 aggregate interface and enter Layer 2 aggregate interface view.	interface bridge-aggregation <i>interface-number</i>	When you create a Layer 2 aggregate interface, the system automatically creates a Layer 2 static aggregation group numbered the same.
4. Configure the aggregation group to operate in dynamic aggregation mode.	link-aggregation mode dynamic	By default, an aggregation group operates in static aggregation mode.
5. Exit to system view.	quit	N/A
6. Assign an Ethernet interface to the aggregation group.	<ol style="list-style-type: none"> a. Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> b. Assign the Ethernet interface to the aggregation group: port link-aggregation group <i>number</i> 	Repeat this step to assign more Layer 2 Ethernet interfaces to the aggregation group.
7. Assign the port an aggregation priority.	link-aggregation port-priority <i>port-priority</i>	Optional By default, the aggregation priority of a port is 32768. Changing the aggregation priority of a port might affect the aggregation state of the ports in the dynamic aggregation group.
8. Set the LACP timeout interval on the port to the short timeout interval (1 second).	lacp period short	Optional By default, the LACP timeout interval on a port is the long timeout interval (30 seconds).

Configuring a Layer 3 dynamic aggregation group (available only on the 5500 EI)

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Set the system LACP priority.	lacp system-priority <i>system-priority</i>	Optional By default, the system LACP priority is 32768. Changing the system LACP priority might affect the aggregation state of the ports in the dynamic aggregation group.
3. Create a Layer 3 aggregate interface and enter Layer 3 aggregate interface view.	interface route-aggregation <i>interface-number</i>	When you create a Layer 3 aggregate interface, the system automatically creates a Layer 3 static aggregation group numbered the same.
4. Configure the aggregation group to operate in dynamic aggregation mode.	link-aggregation mode dynamic	By default, an aggregation group operates in static aggregation mode.
5. Exit to system view.	quit	N/A
6. Assign an Ethernet interface to the aggregation group.	<ul style="list-style-type: none"> a. Enter Layer 3 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> b. Assign the Ethernet interface to the aggregation group: port link-aggregation group <i>number</i> 	Repeat this step to assign more Layer 3 Ethernet interfaces to the aggregation group.
7. Assign the port an aggregation priority.	link-aggregation port-priority <i>port-priority</i>	Optional By default, the aggregation priority of a port is 32768. Changing the aggregation priority of a port might affect the aggregation state of ports in the dynamic aggregation group.
8. Set the LACP timeout interval on the port to the short timeout interval (1 second).	lacp period short	Optional By default, the LACP timeout interval on a port is the long timeout interval (30 seconds).

Configuring an aggregate interface

Most of the configurations that can be performed on Layer 2 or Layer 3 Ethernet interfaces can also be performed on Layer 2 or Layer 3 aggregate interfaces.

Configuring the description of an aggregate interface

You can configure the description of an aggregate interface for administration purposes such as describing the purpose of the interface.

To configure the description of an aggregate interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter aggregate interface view.	<ul style="list-style-type: none"> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter Layer 3 aggregate interface view: interface route-aggregation <i>interface-number</i> 	Use either command.
3. Configure the description of the aggregate interface.	description <i>text</i>	Optional By default, the description of an interface is in the format of <i>interface-name</i> Interface , such as Bridge-Aggregation1 Interface .

Configuring the MTU of a Layer 3 aggregate interface (available only on the 5500 EI)

The MTU of an interface affects IP packets fragmentation and reassembly on the interface.

To change the MTU of a Layer 3 aggregate interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 3 aggregate interface view.	interface route-aggregation <i>interface-number</i>	N/A
3. Configure the MTU of the Layer 3 aggregate interface.	mtu <i>size</i>	Optional 1500 bytes by default.

Enabling link state traps for an aggregate interface

You can configure an aggregate interface to generate linkUp trap messages when its link goes up and linkDown trap messages when its link goes down. For more information, see *Network Management and Monitoring Configuration Guide*.

To enable link state traps on an aggregate interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the trap function globally.	snmp-agent trap enable [standard [linkdown linkup] *]	Optional By default, link state trapping is enabled globally and on all interfaces.

Step	Command	Remarks
3. Enter aggregate interface view.	<ul style="list-style-type: none"> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter Layer 3 aggregate interface view: interface route-aggregation <i>interface-number</i> 	Use either command.
4. Enable link state traps for the aggregate interface.	enable snmp trap updown	Optional Enabled by default.

Limiting the number of Selected ports for an aggregation group

The bandwidth of an aggregate link increases along with the number of selected member ports. To avoid congestion caused by insufficient Selected ports on an aggregate link, you can set the minimum number of Selected ports required for bringing up the specific aggregate interface.

This minimum threshold setting affects the aggregation state of both aggregation member ports and the aggregate interface in the following ways:

- All member ports change to the Unselected state and the link of the aggregate interface goes down, when the number of member ports eligible for being selected is smaller than the minimum threshold.
- When the minimum threshold is reached, the eligible member ports change to the Selected state, and the link of the aggregate interface goes up.

By default, the maximum number of Selected ports allowed in an aggregation group depends on the hardware capabilities of the member ports. After you manually configure the maximum number of Selected ports in an aggregation group, the maximum number of Selected ports allowed in the aggregation group is the lower value of the two upper limits.

You can configure redundancy between two ports using the following guideline: Assign two ports to an aggregation group, and configure the maximum number of Selected ports allowed in the aggregation group as 1. In this way, only one Selected port is allowed in the aggregation group at any point in time, while the Unselected port serves as a backup port.

Configuration guidelines

Follow these guidelines when you configure the port threshold settings:

- If you set a minimum threshold for a static aggregation group, also make the same setting for its peer aggregation group to guarantee correct aggregation.
- Make sure the two link aggregation ends have the same minimum and maximum numbers of selected ports.

Make sure you understand the following impacts of the port threshold settings:

- Configuring the minimum number of Selected ports required to bring up an aggregation group may cause all the member ports in the aggregation group to become unselected.
- Configuring the maximum number of Selected ports in an aggregation group may cause some of the selected member ports in the aggregation group to become unselected.

To limit the number of Selected ports for an aggregation group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter aggregate interface view.	<ul style="list-style-type: none"> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter Layer 3 aggregate interface view: interface route-aggregation <i>interface-number</i> 	Use either command.
3. Set the minimum number of Selected ports for the aggregation group.	link-aggregation selected-port minimum <i>number</i>	Not specified by default.
4. Set the maximum number of Selected ports for the aggregation group.	link-aggregation selected-port maximum <i>number</i>	By default, the maximum number of Selected ports allowed in an aggregation group depends on only the hardware capabilities of the member ports.

Shutting down an aggregate interface

Shutting down or bringing up an aggregate interface affects the aggregation state and link state of ports in the corresponding aggregation group in the following ways:

- When an aggregate interface is shut down, all Selected ports in the corresponding aggregation group become unselected and their link state becomes down.
- When an aggregate interface is brought up, the aggregation state of ports in the corresponding aggregation group is recalculated and their link state becomes up.

To shut down an aggregate interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter aggregate interface view.	<ul style="list-style-type: none"> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter Layer 3 aggregate interface view: interface route-aggregation <i>interface-number</i> 	Use either command.
3. Shut down the aggregate interface.	shutdown	By default, aggregate interfaces are up.

Restoring the default settings for an aggregate interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter aggregate interface view.	<ul style="list-style-type: none">Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i>Enter Layer 3 aggregate interface view: interface route-aggregation <i>interface-number</i>	Use either command.
3. Restore the default settings for the aggregate interface.	default	N/A

Configuring load sharing for link aggregation groups

Configuring load-sharing criteria for link aggregation groups

You can determine how traffic is load-shared in a link aggregation group by configuring load-sharing criteria. The criteria can be MAC addresses, service port numbers, ingress ports, or IP addresses, or any combination. You can also let the system automatically choose link-aggregation load-sharing criteria based on packet types (Layer 2, IPv4, or IPv6, for example).

You can configure global or group-specific load-sharing criteria. A link aggregation group preferentially uses the group-specific load-sharing criteria. If no group-specific load-sharing criteria are available, the group uses the global load-sharing criteria.

NOTE:

The load sharing criteria configuration applies to only unicast packets, and can change the load sharing criteria for unicast packets. Broadcast packets and multicast packets always use the default load sharing criteria.

Configuring the global link-aggregation load-sharing criteria

To configure the global link-aggregation load-sharing criteria:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the global link-aggregation load-sharing criteria.	link-aggregation load-sharing mode { { destination-ip destination-mac destination-port ingress-port source-ip source-mac source-port } }	By default, the system selects the global load sharing criteria according to the packet type.

In system view, the switch supports the following load-sharing criteria and combinations:

- Source IP address
- Destination IP address
- Source MAC address
- Destination MAC address
- Source IP address and destination IP address
- Source IP address and source port
- Destination IP address and destination port
- Any combination of incoming port, source MAC address, and destination MAC address

Configuring group-specific load-sharing criteria

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 aggregate interface view.	interface bridge-aggregation <i>interface-number</i>	N/A
3. Configure the load-sharing criteria for the aggregation group.	link-aggregation load-sharing mode { { destination-ip destination-mac source-ip source-mac } * }	The default load-sharing criteria are the same as the global load-sharing criteria.

In Layer 2 aggregate interface view, the switch supports the following load-sharing criteria and combinations:

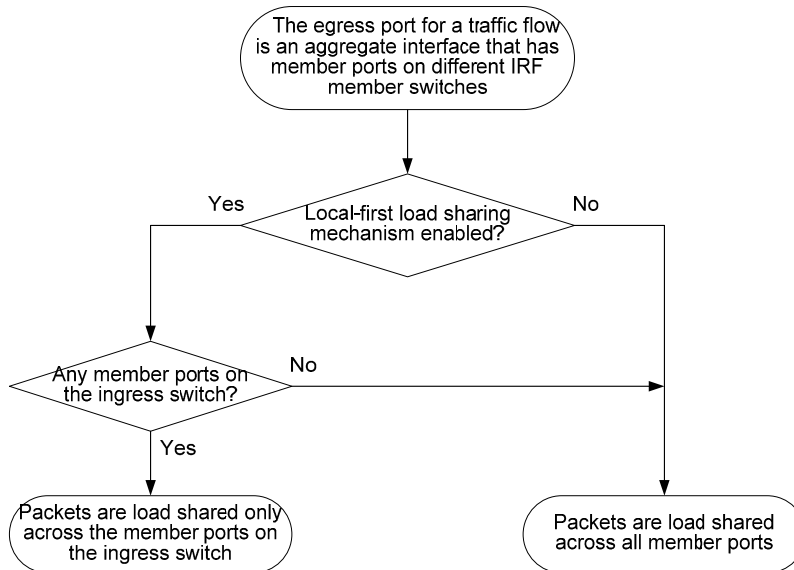

- Automatic load-sharing criteria determined based on the packet type
- Source IP address
- Destination IP address
- Source MAC address
- Destination MAC address
- Destination IP address and source IP address
- Destination MAC address and source MAC address

Enabling local-first load sharing for link aggregation

Use the local-first load sharing mechanism in a cross-switch link aggregation scenario to distribute traffic preferentially across member ports on the ingress switch rather than all member ports.

When you aggregate ports on different member switches in an IRF fabric, you can use local-first load sharing to reduce traffic on IRF links, as shown in [Figure 11](#). For more information about IRF, see *IRF Configuration Guide*.

Figure 11 Local-first link-aggregation load sharing

To enable local-first load sharing for link aggregation:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable local-first load-sharing for link aggregation.	link-aggregation load-sharing mode local-first	Optional Enabled by default.

Enabling link-aggregation traffic redirection

The link-aggregation traffic redirection function can redirect traffic between IRF member switches for a cross-device link aggregation group. Link-aggregation traffic redirection prevents traffic interruption when you reboot IRF member switch that contains link aggregation member ports. For more information about IRF, see *IRF Configuration Guide*.

Link-aggregation traffic redirection applies only to dynamic link aggregation groups and only to known unicast packets.

After link-aggregation traffic redirection is enabled, do not add an Ethernet interface configured with physical state change suppression to an aggregation group. Otherwise, Selected ports in the aggregation group might work improperly. For more information about physical state change suppression, see [Configuring Ethernet interfaces](#).

To enable link-aggregation traffic redirection:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable link-aggregation traffic redirection.	link-aggregation lacp traffic-redirect-notification enable	Optional Disabled by default.

△ CAUTION:

- To prevent traffic interruption, enable link-aggregation traffic redirection on devices at both ends of the aggregate link.
- To prevent packet loss that might occur at a reboot, disable both MSTP and link-aggregation traffic redirection.

Displaying and maintaining Ethernet link aggregation

Task	Command	Remarks
Display information about an aggregate interface or multiple aggregate interfaces.	display interface [bridge-aggregation route-aggregation] [brief [down]] [{ begin exclude include } <i>regular-expression</i>] display interface { bridge-aggregation route-aggregation } <i>interface-number</i> [brief] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the local system ID.	display lacp system-id [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the global or group-specific link-aggregation load-sharing criteria.	display link-aggregation load-sharing mode [interface [{ bridge-aggregation route-aggregation } <i>interface-number</i>]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display detailed link aggregation information for link aggregation member ports.	display link-aggregation member-port [<i>interface-list</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display summary information about all aggregation groups.	display link-aggregation summary [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display detailed information about a specific or all aggregation groups.	display link-aggregation verbose [{ bridge-aggregation route-aggregation } [<i>interface-number</i>]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear LACP statistics for a specific or all link aggregation member ports.	reset lacp statistics [interface <i>interface-list</i>]	Available in user view
Clear statistics for a specific or all aggregate interfaces.	reset counters interface [{ bridge-aggregation route-aggregation } [<i>interface-number</i>]]	Available in user view

Ethernet link aggregation configuration examples

In an aggregation group, only ports that have the same port attributes and class-two configurations (see "[Configuration classes](#)") as the reference port (see "[Reference port](#)") can operate as Selected ports. Make sure that all member ports have the same port attributes and class-two configurations as the reference port. The other settings only need to be configured on the aggregate interface, not on the member ports.

Layer 2 static aggregation configuration example

Network requirements

As shown in Figure 12:

- Device A and Device B are connected through their respective Layer 2 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3.
- Configure a Layer 2 static aggregation group on both Device A and Device B. Enable VLAN 10 at one end of the aggregate link to communicate with VLAN 10 at the other end, and VLAN 20 at one end to communicate with VLAN 20 at the other end.
- Enable traffic to be load-shared across aggregation group member ports based on the source and destination MAC addresses.

Figure 12 Network diagram

Configuration procedure

1. Configure Device A:

Create VLAN 10, and assign port GigabitEthernet 1/0/4 to VLAN 10.

```
<DeviceA> system-view
[DeviceA] vlan 10
[DeviceA-vlan10] port gigabitethernet 1/0/4
[DeviceA-vlan10] quit
```

Create VLAN 20, and assign port GigabitEthernet 1/0/5 to VLAN 20.

```
[DeviceA] vlan 20
[DeviceA-vlan20] port gigabitethernet 1/0/5
[DeviceA-vlan20] quit
```

Create Layer 2 aggregate interface Bridge-Aggregation 1.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] quit
```

Assign ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to link aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
```

```
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/2] quit
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/3] quit
```

Configure Layer 2 aggregate interface Bridge-Aggregation 1 as a trunk port and assign it to VLANs 10 and 20.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port link-type trunk
[DeviceA-Bridge-Aggregation1] port trunk permit vlan 10 20
Please wait... Done.
Configuring GigabitEthernet1/0/1... Done.
Configuring GigabitEthernet1/0/2... Done.
Configuring GigabitEthernet1/0/3... Done.
[DeviceA-Bridge-Aggregation1] quit
```

Configure Device A to use the source and destination MAC addresses of packets as the global link-aggregation load-sharing criteria.

```
[DeviceA] link-aggregation load-sharing mode source-mac destination-mac
```

2. Configure Device B.

Configure Device B using the same instructions that you used to configure Device A.

3. Verify the configurations:

Display summary information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation summary
```

```
Aggregation Interface Type:
BAGG -- Bridge-Aggregation, RAGG -- Route-Aggregation
Aggregation Mode: S -- Static, D -- Dynamic
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Actor System ID: 0x8000, 000f-e2ff-0001
```

AGG	AGG	Partner ID	Select	Unselect	Share
Interface	Mode		Ports	Ports	Type
BAGG1	S	none	3	0	Shar

The output shows that link aggregation group 1 is a load-shared Layer 2 static aggregation group and it contains three Selected ports.

Display the global link-aggregation load-sharing criteria on Device A.

```
[DeviceA] display link-aggregation load-sharing mode
```

```
Link-Aggregation Load-Sharing Mode:
destination-mac address, source-mac address
```

The output shows that all link aggregation groups created on the device perform load sharing based on source and destination MAC addresses.

Layer 2 dynamic aggregation configuration example

Network requirements

As shown in Figure 13:

- Device A and Device B are connected through their respective Layer 2 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3.
- Configure a Layer 2 dynamic aggregation group on both Device A and Device B, enable VLAN 10 at one end of the aggregate link to communicate with VLAN 10 at the other end, and VLAN 20 at one end to communicate with VLAN 20 at the other end.
- Enable traffic to be load-shared across aggregation group member ports based on source and destination MAC addresses.

Figure 13 Network diagram

Configuration procedure

1. Configure Device A:

Create VLAN 10, and assign the port GigabitEthernet 1/0/4 to VLAN 10.

```
<DeviceA> system-view
[DeviceA] vlan 10
[DeviceA-vlan10] port gigabitethernet 1/0/4
[DeviceA-vlan10] quit
```

Create VLAN 20, and assign the port GigabitEthernet 1/0/5 to VLAN 20.

```
[DeviceA] vlan 20
[DeviceA-vlan20] port gigabitethernet 1/0/5
[DeviceA-vlan20] quit
```

Create Layer 2 aggregate interface Bridge-Aggregation 1, and configure the link aggregation mode as dynamic.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] link-aggregation mode dynamic
```

Assign ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to link aggregation group 1 one at a time.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/1] quit
```

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/2] quit
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/3] quit
```

Configure Layer 2 aggregate interface Bridge-Aggregation 1 as a trunk port and assign it to VLANs 10 and 20.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port link-type trunk
[DeviceA-Bridge-Aggregation1] port trunk permit vlan 10 20
Please wait... Done.
Configuring GigabitEthernet1/0/1... Done.
Configuring GigabitEthernet1/0/2... Done.
Configuring GigabitEthernet1/0/3... Done.
[DeviceA-Bridge-Aggregation1] quit
```

Configure the device to use the source and destination MAC addresses of packets as the global link-aggregation load-sharing criteria.

```
[DeviceA] link-aggregation load-sharing mode source-mac destination-mac
```

2. Configure Device B.

Configure Device B using the same instructions that you used to configure Device A.

3. Verify the configurations:

Display summary information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation summary
```

```
Aggregation Interface Type:
BAGG -- Bridge-Aggregation, RAGG -- Route-Aggregation
Aggregation Mode: S -- Static, D -- Dynamic
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Actor System ID: 0x8000, 000f-e2ff-0001
```

AGG	AGG	Partner ID	Select	Unselect	Share
Interface	Mode		Ports	Ports	Type
BAGG1	D	0x8000, 000f-e2ff-0002	3	0	Shar

The output shows that link aggregation group 1 is a load-shared Layer 2 dynamic aggregation group and it contains three Selected ports.

Display the global link-aggregation load-sharing criteria on Device A.

```
[DeviceA] display link-aggregation load-sharing mode
```

```
Link-Aggregation Load-Sharing Mode:
destination-mac address, source-mac address
```

The output shows that all link aggregation groups created on the device perform load sharing based on source and destination MAC addresses.

Layer 3 static aggregation configuration example

Network requirements

As shown in Figure 14:

- Device A and Device B are connected by their Layer 3 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3.
- Configure a Layer 3 static aggregation group on both Device A and Device B. Configure IP addresses and subnet masks for the corresponding Layer 3 aggregate interfaces.
- Enable traffic to be load-shared across aggregation group member ports based on source and destination IP addresses.

Figure 14 Network diagram

Configuration procedure

1. Configure Device A:

Create Layer 3 aggregate interface Route-Aggregation 1, and configure an IP address and subnet mask for the aggregate interface.

```
<DeviceA> system-view
[DeviceA] interface route-aggregation 1
[DeviceA-Route-Aggregation1] ip address 192.168.1.1 24
[DeviceA-Route-Aggregation1] quit
```

Assign Layer 3 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/2] quit
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/3] quit
```

Configure the global link-aggregation load-sharing criteria as the source and destination IP addresses of packets.

```
[DeviceA] link-aggregation load-sharing mode source-ip destination-ip
```

2. Configure Device B.

Configure Device B using the same instructions that you used to configure Device A.

3. Verify the configurations:

Display summary information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation summary
```

Aggregation Interface Type:

```

BAGG -- Bridge-Aggregation, RAGG -- Route-Aggregation
Aggregation Mode: S -- Static, D -- Dynamic
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Actor System ID: 0x8000, 000f-e2ff-0001

```

AGG	AGG	Partner ID	Select	Unselect	Share
Interface	Mode		Ports	Ports	Type
RAGG1	S	none	3	0	Shar

The output shows that link aggregation group 1 is a load-sharing-capable Layer 3 static aggregation group that contains three Selected ports.

```
# Display the global link-aggregation load-sharing criteria on Device A.
```

```
[DeviceA] display link-aggregation load-sharing mode
```

```
Link-Aggregation Load-Sharing Mode:
```

```
destination-ip address, source-ip address
```

The output shows that the global link-aggregation load-sharing criteria are the source and destination IP addresses of packets.

Layer 3 dynamic aggregation configuration example

Network requirements

As shown in [Figure 15](#):

- Device A and Device B are connected by their Layer 3 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3.
- Configure a Layer 3 dynamic aggregation group on both Device A and Device B and configure IP addresses and subnet masks for the corresponding Layer 3 aggregate interfaces.
- Enable traffic to be load-shared across aggregation group member ports based on source and destination IP addresses.

Figure 15 Network diagram

Configuration procedure

1. Configure Device A:

```
# Create Layer 3 aggregate interface Route-Aggregation 1, configure the link aggregation mode as dynamic, and configure an IP address and subnet mask for the aggregate interface.
```

```

<DeviceA> system-view
[DeviceA] interface route-aggregation 1
[DeviceA-Route-Aggregation1] link-aggregation mode dynamic
[DeviceA-Route-Aggregation1] ip address 192.168.1.1 24
[DeviceA-Route-Aggregation1] quit

```

Assign Layer 3 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/2] quit
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/3] quit
```

Configure Device A to use the source and destination IP addresses of packets as the global link-aggregation load-sharing criteria.

```
[DeviceA] link-aggregation load-sharing mode source-ip destination-ip
```

2. Configure Device B.

Configure Device B using the same instructions that you used to configure Device A.

3. Verify the configurations:

Display summary information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation summary
```

Aggregation Interface Type:

BAGG -- Bridge-Aggregation, RAGG -- Route-Aggregation

Aggregation Mode: S -- Static, D -- Dynamic

Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing

Actor System ID: 0x8000, 000f-e2ff-0001

AGG	AGG	Partner ID	Select	Unselect	Share
Interface	Mode		Ports	Ports	Type

RAGG1	D	0x8000, 000f-e2ff-0002	3	0	Shar

The output shows that link aggregation group 1 is a load-shared Layer 3 dynamic aggregation group and it contains three Selected ports.

Display the global link-aggregation load-sharing criteria on Device A.

```
[DeviceA] display link-aggregation load-sharing mode
```

Link-Aggregation Load-Sharing Mode:

```
destination-ip address, source-ip address
```

The output shows that the global link-aggregation load-sharing criteria are the source and destination IP addresses of packets.

Configuring port isolation

Port isolation enables isolating Layer 2 traffic for data privacy and security without using VLANs. You can also use this feature to isolate the hosts in a VLAN from one another.

To use the feature, assign ports to a port isolation group. Ports in an isolation group are called "isolated ports." One isolated port cannot forward Layer 2 traffic to any other isolated port on the same switch, even if they are in the same VLAN. An isolated port can communicate with any port outside the isolation group if they are in the same VLAN.

The switch series supports only one isolation group "isolation group 1." The isolation group is automatically created and cannot be deleted. There is no limit on the number of member ports.

Assigning a port to the isolation group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none">Enter Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i>Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i>Enter port group view: port-group manual <i>port-group-name</i>	<p>Use one of the commands.</p> <ul style="list-style-type: none">In Ethernet interface view, the subsequent configurations apply to the current port.In Layer 2 aggregate interface view, the subsequent configurations apply to the Layer 2 aggregate interface and all its member ports.In port group view, the subsequent configurations apply to all ports in the port group.
3. Assign the port or ports to the isolation group as an isolated port or ports.	port-isolate enable	No ports are added to the isolation group by default.

Displaying and maintaining the isolation group

Port isolation configuration example

Network requirements

As shown in Figure 16, Host A, Host B, and Host C are connected to GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 of Device, and Device is connected to the Internet through GigabitEthernet 1/0/4. All these ports are in the same VLAN.

Configure Device to provide Internet access for all the hosts and isolate them from one another.

Figure 16 Networking diagram

Configuration procedure

Add ports GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to the isolation group.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port-isolate enable
[Device-GigabitEthernet1/0/1] quit
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] port-isolate enable
[Device-GigabitEthernet1/0/2] quit
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] port-isolate enable
```

Display information about the isolation group.

```
<Device> display port-isolate group
Port-isolate group information:
Uplink port support: NO
Group ID: 1
Group members:
    GigabitEthernet 1/0/1    GigabitEthernet 1/0/2    GigabitEthernet 1/0/3
```

Configuring spanning tree protocols

As a Layer 2 management protocol, the Spanning Tree Protocol (STP) eliminates Layer 2 loops by selectively blocking redundant links in a network, putting them in a standby state, which still also allows for link redundancy.

The recent versions of STP include the Rapid Spanning Tree Protocol (RSTP), Per VLAN Spanning Tree (PVST), and the Multiple Spanning Tree Protocol (MSTP).

STP

STP was developed based on the 802.1d standard of IEEE to eliminate loops at the data link layer in a local area network (LAN). Networks often have redundant links as backups in case of failures, but loops are a very serious problem. Devices that run STP detect loops in the network by exchanging information with one another, and eliminate loops by selectively blocking certain ports to prune the loop structure into a loop-free tree structure. This avoids proliferation and infinite cycling of packets that would occur in a loop network, and prevents received duplicate packets from decreasing the performance of network devices.

In the narrow sense, STP refers to IEEE 802.1d STP. In the broad sense, STP refers to the IEEE 802.1d STP and various enhanced spanning tree protocols derived from that protocol.

STP protocol packets

STP uses bridge protocol data units (BPDUs), also known as configuration messages, as its protocol packets.

STP-enabled network devices exchange BPDUs to establish a spanning tree. BPDUs contain sufficient information for the network devices to complete spanning tree calculation.

STP uses the following types of BPDUs:

- **Configuration BPDUs**—Used by network devices to calculate a spanning tree and maintain the spanning tree topology
- **Topology change notification (TCN) BPDUs**—Notify network devices of the network topology changes

Configuration BPDUs contain sufficient information for the network devices to complete spanning tree calculation. Important fields in a configuration BPDU include the following:

- **Root bridge ID**—Consisting of the priority and MAC address of the root bridge.
- **Root path cost**—Cost of the path to the root bridge denoted by the root identifier from the transmitting bridge.
- **Designated bridge ID**—Consisting of the priority and MAC address of the designated bridge.
- **Designated port ID**—Consisting of the priority and global port number of the designated port.
- **Message age**—Age of the configuration BPDU while it propagates in the network.
- **Max age**—Maximum age of the configuration BPDU stored on the switch.
- **Hello time**—Configuration BPDU transmission interval.
- **Forward delay**—Delay that STP bridges use to transition port state.

Basic concepts in STP

Root bridge

A tree network must have a root bridge. The entire network contains only one root bridge. The root bridge is not permanent, but can change with changes of the network topology.

Upon initialization of a network, each device generates and periodically sends configuration BPDUs with itself as the root bridge. After network convergence, only the root bridge generates and periodically sends configuration BPDUs, and the other devices forward the BPDUs.

Root port

On a non-root bridge, the port nearest to the root bridge is the root port. The root port communicates with the root bridge. Each non-root bridge has only one root port. The root bridge has no root port.

Designated bridge and designated port

Table 8 Description of designated bridges and designated ports

Classification	Designated bridge	Designated port
For a device	Device directly connected with the local device and responsible for forwarding BPDUs to the local device	Port through which the designated bridge forwards BPDUs to this device
For a LAN	Device responsible for forwarding BPDUs to this LAN segment	Port through which the designated bridge forwards BPDUs to this LAN segment

As shown in Figure 17, Device B and Device C are directly connected to a LAN. If Device A forwards BPDUs to Device B through port A1, the designated bridge for Device B is Device A, and the designated port of Device B is port A1 on Device A. If Device B forwards BPDUs to the LAN, the designated bridge for the LAN is Device B, and the designated port for the LAN is port B2 on Device B.

Figure 17 Designated bridges and designated ports

Path cost

Path cost is a reference value used for link selection in STP. STP calculates path costs to select the most robust links and block redundant links that are less robust, to prune the network into a loop-free tree.

Calculation process of the STP algorithm

The spanning tree calculation process described in the following sections is a simplified process for example only.

The STP algorithm uses the following calculation process:

1. Initial state

Upon initialization of a device, each port generates a BPDU with the port as the designated port, the device as the root bridge, 0 as the root path cost, and the device ID as the designated bridge ID.

2. Root bridge selection

Initially, each STP-enabled device on the network assumes itself to be the root bridge, with its own device ID as the root bridge ID. By exchanging configuration BPDUs, the devices compare their root bridge IDs to elect the device with the smallest root bridge ID as the root bridge.

3. Non-root bridge: Selection of root port and designated ports

Table 9 Selection of the root port and designated ports

Step	Description
1	A non-root-bridge device regards the port on which it received the optimum configuration BPDU as the root port. Table 10 describes how the optimum configuration BPDU is selected.
2	Based on the configuration BPDU and the path cost of the root port, the device calculates a designated port configuration BPDU for each of the other ports. <ul style="list-style-type: none">• The root bridge ID is replaced with that of the configuration BPDU of the root port.• The root path cost is replaced with that of the configuration BPDU of the root port plus the path cost of the root port.• The designated bridge ID is replaced with the ID of this device.• The designated port ID is replaced with the ID of this port.
3	The device compares the calculated configuration BPDU with the configuration BPDU on the port whose port role will be defined, and acts depending on the result of the comparison. <ul style="list-style-type: none">• If the calculated configuration BPDU is superior, the device considers this port as the designated port, replaces the configuration BPDU on the port with the calculated configuration BPDU, and periodically sends the calculated configuration BPDU.• If the configuration BPDU on the port is superior, the device blocks this port without updating its configuration BPDU. The blocked port can receive BPDUs, but cannot send BPDUs or forward data traffic.

NOTE:

When the network topology is stable, only the root port and designated ports forward user traffic, while other ports are all in the blocked state to receive BPDUs but not forward BPDUs or user traffic.

Table 10 Selection of the optimum configuration BPDU

Step	Actions
1	<p>Upon receiving a configuration BPDU on a port, the device compares the priority of the received configuration BPDU with that of the configuration BPDU generated by the port, and:</p> <ul style="list-style-type: none"> • If the former priority is lower, the device discards the received configuration BPDU and keeps the configuration BPDU the port generated. • If the former priority is higher, the device replaces the content of the configuration BPDU generated by the port with the content of the received configuration BPDU.
2	The device compares the configuration BPDUs of all the ports and chooses the optimum configuration BPDU.

The following are the principles of configuration BPDU comparison:

- The configuration BPDU with the lowest root bridge ID has the highest priority.
- If configuration BPDUs have the same root bridge ID, their root path costs are compared. For example, the root path cost in a configuration BPDU plus the path cost of a receiving port is S. The configuration BPDU with the smallest S value has the highest priority.
- If all configuration BPDUs have the same ports value, their designated bridge IDs, designated port IDs, and the IDs of the receiving ports are compared in sequence. The configuration BPDU that contains the smallest ID wins.

A tree-shape topology forms when the root bridge, root ports, and designated ports are selected.

Figure 18 describes with an example how the STP algorithm works. This example shows a simplified spanning tree calculation process.

Figure 18 The STP algorithm

As shown in Figure 18, the priority values of Device A, Device B, and Device C are 0, 1, and 2, and the path costs of links among the three devices are 5, 10, and 4, respectively.

4. Initial state of each device

Table 11 Initial state of each device

Device	Port name	Configuration BPDU on the port
Device A	Port A1	{0, 0, 0, Port A1}
	Port A2	{0, 0, 0, Port A2}
Device B	Port B1	{1, 0, 1, Port B1}
	Port B2	{1, 0, 1, Port B2}
Device C	Port C1	{2, 0, 2, Port C1}
	Port C2	{2, 0, 2, Port C2}

NOTE:

In Table 11, each configuration BPDU contains the following fields: root bridge ID, root path cost, designated bridge ID, and designated port ID.

5. Comparison process and result on each device

Table 12 Comparison process and result on each device

Device	Comparison process	Configuration BPDU on ports after comparison
Device A	<ul style="list-style-type: none"> Port A1 receives the configuration BPDU of Port B1 {1, 0, 1, Port B1}, finds that its existing configuration BPDU {0, 0, 0, Port A1} is superior to the received configuration BPDU, and discards the received one. Port A2 receives the configuration BPDU of Port C1 {2, 0, 2, Port C1}, finds that its existing configuration BPDU {0, 0, 0, Port A2} is superior to the received configuration BPDU, and discards the received one. Device A finds that it is both the root bridge and designated bridge in the configuration BPDUs of all its ports, and considers itself as the root bridge. It does not change the configuration BPDU of any port and starts to periodically send configuration BPDUs. 	<ul style="list-style-type: none"> Port A1: {0, 0, 0, Port A1} Port A2: {0, 0, 0, Port A2}
Device B	<ul style="list-style-type: none"> Port B1 receives the configuration BPDU of Port A1 {0, 0, 0, Port A1}, finds that the received configuration BPDU is superior to its existing configuration BPDU {1, 0, 1, Port B1}, and updates its configuration BPDU. Port B2 receives the configuration BPDU of Port C2 {2, 0, 2, Port C2}, finds that its existing configuration BPDU {1, 0, 1, Port B2} is superior to the received configuration BPDU, and discards the received one. 	<ul style="list-style-type: none"> Port B1: {0, 0, 0, Port A1} Port B2: {1, 0, 1, Port B2}

Device	Comparison process	Configuration BPDU on ports after comparison
	<ul style="list-style-type: none"> Device B compares the configuration BPDUs of all its ports, decides that the configuration BPDU of Port B1 is the optimum, and selects Port B1 as the root port with the configuration BPDU unchanged. Based on the configuration BPDU and path cost of the root port, Device B calculates a designated port configuration BPDU for Port B2 {0, 5, 1, Port B2}, and compares it with the existing configuration BPDU of Port B2 {1, 0, 1, Port B2}. Device B finds that the calculated one is superior, decides that Port B2 is the designated port, replaces the configuration BPDU on Port B2 with the calculated one, and periodically sends the calculated configuration BPDU. 	<ul style="list-style-type: none"> Root port (Port B1): {0, 0, 0, Port A1} Designated port (Port B2): {0, 5, 1, Port B2}
	<ul style="list-style-type: none"> Port C1 receives the configuration BPDU of Port A2 {0, 0, 0, Port A2}, finds that the received configuration BPDU is superior to its existing configuration BPDU {2, 0, 2, Port C1}, and updates its configuration BPDU. Port C2 receives the original configuration BPDU of Port B2 {1, 0, 1, Port B2}, finds that the received configuration BPDU is superior to the existing configuration BPDU {2, 0, 2, Port C2}, and updates its configuration BPDU. 	<ul style="list-style-type: none"> Port C1: {0, 0, 0, Port A2} Port C2: {1, 0, 1, Port B2}
Device C	<ul style="list-style-type: none"> Device C compares the configuration BPDUs of all its ports, decides that the configuration BPDU of Port C1 is the optimum, and selects Port C1 as the root port with the configuration BPDU unchanged. Based on the configuration BPDU and path cost of the root port, Device C calculates the configuration BPDU of Port C2 {0, 10, 2, Port C2}, and compares it with the existing configuration BPDU of Port C2 {1, 0, 1, Port B2}. Device C finds that the calculated configuration BPDU is superior to the existing one, selects Port C2 as the designated port, and replaces the configuration BPDU of Port C2 with the calculated one. 	<ul style="list-style-type: none"> Root port (Port C1): {0, 0, 0, Port A2} Designated port (Port C2): {0, 10, 2, Port C2}
	<ul style="list-style-type: none"> Port C2 receives the updated configuration BPDU of Port B2 {0, 5, 1, Port B2}, finds that the received configuration BPDU is superior to its existing configuration BPDU {0, 10, 2, Port C2}, and updates its configuration BPDU. Port C1 receives a periodic configuration BPDU {0, 0, 0, Port A2} from Port A2, finds that it is the same as the existing configuration BPDU, and discards the received one. 	<ul style="list-style-type: none"> Port C1: {0, 0, 0, Port A2} Port C2: {0, 5, 1, Port B2}

Device	Comparison process	Configuration BPDU on ports after comparison
	<ul style="list-style-type: none"> Device C finds that the root path cost of Port C1 (10) (root path cost of the received configuration BPDU (0) plus path cost of Port C1 (10)) is larger than that of Port C2 (9) (root path cost of the received configuration BPDU (5) plus path cost of Port C2 (4)), decides that the configuration BPDU of Port C2 is the optimum, and selects Port C2 as the root port with the configuration BPDU unchanged. Based on the configuration BPDU and path cost of the root port, Device C calculates a designated port configuration BPDU for Port C1 {0, 9, 2, Port C1} and compares it with the existing configuration BPDU of Port C1 {0, 0, 0, Port A2}. Device C finds that the existing configuration BPDU is superior to the calculated one and blocks Port C1 with the configuration BPDU unchanged. Then Port C1 does not forward data until a new event triggers a spanning tree calculation process, for example, the link between Device B and Device C is down. 	<ul style="list-style-type: none"> Blocked port (Port C1): {0, 0, 0, Port A2} Root port (Port C2): {0, 5, 1, Port B2}

NOTE:

In Table 12, each configuration BPDU contains the following fields: root bridge ID, root path cost, designated bridge ID, and designated port ID.

After the comparison processes described in Table 12, a spanning tree with Device A as the root bridge is established, and the topology is shown in Figure 19.

Figure 19 The final calculated spanning tree

The configuration BPDU forwarding mechanism of STP

The configuration BPDUs of STP are forwarded following these guidelines:

- Upon network initiation, every device regards itself as the root bridge, generates configuration BPDUs with itself as the root, and sends the configuration BPDUs at a regular hello interval.
- If the root port received a configuration BPDU and the received configuration BPDU is superior to the configuration BPDU of the port, the device increases the message age carried in the configuration BPDU following a certain rule and starts a timer to time the configuration BPDU while sending this configuration BPDU through the designated port.
- If the configuration BPDU received on a designated port has a lower priority than the configuration BPDU of the local port, the port immediately sends its own configuration BPDU in response.

- If a path becomes faulty, the root port on this path no longer receives new configuration BPDUs and the old configuration BPDUs will be discarded due to timeout. The device generates a configuration BPDU with itself as the root and sends the BPDUs and TCN BPDUs. This triggers a new spanning tree calculation process to establish a new path to restore the network connectivity.

However, the newly calculated configuration BPDU cannot be propagated throughout the network immediately, so the old root ports and designated ports that have not detected the topology change continue forwarding data along the old path. If the new root ports and designated ports begin to forward data as soon as they are elected, a temporary loop might occur.

STP timers

The most important timing parameters in STP calculation are forward delay, hello time, and max age.

- Forward delay

Forward delay is the delay time for port state transition.

A path failure can cause spanning tree re-calculation to adapt the spanning tree structure to the change. However, the resulting new configuration BPDU cannot propagate throughout the network immediately. If the newly elected root ports and designated ports start to forward data immediately, a temporary loop will likely occur.

For this reason, as a mechanism for state transition in STP, the newly elected root ports or designated ports require twice the forward delay time before they transit to the forwarding state to make sure that the new configuration BPDU has propagated throughout the network.

- Hello time

The device sends hello packets at the hello time interval to the neighboring devices to make sure that the paths are fault-free.

- Max age

The device uses the max age to determine whether a stored configuration BPDU has expired and discards it if the max age is exceeded.

RSTP

RSTP achieves rapid network convergence by allowing a newly elected root port or designated port to enter the forwarding state much faster under certain conditions than STP.

A newly elected RSTP root port rapidly enters the forwarding state if the old root port on the device has stopped forwarding data and the upstream designated port has started forwarding data.

A newly elected RSTP designated port rapidly enters the forwarding state if it is an edge port (a port that directly connects to a user terminal rather than to another network device or a shared LAN segment) or it connects to a point-to-point link (to another device). Edge ports directly enter the forwarding state. Connecting to a point-to-point link, a designated port enters the forwarding state immediately after the device receives a handshake response from the directly connected device.

PVST

PVST was introduced to improve link bandwidth usage in network environments where multiple virtual LANs (VLANs) exist. Unlike STP and RSTP whose bridges in a LAN must forward their VLAN packets in the same spanning tree, PVST allows each VLAN to build a separate spanning tree.

PVST uses the following BPDUs:

- **STP BPDUs**—Sent by access ports according to the VLAN status, or by trunk ports and hybrid ports according to the status of VLAN 1.
- **PVST BPDUs**—Sent by trunk port and hybrid ports according to the status of permitted VLANs except VLAN 1.

MSTP

STP, RSTP, and PVST limitations

STP does not support rapid state transition of ports. A newly elected port must wait twice the forward delay time before it transits to the forwarding state, even if it connects to a point-to-point link or is an edge port.

Although RSTP supports rapid network convergence, it has the same drawback as STP—All bridges within a LAN share the same spanning tree, so redundant links cannot be blocked based on VLAN, and the packets of all VLANs are forwarded along the same spanning tree.

The number of PVST BPDUs generated grows with that of permitted VLANs on trunk ports. When the status of a trunk port transitions, network devices might be overloaded to re-calculate a large number of spanning trees.

MSTP features

Developed based on IEEE 802.1s, MSTP overcomes the limitations of STP, RSTP, and PVST. In addition to supporting rapid network convergence, it provides a better load sharing mechanism for redundant links by allowing data flows of different VLANs to be forwarded along separate paths.

MSTP provides the following features:

- MSTP supports mapping VLANs to spanning tree instances by means of a VLAN-to-instance mapping table. MSTP can reduce communication overheads and resource usage by mapping multiple VLANs to one instance.
- MSTP divides a switched network into multiple regions, each of which contains multiple spanning trees that are independent of one another.
- MSTP prunes a loop network into a loop-free tree, which avoids proliferation and endless cycling of packets in a loop network. In addition, it supports load balancing of VLAN data by providing multiple redundant paths for data forwarding.

MSTP basic concepts

Figure 20 shows a switched network that comprises four MST regions, each MST region comprising four MSTP devices. Figure 21 shows the networking topology of MST region 3.

Figure 20 Basic concepts in MSTP

Figure 21 Network diagram and topology of MST region 3

MST region

A multiple spanning tree region (MST region) consists of multiple devices in a switched network and the network segments among them. All these devices have the following characteristics:

- A spanning tree protocol enabled
- Same region name

- Same VLAN-to-instance mapping configuration
- Same MSTP revision level
- Physically linked together

Multiple MST regions can exist in a switched network. You can assign multiple devices to the same MST region. In [Figure 20](#), the switched network comprises four MST regions, MST region 1 through MST region 4, and all devices in each MST region have the same MST region configuration.

MSTI

MSTP can generate multiple independent spanning trees in an MST region, and each spanning tree is mapped to the specific VLANs. Each spanning tree is referred to as a multiple spanning tree instance (MSTI).

In [Figure 21](#), MST region 3 comprises three MSTIs, MSTI 1, MSTI 2, and MSTI 0.

VLAN-to-instance mapping table

As an attribute of an MST region, the VLAN-to-instance mapping table describes the mapping relationships between VLANs and MSTIs.

In [Figure 21](#), the VLAN-to-instance mapping table of MST region 3 is: VLAN 1 to MSTI 1, VLAN 2 and VLAN 3 to MSTI 2, and other VLANs to MSTI 0. MSTP achieves load balancing by means of the VLAN-to-instance mapping table.

CST

The common spanning tree (CST) is a single spanning tree that connects all MST regions in a switched network. If you regard each MST region as a device, the CST is a spanning tree calculated by these devices through STP or RSTP.

The blue lines in [Figure 20](#) represent the CST.

IST

An internal spanning tree (IST) is a spanning tree that runs in an MST region. It is also called MSTI 0, a special MSTI to which all VLANs are mapped by default.

In [Figure 20](#), MSTI 0 is the IST in MST region 3.

CIST

The common and internal spanning tree (CIST) is a single spanning tree that connects all devices in a switched network. It consists of the ISTs in all MST regions and the CST.

In [Figure 20](#), the ISTs (MSTI 0) in all MST regions plus the inter-region CST constitute the CIST of the entire network.

Regional root

The root bridge of the IST or an MSTI within an MST region is the regional root of the IST or MSTI. Based on the topology, different spanning trees in an MST region might have different regional roots.

For example, in MST region 3 in [Figure 21](#), the regional root of MSTI 1 is Device B, the regional root of MSTI 2 is Device C, and the regional root of MSTI 0 (also known as the IST) is Device A.

Common root bridge

The common root bridge is the root bridge of the CIST.

In [Figure 20](#), for example, the common root bridge is a device in MST region 1.

Port roles

A port can play different roles in different MSTIs. As shown in [Figure 22](#), an MST region comprises Device A, Device B, Device C, and Device D. Port A1 and port A2 of Device A connect to the common root bridge. Port B2 and Port B3 of Device B form a loop. Port C3 and Port C4 of Device C connect to other MST regions. Port D3 of Device D directly connects to a host.

Figure 22 Port roles

MSTP calculation involves the following port roles:

- **Root port**—Forwards data for a non-root bridge to the root bridge. The root bridge does not have any root port.
- **Designated port**—Forwards data to the downstream network segment or device.
- **Alternate port**—The backup port for a root port or master port. When the root port or master port is blocked, the alternate port takes over.
- **Backup port**—The backup port of a designated port. When the designated port is invalid, the backup port becomes the new designated port. A loop occurs when two ports of the same spanning tree device are interconnected, so the device blocks one of the ports. The blocked port acts as the backup.
- **Edge port**—An edge port does not connect to any network device or network segment, but directly connects to a user host.
- **Master port**—A port on the shortest path from the local MST region to the common root bridge. The master port is not always located on the regional root. It is a root port on the IST or CIST and still a master port on the other MSTIs.
- **Boundary port**—Connects an MST region to another MST region or to an STP/RSTP-running device. In MSTP calculation, a boundary port's role on an MSTI is consistent with its role on the CIST. But that is not true with master ports. A master port on MSTIs is a root port on the CIST.

Port states

In MSTP, a port can be in one of the following states:

- **Forwarding**—The port receives and sends BPDUs, obtains MAC addresses, and forwards user traffic.
- **Learning**—The port receives and sends BPDUs, obtains MAC addresses, but does not forward user traffic. Learning is an intermediate port state.
- **Discarding**—The port receives and sends BPDUs, but does not obtain MAC addresses or forward user traffic.

When in different MSTIs, a port can be in different states. A port state is not exclusively associated with a port role. Table 13 lists the port states that each port role supports. (A check mark [✓] indicates that the port supports this state, while a dash [—] indicates that the port does not support this state.)

Table 13 Port states that different port roles support

Port state (below)	Port role (right) Root port/master port	Designated port	Alternate port	Backup port
Forwarding	✓	✓	—	—
Learning	✓	✓	—	—
Discarding	✓	✓	✓	✓

How MSTP works

MSTP divides an entire Layer 2 network into multiple MST regions, which are connected by a calculated CST. Inside an MST region, multiple spanning trees are calculated. Each spanning tree is an MSTI. Among these MSTIs, MSTI 0 is the IST. Like STP, MSTP uses configuration BPDUs to calculate spanning trees. An important difference is that an MSTP BPDU carries the MSTP configuration of the bridge from which the BPDU is sent.

CIST calculation

The calculation of a CIST tree is also the process of configuration BPDU comparison. During this process, the device with the highest priority is elected as the root bridge of the CIST. MSTP generates an IST within each MST region through calculation. At the same time, MSTP regards each MST region as a single device and generates a CST among these MST regions through calculation. The CST and ISTs constitute the CIST of the entire network.

MSTI calculation

Within an MST region, MSTP generates different MSTIs for different VLANs based on the VLAN-to-instance mappings. For each spanning tree, MSTP performs a separate calculation process similar to spanning tree calculation in STP. For more information, see "[Calculation process of the STP algorithm.](#)"

In MSTP, a VLAN packet is forwarded along the following paths:

- Within an MST region, the packet is forwarded along the corresponding MSTI.
- Between two MST regions, the packet is forwarded along the CST.

Implementation of MSTP on devices

MSTP is compatible with STP and RSTP. Devices that are running MSTP and that are used for spanning tree calculation can identify STP and RSTP protocol packets.

In addition to basic MSTP functions, the following functions are provided for ease of management:

- Root bridge hold
- Root bridge backup
- Root guard
- BPDU guard
- Loop guard
- TC-BPDU guard
- BPDU drop.

Protocols and standards

The spanning tree protocols are documented in the following standards:

- IEEE 802.1d, *Media Access Control (MAC) Bridges*
- IEEE 802.1w, *Part 3: Media Access Control (MAC) Bridges—Amendment 2: Rapid Reconfiguration*
- IEEE 802.1s, *Virtual Bridged Local Area Networks—Amendment 3: Multiple Spanning Trees*

Spanning tree configuration task list

Before configuring a spanning tree, you must determine the spanning tree protocol to be used (STP, RSTP, PVST, or MSTP) and plan the device roles (the root bridge or leaf node).

Configuration restrictions and guidelines

- If GVRP and a spanning tree protocol are enabled on a device at the same time, GVRP packets are forwarded along the CIST. To advertise a certain VLAN within the network through GVRP, be sure that this VLAN is mapped to the CIST when you configure the VLAN-to-instance mapping table. For more information about GVRP, see "[Configuring GVRP](#)."
- The spanning tree configurations are mutually exclusive with any of the following functions on a port: service loopback, RRPP, Smart Link, and BPDU tunneling for STP.
- The spanning tree configurations made in system view take effect globally. Configurations made in Layer 2 Ethernet interface view take effect on the current interface only. Configurations made in port group view take effect on all member ports in the port group. Configurations made in Layer 2 aggregate interface view take effect only on the aggregate interface. Configurations made on an aggregation member port can take effect only after the port is removed from the aggregation group.
- After you enable a spanning tree protocol on a Layer 2 aggregate interface, the system performs spanning tree calculation on the Layer 2 aggregate interface but not on the aggregation member ports. The spanning tree protocol enable state and forwarding state of each selected member port is consistent with those of the corresponding Layer 2 aggregate interface.
- Though the member ports of an aggregation group do not participate in spanning tree calculation, the ports still reserve their spanning tree configurations for participating in spanning tree calculation after leaving the aggregation group.

STP configuration task list

Task	Remarks
Configuring the root bridge	Setting the spanning tree mode Required Configure the device to operate in STP-compatible mode.
	Configuring the root bridge or a secondary root bridge Optional
	Configuring the device priority Optional
	Configuring the network diameter of a switched network Optional
	Configuring spanning tree timers Optional
	Configuring the timeout factor Optional
	Configuring the maximum port rate Optional
	Configuring the mode a port uses to recognize/send MSTP packets Optional
	Enabling outputting port state transition information Optional
	Enabling the spanning tree feature Required
Configuring the leaf nodes	Setting the spanning tree mode Required Configure the device to operate in STP-compatible mode.
	Configuring the device priority Optional
	Configuring the timeout factor Optional
	Configuring the maximum port rate Optional
	Configuring path costs of ports Optional
	Configuring the port priority Optional
	Configuring the mode a port uses to recognize/send MSTP packets Optional
	Enabling outputting port state transition information Optional
Enabling the spanning tree feature Required	
Configuring TC snooping Optional	
Configuring protection functions Optional	

RSTP configuration task list

Task	Remarks
Configuring the root bridge	Setting the spanning tree mode Required Configure the device to operate in RSTP mode.
	Configuring the root bridge or a secondary root bridge Optional
	Configuring the device priority Optional
	Configuring the network diameter of a switched network Optional

Task	Remarks
Configuring spanning tree timers	Optional
Configuring the timeout factor	Optional
Configuring the maximum port rate	Optional

Configuring No Agreement Check	Optional	
Configuring protection functions	Optional	

Setting the spanning tree mode

The spanning tree modes include:

- **STP-compatible mode**—The device sends STP BPDUs through all ports.
- **RSTP mode**—The device sends RSTP BPDUs through all ports, and ports that connect to STP devices automatically transitions to the STP-compatible mode.
- **MSTP mode**—The device sends MSTP BPDUs through all ports, and ports that connect to STP devices automatically transitions to the STP-compatible mode.
- **PVST mode**—The device sends PVST BPDUs through all ports and maintains a spanning tree for each VLAN. The number of VLANs that PVST can maintain instances for depends on the switch model. Suppose the number is n , which is 128 on the 5500 EI Switch Series and 32 on the 5500 SI Switch Series. When you configure PVST on devices of different models in a network, to avoid network failures, make sure that the number of VLANs for which PVST maintains instances does not exceed the lowest n .

The MSTP mode is compatible with the RSTP mode, and the RSTP mode is compatible with the STP mode. The PVST mode's compatibility with the other spanning tree mode varies by port type:

- On an access port, the PVST mode is compatible with any other spanning tree mode in any VLAN.
- On a trunk or hybrid port, the PVST mode is compatible with any other spanning tree mode in only VLAN 1.

Whether you need to specify the MSTI or VLAN for the spanning tree configuration varies with the spanning tree modes.

- In STP-compatible or RSTP mode, do not specify any MSTI or VLAN. Otherwise, the spanning tree configuration is ineffective.
- In MSTP mode, if you specify an MSTI, the spanning tree configuration is effective for the specified MSTI. If you specify a VLAN list, the spanning tree configuration is ineffective. If you do not specify any MSTI or VLAN, the spanning tree configuration is effective for the CIST.
- In PVST mode, if you specify a VLAN list, the spanning tree configuration is effective for the specified VLANs. If you do not specify any VLAN, the spanning tree configuration is ineffective.

To set the spanning tree mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the spanning tree mode.	stp mode { stp rstp mstp pvst }	MSTP mode by default.

Configuring an MST region

Two or more spanning tree devices belong to the same MST region only if they are configured to have the same format selector (0 by default, not configurable), MST region name, MST region revision level, and the same VLAN-to-instance mapping entries in the MST region, and they are connected via a physical link.

Configuration restrictions and guidelines

- The configuration of MST region-related parameters, especially the VLAN-to-instance mapping table, will result in a new spanning tree calculation. To reduce the possibility of topology instability, the MST region configuration takes effect only after you activate it by using the **active region-configuration** command, or enable a spanning tree protocol by using the **stp enable** command in the case that the spanning tree protocol is disabled.
- The device in PVST mode automatically maps VLANs to MSTIs, and supports more MSTIs than in MSTP mode. When you change the spanning tree mode from PVST to MSTP, exceeding VLAN-to-instance mappings (arranged in ascending order of MSTI IDs) are silently deleted and cannot be recovered even if you change the spanning tree mode back. To prevent loss of mappings, do not manually configure VLAN-to-instance mappings in PVST mode.

Configuration procedure

To configure an MST region:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter MST region view.	stp region-configuration	N/A
3. Configure the MST region name.	region-name <i>name</i>	Optional. The MST region name is the MAC address by default.
4. Configure the VLAN-to-instance mapping table.	<ul style="list-style-type: none"> instance <i>instance-id</i> vlan <i>vlan-list</i> vlan-mapping modulo <i>modulo</i> 	Optional. Use either command. All VLANs in an MST region are mapped to the CIST (or MSTI 0) by default.
5. Configure the MSTP revision level of the MST region.	revision-level <i>level</i>	Optional. 0 by default.
6. Display the MST region configurations that are not activated yet.	check region-configuration	Optional.
7. Activate MST region configuration manually.	active region-configuration	N/A
8. Display the activated configuration information of the MST region.	display stp region-configuration [{ begin exclude include } <i>regular-expression</i>]	Optional. Available in any view

Configuring the root bridge or a secondary root bridge

You can have MSTP determine the root bridge of a spanning tree through MSTP calculation, or you can specify the current device as the root bridge or as a secondary root bridge using the commands that the system provides.

A device has independent roles in different spanning trees. It can act as the root bridge in one spanning tree and as a secondary root bridge in another. However, one device cannot be the root bridge and a secondary root bridge in the same spanning tree.

A spanning tree can have one root bridge only. If two or more devices are designated as the root bridge in a spanning tree at the same time, the device with the lowest MAC address wins.

When the root bridge of an instance fails or is shut down, the secondary root bridge (if you have specified one) can take over the role of the primary root bridge. However, if you specify a new primary root bridge for the instance then, the one you specify, not the secondary root bridge will become the root bridge. If you have specified multiple secondary root bridges for an instance, when the root bridge fails, the secondary root bridge with the lowest MAC address is selected as the new root bridge.

Configuration restrictions and guidelines

- You can specify one root bridge for each spanning tree, regardless of the device priority settings. Once you specify a device as the root bridge or a secondary root bridge, you cannot change its priority.

- You can configure the current device as the root bridge by setting the device priority to 0. For the device priority configuration, see "[Configuring the device priority](#)."

Configuring the current device as the root bridge of a specific spanning tree

To configure the current device as the root bridge of a specific spanning tree:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the current device as the root bridge.	<ul style="list-style-type: none"> In STP/RSTP mode: stp root primary In PVST mode: stp vlan <i>vlan-list</i> root primary In MSTP mode: stp [<i>instance instance-id</i>] root primary 	<p>Use one of the commands.</p> <p>By default, a device does not function as the root bridge.</p>

Configuring the current device as a secondary root bridge of a specific spanning tree

To configure the current device as a secondary root bridge of a specific spanning tree:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the current device as a secondary root bridge.	<ul style="list-style-type: none"> In STP/RSTP mode: stp root secondary In PVST mode: stp vlan <i>vlan-list</i> root secondary In MSTP mode: stp [<i>instance instance-id</i>] root secondary 	<p>Use one of the commands.</p> <p>By default, a device does not function as a secondary root bridge.</p>

Configuring the device priority

⚠ CAUTION:

- You cannot change the priority of a device after it is configured as the root bridge or as a secondary root bridge.
- During root bridge selection, if all devices in a spanning tree have the same priority, the one with the lowest MAC address will be selected as the root bridge of the spanning tree.

Device priority is a factor in spanning tree calculation. The priority of a device determines whether the device can be elected as the root bridge of a spanning tree. A lower numeric value indicates a higher priority. You can set the priority of a device to a low value to specify the device as the root bridge of the spanning tree. A spanning tree device can have different priorities in different MSTIs.

To configure the priority of a device in a specified MSTI:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the priority of the current device.	<ul style="list-style-type: none"> In STP/RSTP mode: stp priority <i>priority</i> In PVST mode: stp vlan <i>vlan-list</i> priority <i>priority</i> In MSTP mode: stp [instance <i>instance-id</i>] priority <i>priority</i> 	Use one of the commands. The default setting is 32768.

Configuring the maximum hops of an MST region

By setting the maximum hops of an MST region, you can restrict the region size. The maximum hops configured on the regional root bridge will be used as the maximum hops of the MST region.

Configuration BPDUs sent by the regional root bridge always have a hop count set to the maximum value. When a device receives this configuration BPDU, it decrements the hop count by 1, and uses the new hop count in the BPDUs that it propagates. When the hop count of a BPDU reaches 0, it is discarded by the device that received it. This prevents devices beyond the reach of the maximum hop from participate in spanning tree calculation, so the size of the MST region is limited.

Make this configuration on the root bridge only. All other devices in the MST region use the maximum hop value set for the root bridge.

To configure the maximum number of hops of an MST region:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the maximum hops of the MST region.	stp max-hops <i>hops</i>	20 by default.

Configuring the network diameter of a switched network

Any two terminal devices in a switched network are connected through a specific path composed of a series of devices. The network diameter is the number of devices on the path composed of the most devices. The network diameter is a parameter that indicates the network size. A bigger network diameter indicates a larger network size. Based on the network diameter you configured, the system automatically sets an optimal hello time, forward delay, and max age for the device.

To configure the network diameter of a switched network:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Configure the network diameter of the switched network.	<ul style="list-style-type: none"> In STP/RSTP/MSTP mode: stp bridge-diameter <i>diameter</i> In PVST mode: stp vlan <i>vlan-list</i> bridge-diameter <i>diameter</i> 	<p>Use one of the commands.</p> <p>The default setting is 7.</p>

NOTE:

- In STP/RSTP/MSTP mode, each MST region is considered as a device and the configured network diameter is effective only for the CIST (or the common root bridge), but not for MSTIs.
- In PVST mode, the network diameter configuration is effective on the root bridge only.

Configuring spanning tree timers

The following timers are used for spanning tree calculation:

- Forward delay

It is the delay time for port state transition. To prevent temporary loops on a network, the spanning tree sets an intermediate port state, the learning state, before it transitions from the discarding state to the forwarding state, and requires that the port transitions its state after a forward delay timer to make sure that the state transition of the local port keeps synchronized with the peer.
- Hello time

The device detects whether a link failure has occurred with the hello time interval. The spanning tree sends a configuration BPDU every hello time interval. If the device receives no configuration BPDUs within the hello time interval, it recalculates the spanning tree.
- Max age

In the CIST of an MSTP network or each VLAN of a PVST network, the device uses the max age parameter to determine whether a configuration BPDU received by a port has expired. If a port receives a configuration BPDU that has expired, that MSTI must be re-calculated. The max age timer is ineffective for MSTIs.

To avoid frequent network changes, be sure that the settings of the hello time, forward delay and max age timers meet the following formulas:

 - $2 \times (\text{forward delay} - 1 \text{ second}) \leq \text{max age}$
 - $\text{Max age} \leq 2 \times (\text{hello time} + 1 \text{ second})$

HP does not recommend you to manually set the spanning tree timers. Instead, you can specify the network diameter and let spanning tree protocols automatically calculate the timers based on the network diameter. If the network diameter uses the default value, the timers also use their default values.

Configure the timers on the root bridge only, and the timer settings on the root bridge apply to all devices on the entire switched network.

Configuration restrictions and guidelines

- The length of the forward delay timer is related to the network diameter of the switched network. The larger the network diameter is, the longer the forward delay time should be. If the forward delay timer is too short, temporary redundant paths might occur. If the forward delay timer is too long, network convergence might take a long time. HP recommends you to use the default setting.

- An appropriate hello time setting enables the device to quickly detect link failures on the network without using excessive network resources. If the hello time is too long, the device will mistake packet loss as a link failure and trigger a new spanning tree calculation process. If the hello time is too short, the device will frequently send the same configuration BPDUs, which adds the device burden and wastes network resources. HP recommends you to use the default setting.
- If the max age timer is too short, the device will frequently begin spanning tree calculation and might mistake network congestion as a link failure. If the max age timer is too long, the device might fail to quickly detect link failures and begin spanning tree calculations, reducing the auto-sensing capability of the network. HP recommends you to use the default setting.

Configuration procedure

To configure the spanning tree timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the forward delay timer.	<ul style="list-style-type: none"> • In STP/RSTP/MSTP mode: stp timer forward-delay time • In PVST mode: stp vlan vlan-list timer forward-delay time 	<p>Optional. Use one of the commands. The default setting is 15 seconds.</p>
3. Configure the hello timer.	<ul style="list-style-type: none"> • In STP/RSTP/MSTP mode: stp timer hello time • In PVST mode: stp vlan vlan-list timer hello time 	<p>Optional. Use one of the commands. The default setting is 2 seconds.</p>
4. Configure the max age timer.	<ul style="list-style-type: none"> • In STP/RSTP/MSTP mode: stp timer max-age time • In PVST mode: stp vlan vlan-list timer max-age time 	<p>Optional. Use one of the commands. The default setting is 20 seconds.</p>

Configuring the timeout factor

The timeout factor is a parameter used to decide the timeout time, in the following formula: Timeout time = timeout factor × 3 × hello time.

After the network topology is stabilized, each non-root-bridge device forwards configuration BPDUs to the downstream devices at the interval of hello time to determine whether any link is faulty. If a device does not receive a BPDU from the upstream device within nine times the hello time, it assumes that the upstream device has failed and starts a new spanning tree calculation process.

Sometimes a device might fail to receive a BPDU from the upstream device because the upstream device is busy. If a spanning tree calculation occurs, the calculation can fail and also waste network resources. In a stable network, you can prevent undesired spanning tree calculations by setting the timeout factor to 5, 6, or 7.

To configure the timeout factor:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Configure the timeout factor of the device.	stp timer-factor <i>factor</i>	3 by default.

Configuring the maximum port rate

The maximum rate of a port refers to the maximum number of BPDUs the port can send within each hello time. The maximum rate of a port is related to the physical status of the port and the network structure.

The higher the maximum port rate is, the more BPDUs will be sent within each hello time, and the more system resources will be used. By setting an appropriate maximum port rate, you can limit the rate at which the port sends BPDUs and prevent spanning tree protocols from using excessive network resources when the network becomes unstable. HP recommends you to use the default setting.

To configure the maximum rate of a port or a group of ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use one of the commands.
3. Configure the maximum rate of the ports.	stp transmit-limit <i>limit</i>	10 by default.

Configuring edge ports

If a port directly connects to a user terminal rather than another device or a shared LAN segment, this port is regarded as an edge port. When network topology change occurs, an edge port will not cause a temporary loop. Because a device does not determine whether a port is directly connected to a terminal, you must manually configure the port as an edge port. After that, the port can transition rapidly from the blocked state to the forwarding state.

Configuration restrictions and guidelines

- If BPDU guard is disabled, a port set as an edge port will become a non-edge port again if it receives a BPDU from another port. To restore the edge port, re-enable it.
- If a port directly connects to a user terminal, configure it as an edge port and enable BPDU guard for it. This enables the port to transition to the forwarding state quickly while ensuring network security.
- You cannot configure edge port settings and loop guard on a port at the same time.

Configuration procedure

To specify a port or a group of ports as edge port or ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use one of the commands.
3. Configure the current ports as edge ports.	stp edged-port enable	All ports are non-edge ports by default.

Configuring path costs of ports

Path cost is a parameter related to the rate of a port. On a spanning tree device, a port can have different path costs in different MSTIs. Setting appropriate path costs allows VLAN traffic flows to be forwarded along different physical links, achieving VLAN-based load balancing.

You can have the device automatically calculate the default path cost, or you can configure the path cost for ports.

Specifying a standard for the device to use when it calculates the default path cost

⚠ CAUTION:

If you change the standard that the device uses to calculate the default path costs, you restore the path costs to the default.

You can specify a standard for the device to use in automatic calculation for the default path cost. The device supports the following standards:

- **dot1d-1998**—The device calculates the default path cost for ports based on IEEE 802.1d-1998.
- **dot1t**—The device calculates the default path cost for ports based on IEEE 802.1t.
- **legacy**—The device calculates the default path cost for ports based on a private standard.

Table 14 shows the mappings between the link speed and the path cost.

Table 14 Mappings between the link speed and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
0	N/A	65535	200,000,000	200,000
10 Mbps	Single port		2,000,000	2000
	Aggregate interface containing 2 Selected ports	100	1,000,000	1800
	Aggregate interface containing 3 Selected ports		666,666	1600

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
100 Mbps	Aggregate interface containing 4 Selected ports	19	500,000	1400
	Single port		200,000	200
	Aggregate interface containing 2 Selected ports		100,000	180
	Aggregate interface containing 3 Selected ports		66,666	160
	Aggregate interface containing 4 Selected ports		50,000	140
1000 Mbps	Single port	4	20,000	20
	Aggregate interface containing 2 Selected ports		10,000	18
	Aggregate interface containing 3 Selected ports		6666	16
	Aggregate interface containing 4 Selected ports		5000	14
10 Gbps	Single port	2	2000	2
	Aggregate interface containing 2 Selected ports		1000	1
	Aggregate interface containing 3 Selected ports		666	1
	Aggregate interface containing 4 Selected ports		500	1

Configuration restrictions and guidelines

- When it calculates path cost for an aggregate interface, IEEE 802.1t takes into account the number of Selected ports in its aggregation group, but IEEE 802.1d-1998 does not. The calculation formula of IEEE 802.1t is: Path cost = 200,000,000/link speed (in 100 kbps), where link speed is the sum of the link speed values of the Selected ports in the aggregation group.
- When multiple ports operate at a rate higher than 10 Gbps and the standard for default path cost calculation is **dot1d-1998** or **legacy**, the path cost of a single port or an aggregate interface takes the smallest value. As a result, the forwarding path selected might not be optimal. To solve this problem, use **dot1t** as the standard for default path cost calculation, or manually set the path cost for a port ([Configuring path costs of ports](#)).

Configuration procedure

To specify a standard for the device to use when it calculates the default path cost:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Specify a standard for the device to use when it calculates the default path costs of its ports.	stp pathcost-standard { dot1d-1998 dot1t legacy }	Optional. legacy by default.

Configuring path costs of ports

When the path cost of a port changes, the system re-calculates the role of the port and initiates a state transition.

To configure the path cost of ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use one of the commands.
3. Configure the path cost of the ports.	<ul style="list-style-type: none"> In STP/RSTP mode: stp cost <i>cost</i> In PVST mode: stp vlan <i>vlan-list</i> cost <i>cost</i> In MSTP mode: stp [instance <i>instance-id</i>] cost <i>cost</i> 	Use one of the commands. By default, the system automatically calculates the path cost of each port.

Configuration example

In MSTP mode, specify the device to calculate the default path costs of its ports by using IEEE 802.1d-1998, and set the path cost of GigabitEthernet 1/0/3 to 200 on MSTI 2.

```
<Sysname> system-view
[Sysname] stp pathcost-standard dot1d-1998
[Sysname] interface gigabitethernet 1/0/3
[Sysname-GigabitEthernet1/0/3] stp instance 2 cost 200
```

In PVST mode, specify the device to calculate the default path costs of its ports by using IEEE 802.1d-1998, and set the path cost of GigabitEthernet 1/0/3 to 2000 on VLANs 20 through 30.

```
<Sysname> system-view
[Sysname] stp mode pvst
[Sysname] stp pathcost-standard dot1d-1998
[Sysname] interface gigabitethernet 1/0/3
[Sysname-GigabitEthernet1/0/3] stp vlan 20 to 30 cost 2000
```

Configuring the port priority

When the priority of a port changes, MSTP re-calculates the role of the port and initiates a state transition. The priority of a port is an important factor in determining whether the port can be elected as the root port of a device. If all other conditions are the same, the port with the highest priority will be elected as the root port.

On a spanning tree device, a port can have different priorities and play different roles in different spanning trees, so that data of different VLANs can be propagated along different physical paths, implementing per-VLAN load balancing. You can set port priority values based on the actual networking requirements.

To configure the priority of a port or a group of ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none">Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i>Enter port group view: port-group manual <i>port-group-name</i>	Use one of the commands.
3. Configure the port priority.	<ul style="list-style-type: none">In STP/RSTP mode: stp port priority <i>priority</i>In PVST mode: stp vlan <i>vlan-list</i> port priority <i>priority</i>In MSTP mode: stp [instance <i>instance-id</i>] port priority <i>priority</i>	Use one of the commands. The default setting is 128.

Configuring the port link type

A point-to-point link directly connects two devices. If two root ports or designated ports are connected over a point-to-point link, they can rapidly transition to the forwarding state after a proposal-agreement handshake process.

Configuration restrictions and guidelines

- You can configure the link type as point-to-point for a Layer 2 aggregate interface or a port that operates in full duplex mode. HP recommends you to use the default setting and let the device to automatically detect the port link type.
- The **stp point-to-point force-false** or **stp point-to-point force-true** command configured on a port in MSTP or PVST mode is effective for all MSTIs or VLANs.
- If the physical link to which the port connects is not a point-to-point link but you set it to be one, the configuration might bring a temporary loop.

Configuration procedure

To configure the link type of a port or a group of ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use one of the commands.
3. Configure the port link type.	stp point-to-point { auto force-false force-true }	By default, the link type is auto where the port automatically detects the link type.

Configuring the mode a port uses to recognize/send MSTP packets

A port can receive/send MSTP packets in the following formats:

- **dot1s**—802.1s-compliant standard format
- **legacy**—Compatible format

By default, the packet format recognition mode of a port is **auto**. The port automatically distinguishes the two MSTP packet formats, and determines the format of packets that it will send based on the recognized format.

You can configure the MSTP packet format on a port. When operating in MSTP mode after the configuration, the port sends and receives only MSTP packets of the format that you have configured to communicate with devices that send packets of the same format.

MSTP provides MSTP packet format incompatibility guard. In MSTP mode, if a port is configured to recognize/send MSTP packets in a mode other than **auto**, and if it receives a packet in a format different from the specified type, the port becomes a designated port and remains in the discarding state to prevent the occurrence of a loop.

MSTP provides MSTP packet format frequent change guard. If a port receives MSTP packets of different formats frequently, the MSTP packet format configuration contains errors. If the port is operating in MSTP mode, it will be shut down for protection. Ports disabled in this way can be re-activated after a detection interval. For more information about the detection interval, see *Fundamentals Configuration Guide*.

To configure the MSTP packet format to be supported on a port or a group of ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use one of the commands.

Step	Command	Remarks
3. Configure the mode that the port uses to recognize/send MSTP packets.	stp compliance { auto dot1s legacy }	auto by default.

Enabling outputting port state transition information

In a large-scale spanning tree network, you can enable devices to output the port state transition information of all MSTIs or the specified MSTI in order to monitor the port states in real time.

To enable outputting port state transition information:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable outputting port state transition information.	<ul style="list-style-type: none"> In STP/RSTP mode: stp port-log instance 0 In PVST mode: stp port-log vlan <i>vlan-list</i> In MSTP mode: stp port-log instance { <i>instance-id</i> all } 	Use one of the commands. Enabled by default.

Enabling the spanning tree feature

You must enable the spanning tree feature for the device before any other spanning tree related configurations can take effect.

Configuration restrictions and guidelines

- To globally enable or disable the spanning tree feature (not for VLANs), use the **stp enable** command or **undo stp enable** command in system view. To enable or disable the spanning tree feature for specific VLANs, use the **stp vlan enable** command or **undo stp vlan enable** command.
- You can disable the spanning tree feature for certain ports with the **undo stp enable** command to exclude them from spanning tree calculation and save CPU resources of the device.
- In PVST mode, when you globally enable the spanning tree feature, the device automatically enables the spanning tree feature for the first n (which is the number of PVST instances that the switch supports and is 128 for the 5500 EI switch and 32 for the 5500 SI switch) of the existing VLANs by default. To enable the spanning tree feature for other VLANs, you must first disable the spanning tree feature for certain VLANs. This guideline does not apply if the number of existing VLANs on the switch does not exceed n .

Enabling the spanning tree feature (in STP/RSTP/MSTP mode)

In STP/RSTP/MSTP mode, make sure that the spanning tree feature is enabled globally and on the desired ports.

To enable the spanning tree feature in STP/RSTP/MSTP mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the spanning tree feature globally.	stp enable	By default, the spanning tree feature is disabled globally.
3. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
4. Enable the spanning tree feature for the port or group of ports.	stp enable	Optional. By default, the spanning tree feature is enabled for all ports.

Enabling the spanning tree feature (in PVST mode)

In PVST mode, make sure that the spanning tree feature is enabled globally and on the desired VLANs and ports.

To enable the spanning tree feature in PVST mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Globally enable the spanning tree feature.	stp enable	By default, the spanning tree feature is disabled globally.
3. Enable the spanning tree feature on specific VLANs.	stp vlan <i>vlan-list</i> enable	By default, the spanning tree feature is enabled on VLANs.
4. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
5. Enable the spanning tree feature for the port or group of ports.	stp enable	Optional. By default, the spanning tree feature is enabled on all ports.

Performing mCheck

If a port on a device that is running MSTP, RSTP, or PVST connects to an STP device, this port automatically transitions to the STP-compatible mode. However, it cannot automatically transition back to the original mode under the following circumstances:

- The STP device is shut down or removed.
- The STP device transitions to the MSTP, RSTP, or PVST mode.

Suppose Device A running STP, Device B with no spanning tree feature enabled, and Device C running RSTP or MSTP are connected in order. Device B will transparently transmit the STP BPDUs, and the port on Device C and connecting to Device B will transition to the STP mode. After you enable the spanning tree feature on Device B, to run RSTP or MSTP between Device B and Device C, you must perform an mCheck operation on the ports interconnecting Device B and Device C, in addition to configuring the spanning tree to operate in RSTP or MSTP mode on Device B.

To forcibly transition the port to operate in the original mode, you can perform an mCheck operation. The following methods for performing mCheck produce the same result.

Performing mCheck globally

Step	Command
1. Enter system view.	system-view
2. Perform mCheck.	stp mcheck

Performing mCheck in interface view

Step	Command
1. Enter system view.	system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.	interface <i>interface-type interface-number</i>
3. Perform mCheck.	stp mcheck

NOTE:

An mCheck operation takes effect on a device that operates in MSTP, RSTP, or PVST mode.

Configuring Digest Snooping

As defined in IEEE 802.1s, connected devices are in the same region only when their MST region-related configurations (region name, revision level, and VLAN-to-instance mappings) are identical. A spanning tree device identifies devices in the same MST region by determining the configuration ID in BPDU packets. The configuration ID includes the region name, revision level, and configuration digest, which is in 16-byte length and is the result calculated via the HMAC-MD5 algorithm based on VLAN-to-instance mappings.

Spanning tree implementations vary with vendors, and the configuration digests calculated using private keys is different, so devices of different vendors in the same MST region cannot communicate with each other.

To enable communication between an HP device and a third-party device, enable the Digest Snooping feature on the port that connects the HP device to the third-party device in the same MST region.

Configuration restrictions and guidelines

- Before you enable Digest Snooping, make sure that associated devices of different vendors are connected and run spanning tree protocols.

- With digest snooping enabled, in-the-same-region verification does not require comparison of configuration digest, so the VLAN-to-instance mappings must be the same on associated ports.
- With global Digest Snooping enabled, modification of VLAN-to-instance mappings and removal of the current region configuration via the **undo stp region-configuration** command are not allowed. You can modify only the region name and revision level.
- To make Digest Snooping take effect, you must enable it both globally and on associated ports. To make the configuration effective on all configured ports and while reducing impact on the network, enable Digest Snooping on all associated ports first and then globally.
- To prevent loops, do not enable Digest Snooping on MST region edge ports.
- HP recommends you to enable Digest Snooping first and then the spanning tree feature. To avoid causing traffic interruption, do not configure Digest Snooping when the network is already working well.

Configuration procedure

You can enable Digest Snooping only on the HP device that is connected to a third-party device that uses its private key to calculate the configuration digest.

To configure Digest Snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> • Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable Digest Snooping on the interface or port group.	stp config-digest-snooping	Disabled by default.
4. Return to system view.	quit	N/A
5. Enable global Digest Snooping.	stp config-digest-snooping	Disabled by default.

Digest Snooping configuration example

Network requirements

As shown in [Figure 23](#), Device A and Device B connect to Device C, which is a third-party device. All these devices are in the same region.

Enable Digest Snooping on the ports of Device A and Device B that connect to Device C, so that the three devices can communicate with one another.

Figure 23 Digest Snooping configuration

Configuration procedure

Enable Digest Snooping on GigabitEthernet 1/0/1 of Device A and enable global Digest Snooping on Device A.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] stp config-digest-snooping
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] stp config-digest-snooping
```

Enable Digest Snooping on GigabitEthernet 1/0/1 of Device B and enable global Digest Snooping on Device B.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] stp config-digest-snooping
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] stp config-digest-snooping
```

Configuring No Agreement Check

In RSTP and MSTP, the following types of messages are used for rapid state transition on designated ports:

- **Proposal**—Sent by designated ports to request rapid transition
- **Agreement**—Used to acknowledge rapid transition requests

Both RSTP and MSTP devices can perform rapid transition on a designated port only when the port receives an agreement packet from the downstream device. RSTP and MSTP devices have the following differences:

- For MSTP, the root port of the downstream device sends an agreement packet only after it receives an agreement packet from the upstream device.
- For RSTP, the downstream device sends an agreement packet regardless of whether an agreement packet from the upstream device is received.

Figure 24 Rapid state transition of an MSTP designated port

Figure 25 Rapid state transition of an RSTP designated port

If the upstream device is a third-party device, the rapid state transition implementation might be limited. For example, when the upstream device uses a rapid transition mechanism similar to that of RSTP, and the downstream device adopts MSTP and does not operate in RSTP mode, the root port on the downstream device receives no agreement packet from the upstream device and sends no agreement packets to the upstream device. As a result, the designated port of the upstream device fails to transit rapidly, and can only change to the forwarding state after a period twice the Forward Delay.

You can enable the No Agreement Check feature on the downstream device's port to enable the designated port of the upstream device to transit its state rapidly.

Configuration prerequisites

Before you configure the No Agreement Check function, complete the following tasks:

- Connect a device to a third-party upstream device that supports spanning tree protocols via a point-to-point link.
- Configure the same region name, revision level and VLAN-to-instance mappings on the two devices, assigning them to the same region.

Configuration procedure

To make the No Agreement Check feature take effect, enable it on the root port.

To configure No Agreement Check:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable No Agreement Check.	stp no-agreement-check	Disabled by default.

No Agreement Check configuration example

Network requirements

As shown in Figure 26:

- Device A connects to a third-party device that has a different spanning tree implementation. Both devices are in the same region.
- The third-party device (Device B) is the regional root bridge, and Device A is the downstream device.

Figure 26 Network diagram

Configuration procedure

Enable No Agreement Check on GigabitEthernet 1/0/1 of Device A.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] stp no-agreement-check
```

Configuring TC snooping

Figure 27 shows a topology change (TC) snooping application scenario. Device A and Device B form an IRF fabric and do not have the spanning tree feature enabled. The IRF fabric connects to two user networks, in which all devices are enabled with the spanning tree feature. The user networks are dual-uplinked to the IRF fabric for high availability. The IRF fabric transparently transmits BPDUs in every user network.

Figure 27 TC snooping application scenario

In the network, the IRF fabric transparently transmits the received BPDUs and does not participate in spanning tree calculations. When a topology change occurs to the IRF fabric or user networks, the IRF fabric may need a long time to learn the correct MAC address table entries and ARP entries, resulting in long network disruption. To avoid the network disruption, you can enable TC snooping on the IRF fabric.

With TC snooping enabled, a device actively updates the MAC address table entries and ARP entries upon receiving TC-BPDUs, so that the device can normally forward the user traffic.

For more information about MAC address table entries, see "[Configuring the MAC address table.](#)"

For more information about ARP, see *Layer 3—IP Services Configuration Guide*.

Configuration restrictions and guidelines

- TC snooping and STP are mutually exclusive. You must globally disable the spanning tree feature before enable TC snooping.
- TC snooping does not take effect on the ports on which BPDU tunneling is enabled for spanning tree protocols. For more information about BPDU tunneling, see "[Configuring BPDU tunneling.](#)"
- TC snooping does not support PVST TC-BPDUs. As a result, TC snooping does not take effect in a PVST network.

Configuration procedure

To configure TC snooping:

Step	Command	Description
1. Enter system view.	system-view	N/A
2. Globally disable the spanning tree feature.	undo stp enable	By default, the spanning tree feature is disabled globally.
3. Enable TC snooping.	stp tc-snooping	Disabled by default.

Configuring protection functions

A spanning tree device supports the following protection functions:

- BPDU guard
- Root guard
- Loop guard
- TC-BPDU guard
- BPDU drop

Configuration prerequisites

The spanning tree feature has been correctly configured on the device.

Enabling BPDU guard

For access layer devices, the access ports can directly connect to the user terminals (such as PCs) or file servers. The access ports are configured as edge ports to allow rapid transition. When these ports receive configuration BPDUs, the system automatically sets the ports as non-edge ports and starts a new spanning tree calculation process. This causes a change of network topology. Under normal conditions, these ports should not receive configuration BPDUs. However, if someone forges configuration BPDUs maliciously to attack the devices, the network will become unstable.

The spanning tree protocol provides the BPDU guard function to protect the system against such attacks. With the BPDU guard function enabled on the devices, when edge ports receive configuration BPDUs, the system closes these ports and notifies the NMS that these ports have been closed by the spanning tree protocol. The device will reactivate the closed ports after a detection interval. For more information about this detection interval, see *Fundamentals Configuration Guide*.

Configure BPDU guard on a device with edge ports configured.

To enable BPDU guard:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the BPDU guard function for the device.	stp bpdu-protection	Disabled by default.

NOTE:

BPDU guard does not take effect on loopback-testing-enabled ports. For more information about loopback testing, see "[Configuring Ethernet interfaces](#)."

Enabling root guard

The root bridge and secondary root bridge of a spanning tree should be located in the same MST region. Especially for the CIST, the root bridge and secondary root bridge are put in a high-bandwidth core region during network design. However, due to possible configuration errors or malicious attacks in the network, the legal root bridge might receive a configuration BPDU with a higher priority. Another device will supersede the current legal root bridge, causing an undesired change of the network topology. The

traffic that should go over high-speed links is switched to low-speed links, resulting in network congestion.

To prevent this situation, MSTP provides the root guard function. If the root guard function is enabled on a port of a root bridge, this port plays the role of designated port on all MSTIs. After this port receives a configuration BPDU with a higher priority from an MSTI, it immediately sets that port to the listening state in the MSTI, without forwarding the packet. This is equivalent to disconnecting the link connected with this port in the MSTI. If the port receives no BPDUs with a higher priority within twice the forwarding delay, it reverts to its original state.

Configure root guard on a designated port.

To enable root guard:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable the root guard function for the port(s).	stp root-protection	Disabled by default.

NOTE:

You cannot configure root guard and loop guard on a port at the same time.

Enabling loop guard

A device that keeps receiving BPDUs from the upstream device can maintain the state of the root port and blocked ports. However, link congestion or unidirectional link failures might cause these ports to fail to receive BPDUs from the upstream devices. The device will reselect the port roles: Those ports in forwarding state that failed to receive upstream BPDUs will become designated ports, and the blocked ports will transition to the forwarding state, resulting in loops in the switched network. The loop guard function can suppress the occurrence of such loops.

The initial state of a loop guard-enabled port is discarding in every MSTI. When the port receives BPDUs, its state transitions normally. Otherwise, it stays in the discarding state to prevent temporary loops.

Configure loop guard on the root port and alternate ports of a device.

To enable loop guard:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable the loop guard function for the ports.	stp loop-protection	Disabled by default.

NOTE:

- Do not enable loop guard on a port that connects user terminals. Otherwise, the port will stay in the discarding state in all MSTIs because it cannot receive BPDUs.
- You cannot configure edge port settings and loop guard, or configure root guard and loop guard on a port at the same time.

Enabling TC-BPDU guard

When a switch receives topology change (TC) BPDUs (the BPDUs that notify devices of topology changes), the switch flushes its forwarding address entries. If someone forges TC-BPDUs to attack the switch, the switch will receive a large number of TC-BPDUs within a short time and be busy with forwarding address entry flushing. This affects network stability.

With the TC-BPDU guard function, you can set the maximum number of immediate forwarding address entry flushes that the device can perform every a specified period of time (10 seconds). For TC-BPDUs received in excess of the limit, the device performs a forwarding address entry flush when the time period expires. This prevents frequent flushing of forwarding address entries.

To enable TC-BPDU guard:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the TC-BPDU guard function.	stp tc-protection enable	Optional. Enabled by default.
3. Configure the maximum number of forwarding address entry flushes that the device can perform every 10 seconds.	stp tc-protection threshold <i>number</i>	Optional. 6 by default.

NOTE:

HP does not recommend you disable this feature.

Enabling BPDU drop

In a spanning tree network, after receiving BPDUs, the device performs STP calculation according to the received BPDUs and forwards received BPDUs to other devices in the network. This allows malicious attackers to attack the network by forging BPDUs. By continuously sending forged BPDUs, they can make

all the devices in the network perform STP calculations all the time. As a result, problems such as CPU overload and BPDU protocol status errors occur.

To avoid this problem, you can enable BPDU drop on ports. A BPDU drop-enabled port does not receive any BPDUs and is invulnerable to forged BPDU attacks.

To enable BPDU drop on an Ethernet interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable BPDU drop on the current interface.	bpdu-drop any	Disabled by default.

NOTE:

Because a port with BPDU drop enabled also drops the received 802.1X packets, do not enable BPDU drop and 802.1X on a port at the same time. For more information about 802.1X, see *Security Configuration Guide*.

Displaying and maintaining the spanning tree

Task	Command	Remarks
Display information about ports blocked by spanning tree protection functions.	display stp abnormal-port [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BPDU statistics on ports.	display stp bpdu-statistics [interface <i>interface-type interface-number</i> [instance <i>instance-id</i>]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about ports shut down by spanning tree protection functions.	display stp down-port [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the historical information of port role calculation for the specified MSTI or all MSTIs.	display stp [instance <i>instance-id</i> vlan <i>vlan-id</i>] history [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Spanning tree configuration examples

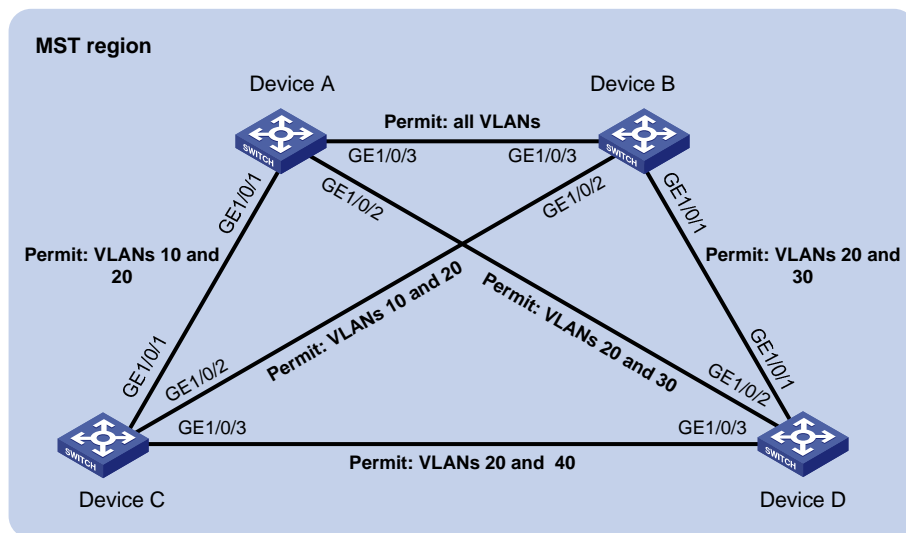

MSTP configuration example

Network requirements

As shown in [Figure 28](#):

- All devices on the network are in the same MST region. Device A and Device B work at the distribution layer. Device C and Device D work at the access layer.
- Configure MSTP so that packets of different VLANs are forwarded along different spanning trees: Packets of VLAN 10 are forwarded along MSTI 1, those of VLAN 30 are forwarded along MSTI 3, those of VLAN 40 are forwarded along MSTI 4, and those of VLAN 20 are forwarded along MSTI 0.
- VLAN 10 and VLAN 30 are terminated on the distribution layer devices, and VLAN 40 is terminated on the access layer devices. The root bridges of MSTI 1 and MSTI 3 are Device A and Device B, respectively, and the root bridge of MSTI 4 is Device C.

Figure 28 Network diagram

Configuration procedure

1. Configure VLANs and VLAN member ports (Details not shown.).
Create VLAN 10, VLAN 20, and VLAN 30 on Device A and Device B, respectively, VLAN 10, VLAN 20, and VLAN 40 on Device C, and VLAN 20, VLAN 30, and VLAN 40 on Device D. Configure the ports on these devices as trunk ports and assign them to related VLANs.
2. Configure Device A:
Enter MST region view; configure the MST region name as **example**; map VLAN 10, VLAN 30, and VLAN 40 to MSTI 1, MSTI 3, and MSTI 4, respectively; configure the revision level of the MST region as 0.

```

<DeviceA> system-view
[DeviceA] stp region-configuration
[DeviceA-mst-region] region-name example
[DeviceA-mst-region] instance 1 vlan 10
[DeviceA-mst-region] instance 3 vlan 30

[DeviceC-mst-region] revision-level 0
# Activate MST region configuration.
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit

```

Specify the current device as the root bridge of MSTI 4.

```
[DeviceC] stp instance 4 root primary
```

Enable the spanning tree feature globally.

```
[DeviceC] stp enable
```

5. Configure Device D:

Enter MST region view, configure the MST region name as **example**, map VLAN 10, VLAN 30, and VLAN 40 to MSTI 1, MSTI 3, and MSTI 4, respectively, and configure the revision level of the MST region as 0.

```
<DeviceD> system-view
```

```
[DeviceD] stp region-configuration
```

```
[DeviceD-mst-region] region-name example
```

```
[DeviceD-mst-region] instance 1 vlan 10
```

```
[DeviceD-mst-region] instance 3 vlan 30
```

```
[DeviceD-mst-region] instance 4 vlan 40
```

```
[DeviceD-mst-region] revision-level 0
```

Activate MST region configuration.

```
[DeviceD-mst-region] active region-configuration
```

```
[DeviceD-mst-region] quit
```

Enable the spanning tree feature globally.

```
[DeviceD] stp enable
```

6. Verify the configurations:

You can use the **display stp brief** command to display brief spanning tree information on each device after the network is stable.

Display brief spanning tree information on Device A.

```
[DeviceA] display stp brief
```

MSTID	Port	Role	STP State	Protection
0	GigabitEthernet1/0/1	ALTE	DISCARDING	NONE
0	GigabitEthernet1/0/2	DESI	FORWARDING	NONE
0	GigabitEthernet1/0/3	ROOT	FORWARDING	NONE
1	GigabitEthernet1/0/1	DESI	FORWARDING	NONE
1	GigabitEthernet1/0/3	DESI	FORWARDING	NONE
3	GigabitEthernet1/0/2	DESI	FORWARDING	NONE
3	GigabitEthernet1/0/3	ROOT	FORWARDING	NONE

Display brief spanning tree information on Device B.

```
[DeviceB] display stp brief
```

MSTID	Port	Role	STP State	Protection
0	GigabitEthernet1/0/1	DESI	FORWARDING	NONE
0	GigabitEthernet1/0/2	DESI	FORWARDING	NONE
0	GigabitEthernet1/0/3	DESI	FORWARDING	NONE
1	GigabitEthernet1/0/2	DESI	FORWARDING	NONE
1	GigabitEthernet1/0/3	ROOT	FORWARDING	NONE
3	GigabitEthernet1/0/1	DESI	FORWARDING	NONE
3	GigabitEthernet1/0/3	DESI	FORWARDING	NONE

Display brief spanning tree information on Device C.

```
[DeviceC] display stp brief
```

MSTID	Port	Role	STP State	Protection
-------	------	------	-----------	------------

```

0      GigabitEthernet1/0/1      DESI FORWARDING NONE
0      GigabitEthernet1/0/2      ROOT FORWARDING NONE
0      GigabitEthernet1/0/3      DESI FORWARDING NONE
1      GigabitEthernet1/0/1      ROOT FORWARDING NONE
1      GigabitEthernet1/0/2      ALTE DISCARDING NONE
4      GigabitEthernet1/0/3      DESI FORWARDING NONE

```

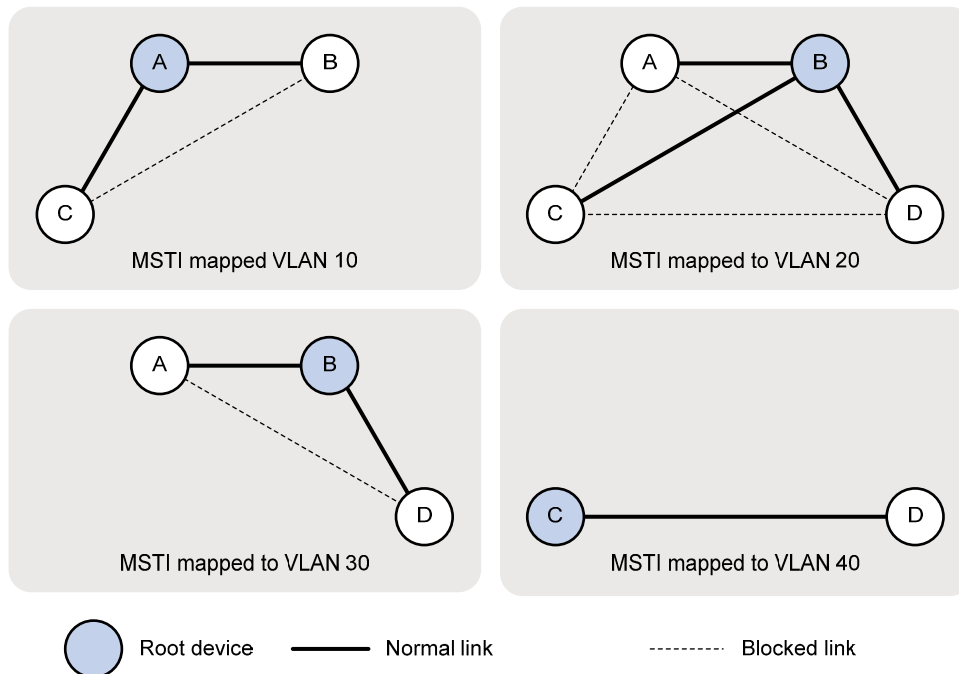

Display brief spanning tree information on Device D.

```
[DeviceD] display stp brief
```

MSTID	Port	Role	STP State	Protection
0	GigabitEthernet1/0/1	ROOT	FORWARDING	NONE
0	GigabitEthernet1/0/2	ALTE	DISCARDING	NONE
0	GigabitEthernet1/0/3	ALTE	DISCARDING	NONE
3	GigabitEthernet1/0/1	ROOT	FORWARDING	NONE
3	GigabitEthernet1/0/2	ALTE	DISCARDING	NONE
4	GigabitEthernet1/0/3	ROOT	FORWARDING	NONE

Based on the output, you can draw the MSTI mapped to each VLAN, as shown in [Figure 29](#).

Figure 29 MSTIs mapped to different VLANs

PVST configuration example

Network requirements

As shown in [Figure 30](#):

- Device A and Device B work at the distribution layer. Device C and Device D work at the access layer.
- Configure PVST so that packets of different VLANs are forwarded along different spanning trees.

- VLAN 10, VLAN 20, and VLAN 30 are terminated on the distribution layer devices, and VLAN 40 is terminated on the access layer devices. The root bridge of VLAN 10 and VLAN 20 is Device A, that of VLAN 30 is Device B, and that of VLAN 40 is Device C.

Figure 30 Network diagram

Configuration procedure

1. Configure VLANs and VLAN member ports. (Details not shown.)
Create VLAN 10, VLAN 20, and VLAN 30 on Device A and Device B, respectively, VLAN 10, VLAN 20, and VLAN 40 on Device C, and VLAN 20, VLAN 30, and VLAN 40 on Device D. Configure the ports on these devices as trunk ports and assign them to related VLANs.
2. Configure Device A:
 - # Set the spanning tree mode to PVST.

```
<DeviceA> system-view
[DeviceA] stp mode pvst
```
- # Specify the device as the root bridge of VLAN 10 and VLAN 20.

```
[DeviceA] stp vlan 10 20 root primary
```
- # Enable the spanning tree feature globally and for VLANs 10, 20, and 30.

```
[DeviceA] stp enable
[DeviceA] stp vlan 10 20 30 enable
```
3. Configure Device B:
 - # Set the spanning tree mode to PVST.

```
<DeviceB> system-view
[DeviceB] stp mode pvst
```
- # Specify the device as the root bridge of VLAN 30.

```
[DeviceB] stp vlan 30 root primary
```
- # Enable the spanning tree feature globally and for VLANs 10, 20, and 30.

```
[DeviceB] stp enable
[DeviceB] stp vlan 10 20 30 enable
```
4. Configure Device C:
 - # Set the spanning tree mode to PVST.

```
<DeviceC> system-view
[DeviceC] stp mode pvst
```

Specify the current device as the root bridge of VLAN 40.

```
[DeviceC] stp vlan 40 root primary
```

Enable the spanning tree feature globally and for VLANs 10, 20, and 40.

```
[DeviceC] stp enable
```

```
[DeviceC] stp vlan 10 20 40 enable
```

5. Configure Device D:

Set the spanning tree mode to PVST.

```
<DeviceD> system-view
```

```
[DeviceD] stp mode pvst
```

Enable the spanning tree feature globally and for VLANs 20, 30, and 40.

```
[DeviceD] stp enable
```

```
[DeviceD] stp vlan 20 30 40 enable
```

6. Verify the configurations:

You can use the **display stp brief** command to display brief spanning tree information on each device after the network is stable.

Display brief spanning tree information on Device A.

```
[DeviceA] display stp brief
```

VLAN	Port	Role	STP State	Protection
10	GigabitEthernet1/0/1	DESI	DISCARDING	NONE
10	GigabitEthernet1/0/3	DESI	FORWARDING	NONE
20	GigabitEthernet1/0/1	DESI	FORWARDING	NONE
20	GigabitEthernet1/0/2	DESI	FORWARDING	NONE
20	GigabitEthernet1/0/3	DESI	FORWARDING	NONE
30	GigabitEthernet1/0/2	DESI	FORWARDING	NONE
30	GigabitEthernet1/0/3	ROOT	FORWARDING	NONE

Display brief spanning tree information on Device B.

```
[DeviceB] display stp brief
```

10	GigabitEthernet1/0/2	DESI	FORWARDING	NONE
10	GigabitEthernet1/0/3	ROOT	FORWARDING	NONE
20	GigabitEthernet1/0/1	DESI	FORWARDING	NONE
20	GigabitEthernet1/0/2	DESI	FORWARDING	NONE
20	GigabitEthernet1/0/3	ROOT	FORWARDING	NONE
30	GigabitEthernet1/0/1	DESI	FORWARDING	NONE
30	GigabitEthernet1/0/3	DESI	FORWARDING	NONE

Display brief spanning tree information on Device C.

```
[DeviceC] display stp brief
```

VLAN	Port	Role	STP State	Protection
10	GigabitEthernet1/0/1	ROOT	FORWARDING	NONE
10	GigabitEthernet1/0/2	ALTE	FORWARDING	NONE
20	GigabitEthernet1/0/1	ROOT	FORWARDING	NONE
20	GigabitEthernet1/0/2	ALTE	FORWARDING	NONE
20	GigabitEthernet1/0/3	DESI	DISCARDING	NONE
40	GigabitEthernet1/0/3	DESI	FORWARDING	NONE

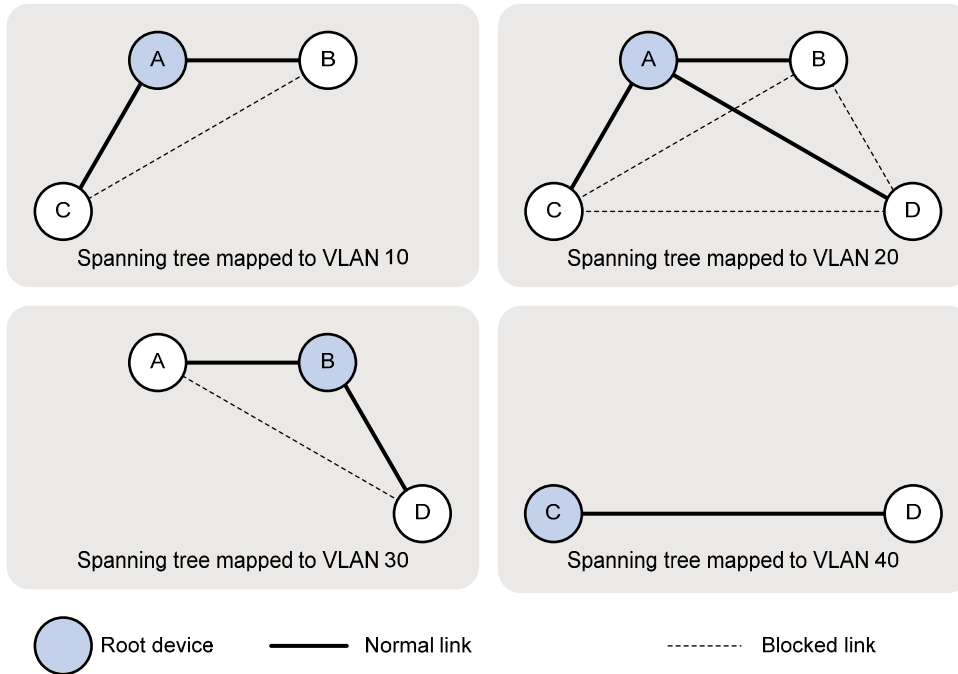

Display brief spanning tree information on Device D.

```
[DeviceD] display stp brief
```

VLAN	Port	Role	STP State	Protection
20	GigabitEthernet1/0/1	ALTE	FORWARDING	NONE
20	GigabitEthernet1/0/2	ROOT	DISCARDING	NONE
20	GigabitEthernet1/0/3	ALTE	DISCARDING	NONE
30	GigabitEthernet1/0/1	ROOT	FORWARDING	NONE
30	GigabitEthernet1/0/2	ALTE	DISCARDING	NONE
40	GigabitEthernet1/0/3	ROOT	FORWARDING	NONE

Based on the output, you can draw the spanning tree mapped to each VLAN, as shown in [Figure 31](#).

Figure 31 Spanning trees mapped to different VLANs

Configuring BPDU tunneling

Overview

As a Layer 2 tunneling technology, BPDU tunneling enables Layer 2 protocol packets from geographically dispersed customer networks to be transparently transmitted over specific tunnels across a service provider network.

Background

Dedicated lines are used in a service provider network to build user-specific Layer 2 networks. As a result, a user network consists of parts located at different sides of the service provider network. As shown in Figure 32, the devices for User A are CE 1 and CE 2, both of which belong to VLAN 100. User A's network is divided into network 1 and network 2, which are connected by the service provider network. When a Layer 2 protocol (for example, STP) runs on both network 1 and network 2, the Layer 2 protocol packets must be transmitted over the service provider network to implement Layer 2 protocol calculation (for example, spanning tree calculation). When receiving a Layer 2 protocol packet, the PEs cannot determine whether the packet is from the user network or the service provider network, and must deliver the packet to the CPU for processing. In this case, the Layer 2 protocol calculation in User A's network is mixed with that in the service provider network, and the user network cannot implement independent Layer 2 protocol calculation.

Figure 32 BPDU tunneling application scenario

BPDU tunneling addresses this problem. With BPDU tunneling, Layer 2 protocol packets from customer networks can be transparently transmitted over the service provider network in the following workflow:

1. After receiving a Layer 2 protocol packet from CE 1, PE 1 encapsulates the packet, replaces its destination MAC address with a specific multicast MAC address, and forwards the packet to the service provider network.
2. The encapsulated Layer 2 protocol packet (called bridge protocol data unit, BPDU) is forwarded to PE 2 at the other end of the service provider network, which de-encapsulates the packet, restores the original destination MAC address of the packet, and then sends the packet to CE 2.

HP devices support BPDU tunneling for the following protocols:

- Cisco Discovery Protocol (CDP)
- Device Link Detection Protocol (DLDP)

- Ethernet Operation, Administration and Maintenance (EOAM)
- GARP VLAN Registration Protocol (GVRP)
- HW Group Management Protocol (HGMP)
- Link Aggregation Control Protocol (LACP)
- Link Layer Discovery Protocol (LLDP)
- Port Aggregation Protocol (PAGP)
- Per VLAN Spanning Tree (PVST)
- Spanning Tree Protocol (STP)
- Unidirectional Link Direction (UDLD)
- VLAN Trunking Protocol (VTP)

BPDU tunneling implementation

The BPDU tunneling implementations for different protocols are all similar. This section uses the Spanning Tree Protocol (STP) to describe how to implement BPDU tunneling.

This document uses the term *STP* in a broad sense. It includes STP, RSTP, and MSTP.

STP calculates the topology of a network by transmitting BPDUs among devices in the network. For more information, see "[Configuring spanning tree protocols.](#)"

To avoid loops in your network, you can enable STP on your devices. When the topology changes at one side of the customer network, devices at that side of the customer network send BPDUs to devices on the other side of the customer network to ensure consistent spanning tree calculation in the entire customer network. However, because BPDUs are Layer 2 multicast frames, all STP-enabled devices, both in the customer network and in the service provider network, can receive and process these BPDUs. In this case, neither the service provider network nor the customer network can correctly calculate its independent spanning tree.

BPDU tunneling allows each network to calculate an independent spanning tree with STP.

BPDU tunneling delivers the following benefits:

- BPDUs can be transparently transmitted. BPDUs of one customer network can be broadcast in a specific VLAN across the service provider network, allowing that customer's geographically dispersed networks to implement consistent spanning tree calculation across the service provider network.
- BPDUs of different customer networks can be confined within different VLANs for transmission on the service provider network. This enables each customer network to perform independent spanning tree calculation.

Figure 33 BPDU tunneling implementation

The upper section of [Figure 33](#) represents the service provider network (ISP network). The lower section, including User A network 1 and User A network 2, represents the customer networks. Enabling BPDU tunneling on edge devices (PE 1 and PE 2) in the service provider network allows BPDUs of User A network 1 and User A network 2 to be transparently transmitted through the service provider network. This ensures consistent spanning tree calculation throughout User A network, without affecting the spanning tree calculation of the service provider network.

Assume that a BPDU is sent from User A network 1 to User A network 2. The BPDU is sent by using the following workflow.

1. At the ingress of the service provider network, PE 1 changes the destination MAC address of the BPDU from 0x0180-C200-0000 to a special multicast MAC address, 0x010F-E200-0003 (the default multicast MAC address), for example. In the service provider network, the modified BPDU is forwarded as a data packet in the VLAN assigned to User A.
2. At the egress of the service provider network, PE 2 recognizes the BPDU with the destination MAC address 0x010F-E200-0003, restores its original destination MAC address 0x0180-C200-0000, and then sends the BPDU to CE 2.

NOTE:

Through configuration, make sure that the VLAN tags carried in BPDUs are neither changed nor removed during the transparent transmission in the service provider network. Otherwise, the devices in the service provider network will fail to transparently transmit the customer network BPDUs correctly.

Enabling BPDU tunneling

Configuration prerequisites

Before configuring BPDU tunneling for a protocol, perform the following tasks:

- Enable the protocol in the customer network.
- Assign the port on which you want to enable BPDU tunneling on the PE device and the connected port on the CE device to the same VLAN.
- Configure ports that connect network devices in the service provider network as trunk ports that allow packets of any VLAN to pass through.

Configuration restrictions and guidelines

- Settings made in Layer 2 Ethernet interface view or Layer 2 aggregate interface view take effect only on the current port. Settings made in port group view take effect on all ports in the port group.
- Before you enable BPDU tunneling for DLDAP, EOAM, GVRP, HGMP, LLDP, or STP on a port, disable the protocol on the port first.
- Because PVST is a special STP protocol, you must do two things before you enable BPDU tunneling for PVST on a port: first, disable STP; second, enable BPDU tunneling for STP on the port.
- Do not enable BPDU tunneling for DLDAP, EOAM, LACP, LLDP, PAGP, or UDLD on the member port of a Layer 2 aggregation group.

Enabling BPDU tunneling

You can enable BPDU tunneling for different protocols in different views.

Enabling BPDU tunneling for a protocol in Layer 2 Ethernet interface view or port group view

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none">• Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i>• Enter port group view: port-group manual <i>port-group-name</i>	Use either command.
3. Enable BPDU tunneling for a protocol.	bpdu-tunnel dot1q { cdp dldp eoam gvrp hgmp lacp lldp pagp pvst stp udld vtp }	Disabled by default.

Enabling BPDU tunneling for a protocol in Layer 2 aggregate interface view

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 aggregate interface view.	interface bridge-aggregation <i>interface-number</i>	N/A
3. Enable BPDU tunneling for a protocol on the Layer 2 aggregate interface.	bpdu-tunnel dot1q { cdp gvrp hgmp pvst stp vtp }	Disabled by default.

Configuring destination multicast MAC address for BPDUs

By default, the destination multicast MAC address for BPDUs is 0x010F-E200-0003. You can change it to 0x0100-0CCD-CDD0, 0x0100-0CCD-CDD1, or 0x0100-0CCD-CDD2.

To configure destination multicast MAC address for BPDUs:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the destination multicast MAC address for BPDUs.	bpdu-tunnel tunnel-dmac <i>mac-address</i>	Optional. 0x010F-E200-0003 by default.

NOTE:

For BPDUs to be recognized, the destination multicast MAC addresses configured for BPDU tunneling must be the same on the edge devices on the service provider network.

BPDU tunneling configuration examples

BPDU tunneling for STP configuration example

Network requirements

As shown in Figure 34:

- CE 1 and CE 2 are edge devices on the geographically dispersed network of User A; PE 1 and PE 2 are edge devices on the service provider network.
- All ports that connect service provider devices and customer devices are access ports and belong to VLAN 2. All ports that interconnect service provider devices are trunk ports and allow packets of any VLAN to pass through.
- MSTP is enabled on User A's network.

After the configuration, CE 1 and CE 2 must implement consistent spanning tree calculation across the service provider network, and the destination multicast MAC address carried in BPDUs must be 0x0100-0CCD-CDD0.

Figure 34 Network diagram

Configuration procedure

1. Configure PE 1:

Configure the destination multicast MAC address for BPDUs as 0x0100-0CCD-CDD0.

```
<PE1> system-view
```

```
[PE1] bpdu-tunnel tunnel-dmac 0100-0ccd-cdd0
```

```

# Create VLAN 2 and assign GigabitEthernet 1/0/1 to VLAN 2.
[PE1] vlan 2
[PE1-vlan2] quit
[PE1] interface gigabitEthernet 1/0/1
[PE1-GigabitEthernet1/0/1] port access vlan 2
# Disable STP on GigabitEthernet 1/0/1, and then enable BPDU tunneling for STP on it.
[PE1-GigabitEthernet1/0/1] undo stp enable
[PE1-GigabitEthernet1/0/1] bpdu-tunnel dot1q stp

```

2. Configure PE 2:

```

# Configure the destination multicast MAC address for BPDUs as 0x0100-0CCD-CDD0.
<PE2> system-view
[PE2] bpdu-tunnel tunnel-dmac 0100-0ccd-cdd0
# Create VLAN 2 and assign GigabitEthernet 1/0/2 to VLAN 2.
[PE2] vlan 2
[PE2-vlan2] quit
[PE2] interface gigabitEthernet 1/0/2
[PE2-GigabitEthernet1/0/2] port access vlan 2
# Disable STP on GigabitEthernet 1/0/2, and then enable BPDU tunneling for STP on it.
[PE2-GigabitEthernet1/0/2] undo stp enable
[PE2-GigabitEthernet1/0/2] bpdu-tunnel dot1q stp

```

BPDU tunneling for PVST configuration example

Network requirements

As shown in [Figure 35](#):

- CE 1 and CE 2 are edge devices on the geographically dispersed network of User A. PE 1 and PE 2 are edge devices on the service provider network.
- All ports that connect service provider devices and customer devices and those that interconnect service provider devices are trunk ports and allow packets of any VLAN to pass through.
- PVST is enabled for VLANs 1 through 4094 on User A's network.

After the configuration, CE 1 and CE 2 must implement consistent PVST calculation across the service provider network, and the destination multicast MAC address carried in BPDUs must be 0x0100-0CCD-CDD0.

Figure 35 Network diagram

Configuration procedure

1. Configure PE 1:

Configure the destination multicast MAC address for BPDUs as 0x0100-0CCD-CDD0.

```
<PE1> system-view
```

```
[PE1] bpdu-tunnel tunnel-dmac 0100-0ccd-cdd0
```

Configure GigabitEthernet 1/0/1 as a trunk port and assign it to all VLANs.

```
[PE1] interface gigabitethernet 1/0/1
```

```
[PE1-GigabitEthernet1/0/1] port link-type trunk
```

```
[PE1-GigabitEthernet1/0/1] port trunk permit vlan all
```

Disable STP on GigabitEthernet 1/0/1, and then enable BPDU tunneling for STP and PVST on it.

```
[PE1-GigabitEthernet1/0/1] undo stp enable
```

```
[PE1-GigabitEthernet1/0/1] bpdu-tunnel dot1q stp
```

```
[PE1-GigabitEthernet1/0/1] bpdu-tunnel dot1q pvst
```

2. Configure PE 2:

Configure the destination multicast MAC address for BPDUs as 0x0100-0CCD-CDD0.

```
<PE2> system-view
```

```
[PE2] bpdu-tunnel tunnel-dmac 0100-0ccd-cdd0
```

Configure GigabitEthernet 1/0/2 as a trunk port and assign it to all VLANs.

```
[PE2] interface gigabitethernet 1/0/2
```

```
[PE2-GigabitEthernet1/0/2] port link-type trunk
```

```
[PE2-GigabitEthernet1/0/2] port trunk permit vlan all
```

Disable STP on GigabitEthernet 1/0/2, and then enable BPDU tunneling for STP and PVST on it.

```
[PE2-GigabitEthernet1/0/2] undo stp enable
```

```
[PE2-GigabitEthernet1/0/2] bpdu-tunnel dot1q stp
```

```
[PE2-GigabitEthernet1/0/2] bpdu-tunnel dot1q pvst
```

Configuring VLANs

Overview

Ethernet is a network technology based on the Carrier Sense Multiple Access/Collision Detect (CSMA/CD) mechanism. Because the medium is shared, collisions and excessive broadcasts are common on Ethernet networks. To address the issue, virtual LAN (VLAN) was introduced to break a LAN down into separate VLANs. VLANs are isolated from each other at Layer 2. A VLAN is a bridging domain, and contains all broadcast traffic within it.

Figure 36 A VLAN diagram

A VLAN is logically divided on an organizational basis rather than on a physical basis. For example, using VLAN, all workstations and servers that a particular workgroup uses can be assigned to the same VLAN, regardless of their physical locations.

VLAN technology delivers the following benefits:

1. Confining broadcast traffic within individual VLANs. This reduces bandwidth waste and improves network performance.
2. Improving LAN security. By assigning user groups to different VLANs, you can isolate them at Layer 2. To enable communication between VLANs, routers or Layer 3 switches are required.
3. Creating flexible virtual workgroups. Because users from the same workgroup can be assigned to the same VLAN regardless of their physical locations, network construction and maintenance are much easier and more flexible.

VLAN fundamentals

To enable a network device to identify frames of different VLANs, a VLAN tag field is inserted into the data link layer encapsulation.

The format of VLAN-tagged frames is defined in IEEE 802.1Q issued by the Institute of Electrical and Electronics Engineers (IEEE) in 1999.

The Ethernet II encapsulation format is used here. Besides the Ethernet II encapsulation format, Ethernet also supports other encapsulation formats, including 802.2 LLC, 802.2 SNAP, and 802.3 raw. The VLAN tag fields are added to frames encapsulated in these formats for VLAN identification.

In the header of a traditional Ethernet data frame, the field after the destination MAC address and the source MAC address is the Type field, which indicates the upper layer protocol type, as shown in [Figure 37](#).

Figure 37 Traditional Ethernet frame format

IEEE 802.1Q inserts a four-byte VLAN tag after the DA&SA field, as shown in [Figure 38](#).

Figure 38 Position and format of VLAN tag

The fields of a VLAN tag are tag protocol identifier (TPID), priority, canonical format indicator (CFI), and VLAN ID.

- The 16-bit TPID field with a value of 0x8100 indicates that the frame is VLAN-tagged.
- The 3-bit priority field indicates the 802.1p priority of the frame.
- The 1-bit CFI field specifies whether the MAC addresses are encapsulated in the standard format when packets are transmitted across different media. A value of 0 indicates that MAC addresses are encapsulated in the standard format. A value of 1 indicates that MAC addresses are encapsulated in a non-standard format. The value of the field is 0 by default.
- The 12-bit VLAN ID field identifies the VLAN that the frame belongs to. The VLAN ID range is 0 to 4095. Because 0 and 4095 are reserved, a VLAN ID actually ranges from 1 to 4094.

A network device handles an incoming frame depending on whether the frame is VLAN tagged, and the value of the VLAN tag, if any. For more information, see "[Introduction to port-based VLAN.](#)"

NOTE:

When a frame carrying multiple VLAN tags passes through, the switch processes the frame according to its outer VLAN tag, and transmits the inner tags as payload.

VLAN types

You can implement VLANs based on the following criteria:

- Port
- MAC address
- Protocol
- IP subnet
- Policy
- Other criteria

This chapter covers port-based VLAN, MAC-based VLAN, protocol-based VLAN, and IP subnet-based VLAN. The port-based VLAN implementation is the basis of all other VLAN implementations. To use any other VLAN implementations, you must configure port-based VLAN settings.

You can configure all these types of VLANs on a port at the same time. When the switch is determining which VLAN a packet that passes through the port should be assigned to, it looks up the VLANs in the default order of MAC-based VLAN, IP sub-based VLAN, protocol-based VLAN, and port-based VLAN.

Protocols and standards

IEEE 802.1Q, *IEEE Standards for Local and Metropolitan Area Networks: Virtual Bridged Local Area Networks*

Configuring basic VLAN settings

Configuration restrictions and guidelines

- As the default VLAN, VLAN 1 cannot be created or removed.
- You cannot manually create or remove VLANs reserved for special purposes.
- To delete a protocol reserved VLAN, voice VLAN, management VLAN, dynamic VLAN, VLAN with a QoS policy applied, control VLAN for a smart link group, control VLAN for an RRPP domain, remote probe VLAN for remote port mirroring, remove the configuration from the VLAN first, and execute the **undo vlan** command.

Configuration procedure

To configure basic VLAN settings:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create VLANs.	vlan { <i>vlan-id1</i> [to <i>vlan-id2</i>] all }	Optional. Use this command to create VLANs in bulk.
3. Enter VLAN view.	vlan <i>vlan-id</i>	By default, only the default VLAN (VLAN 1) exists in the system. If the specified VLAN does not exist, this command creates the VLAN first.
4. Configure a name for the VLAN.	name <i>text</i>	Optional. By default, the name of a VLAN is its VLAN ID (VLAN 0001 , for example).
5. Configure the description of the VLAN.	description <i>text</i>	Optional. VLAN ID is used by default. (VLAN 0001 , for example).

Configuring basic settings of a VLAN interface

For hosts of different VLANs to communicate, you must use a router or Layer 3 switch to perform Layer 3 forwarding. You use VLAN interfaces to achieve this.

VLAN interfaces are virtual interfaces used for Layer 3 communication between different VLANs. They do not exist as physical entities on devices. For each VLAN, you can create one VLAN interface. You can assign the VLAN interface an IP address and specify it as the gateway of the VLAN to forward traffic destined for an IP subnet different from that of the VLAN.

Configuration procedure

To configure basic settings of a VLAN interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VLAN interface and enter VLAN interface view.	interface vlan-interface <i>vlan-interface-id</i>	If the VLAN interface already exists, you enter its view directly.
3. Assign an IP address to the VLAN interface.	ip address <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } [<i>sub</i>]	Optional. By default, no IP address is assigned to any VLAN interface.
4. Configure the description of the VLAN interface.	description <i>text</i>	Optional. By default, the description of a VLAN is the VLAN interface name. For example, Vlan-interface1 Interface .
5. Set the MTU for the VLAN interface.	mtu <i>size</i>	Optional. By default, the MTU is 1500 bytes.
6. Restore the default settings for the VLAN interface.	default	Optional.
7. Shut down the VLAN interface.	shutdown	Optional. By default, a VLAN interface is in the up state. The VLAN interface is up if one or more ports in the VLAN is up, and goes down if all ports in the VLAN go down. A VLAN interface shut down with the shutdown command is in the DOWN (Administratively) state until you bring it up, regardless of how the state of the ports in the VLAN changes.

NOTE:

Before you create a VLAN interface for a VLAN, create the VLAN.

VLAN interface configuration example

Network requirements

As shown in [Figure 39](#), PC A is assigned to VLAN 5. PC B is assigned to VLAN 10. The PCs belong to different IP subnets and cannot communicate with each other.

Configure VLAN interfaces on Switch A and configure the PCs to enable Layer 3 communication between the PCs.

Figure 39 Network diagram

Configuration procedure

1. Configure Switch A:

Create VLAN 5 and assign GigabitEthernet 1/0/1 to it.

```
<SwitchA> system-view
```

```
[SwitchA] vlan 5
```

```
[SwitchA-vlan5] port GigabitEthernet 1/0/1
```

Create VLAN 10 and assign GigabitEthernet 1/0/2 to it.

```
[SwitchA-vlan5] vlan 10
```

```
[SwitchA-vlan10] port GigabitEthernet 1/0/2
```

```
[SwitchA-vlan10] quit
```

Create VLAN-interface 5 and configure its IP address as 192.168.0.10/24.

```
[SwitchA] interface vlan-interface 5
```

```
[SwitchA-Vlan-interface5] ip address 192.168.0.10 24
```

```
[SwitchA-Vlan-interface5] quit
```

Create VLAN-interface 10 and configure its IP address as 192.168.1.20/24.

```
[SwitchA] interface vlan-interface 10
```

```
[SwitchA-Vlan-interface10] ip address 192.168.1.20 24
```

```
[SwitchA-Vlan-interface10] return
```

2. Configure PC A:

Configure the default gateway of the PC as 192.168.0.10.

3. Configure PC B:

Configure the default gateway of the PC as 192.168.1.20.

Verifying the configurations

1. The PCs can ping each other.

2. Display brief information about Layer 3 interfaces on Switch A to verify the configuration.

```
<SwitchA> display ip interface brief
*down: administratively down
(s): spoofing
Interface                Physical Protocol IP Address      Description
Vlan-interface5         up        up        192.168.0.10    Vlan-inte...
Vlan-interface10       up        up        192.168.1.20    Vlan-inte...
```

Configuring port-based VLANs

Introduction to port-based VLAN

Port-based VLANs group VLAN members by port. A port forwards traffic for a VLAN only after it is assigned to the VLAN.

Port link type

You can configure the link type of a port as access, trunk, or hybrid. The link types use the following VLAN tag handling methods:

- An access port belongs to only one VLAN and sends traffic untagged. It is usually used to connect a terminal device unable to identify VLAN tagged-packets or when separating different VLAN members is unnecessary.
- A trunk port can carry multiple VLANs to receive and send traffic for them. Except traffic from the port VLAN ID (PVID), traffic sent through a trunk port will be VLAN tagged. Usually, ports that connect network devices are configured as trunk ports.
- Like a trunk port, a hybrid port can carry multiple VLANs to receive and send traffic for them. Unlike a trunk port, a hybrid port allows traffic of all VLANs to pass through VLAN untagged. You can configure a port connected to a network device or user terminal as a hybrid port.

PVID

By default, VLAN 1 is the PVID for all ports. You can configure the PVID for a port as required.

When you configure the PVID on a port, use the following guidelines:

- An access port can join only one VLAN. The VLAN to which the access port belongs is the PVID of the port. The PVID of the access port changes along with the VLAN to which the port belongs.
- A trunk or hybrid port can join multiple VLANs. You can configure a PVID for the port.
- You can use a nonexistent VLAN as the PVID for a hybrid or trunk port but not for an access port. After you use the **undo vlan** command to remove the VLAN that an access port resides in, the PVID of the port changes to VLAN 1. The removal of the VLAN specified as the PVID of a trunk or hybrid port, however, does not affect the PVID setting on the port.

When you configure a PVID, follow these guidelines:

- Do not set the voice VLAN as the PVID of a port in automatic voice VLAN assignment mode. For information about voice VLAN, see "[Configuring a voice VLAN](#)."
- HP recommends that you set the same PVID ID for local and remote ports.
- Make sure that a port is assigned to its PVID. Otherwise, when the port receives frames tagged with the PVID or untagged frames (including protocol packets such as MSTP BPDUs), the port filters out these frames.

The following table shows how ports of different link types handle frames:

Port type	Actions (in the inbound direction)		Actions (in the outbound direction)
	Untagged frame	Tagged frame	
Access	Tags the frame with the PVID tag.	<ul style="list-style-type: none"> Receives the frame if its VLAN ID is the same as the PVID. Drops the frame if its VLAN ID is different from the PVID. 	Removes the VLAN tag and sends the frame.
Trunk	<p>Checks whether the PVID is permitted on the port:</p> <ul style="list-style-type: none"> If yes, tags the frame with the PVID tag. If not, drops the frame. 	<ul style="list-style-type: none"> Receives the frame if its VLAN is carried on the port. Drops the frame if its VLAN is not carried on the port. 	<ul style="list-style-type: none"> Removes the tag and send the frame if the frame carries the PVID tag and the port belongs to the PVID. Sends the frame without removing the tag if its VLAN is carried on the port but is different from the PVID.
Hybrid			Sends the frame if its VLAN is carried on the port. The frame is sent with the VLAN tag removed or intact depending on your configuration via the port hybrid vlan command. This is true of the PVID.

Assigning an access port to a VLAN

You can assign an access port to a VLAN in VLAN view, interface view (including Layer 2 Ethernet interface view, and Layer 2 aggregate interface view), or port group view.

To assign one or multiple access ports to a VLAN in VLAN view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	If the specified VLAN does not exist, this command creates the VLAN first.
3. Assign one or a group of access ports to the VLAN.	port <i>interface-list</i>	By default, all ports belong to VLAN 1.

To assign an access port (in interface view) or multiple access ports (in port group view) to a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	<p>Use any command.</p> <ul style="list-style-type: none"> The configuration made in Layer 2 Ethernet interface view applies only to the port. The configuration made in port group view applies to all ports in the port group. The configuration made in Layer 2 aggregate interface view applies to the aggregate interface and its aggregation member ports. If the system fails to apply the configuration to the aggregate interface, it stops applying the configuration to aggregation member ports. If the system fails to apply the configuration to an aggregation member port, it skips the port and moves to the next member port.
3. Configure the link type of the ports as access.	port link-type access	Optional. By default, all ports are access ports.
4. Assign the access ports to a VLAN.	port access vlan <i>vlan-id</i>	Optional. By default, all access ports belong to VLAN 1.

NOTE:

- Before you assign an access port to a VLAN, create the VLAN.
- In VLAN view, you can assign only Layer 2 Ethernet interfaces to the VLAN.

Assigning a trunk port to a VLAN

A trunk port can carry multiple VLANs. You can assign it to a VLAN in interface view (including Layer 2 Ethernet interface view, and Layer 2 aggregate interface view) or port group view.

To assign a trunk port to one or multiple VLANs:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	<p>Use any command.</p> <ul style="list-style-type: none"> The configuration made in Layer 2 Ethernet interface view applies only to the port. The configuration made in port group view applies to all ports in the port group. The configuration made in Layer 2 aggregate interface view applies to the aggregate interface and its aggregation member ports. If the system fails to apply the configuration to the aggregate interface, it stops applying the configuration to aggregation member ports. If the system fails to apply the configuration to an aggregation member port, it skips the port and moves to the next member port.
3. Configure the link type of the ports as trunk.	port link-type trunk	<p>By default, all ports are access ports.</p> <p>To change the link type of a port from trunk to hybrid or vice versa, you must set the link type to access first.</p>
4. Assign the trunk ports to the specified VLANs.	port trunk permit vlan { <i>vlan-id-list</i> all }	By default, a trunk port carries only VLAN 1.
5. Configure the PVID of the trunk ports.	port trunk pvid vlan <i>vlan-id</i>	<p>Optional.</p> <p>By default, the PVID is VLAN 1.</p>

NOTE:

After configuring the PVID for a trunk port, you must use the **port trunk permit vlan** command to configure the trunk port to allow packets from the PVID to pass through, so that the egress port can forward packets from the PVID.

Assigning a hybrid port to a VLAN

A hybrid port can carry multiple VLANs. You can assign it to a VLAN in interface view (including Ethernet interface view, and Layer 2 aggregate interface view) or port group view.

To assign a hybrid port to one or multiple VLANs:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
		Use any command.
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	<ul style="list-style-type: none"> The configuration made in Ethernet interface view applies only to the port. The configuration made in port group view applies to all ports in the port group. The configuration made in Layer 2 aggregate interface view applies to the aggregate interface and its aggregation member ports. If the system fails to apply the configuration to the aggregate interface, it stops applying the configuration to aggregation member ports. If the system fails to apply the configuration to an aggregation member port, it skips the port and moves to the next member port.
3. Configure the link type of the ports as hybrid.	port link-type hybrid	By default, all ports are access ports. To change the link type of a port from trunk to hybrid or vice versa, you must set the link type to access first.
4. Assign the hybrid ports to the specified VLANs.	port hybrid vlan <i>vlan-id-list</i> { tagged untagged }	By default, a hybrid port allows only packets of VLAN 1 to pass through untagged.
5. Configure the PVID of the hybrid ports.	port hybrid pvid vlan <i>vlan-id</i>	Optional. By default, the PVID is VLAN 1.

NOTE:

- Before you assign a hybrid port to a VLAN, create the VLAN.
- After configuring the PVID for a hybrid port, you must use the **port hybrid vlan** command to configure the hybrid port to allow packets from the PVID to pass through, so that the egress port can forward packets from the PVID.

Port-based VLAN configuration example

Network requirements

As shown in [Figure 40](#):

- Host A and Host C belong to Department A, and access the enterprise network through different devices. Host B and Host D belong to Department B. They also access the enterprise network through different devices.
- To ensure communication security and avoid broadcast storms, VLANs are configured in the enterprise network to isolate Layer 2 traffic of different departments. VLAN 100 is assigned to Department A, and VLAN 200 is assigned to Department B.
- Make sure that hosts within the same VLAN can communicate with each other. Host A can communicate with Host C, and Host B can communicate with Host D.

Figure 40 Network diagram

Configuration procedure

1. Configure Device A:

Create VLAN 100, and assign port GigabitEthernet 1/0/1 to VLAN 100.

```
<DeviceA> system-view
[DeviceA] vlan 100
[DeviceA-vlan100] port gigabitethernet 1/0/1
[DeviceA-vlan100] quit
```

Create VLAN 200, and assign port GigabitEthernet 1/0/2 to VLAN 200.

```
[DeviceA] vlan 200
[DeviceA-vlan200] port gigabitethernet 1/0/2
[DeviceA-vlan200] quit
```

Configure port GigabitEthernet 1/0/3 as a trunk port, and assign it to VLANs 100 and 200, to enable GigabitEthernet 1/0/3 to forward traffic of VLANs 100 and 200 to Device B.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-type trunk
[DeviceA-GigabitEthernet1/0/3] port trunk permit vlan 100 200
Please wait... Done.
```

2. Configure Device B as you configure Device A.

3. Configure Host A and Host C to be on the same IP subnet, 192.168.100.0/24, for example. Configure Host B and Host D to be on the same IP subnet, 192.168.200.0/24, for example.

Verifying the configurations

1. Host A and Host C and ping each other successfully, but they both fail to ping Host B. Host B and Host D and ping each other successfully, but they both fail to ping Host A.

2. Determine whether the configuration is successful by displaying relevant VLAN information.

Display information about VLANs 100 and 200 on Device A.

```
[DeviceA-GigabitEthernet1/0/3] display vlan 100
VLAN ID: 100
VLAN Type: static
Route Interface: not configured
Description: VLAN 0100
Name: VLAN 0100
Tagged Ports:
  GigabitEthernet1/0/3
Untagged Ports:
  GigabitEthernet1/0/1
```

```
[DeviceA-GigabitEthernet1/0/3] display vlan 200
VLAN ID: 200
VLAN Type: static
Route Interface: not configured
Description: VLAN 0200
Name: VLAN 0200
Tagged Ports:
  GigabitEthernet1/0/3
Untagged Ports:
  GigabitEthernet1/0/2
```

Configuring MAC-based VLANs

Introduction to MAC-based VLAN

The MAC-based VLAN feature assigns hosts to a VLAN based on their MAC addresses. This feature is usually used in conjunction with security technologies such as 802.1X to provide secure, flexible network access for terminal devices.

Static MAC-based VLAN assignment

Static MAC-based VLAN assignment applies to networks containing a small number of VLAN users. In such a network, you can create a MAC address-to-VLAN map containing multiple MAC address-to-VLAN entries on a port, enable the MAC-based VLAN feature on the port, and assign the port to MAC-based VLANs.

With static MAC-based VLAN assignment configured on a port, the device processes received frames by using the following guidelines:

- When the port receives an untagged frame, the device looks up the MAC address-to-VLAN map based on the source MAC address of the frame for a match.
 - a. The device first performs a fuzzy match. In the fuzzy match, the device searches the MAC address-to-VLAN entries whose masks are not all-Fs and performs a logical AND operation on the source MAC address and each mask. If the result of an AND operation matches the corresponding MAC address, the device tags the frame with the corresponding VLAN ID. Only the 5500 EI Switch Series supports fuzzy match.
 - b. If the fuzzy match fails, the device performs an exact match. In the exact match, the device searches the MAC address-to-VLAN entries whose masks are all-Fs. If the MAC address of a MAC address-to-VLAN entry matches the source MAC address of the untagged frame, the device tags the frame with the corresponding VLAN ID.
 - c. If no match is found, the device assigns a VLAN to the frame by using other criteria, such as IP subnet or protocol, and forwards the frame.
 - d. If no VLAN is available, the device tags the frame with the PVID of the receiving port and forwards the frame.
- When the port receives a tagged frame, the port forwards the frame if the VLAN ID of the frame is permitted by the port, or otherwise drops the frame.

Dynamic MAC-based VLAN assignment

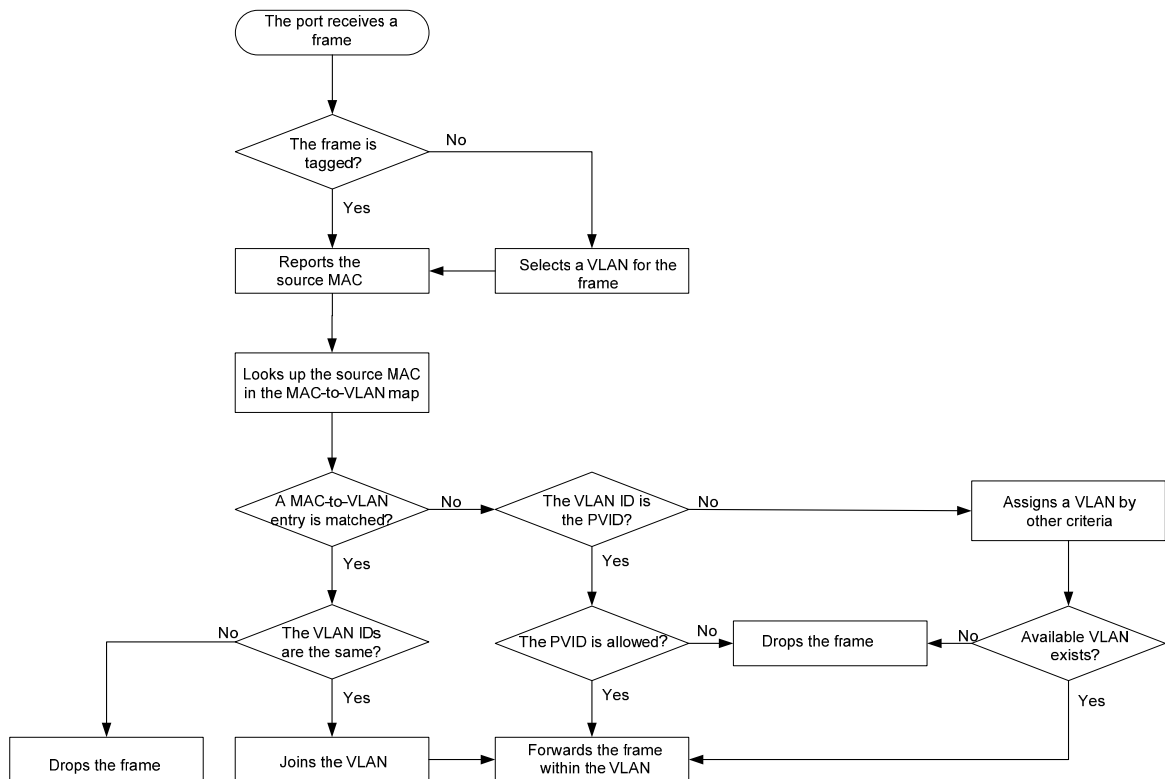

When you cannot determine the target MAC-based VLANs of a port, you can use dynamic MAC-based VLAN assignment on the port. To do that, you can create a MAC address-to-VLAN map containing

multiple MAC address-to-VLAN entries, and enable the MAC-based VLAN feature and dynamic MAC-based VLAN assignment on the port.

Dynamic MAC-based VLAN assignment uses the following workflows.

1. When the port receives a frame, the port first determines whether the frame is tagged.
 - If yes, the port reports the source MAC address of the frame.
 - If not, the port selects a VLAN for the frame by tagging the untagged frame with the PVID tag and obtaining the tag, and then reports the source MAC address of the frame.
2. After reporting the source MAC address of the frame, the port looks up the source MAC address in the MAC-to-VLAN map, and processes the frame as follows:
 - If the source MAC address of the frame matches a MAC address-to-VLAN entry configured on the port, the port checks whether the VLAN ID of the frame is the same as the VLAN in the MAC-to-VLAN entry.
 - a. If yes, the port dynamically joins the VLAN and forwards the frame.
 - b. If not, the port drops the frame.
 - If the source MAC address of the frame matches no MAC-to-VLAN entry, the port processes the frame depending on whether the VLAN ID of the frame is the PVID.
 - c. If yes, the port determines whether it allows PVID: if yes, the port tags the frame with the PVID and forwards the frame; if not, the port drops the frame.
 - d. If not, the port assigns a VLAN to the frame by using other criteria, such as IP subnet or protocol, and forwards the frame. If no VLAN is available, the port drops the frame.

Figure 41 Flowchart for processing a frame in dynamic MAC-based VLAN assignment

When you configure dynamic MAC-based VLAN assignment, follow these guidelines:

- When a port is assigned to the corresponding VLAN in a MAC address-to-VLAN entry, but has not been assigned to the VLAN by using the **port hybrid vlan** command, the port sends packets from the VLAN with VLAN tags removed.
- If you configure both static and dynamic MAC-based VLAN assignment on the same port, dynamic MAC-based VLAN assignment applies.

Dynamic MAC-based VLAN

You can use dynamic MAC-based VLAN with access authentication (such as 802.1X authentication based on MAC addresses) to implement secure, flexible terminal access. After configuring dynamic MAC-based VLAN on the device, you must configure the username-to-VLAN entries on the access authentication server.

When a user passes authentication of the access authentication server, the device obtains VLAN information from the server, generates a MAC address-to-VLAN entry by using the source MAC address of the user packet and the VLAN information, and assigns the port to the MAC-based VLAN. When the user goes offline, the device automatically deletes the MAC address-to-VLAN entry, and removes the port from the MAC-based VLAN. For more information about 802.1X, MAC, and portal authentication, see *Security Configuration Guide*.

Configuration restrictions and guidelines

When you configure a MAC-based VLAN, follow these guidelines:

- MAC-based VLANs are available only on hybrid ports.
- You cannot configure super VLANs in the MAC address-to-VLAN entries.
- With dynamic MAC-based VLAN assignment enabled, packets are delivered to the CPU for processing. The packet processing mode has the highest priority and overrides the configuration of MAC learning limit and disabling of MAC address learning. When dynamic MAC-based VLAN assignment is enabled, do not configure the MAC learning limit or disable MAC address learning.
- Do not use dynamic MAC-based VLAN assignment together with 802.X and MAC authentication.
- In dynamic MAC-based VLAN assignment, the port that receives a packet with an unknown source MAC address can be successfully assigned to the matched VLAN only when the matched VLAN is a static VLAN.
- The MAC-based VLAN feature is mainly configured on the downlink ports of the user access devices. Do not enable this function together with link aggregation.
- With MSTP enabled, if a port is blocked in the MST instance (MSTI) of the target MAC-based VLAN, the port drops the received packets, instead of delivering them to the CPU. As a result, the receiving port will not be dynamically assigned to the corresponding VLAN. Do not configure dynamic MAC-based VLAN assignment together with MSTP, because the former is mainly configured on the access side.
- When you configure MAC-to-VLAN entries, if you specify the 802.1p priority for the VLAN of a MAC address, you must configure the **qos trust dot1p** command on the corresponding port, so that the port trusts the 802.1p priority of incoming packets and your configuration takes effect. For more information about the **qos trust dot1p** command, see *ACL and QoS Command Reference*.

Configuration procedure

To configure static MAC-based VLAN assignment:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Associate a specific MAC address with a VLAN.	mac-vlan mac-address <i>mac-address</i> [mask <i>mac-mask</i>] vlan <i>vlan-id</i> [priority <i>priority</i>]	The mask keyword is available on only the 5500 EI Switch Series.
3. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	<p>Use either command.</p> <ul style="list-style-type: none"> The configuration made in Ethernet interface view applies only to the port. The configuration made in port group view applies to all ports in the port group.
4. Configure the link type of the ports as hybrid.	port link-type hybrid	By default, all ports are access ports.
5. Configure the hybrid ports to permit packets from specific MAC-based VLANs to pass through.	port hybrid vlan <i>vlan-id-list</i> { tagged untagged }	By default, a hybrid port only permits the packets from VLAN 1 to pass through.
6. Enable the MAC-based VLAN feature.	mac-vlan enable	Disabled by default.
7. Configure VLAN matching precedence.	vlan precedence { mac-vlan ip-subnet-vlan }	Optional. By default, VLANs are preferably matched based on MAC addresses.

To configure dynamic MAC-based VLAN assignment:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Associate MAC addresses with a VLAN.	mac-vlan mac-address <i>mac-address</i> vlan <i>vlan-id</i> [priority <i>priority</i>]	N/A
3. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Configure the link type of the port as hybrid.	port link-type hybrid	By default, all ports are access ports.
5. Enable the MAC-based VLAN feature.	mac-vlan enable	Disabled by default.

Step	Command	Remarks
6. Enable dynamic MAC-based VLAN assignment.	mac-vlan trigger enable	By default, dynamic MAC-based VLAN assignment is disabled. When you use the mac-vlan trigger enable command to enable dynamic MAC-based VLAN assignment, HP recommends that you configure the vlan precedence mac-vlan command, so that VLANs are assigned based on single MAC addresses preferentially. When dynamic MAC-based VLAN assignment is enabled, HP does not recommend configuring the vlan precedence ip-subnet-vlan command, which will make the system assign VLANs based on IP subnets, because the configuration does not take effect.
7. Configure VLAN matching precedence.	vlan precedence mac-vlan	Optional. By default, VLANs are preferentially matched based on MAC addresses.
8. Disable the PVID of the port from forwarding packets with unknown source MAC addresses that do not match any MAC address-to-VLAN entry.	port pvid disable	Optional. By default, when a port receives a packet with an unknown source MAC address that does not match to any MAC address-to-VLAN entry, it forwards the packet in its PVID.

To configure dynamic MAC-based VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	<p>Use either command.</p> <ul style="list-style-type: none"> The configuration made in Ethernet interface view applies only to the port. The configuration made in port group view applies to all ports in the port group.
3. Configure the link type of the ports as hybrid.	port link-type hybrid	By default, all ports are access ports.
4. Configure the hybrid ports to permit packets from specific MAC-based VLANs to pass through.	port hybrid vlan <i>vlan-id-list</i> { tagged untagged }	By default, a hybrid port only permits the packets of VLAN 1 to pass through.
5. Enable the MAC-based VLAN feature.	mac-vlan enable	Disabled by default.
6. Configure 802.1X/MAC/port authentication or any combination.	For more information, see <i>Security Command Reference</i> .	N/A

MAC-based VLAN configuration example

Network requirements

As shown in Figure 42:

- GigabitEthernet 1/0/1 of Device A and Device C are each connected to a meeting room. Laptop 1 and Laptop 2 are used for meetings and might be used in either of the two meeting rooms.
- Different departments own Laptop 1 and Laptop 2. The two departments use VLAN 100 and VLAN 200, respectively. Each laptop must be able to access only its own department server, no matter which meeting room it is used in.
- The MAC address of Laptop 1 is 000D-88F8-4E71, and that of Laptop 2 is 0014-222C-AA69.

Figure 42 Network diagram

Configuration consideration

- Create VLANs 100 and 200.
- Configure the uplink ports of Device A and Device C as trunk ports, and assign them to VLANs 100 and 200.
- Configure the downlink ports of Device B as trunk ports, and assign them to VLANs 100 and 200. Assign the uplink ports of Device B to VLANs 100 and 200.
- Associate the MAC address of Laptop 1 with VLAN 100, and associate the MAC address of Laptop 2 with VLAN 200.

Configuration procedure

1. Configure Device A:
Create VLANs 100 and 200.

```
<DeviceA> system-view  
[DeviceA] vlan 100
```

```
[DeviceA-vlan100] quit
[DeviceA] vlan 200
[DeviceA-vlan200] quit

# Associate the MAC address of Laptop 1 with VLAN 100, and associate the MAC address of
Laptop 2 with VLAN 200.
```

```
[DeviceA] mac-vlan mac-address 000d-88f8-4e71 vlan 100
```

```
[DeviceA] mac-vlan mac-address 0014-222c-aa69 vlan 200
```

```
# Configure Laptop 1 and Laptop 2 to access the network through GigabitEthernet 1/0/1.
Configure GigabitEthernet 1/0/1 as a hybrid port that sends packets of VLANs 100 and 200
untagged, and enable the MAC-based VLAN feature on it.
```

```
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] port link-type hybrid
```

```
[DeviceA-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
```

```
Please wait... Done.
```

```
[DeviceA-GigabitEthernet1/0/1] mac-vlan enable
```

```
[DeviceA-GigabitEthernet1/0/1] quit
```

```
# To enable the laptops to access Server 1 and Server 2, configure the uplink port GigabitEthernet
1/0/2 as a trunk port, and assign it to VLANs 100 and 200.
```

```
[DeviceA] interface gigabitethernet 1/0/2
```

```
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
```

```
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 100 200
```

```
[DeviceA-GigabitEthernet1/0/2] quit
```

2. Configure Device B:

```
# Create VLANs 100 and 200. Assign GigabitEthernet 1/0/13 to VLAN 100, and assign
GigabitEthernet 1/0/14 to VLAN 200.
```

```
<DeviceB> system-view
```

```
[DeviceB] vlan 100
```

```
[DeviceB-vlan100] port gigabitethernet 1/0/13
```

```
[DeviceB-vlan100] quit
```

```
[DeviceB] vlan 200
```

```
[DeviceB-vlan200] port gigabitethernet 1/0/14
```

```
[DeviceB-vlan200] quit
```

```
# Configure GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 as trunk ports, and assign them
to VLANs 100 and 200.
```

```
[DeviceB] interface gigabitethernet 1/0/3
```

```
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
```

```
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 100 200
```

```
[DeviceB-GigabitEthernet1/0/3] quit
```

```
[DeviceB] interface gigabitethernet 1/0/4
```

```
[DeviceB-GigabitEthernet1/0/4] port link-type trunk
```

```
[DeviceB-GigabitEthernet1/0/4] port trunk permit vlan 100 200
```

```
[DeviceB-GigabitEthernet1/0/4] quit
```

3. Configure Device C:

```
Configure Device C as you configure Device A.
```

Verifying the configurations

1. Laptop 1 can access Server 1 only, and Laptop 2 can access Server 2 only.

2. On Device A and Device C, you can see that VLAN 100 is associated with the MAC address of Laptop 1, and VLAN 200 is associated with the MAC address of Laptop 2.

```
[DeviceA] display mac-vlan all
The following MAC VLAN addresses exist:
S:Static D:Dynamic
MAC ADDR          MASK                VLAN ID  Prio  STATE
-----
000d-88f8-4e71    ffff-ffff-ffff    100      0     S
0014-222c-aa69    ffff-ffff-ffff    200      0     S

Total MAC VLAN address count:2
```

Configuration guidelines

1. MAC-based VLAN can be configured only on hybrid ports.
2. MAC-based VLAN is usually configured on the downlink ports of access layer devices, and cannot be configured together with the link aggregation function.

Configuring protocol-based VLANs

Introduction to protocol-based VLAN

You use the protocol-based VLAN feature to assign packets to VLANs by their application type.

The protocol-based VLAN feature assigns inbound packets to different VLANs based on their protocol type and encapsulation format. The protocols available for VLAN assignment include IP, IPX, and AppleTalk (AT), and the encapsulation formats include Ethernet II, 802.3 raw, 802.2 LLC, and 802.2 SNAP.

A protocol template defines a protocol type and an encapsulation format. A protocol-based VLAN ID and a protocol index, combined, can uniquely identify a protocol template. You can assign multiple protocol templates to a protocol-based VLAN.

Protocol-based VLAN assignment is available only on hybrid ports, and a protocol template applies only to untagged packets.

When an untagged packet arrives, a protocol-based VLAN assignment enabled hybrid port processes the packet by using the following workflow:

- If the protocol type and encapsulation format in the packet matches a protocol template, the packet is tagged with the VLAN tag specific to the protocol template.
- If no protocol template is matched, the packet is tagged with the PVID of the port.

The port processes a tagged packet as it processes tagged packets of a port-based VLAN.

- If the port is in the same VLAN as the packet, it forwards the packet.
- If not, the port drops the packet.

Configuration restrictions and guidelines

A protocol-based VLAN processes only untagged inbound packets, whereas the voice VLAN in automatic mode processes only tagged voice traffic. Do not configure a VLAN as both a protocol-based VLAN and a voice VLAN. For more information, see "[Configuring a voice VLAN.](#)"

Configuration procedure

To configure a protocol-based VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	If the specified VLAN does not exist, this command creates the VLAN first.
3. Create a protocol template for the VLAN.	protocol-vlan [<i>protocol-index</i>] { at ipv4 ipv6 ipx { ethernetii llc raw snap } mode { ethernetii etertype <i>etype-id</i> llc { dsap <i>dsap-id</i> ssap <i>ssap-id</i> } snap etertype <i>etype-id</i> }	Not configured by default.
4. Exit VLAN view.	quit	N/A
5. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type interface-number</i> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	<p>Use any command.</p> <ul style="list-style-type: none"> The configuration made in Ethernet interface view applies only to the port. The configuration made in port group view applies to all ports in the port group. The configuration made in Layer 2 aggregate interface view applies to the aggregate interface and its aggregation member ports. If the system fails to apply the configuration to the aggregate interface, it stops applying the configuration to aggregation member ports. If the system fails to apply the configuration to an aggregation member port, it skips the port and moves to the next member port.
6. Configure the port link type as hybrid.	port link-type hybrid	By default, all ports are access ports.
7. Assign the hybrid port to the specified protocol-based VLANs.	port hybrid vlan <i>vlan-id-list</i> { tagged untagged }	By default, a hybrid port is only in VLAN 1.
8. Assign the protocol template you have created to the hybrid port.	port hybrid protocol-vlan <i>vlan-id</i> { <i>protocol-index</i> [to <i>protocol-end</i>] all }	N/A

Protocol-based VLAN configuration example

Network requirements

In a lab environment, as shown in [Figure 43](#), most hosts run the IPv4 protocol, and the rest of the hosts run the IPv6 protocol for teaching purposes. To avoid interference, isolate IPv4 traffic and IPv6 traffic at Layer 2.

Figure 43 Network diagram

Configuration consideration

Create VLANs 100 and 200. Associate VLAN 100 with IPv4, and associate VLAN 200 with IPv6. Configure protocol-based VLANs to isolate IPv4 traffic and IPv6 traffic at Layer 2.

Configuration procedure

1. Configure Device:

Create VLAN 100, and assign port GigabitEthernet 1/0/11 to VLAN 100.

```
<Device> system-view
[Device] vlan 100
[Device-vlan100] description protocol VLAN for IPv4
[Device-vlan100] port gigabitethernet 1/0/11
[Device-vlan100] quit
```

Create VLAN 200, and assign port GigabitEthernet 1/0/12 to VLAN 200.

```
[Device] vlan 200
[Device-vlan200] description protocol VLAN for IPv6
[Device-vlan200] port gigabitethernet 1/0/12
```

Create an IPv6 protocol template in the view of VLAN 200, and create an IPv4 protocol template in the view of VLAN 100.

```
[Device-vlan200] protocol-vlan 1 ipv6
[Device-vlan200] quit
[Device] vlan 100
[Device-vlan100] protocol-vlan 1 ipv4
[Device-vlan100] quit
```

Configure port GigabitEthernet 1/0/1 as a hybrid port that forwards packets of VLANs 100 and 200 untagged.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port link-type hybrid
```

```
[Device-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
Please wait... Done.
```

Associate port GigabitEthernet 1/0/1 with the IPv4 protocol template of VLAN 100 and the IPv6 protocol template of VLAN 200.

```
[Device-GigabitEthernet1/0/1] port hybrid protocol-vlan vlan 100 1
[Device-GigabitEthernet1/0/1] port hybrid protocol-vlan vlan 200 1
[Device-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a hybrid port that forwards packets of VLANs 100 and 200 untagged, and associate GigabitEthernet 1/0/2 with the IPv4 protocol template of VLAN 100 and the IPv6 protocol template of VLAN 200.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] port link-type hybrid
[Device-GigabitEthernet1/0/2] port hybrid vlan 100 200 untagged
Please wait... Done.
[Device-GigabitEthernet1/0/2] port hybrid protocol-vlan vlan 100 1
[Device-GigabitEthernet1/0/2] port hybrid protocol-vlan vlan 200 1
```

2. Keep the default settings of L2 Switch A and L2 Switch B.
3. Configure IPv4 Host A, IPv4 Host B, and IPv4 Server to be on the same IP subnet (192.168.100.0/24, for example), and configure IPv6 Host A, IPv6 Host B, and IPv6 Server to be on the same IP subnet (2001::1/64, for example).

Verifying the configurations

1. The hosts and the server in VLAN 100 can ping one another successfully. The hosts and the server in VLAN 200 can ping one another successfully. The hosts or server in VLAN 100 cannot ping the hosts and server in VLAN 200, and vice versa.
2. Display protocol-based VLAN information on Device to determine whether the configurations have become valid.

Display protocol-based VLAN configuration on Device.

```
[Device-GigabitEthernet1/0/2] display protocol-vlan vlan all
VLAN ID:100
  Protocol Index      Protocol Type
=====
  1                   ipv4
VLAN ID:200
  Protocol Index      Protocol Type
=====
  1                   ipv6
```

Display protocol-based VLAN information on the ports of Device.

```
[Device-GigabitEthernet1/0/2] display protocol-vlan interface all
Interface: GigabitEthernet 1/0/1
  VLAN ID  Protocol Index      Protocol Type
=====
  100      1                   ipv4
  200      1                   ipv6
Interface: GigabitEthernet 1/0/2
  VLAN ID  Protocol Index      Protocol Type
=====
  100      1                   ipv4
```

Configuration guidelines

Protocol-based VLAN configuration applies only to hybrid ports.

Configuring IP subnet-based VLANs

In this approach, packets are assigned to VLANs based on their source IP addresses and subnet masks. A port configured with IP subnet-based VLANs assigns a received untagged packet to a VLAN based on the source address of the packet.

This feature is used to assign packets from the specified IP subnet or IP address to a specific VLAN.

Configuration procedure

⚠ IMPORTANT:

This feature is applicable only on hybrid ports.

To configure an IP subnet-based VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Associate an IP subnet with the VLAN.	ip-subnet-vlan [<i>ip-subnet-index</i>] ip <i>ip-address</i> [<i>mask</i>]	The IP subnet or IP address to be associated with a VLAN cannot be a multicast subnet or a multicast address.
4. Return to system view.	quit	N/A
5. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter Layer 2 aggregate interface view: interface bridge-aggregation <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	<p>Use any command.</p> <ul style="list-style-type: none"> The configuration made in Ethernet interface view applies only to the port. The configuration made in port group view applies to all ports in the port group. The configuration made in Layer 2 aggregate interface view applies to the aggregate interface and its aggregation member ports. If the system fails to apply the configuration to the aggregate interface, it stops applying the configuration to aggregation member ports. If the system fails to apply the configuration to an aggregation member port, it skips the port and moves to the next member port.
6. Configure port link type as hybrid.	port link-type hybrid	By default, all ports are access ports.

Step	Command	Remarks	
7.	Configure the hybrid ports to permit the specified IP subnet-based VLANs to pass through.	port hybrid vlan <i>vlan-id-list</i> { tagged untagged }	By default, a hybrid port allows only packets from VLAN 1 to pass through untagged.
8.	Associate the hybrid ports with the specified IP subnet-based VLAN.	port hybrid ip-subnet-vlan <i>vlan</i> <i>vlan-id</i>	Not configured by default.

IP subnet-based VLAN configuration example

Network requirements

As shown in Figure 44, the hosts in the office belong to different IP subnets 192.168.5.0/24 and 192.168.50.0/24.

Configure Device C to transmit packets over separate VLANs based on their source IP addresses.

Figure 44 Network diagram

Configuration consideration

- Create VLANs 100 and 200.
- Associate IP subnets with the VLANs.
- Assign ports to the VLANs.

Configuration procedure

Associate IP subnet 192.168.5.0/24 with VLAN 100.

```
<DeviceC> system-view
```

```

[DeviceC] vlan 100
[DeviceC-vlan100] ip-subnet-vlan ip 192.168.5.0 255.255.255.0
[DeviceC-vlan100] quit

# Associate IP subnet 192.168.50.0/24 with VLAN 200.
[DeviceC] vlan 200
[DeviceC-vlan200] ip-subnet-vlan ip 192.168.50.0 255.255.255.0
[DeviceC-vlan200] quit

# Configure interface GigabitEthernet 1/0/11 to permit packets of VLAN 100 to pass through.
[DeviceC] interface GigabitEthernet 1/0/11
[DeviceC-GigabitEthernet1/0/11] port link-type hybrid
[DeviceC-GigabitEthernet1/0/11] port hybrid vlan 100 tagged
Please wait... Done.
[DeviceC-GigabitEthernet1/0/11] quit

# Configure interface GigabitEthernet 1/0/12 to permit packets of VLAN 200 to pass through.
[DeviceC] interface GigabitEthernet 1/0/12
[DeviceC-GigabitEthernet1/0/12] port link-type hybrid
[DeviceC-GigabitEthernet1/0/12] port hybrid vlan 200 tagged
Please wait... Done.
[DeviceC-GigabitEthernet1/0/12] quit

# Associate interface GigabitEthernet 1/0/1 with IP subnet-based VLANs 100 and 200.
[DeviceC] interface GigabitEthernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] port link-type hybrid
[DeviceC-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
Please wait... Done.
[DeviceC-GigabitEthernet1/0/1] port hybrid ip-subnet-vlan vlan 100
[DeviceC-GigabitEthernet1/0/1] port hybrid ip-subnet-vlan vlan 200
[DeviceC-GigabitEthernet1/0/1] return

```

Verifying the configurations

```

# Display the IP subnet information for all VLANs.
<Device C> display ip-subnet-vlan vlan all
VLAN ID: 100
Subnet Index      IP Address      Subnet Mask
=====
      0          192.168.5.0    255.255.255.0
VLAN ID: 200
Subnet Index      IP Address      Subnet Mask
=====
      0          192.168.50.0   255.255.255.0

# Display the IP subnet-based VLAN information on GigabitEthernet 1/0/1.
<DeviceC> display ip-subnet-vlan interface GigabitEthernet 1/0/1
Interface: GigabitEthernet1/0/1
VLAN ID  Subnet-Index  IP ADDRESS      NET MASK
=====
    100         0          192.168.5.0    255.255.255.0
    200         0          192.168.50.0   255.255.255.0

```

Configuration guidelines

The IP subnet-based VLAN configurations are only effective on hybrid ports.

Displaying and maintaining VLAN

Task	Command	Remarks
Display VLAN information.	display vlan [<i>vlan-id1</i> [<i>to</i> <i>vlan-id2</i>] all dynamic reserved static] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display VLAN interface information.	display interface [<i>vlan-interface</i>] [brief [down]] [{ begin exclude include } <i>regular-expression</i>] display interface <i>vlan-interface</i> <i>vlan-interface-id</i> [brief] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display hybrid ports or trunk ports on the device.	display port { hybrid trunk } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MAC address-to-VLAN entries.	display mac-vlan { all dynamic mac-address <i>mac-address</i> [mask <i>mac-mask</i>] static vlan <i>vlan-id</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Configuring a super VLAN (available only on the 5500 EI)

Overview

Super VLAN, also called VLAN aggregation, was introduced to save IP address space.

A super VLAN is associated with multiple sub-VLANs. You can create a VLAN interface for a super VLAN and assign an IP address for the VLAN interface. However, you cannot create a VLAN interface for a sub-VLAN. You can assign a physical port to a sub-VLAN, but not to a super VLAN. All ports of a sub-VLAN use the VLAN interface IP address of the associated super VLAN. Packets cannot be forwarded between sub-VLANs at Layer 2.

To enable Layer 3 communication between sub-VLANs, create a super VLAN and the VLAN interface, and enable local proxy Address Resolution Protocol (ARP) or local proxy Neighbor Discovery (ND) on the VLAN interface depending on the VLAN interface IP address type (IPv4 or IPv6) as follows:

- In an IPv4 network, enable local proxy ARP on the VLAN interface, so that the super VLAN can forward and process ARP requests and replies.
- In an IPv6 network, enable local proxy ND on the VLAN interface, so that the super VLAN can forward and process the Neighbor Solicitation (NS) messages and Neighbor Advertisement (NA) messages.

Configuration procedure

To configure a super VLAN, complete the following tasks:

1. Configure sub-VLANs.
2. Configure a super VLAN, and associate the super VLAN with the sub-VLANs configured earlier.
3. Configure a VLAN interface for the super VLAN. The VLAN interface enables communication among hosts and sub-VLANs.

Configuring sub-VLANs

To configure a sub-VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a sub-VLAN and enter VLAN view.	vlan <i>vlan-id</i>	If the specified VLAN already exists, this command enters VLAN view only.

NOTE:

To configure more sub-VLANs, repeat these steps.

Configuring a super VLAN

To configure a super VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	If the specified VLAN does not exist, this command creates the VLAN first, and then enters VLAN view.
3. Configure the VLAN as a super VLAN.	supervlan	Not configured by default.
4. Associate the super VLAN with the specified sub-VLANs.	subvlan <i>vlan-list</i>	VLANs specified by <i>vlan-list</i> must be the sub-VLANs configured earlier.

NOTE:

- When dynamic MAC-based VLAN assignment is enabled on a port, you cannot configure VLANs of the MAC address-to-VLAN entries as super VLANs.
- When a VLAN is configured as an isolate-user-VLAN or associated with secondary VLANs, you cannot configure the VLAN as a super VLAN.

Configure a VLAN interface for the super VLAN

When you a VLAN interface for the super VLAN, follow these guidelines:

- Configure the IP address of the VLAN interface with that of the corresponding super VLAN.
- For more information about local proxy ARP and proxy ND functions, see *Layer 3—IP Services Configuration Guide*. For more information about **local-proxy-arp enable** and **local-proxy-nd enable** commands, see *Layer 3—IP Services Command Reference*.
- You cannot configure a super VLAN as the guest VLAN for a port, and vice versa. For more information about guest VLANs, see *Security Configuration Guide*.
- You can configure Layer 2 multicast for a super VLAN, but the configuration is ineffective.
- You can configure DHCP, Layer 3 multicast, and dynamic routing for the VLAN interface of a super VLAN. However, only DHCP takes effect.
- HP does not recommend configuring VRRP for the VLAN interface of a super VLAN, because it affects network performance. For more information about VRRP, see *High Availability Configuration Guide*.

To configure a VLAN interface for the super VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VLAN interface, and enter VLAN interface view.	interface vlan-interface <i>vlan-interface-id</i>	The value of <i>vlan-interface-id</i> must be the ID of the super VLAN.
3. Configure the IP address of the VLAN interface.	<ul style="list-style-type: none"> • ip address <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } [sub] • ipv6 address { <i>ipv6-address</i> { <i>prefix-length</i> link-local } <i>ipv6-address/prefix-length</i> [anycast eui-64] auto [link-local] } 	Use either command. By default, the IP address of a VLAN interface is not configured.

Step	Command	Remarks
4.	Enable local proxy ARP. local-proxy-arp enable	Use either command.
5.	Enable local proxy ND. local-proxy-nd enable	Disabled by default.

Displaying and maintaining super VLAN

Task	Command	Remarks
Display the mapping between a super VLAN and its sub-VLANs.	display supervlan [<i>supervlan-id</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Super VLAN configuration example

Network requirements

As shown in Figure 45:

- Create super VLAN 10, and configure its VLAN interface IP address as 10.0.0.1/24.
- Create the sub-VLANs VLAN 2, VLAN 3, and VLAN 5.
- Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to VLAN 2, GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to VLAN 3, and GigabitEthernet 1/0/5 and GigabitEthernet 1/0/6 to VLAN 5.
- The sub-VLANs are isolated at Layer 2 but connected at Layer 3.

Figure 45 Network diagram

Configuration procedure

Create VLAN 10, and configure its VLAN interface IP address as 10.0.0.1/24.

```
<Sysname> system-view
[Sysname] vlan 10
[Sysname-vlan10] quit
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ip address 10.0.0.1 255.255.255.0
```

Enable local proxy ARP.

```
[Sysname-Vlan-interface10] local-proxy-arp enable
[Sysname-Vlan-interface10] quit
```

```

Configuring an isolate-user-VLAN

Overview

An isolate-user-VLAN uses a two-tier VLAN structure. In this approach, the following types of VLANs, isolate-user-VLAN and secondary VLAN, are configured on the same device.

The following are the characteristics of the isolate-user-VLAN implementation:

- Isolate-user-VLANs are mainly used for upstream data exchange. An isolate-user-VLAN can be associated with multiple secondary VLANs. As the upstream device identifies only the isolate-user-VLAN and not the secondary VLANs, network configuration is simplified and VLAN resources are saved.
- You can isolate the Layer 2 traffic of different users by assigning the ports connected to them to different secondary VLANs. To enable communication between secondary VLANs associated with the same isolate-user-VLAN, you can enable local proxy ARP on the upstream device (for example, Device A in [Figure 46](#)) to realize Layer 3 communication between the secondary VLANs.

As shown in [Figure 46](#), the isolate-user-VLAN function is enabled on Device B. VLAN 10 is the isolate-user-VLAN. VLAN 2, VLAN 5, and VLAN 8 are secondary VLANs associated with VLAN 10 and are invisible to Device A.

Figure 46 An isolate-user-VLAN example

To configure an isolate-user-VLAN, complete the following tasks:

1. Configure the isolate-user-VLAN.
2. Configure the secondary VLANs.
3. Configure uplink and downlink ports:
 - Configure the uplink ports, for example, the port connecting Device B to Device A in [Figure 46](#), to operate in **promiscuous** mode in the specified VLAN, so that the uplink ports can be added to the specified isolate-user-VLAN and the secondary VLANs associated with the isolate-user-VLAN synchronously.
 - Configure the downlink ports, for example, the ports connecting Device B to hosts in [Figure 46](#), to operate in host mode, so that the downlink ports can be added to the isolate-user-VLAN associated with the secondary VLAN synchronously.

- For more information about the promiscuous and host mode commands, see *Layer 2—LAN Switching Command Reference*.
- 4. Associate the isolate-user-VLAN with the specified secondary VLANs.

Configuration restrictions and guidelines

- To enable users in the isolate-user-VLAN to communicate with other networks at Layer 3, follow these steps:
 - a. Configure VLAN interfaces for the isolate-user-VLAN and the secondary VLANs, and configure the gateway IP address for the isolate-user-VLAN interface (you do not need to configure IP addresses for the secondary VLAN interfaces).
 - b. You must configure the **isolated-vlan enable** command for at least one secondary VLAN to isolate the ports in the secondary VLAN.
- The dynamic MAC addresses entries learned in the isolate-user-VLAN are automatically synchronized to all the secondary VLANs, and the dynamic MAC address entries learned in a secondary VLAN are automatically synchronized to the isolate-user-VLAN. Static MAC address entries cannot be automatically synchronized. If you have configured static MAC address entries in the isolate-user-VLAN, you should also configure the same static MAC address entries in the secondary VLANs to avoid broadcasts, and vice versa.
- You cannot configure the member port of a service loopback group as the uplink or downlink port of an isolate-user-VLAN. For more information about the service loopback group, see "[Configuring a service loopback group \(available only on the 5500 EI\)](#)."

Configuration procedure

To configure an isolate-user-VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VLAN and enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Configure the VLAN as an isolate-user-VLAN.	isolate-user-vlan enable	Not configured by default.
4. Return to system view.	quit	N/A
5. Create secondary VLANs.	vlan { <i>vlan-id1</i> [<i>to</i> <i>vlan-id2</i>] all }	N/A
6. Configure Layer 2 isolation between ports in the same secondary VLAN.	isolated-vlan enable	Optional. By default, ports in the same secondary VLAN can communicate with one another at Layer 2. This configuration takes effect only after you configure the downlink ports to operate in host mode and associate the secondary VLANs with an isolate-user-VLAN.
7. Return to system view.	quit	N/A

Step	Command	Remarks
8. Configure the uplink port.	<ul style="list-style-type: none"> a. Enter Layer 2 Ethernet or aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Or interface bridge-aggregation <i>interface-number</i> b. Configure the port to operate in promiscuous mode in a specific VLAN: port isolate-user-vlan <i>vlan-id</i> promiscuous 	N/A
9. Return to system view.	quit	N/A
10. Configure the downlink port.	<ul style="list-style-type: none"> a. Enter Layer 2 Ethernet or aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Or interface bridge-aggregation <i>interface-number</i> b. Configure the link type of the port: port link-type { access hybrid trunk } c. Assign ports to the secondary VLAN: Access port: port access vlan <i>vlan-id</i> Hybrid port: port hybrid vlan <i>vlan-id-list</i> { tagged untagged } Trunk port: port trunk permit vlan { <i>vlan-id-list</i> all } d. Configure the port to operate in host mode: port isolate-user-vlan host 	N/A
11. Return to system view.	quit	N/A
12. Associate the isolate-user-VLAN with the specified secondary VLANs.	isolate-user-vlan <i>isolate-user-vlan-id</i> secondary <i>secondary-vlan-id</i> [to <i>secondary-vlan-id</i>]	Not configured by default.

Displaying and maintaining isolate-user-VLAN

Task	Command	Remarks
Display the mapping between an isolate-user-VLAN and its secondary VLANs.	display isolate-user-vlan [<i>isolate-user-vlan-id</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Isolate-user-VLAN configuration example

Network requirements

As shown in [Figure 47](#):

- Connect Device A to downstream devices Device B and Device C.
- Configure VLAN 5 on Device B as an isolate-user-VLAN, assign the uplink port GigabitEthernet 1/0/5 to VLAN 5, and associate VLAN 5 with secondary VLANs VLAN 2 and VLAN 3. Assign GigabitEthernet 1/0/2 to VLAN 2 and GigabitEthernet 1/0/1 to VLAN 3.
- Configure VLAN 6 on Device C as an isolate-user-VLAN, assign the uplink port GigabitEthernet 1/0/5 to VLAN 6, and associate VLAN 6 with secondary VLANs VLAN 3 and VLAN 4. Assign GigabitEthernet 1/0/3 to VLAN 3 and GigabitEthernet 1/0/4 to VLAN 4.
- As far as Device A is concerned, Device B only has VLAN 5 and Device C only has VLAN 6.

Figure 47 Network diagram

Configuration procedure

The following part provides only the configuration on Device B and Device C.

1. Configure Device B:

Configure the isolate-user-VLAN.

```
<DeviceB> system-view
[DeviceB] vlan 5
[DeviceB-vlan5] isolate-user-vlan enable
[DeviceB-vlan5] quit
```

Create secondary VLANs.

```
[DeviceB] vlan 2 to 3
```

Configure the uplink port GigabitEthernet 1/0/5 to operate in promiscuous mode in VLAN 5.

```
[DeviceB] interface gigabitethernet 1/0/5
[DeviceB-GigabitEthernet1/0/5] port isolate-user-vlan 5 promiscuous
```

```
[DeviceB-GigabitEthernet1/0/5] quit
# Assign downlink ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to VLAN 3 and
VLAN 2, respectively, and configure the ports to operate in host mode.
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port access vlan 3
[DeviceB-GigabitEthernet1/0/1] port isolate-user-vlan host
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port access vlan 2
[DeviceB-GigabitEthernet1/0/2] port isolate-user-vlan host
[DeviceB-GigabitEthernet1/0/2] quit
# Associate the isolate-user-VLAN with the secondary VLANs.
[DeviceB] isolate-user-vlan 5 secondary 2 to 3
```

2. Configure Device C:

Configure the isolate-user-VLAN.

```
<DeviceC> system-view
[DeviceC] vlan 6
[DeviceC-vlan6] isolate-user-vlan enable
[DeviceC-vlan6] quit
```

Create secondary VLANs.

```
[DeviceC] vlan 3 to 4
```

Configure the uplink port GigabitEthernet 1/0/5 to operate in promiscuous mode in VLAN 6.

```
[DeviceC] interface gigabitethernet 1/0/5
[DeviceC-GigabitEthernet1/0/5] port isolate-user-vlan 6 promiscuous
[DeviceC-GigabitEthernet1/0/5] quit
```

Configure downlink ports GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to VLAN 3 and VLAN 4, respectively, and configure the ports to operate in host mode.

```
[DeviceC] interface gigabitethernet 1/0/3
[DeviceC-GigabitEthernet1/0/3] port access vlan 3
[DeviceC-GigabitEthernet1/0/3] port isolate-user-vlan host
[DeviceC-GigabitEthernet1/0/3] quit
[DeviceC] interface gigabitethernet 1/0/4
[DeviceC-GigabitEthernet1/0/4] port access vlan 4
[DeviceC-GigabitEthernet1/0/4] port isolate-user-vlan host
[DeviceC-GigabitEthernet1/0/4] quit
```

Associate the isolate-user-VLAN with the secondary VLANs.

```
[DeviceC] isolate-user-vlan 6 secondary 3 to 4
```

Verifying the configuration

Display the isolate-user-VLAN configuration on Device B.

```
[DeviceB] display isolate-user-vlan
Isolate-user-VLAN VLAN ID : 5
Secondary VLAN ID : 2-3

VLAN ID: 5
VLAN Type: static
Isolate-user-VLAN type : isolate-user-VLAN
```

Configuring a voice VLAN

Overview

A voice VLAN is configured for voice traffic. After assigning the ports that connect to voice devices to a voice VLAN, the system automatically configures quality of service (QoS) parameters for voice traffic, to improve the transmission priority of voice traffic and ensure voice quality.

Common voice devices include IP phones and integrated access devices (IADs). Only IP phones are used in the voice VLAN configuration examples in this document.

OUI addresses

A device determines whether a received packet is a voice packet by evaluating its source MAC address. A packet whose source MAC address complies with the Organizationally Unique Identifier (OUI) address of the voice device is regarded as voice traffic.

You can remove the default OUI address of a device manually and then add new ones manually. You can configure the OUI addresses of a device in advance or use the default OUI addresses. [Table 15](#) lists the default OUI address for each vendor's devices.

Table 15 The default OUI addresses of different vendors

Number	OUI address	Vendor
1	0001-E300-0000	Siemens phone
2	0003-6B00-0000	Cisco phone
3	0004-0D00-0000	Avaya phone
4	00D0-1E00-0000	Pingtel phone
5	0060-B900-0000	Philips/NEC phone
6	00E0-7500-0000	Polycom phone
7	00E0-BB00-0000	3Com phone

In general, as the first 24 bits of a MAC address (in binary format), an OUI address is a globally unique identifier that IEEE assigns to a vendor. In this document, however, OUI addresses are addresses that the system uses to determine whether a received packet is a voice packet. They are the results of the AND operation of the arguments *mac-address* and *oui-mask* in the **voice vlan mac-address** command.

Voice VLAN assignment modes

A port can be assigned to a voice VLAN in one of the following modes:

- **Automatic mode**—The system matches the source MAC address carried in the untagged packets sent when an IP phone is powered on against the device's OUI addresses. If the system finds a match, it automatically assigns the receiving port to the voice VLAN, issues ACL rules, and configures the packet precedence. You can configure a voice VLAN aging time on the device. The system will remove a port from the voice VLAN if no packet is received from the port during the aging time. The system automatically assigns ports to, or removes ports from, a voice VLAN.

Automatic mode is suitable for scenarios where PCs and IP phones connected in series access the network through the device and ports on the device transmit both voice traffic and data traffic at the same time, as shown in Figure 48. When the voice VLAN works normally, when the system reboots, the system reassigns ports in automatic voice VLAN assignment mode to the voice VLAN after the reboot, ensuring that existing voice connections can work normally. In this case, voice traffic streams do not trigger port assignment to the voice VLAN.

Figure 48 PCs and IP phones connected in series access the network

- Manual mode**—You must manually assign an IP phone accessing port to a voice VLAN. Then, the system matches the source MAC addresses carried in the packets against the device’s OUI addresses. If the system finds a match, it issues ACL rules and configures the packet precedence. In this mode, you must manually assign ports to, or remove ports from, a voice VLAN. Manual mode is suitable for scenarios where only IP phones access the network through the device and ports on the device transmit only voice traffic, as shown in Figure 49. In this mode, ports assigned to a voice VLAN transmit voice traffic exclusively, which prevents the impact of data traffic on the transmission of voice traffic.

Figure 49 Only IP phones access the network

Both modes forward tagged packets according to their tags.

Table 16 and Table 17 list the configurations required for ports of different link types to support tagged or untagged voice traffic sent from IP phones when different voice VLAN assignment modes are configured.

- IP phones send tagged voice traffic

Table 16 Required configurations on ports of different link types for them to support tagged voice traffic

Port link type	Voice VLAN assignment mode	Support for tagged voice traffic	Configuration requirements
Access	Automatic	No	N/A
	Manual		
Trunk	Automatic	Yes	The PVID of the port cannot be the voice VLAN.

Port link type	Voice VLAN assignment mode	Support for tagged voice traffic	Configuration requirements
	Manual		The PVID of the port cannot be the voice VLAN. Configure the port to permit packets of the voice VLAN to pass through.
	Automatic		The PVID of the port cannot be the voice VLAN.
Hybrid	Manual	Yes	The PVID of the port cannot be the voice VLAN. Configure the port to permit packets of the voice VLAN to pass through tagged.

- IP phones send untagged voice traffic

When IP phones send untagged voice traffic, you can only configure the voice traffic receiving ports on the device to operate in manual voice VLAN assignment mode.

Table 17 Required configurations on ports of different link types for them to support tagged voice traffic

Port link type	Voice VLAN assignment mode	Support for untagged voice traffic	Configuration requirements
Access	Automatic	No	N/A
	Manual	Yes	Configure the PVID of the port as the voice VLAN.
Trunk	Automatic	No	N/A
	Manual	Yes	Configure the PVID of the port as the voice VLAN and assign the port to the voice VLAN.
Hybrid	Automatic	No	N/A
	Manual	Yes	Configure the PVID of the port as the voice VLAN and configure the port to permit packets of the voice VLAN to pass through untagged.

When you configure the voice VLAN assignment modes, follow these guidelines:

- If an IP phone sends tagged voice traffic and its accessing port is configured with 802.1X authentication and guest VLAN, assign different VLAN IDs for the voice VLAN, the PVID of the connecting port, and the 802.1X guest VLAN.
- If an IP phone sends untagged voice traffic, to implement the voice VLAN feature, you must configure the PVID of the IP phone's accessing port as the voice VLAN. As a result, you cannot implement 802.1X authentication.
- The PVID is VLAN 1 for all ports by default. You can configure the PVID of a port and assign a port to certain VLANs by using commands. For more information, see "[Configuring VLANs.](#)"
- Use the **display interface** command to display the PVID of a port and the VLANs to which the port is assigned.

Security mode and normal mode of voice VLANs

Depending on their inbound packet filtering mechanisms, voice VLAN-enabled ports operate in the following modes:

- **Normal mode**—Voice VLAN-enabled ports receive packets that carry the voice VLAN tag, and forward packets in the voice VLAN without comparing their source MAC addresses against the OUI addresses configured for the device. If the PVID of the port is the voice VLAN and the port operates

in manual VLAN assignment mode, the port forwards all received untagged packets in the voice VLAN. In normal mode, voice VLANs are vulnerable to traffic attacks. Malicious users might send large quantities of forged voice packets to consume the voice VLAN bandwidth, affecting normal voice communication.

- **Security mode**—Only voice packets whose source MAC addresses match the recognizable OUI addresses can pass through the voice VLAN-enabled inbound port, but all other packets are dropped.

In a safe network, you can configure the voice VLANs to operate in normal mode, reducing the consumption of system resources due to source MAC addresses checking.

TIP:

HP does not recommend you transmit both voice traffic and non-voice traffic in a voice VLAN. If you must transmit both voice traffic and nonvoice traffic, make sure that the voice VLAN security mode is disabled.

Table 18 How a voice VLAN-enabled port processes packets in security and normal mode

Voice VLAN mode	Packet type	Packet processing mode
Security mode	Untagged packets	If the source MAC address of a packet matches an OUI address configured for the device, it is forwarded in the voice VLAN; otherwise, it is dropped.
	Packets that carry the voice VLAN tag	
	Packets that carry other tags	Forwarded or dropped depending on whether the port allows packets of these VLANs to pass through
Normal mode	Untagged packets	The port does not determine the source MAC addresses of inbound packets. In this way, both voice traffic and non-voice traffic can be transmitted in the voice VLAN.
	Packets that carry the voice VLAN tag	
	Packets that carry other tags	Forwarded or dropped depending on whether the port allows packets of these VLANs to pass through

Configuration prerequisites

Before you configure a voice VLAN, complete the following tasks:

- Create a VLAN.
- Configure QoS priority settings for voice VLAN traffic on an interface before you enable voice VLAN on the interface.

If the configuration order is reversed, your priority configuration will fail. For more information, see "[Configuring QoS priority settings for voice traffic on an interface.](#)"

- Configure the voice VLAN assignment mode.

For more information, see "[Configuring a port to operate in automatic voice VLAN assignment mode](#)" and "[Configuring a port to operate in manual voice VLAN assignment mode.](#)"

Configuring QoS priority settings for voice traffic on an interface

In voice VLAN applications, you can improve the quality of voice traffic by configuring the appropriate QoS priority settings, including the Class of Service (CoS) and Differentiated Services Code Point (DSCP) values, for voice traffic. Voice traffic carries its own QoS priority settings. You can configure the device either to modify or not to modify the QoS priority settings carried by incoming voice traffic.

Configuration restrictions and guidelines

Configure the QoS priority settings for voice traffic on an interface before you enable voice VLAN on the interface. If the configuration order is reversed, your priority trust setting will fail.

Configuration procedure

To configure QoS priority settings for voice traffic:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the interface to trust the QoS priority settings in incoming voice traffic, but not to modify the CoS and DSCP values marked for incoming traffic of the voice VLAN.	voice vlan qos trust	Use either command. By default, an interface modifies the CoS value and the DSCP value marked for voice VLAN traffic into 6 and 46, respectively.
4. Configure the interface to modify the CoS and DSCP values marked for incoming traffic of the voice VLAN into specified values.	voice vlan qos <i>cos-value</i> <i>dscp-value</i>	The voice vlan qos command and the voice vlan qos trust command can overwrite each other, whichever is configured last.

Configuring a port to operate in automatic voice VLAN assignment mode

To set a port to operate in automatic voice VLAN assignment mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Set the voice VLAN aging time.	voice vlan aging <i>minutes</i>	Optional. By default, the aging time of a voice VLAN is 1440 minutes. The voice VLAN aging time configuration is only applicable on ports in automatic voice VLAN assignment mode.
3. Enable the voice VLAN security mode.	voice vlan security enable	Optional. By default, the voice VLAN security mode is enabled.
4. Add a recognizable OUI address.	voice vlan mac-address <i>oui mask oui-mask [description text]</i>	Optional. By default, each voice VLAN has default OUI addresses configured. For the default OUI addresses of different vendors, see Table 15 .
5. Enter Ethernet interface view.	interface <i>interface-type interface-number</i>	N/A
6. Configure the port to operate in automatic voice VLAN assignment mode.	voice vlan mode auto	Optional. By default, the automatic voice VLAN assignment mode is enabled. The voice VLAN assignment modes on different ports are independent of one another.
7. Enable the voice VLAN feature.	voice vlan <i>vlan-id</i> enable	By default, the voice VLAN feature is disabled.

NOTE:

A protocol-based VLAN on a hybrid port can process only untagged inbound packets, whereas the voice VLAN in automatic mode on a hybrid port can process only tagged voice traffic. Do not configure a VLAN as both a protocol-based VLAN and a voice VLAN. For more information, see "[Configuring VLANs](#)."

Configuring a port to operate in manual voice VLAN assignment mode

Configuration restrictions and guidelines

- You can configure different voice VLANs on different ports at the same time. However, you can configure one port with only one voice VLAN, and this voice VLAN must be a static VLAN that already exists on the device.
- You cannot enable voice VLAN on the member ports of a link aggregation group. For more information about the member ports, see "[Configuring Ethernet link aggregation](#)."
- To make voice VLAN take effect on a port that is enabled with voice VLAN and operates in manual voice VLAN assignment mode, you must assign the port to the voice VLAN manually.

Configuration procedure

To set a port to operate in manual voice VLAN assignment mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the voice VLAN security mode.	voice vlan security enable	Optional. By default, the voice VLAN security mode is enabled.
3. Add a recognizable OUI address.	voice vlan mac-address <i>oui mask</i> <i>oui-mask</i> [description <i>text</i>]	Optional. By default, each voice VLAN has default OUI addresses configured. For the default OUI addresses of different vendors, see Table 15 .
4. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
5. Configure the port to operate in manual voice VLAN assignment mode.	undo voice vlan mode auto	By default, the manual voice VLAN assignment mode is disabled.
6. Assign the access, trunk, or hybrid port in manual voice VLAN assignment mode to the voice VLAN.	For the configuration procedure, see " Configuring VLANs ."	After you assign an access port to the voice VLAN, the voice VLAN becomes the PVID of the port automatically.
7. Configure the voice VLAN as the PVID of the trunk or hybrid port.	For the configuration procedure, see " Configuring VLANs ."	Optional. This operation is required for untagged inbound voice traffic and prohibited for tagged inbound voice traffic.
8. Enable voice VLAN on the port.	voice vlan <i>vlan-id</i> enable	Disabled by default.

Displaying and maintaining voice VLAN

Task	Command	Remarks
Display the voice VLAN state.	display voice vlan state [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the OUI addresses that the system supports.	display voice vlan oui [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Voice VLAN configuration examples

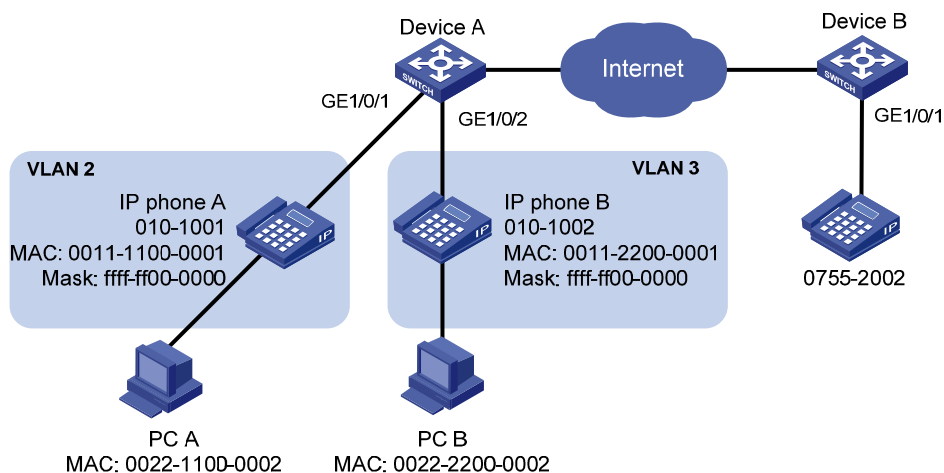

Automatic voice VLAN mode configuration example

Network requirements

As shown in [Figure 50](#),

- The MAC address of IP phone A is 0011-1100-0001. The phone connects to a downstream device named PC A whose MAC address is 0022-1100-0002 and to GigabitEthernet 1/0/1 on an upstream device named Device A.
- The MAC address of IP phone B is 0011-2200-0001. The phone connects to a downstream device named PC B whose MAC address is 0022-2200-0002 and to GigabitEthernet 1/0/2 on Device A.
- Device A uses voice VLAN 2 to transmit voice packets for IP phone A and uses voice VLAN 3 to transmit voice packets for IP phone B.
- Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to operate in automatic voice VLAN assignment mode. In addition, if one of them has not received any voice packet in 30 minutes, the port is removed from the corresponding voice VLAN automatically.

Figure 50 Network diagram

Configuration procedure

Create VLAN 2 and VLAN 3.

```
<DeviceA> system-view
[DeviceA] vlan 2 to 3
Please wait... Done.
```

Set the voice VLAN aging time to 30 minutes.

```
[DeviceA] voice vlan aging 30
```

Since GigabitEthernet 1/0/1 might receive both voice traffic and data traffic at the same time, to ensure the quality of voice packets and effective bandwidth use, configure voice VLANs to operate in security mode. Configure the voice VLANs to transmit only voice packets. By default, voice VLANs operate in security mode. (Optional)

```
[DeviceA] voice vlan security enable
```

Configure the allowed OUI addresses as MAC addresses prefixed by 0011-1100-0000 or 0011-2200-0000. In this way, Device A identifies packets whose MAC addresses match any of the configured OUI addresses as voice packets.

```
[DeviceA] voice vlan mac-address 0011-1100-0001 mask ffff-ff00-0000 description IP phone A
[DeviceA] voice vlan mac-address 0011-2200-0001 mask ffff-ff00-0000 description IP phone B
```

Configure GigabitEthernet 1/0/1 as a hybrid port.

```
[DeviceA] interface gigabitethernet 1/0/1
```

```

[DeviceA-GigabitEthernet1/0/1] port link-type hybrid

# Configure GigabitEthernet 1/0/1 to operate in automatic voice VLAN assignment mode. By default,
a port operates in automatic voice VLAN assignment mode. (Optional)
[DeviceA-GigabitEthernet1/0/1] voice vlan mode auto

# Configure VLAN 2 as the voice VLAN for GigabitEthernet 1/0/1.
[DeviceA-GigabitEthernet1/0/1] voice vlan 2 enable
[DeviceA-GigabitEthernet1/0/1] quit

# Configure GigabitEthernet 1/0/2.
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type hybrid
[DeviceA-GigabitEthernet1/0/2] voice vlan mode auto
[DeviceA-GigabitEthernet1/0/2] voice vlan 3 enable

```

Verifying the configurations

Display the OUI addresses, OUI address masks, and description strings.

```

<DeviceA> display voice vlan oui

Manual voice VLAN assignment mode configuration example

Network requirements

As shown in [Figure 51](#),

- Create VLAN 2 and configure it as a voice VLAN that permits only voice traffic to pass through.
- The IP phones send untagged voice traffic. Configure GigabitEthernet 1/0/1 as a hybrid port.

- Configure GigabitEthernet 1/0/1 to operate in manual voice VLAN assignment mode. Configure GigabitEthernet 1/0/1 to allow voice traffic with an OUI address of 0011-2200-0000, a mask of ffff-ff00-0000, and a description string of **test** to be forwarded in the voice VLAN.

Figure 51 Network diagram

Configuration procedure

Configure the voice VLAN to operate in security mode. A voice VLAN operates in security mode by default. (Optional)

```
<DeviceA> system-view
[DeviceA] voice vlan security enable
```

Add a recognizable OUI address 0011-2200-0000.

```
[DeviceA] voice vlan mac-address 0011-2200-0000 mask ffff-ff00-0000 description test
```

Create VLAN 2.

```
[DeviceA] vlan 2
[DeviceA-vlan2] quit
```

Configure GigabitEthernet 1/0/1 to operate in manual voice VLAN assignment mode.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo voice vlan mode auto
```

Configure GigabitEthernet 1/0/1 as a hybrid port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type hybrid
```

Configure the voice VLAN (VLAN 2) as the PVID of GigabitEthernet 1/0/1 and configure GigabitEthernet 1/0/1 to permit the voice traffic of VLAN 2 to pass through untagged.

```
[DeviceA-GigabitEthernet1/0/1] port hybrid pvid vlan 2
[DeviceA-GigabitEthernet1/0/1] port hybrid vlan 2 untagged
```

Enable voice VLAN on GigabitEthernet 1/0/1.

```
[DeviceA-GigabitEthernet1/0/1] voice vlan 2 enable
```

Verifying the configurations

Display the OUI addresses, OUI address masks, and description strings.

```
<DeviceA> display voice vlan oui
```

Oui Address	Mask	Description
0001-e300-0000	ffff-ff00-0000	Siemens phone
0003-6b00-0000	ffff-ff00-0000	Cisco phone
0004-0d00-0000	ffff-ff00-0000	Avaya phone
0011-2200-0000	ffff-ff00-0000	test
00d0-1e00-0000	ffff-ff00-0000	Pingtel phone

```
0060-b900-0000 ffff-ff00-0000 Philips/NEC phone
00e0-7500-0000 ffff-ff00-0000 Polycom phone
00e0-bb00-0000 ffff-ff00-0000 3com phone
```

Display the states of voice VLANs.

```
<DeviceA> display voice vlan state
```

```
Maximum of Voice VLANs: 8
```

```
Current Voice VLANs: 1
```

```
Voice VLAN security mode: Security
```

```
Voice VLAN aging time: 1440 minutes
```

```
Voice VLAN enabled port and its mode:

PORT	VLAN	MODE	COS	DSCP

GigabitEthernet1/0/1	2	MANUAL	6	46

Configuring GVRP

The Generic Attribute Registration Protocol (GARP) provides a generic framework for devices in a switched LAN, such as end stations and switches, to register and deregister attribute values. The GARP VLAN Registration Protocol (GVRP) is a GARP application that registers and deregisters VLAN attributes. GVRP uses the operating mechanism of GARP to maintain and propagate dynamic VLAN registration information for GVRP devices on the network.

Overview

GARP

GARP provides a mechanism that allows participants in a GARP application to distribute, propagate, and register—with other participants in a LAN—the attributes specific to the GARP application, such as VLAN or multicast address attributes.

How GARP works

Each port that participates in a GARP application (GVRP, for example) is a GARP participant.

GARP enables GARP participants to propagate attribute values throughout the switched LAN. As shown in Figure 52, a GARP participant registers and deregisters its attribute values with other GARP participants by sending and withdrawing declarations, and registers and deregisters the attribute values of other participants according to the declarations and withdrawals that it has received.

Figure 52 How GARP works

For example, a GVRP-enabled port registers and deregisters VLAN in the following cases.

- When the port receives a VLAN attribute declaration, it registers the VLAN attribute and joins the VLAN.
- When the port receives a VLAN withdrawal, it deregisters the VLAN and leaves the VLAN.

GARP messages

A GARP participant exchanges information with other GARP participants by sending GARP messages: Join, Leave, and LeaveAll. As a GARP application, GVRP also uses GARP messages for information exchange.

- Join messages

A GARP participant sends Join messages when it wishes to declare its attribute values or receives Join messages from other GARP participants.

Join messages fall into JoinEmpty and JoinIn. A GARP participant sends JoinEmpty messages to declare attribute values that it has not registered. It sends JoinIn messages to declare attribute values that it has registered.

- Leave messages

A GARP participant sends Leave messages when it wishes to withdraw declarations of its attribute values (because, for example, it has deregistered its attribute values), or receives Leave messages from other participants.

Leave messages fall into LeaveEmpty and LeaveIn. A GARP participant sends LeaveEmpty messages to withdraw declarations of the attribute values that it has not registered. It sends LeaveIn messages to withdraw declarations of the attribute values that it has registered.

- LeaveAll messages

A GARP participant sends a LeaveAll message when it declares that it is deregistering all attribute values or receives LeaveAll messages from other participants. If any participants want to maintain the registration for a particular attribute value, they must send a Join message.

GARP timers

HP's implementation of GARP uses the following timers to control GARP message transmission:

- Hold timer

The Hold timer sets the delay that a GARP participant waits before sending a Join or Leave message.

When an attribute value changes or a Join or Leave message arrives, the GARP participant does not send the message immediately. Rather, it assembles Join and Leave messages in the least number of GARP PDUs, and sends them out when the Hold timer expires. This timer reduces the number of GARP PDUs and saves bandwidth.

- Join timer

A GARP participant might declare an attribute twice to ensure reliable transmission. The Join timer sets the interval between the two declarations.

A GARP participant starts a Join timer when it declares an attribute value or receives a JoinIn message for the attribute value. If the GARP participant does not receive any declaration for the attribute value when the Join timer expires, it re-declares the attribute value.

Because all attributes of a GARP participant share the same Join timer, you must set the Join timer long enough so that all attributes can be sent out in one declaration.

- Leave timer

A GARP participant starts a Leave timer when it receives a Leave message for an attribute value. If the GARP participant receives no Join message for the attribute value before the timer expires, it deregisters the attribute value.

- LeaveAll timer

When a GARP application is enabled, a LeaveAll timer starts. The GARP participant sends a LeaveAll message when the timer expires. Then, the LeaveAll timer restarts to begin a new cycle. The LeaveAll timer and all other GARP timers also restart when the GARP participant receives a LeaveAll message.

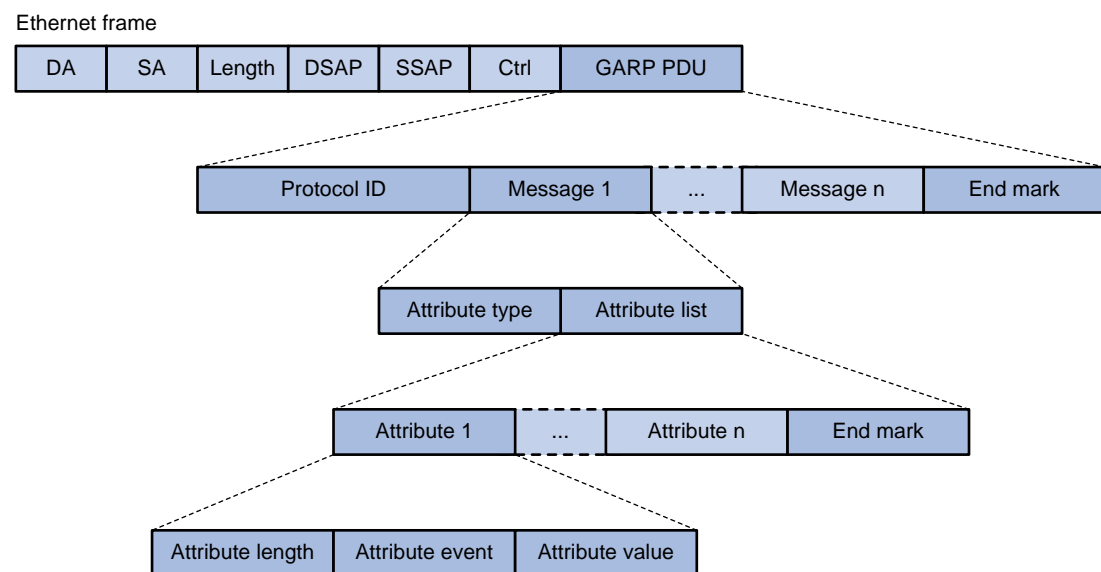

When you configure GARP timers, follow these guidelines:

- The settings of GARP timers apply to all GARP applications, such as GVRP, on a LAN.

- On a GARP-enabled network, each port maintains its own Hold, Join, and Leave timers, but only one LeaveAll timer is maintained on each device. This LeaveAll timer applies to all ports on the device.
- The value ranges for the Hold, Join, Leave, and LeaveAll timers are dependent on one another. See [Table 20](#) for their dependencies.
- Set the LeaveAll timer greater than any Leave timer and not smaller than its default value, 1000 centiseconds. Each time a LeaveAll timer expires, a network-wide re-join occurs.
- A device can send LeaveAll messages at the interval set by its LeaveAll timer or the LeaveAll timer of another device on the network, whichever is smaller. This is because each time a device on the network receives a LeaveAll message, it resets its LeaveAll timer.

GARP PDU format

Figure 53 GARP PDU format

As shown in [Figure 53](#), GARP PDUs are encapsulated in IEEE 802.3 Ethernet frames.

Table 19 GARP PDU fields

Field	Description	Value
Protocol ID	Protocol identifier for GARP	0x0001
Message	One or multiple messages, each of which contains an attribute type and an attribute list	N/A
End mark	Indicates the end of a GARP PDU	0x00
Attribute type	Defined by the GARP application	0x01 for GVRP, which indicates the VLAN ID attribute
Attribute list	Contains one or multiple attributes	N/A
Attribute	Consists of an attribute length, an attribute event, and an attribute value	N/A
Attribute length	Length of an attribute, inclusive of the attribute length field	2 to 255 (in bytes)

Field	Description	Value
Attribute event	Event that the attribute describes	<ul style="list-style-type: none"> • 0x00—LeaveAll event • 0x01—JoinEmpty event • 0x02—JoinIn event • 0x03—LeaveEmpty event • 0x04—LeaveIn event • 0x05—Empty event
Attribute value	Attribute value	VLAN ID for GVRP If the value of the attribute event field is 0x00 (LeaveAll event), the attribute value field is invalid.

The destination MAC addresses of GARP messages are multicast MAC addresses, and vary with GARP applications. For example, the destination MAC address of GVRP is 01-80-C2-00-00-21.

GVRP

GVRP overview

As a GARP application, GVRP uses the operating mechanism of GARP to maintain and propagate dynamic VLAN registrations throughout a switched LAN.

In a switched LAN, each GVRP-enabled switch sends and receives VLAN declarations and withdrawals from other GVRP-enabled switches, and dynamically updates its local database, including active VLAN members and through which port each VLAN member can be reached. This makes sure that all GVRP-enabled switches in a LAN maintain the same VLAN information.

The VLAN information propagated by GVRP includes not only manually configured static VLAN information but also dynamic VLAN information from other switches.

GVRP registration modes

GVRP is available on trunk ports. It provides the following registration modes:

- **Normal mode**—Performs dynamic VLAN registrations and deregistrations on the trunk port, and sends declarations and withdrawals for dynamic and static VLANs. VLANs manually configured are called static VLANs, and VLANs created by GVRP are called dynamic VLANs.
- **Fixed mode**—Disables the trunk port to register or withdraw dynamic VLAN information, but allows the port to send declarations for static VLANs. A trunk port in this mode carries only static VLANs, even if it has been assigned to all VLANs.
- **Forbidden mode**—Disables the trunk port to register or withdraw dynamic VLAN information, and allows the port to send declarations only for VLAN 1. A trunk port in this mode carries only VLAN 1 even if it has been assigned to any other VLANs.

Protocols and standards

IEEE 802.1Q, *Virtual Bridged Local Area Networks*

GVRP configuration task list

When you configure GVRP, follow these guidelines:

- GVRP configuration made in Ethernet interface view or Layer 2 aggregate interface view takes effect on the current interface only; GVRP configuration made in port group view takes effect on all the member ports in the group.
- GVRP configuration made on a member port in an aggregation group takes effect only after the port is removed from the aggregation group.

Complete these tasks to configure GVRP:

Task	Remarks
Configuring GVRP functions	Required
Configuring the GARP timers	Optional

Configuring GVRP functions

Before enabling GVRP on a port, you must enable GVRP globally. In addition, you can configure GVRP only on trunk ports, and you must assign the involved trunk ports to all dynamic VLANs.

Configuration restrictions and guidelines

- GVRP is mutually exclusive with service loopback.
- GVRP can work with STP, RSTP, or MSTP CIST but not PVST. When GVRP runs on the CIST, blocked ports on the CIST cannot receive or send GVRP packets. For more information about STP, RSTP, MSTP CIST, and PVST, see "[Configuring spanning tree protocols.](#)"
- Do not enable both GVRP and remote port mirroring. Otherwise, GVRP may register the remote probe VLAN to unexpected ports, resulting in undesired duplicates to be received by the monitor port. For more information about port mirroring, see *Network Management and Monitoring Configuration Guide*.
- Enabling GVRP on a Layer 2 aggregate interface enables both the aggregate interface and all selected member ports in the corresponding link aggregation group to participate in dynamic VLAN registration and deregistration.

Configuration procedure

To configure GVRP functions on a trunk port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable GVRP globally.	gvrp	Globally disabled by default.
3. Enter Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> • Enter Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.

Step	Command	Remarks
4. Configure the link type of the ports as trunk.	port link-type trunk	Access by default. For more information about the port link-type trunk command, see <i>Layer 2—LAN Switching Command Reference</i> .
5. Assign the trunk ports to all VLANs.	port trunk permit vlan all	By default, a trunk port is assigned to VLAN 1 only. For more information about the port trunk permit vlan all command, see <i>Layer 2—LAN Switching Command Reference</i> .
6. Enable GVRP on the ports.	gvrp	Disabled by default.
7. Configure the GVRP registration mode on the port.	gvrp registration { fixed forbidden normal }	Optional. normal by default.

Configuring the GARP timers

To configure the GARP timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the GARP LeaveAll timer.	garp timer leaveall timer-value	Optional. 1000 centiseconds by default. The LeaveAll timer applies to all ports.
3. Enter Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Ethernet interface view or Layer 2 aggregate interface view: interface interface-type interface-number Enter port group view: port-group manual port-group-name 	Use either command.
4. Configure the Hold timer.	garp timer hold timer-value	Optional. 10 centiseconds by default.
5. Configure the Join timer.	garp timer join timer-value	Optional. 20 centiseconds by default.
6. Configure the Leave timer.	garp timer leave timer-value	Optional. 60 centiseconds by default.

As shown in [Table 20](#), the value ranges for GARP timers are dependent on one another; use the following guidelines to configure GARP timers:

- If you want to set a value beyond the value range for a timer, you can change the value range by tuning the value of another related timer.

- If you want to restore the default settings of the timers, restore the Hold timer first, followed by the Join, Leave, and LeaveAll timers.

Table 20 Dependencies of the GARP timers

Timer	Lower limit	Upper limit
Hold	10 centiseconds	No greater than half of the Join timer
Join	No less than twice the Hold timer	Less than half of the Leave timer
Leave	Greater than twice the Join timer	Less than the LeaveAll timer
LeaveAll	Greater than the Leave timer	32,765 centiseconds

NOTE:

To keep the dynamic VLANs learned through GVRP stable, do not set the LeaveAll timer smaller than its default value, 1000 centiseconds.

Displaying and maintaining GVRP

Task	Command	Remarks
Display statistics about GARP on ports.	display garp statistics [interface <i>interface-list</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display GARP timers on ports.	display garp timer [interface <i>interface-list</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the local VLAN information that GVRP maintains on ports.	display gvrp local-vlan interface <i>interface-type interface-number</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the current GVRP state in the specified VLANs on ports.	display gvrp state interface <i>interface-type interface-number</i> vlan <i>vlan-id</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display GVRP statistics on ports.	display gvrp statistics [interface <i>interface-list</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the global GVRP state.	display gvrp status [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information about dynamic VLAN operations on ports.	display gvrp vlan-operation interface <i>interface-type interface-number</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear the GARP statistics on ports.	reset garp statistics [interface <i>interface-list</i>]	Available in user view

GVRP configuration examples

GVRP normal registration mode configuration example

Network requirements

As shown in [Figure 54](#):

- Device A and Device B are connected through their ports GigabitEthernet 1/0/1.
- Enable GVRP and configure the normal registration mode on ports to enable the registration and deregistration of dynamic and static VLAN information between the two devices.

Figure 54 Network diagram

Configuration procedure

1. Configure Device A:

Enable GVRP globally.

```
<DeviceA> system-view
```

```
[DeviceA] gvrp
```

Configure port GigabitEthernet 1/0/1 as a trunk port, and assign it to all VLANs.

```
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan all
```

Enable GVRP on trunk port GigabitEthernet 1/0/1.

```
[DeviceA-GigabitEthernet1/0/1] gvrp
```

```
[DeviceA-GigabitEthernet1/0/1] quit
```

Create VLAN 2 (a static VLAN).

```
[DeviceA] vlan 2
```

```
[DeviceA-vlan2] quit
```

2. Configure Device B:

Enable GVRP globally.

```
<DeviceB> system-view
```

```
[DeviceB] gvrp
```

Configure port GigabitEthernet 1/0/1 as a trunk port, and assign it to all VLANs.

```
[DeviceB] interface gigabitethernet 1/0/1
```

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan all
```

Enable GVRP on trunk port GigabitEthernet 1/0/1.

```
[DeviceB-GigabitEthernet1/0/1] gvrp
```

```
[DeviceB-GigabitEthernet1/0/1] quit
```

Create VLAN 3 (a static VLAN).

```
[DeviceB] vlan 3
```

```
[DeviceB-vlan3] quit
```

3. Verify the configuration:

Use the **display gvrp local-vlan** command to display the local VLAN information that GVRP maintains on ports. For example:

Display the local VLAN information that GVRP maintains on port GigabitEthernet 1/0/1 of Device A.

```
[DeviceA] display gvrp local-vlan interface gigabitethernet 1/0/1
```

```
Following VLANs exist in GVRP local database:
```

```
1(default),2-3
```

According to the output, information about VLAN 1, static VLAN information of VLAN 2 on the local device, and dynamic VLAN information of VLAN 3 on Device B are all registered through GVRP.

Display the local VLAN information that GVRP maintains on port GigabitEthernet 1/0/1 of Device B.

```
[DeviceB] display gvrp local-vlan interface gigabitethernet 1/0/1
```

Following VLANs exist in GVRP local database:

```
1(default),2-3
```

According to the output, information about VLAN 1, static VLAN information of VLAN 3 on the local device, and dynamic VLAN information of VLAN 2 on Device A are all registered through GVRP.

GVRP fixed registration mode configuration example

Network requirements

As shown in [Figure 55](#):

- Device A and Device B are connected through their ports GigabitEthernet 1/0/1.
- Enable GVRP and configure the fixed registration mode on ports to enable the registration and deregistration of static VLAN information between the two devices.

Figure 55 Network diagram

Configuration procedure

1. Configure Device A:

Enable GVRP globally.

```
<DeviceA> system-view
```

```
[DeviceA] gvrp
```

Configure port GigabitEthernet 1/0/1 as a trunk port, and assign it to all VLANs.

```
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan all
```

Enable GVRP on GigabitEthernet 1/0/1 and set the GVRP registration mode to fixed on the port.

```
[DeviceA-GigabitEthernet1/0/1] gvrp
```

```
[DeviceA-GigabitEthernet1/0/1] gvrp registration fixed
```

```
[DeviceA-GigabitEthernet1/0/1] quit
```

Create VLAN 2 (a static VLAN).

```
[DeviceA] vlan 2
```

```
[DeviceA-vlan2] quit
```

2. Configure Device B:

Enable GVRP globally.

```
<DeviceB> system-view
```

```

[DeviceB] gvrp
# Configure port GigabitEthernet 1/0/1 as a trunk port, and assign it to all VLANs.
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan all
# Enable GVRP on GigabitEthernet 1/0/1, and set the GVRP registration mode to fixed on the
port.
[DeviceB-GigabitEthernet1/0/1] gvrp
[DeviceB-GigabitEthernet1/0/1] gvrp registration fixed
[DeviceB-GigabitEthernet1/0/1] quit
# Create VLAN 3 (a static VLAN).
[DeviceB] vlan 3
[DeviceB-vlan3] quit

```

3. Verify the configuration:

Use the **display gvrp local-vlan** command to display the local VLAN information that GVRP maintains on ports. For example:

Display the local VLAN information that GVRP maintains on port GigabitEthernet 1/0/1 of Device A.

```

[DeviceA] display gvrp local-vlan interface gigabitethernet 1/0/1
Following VLANs exist in GVRP local database:
 1(default), 2

```

According to the output, information about VLAN 1 and static VLAN information of VLAN 2 on the local device are registered through GVRP, but dynamic VLAN information of VLAN 3 on Device B is not.

Display the local VLAN information that GVRP maintains on port GigabitEthernet 1/0/1 of Device B.

```

[DeviceB] display gvrp local-vlan interface gigabitethernet 1/0/1
Following VLANs exist in GVRP local database:
 1(default), 3

```

According to the output, information about VLAN 1 and static VLAN information of VLAN 3 on the local device are registered through GVRP, but dynamic VLAN information of VLAN 2 on Device A is not.

GVRP forbidden registration mode configuration example

Network requirements

As shown in [Figure 56](#):

- Device A and Device B are connected through their ports GigabitEthernet 1/0/1.
- Enable GVRP and configure the forbidden registration mode on ports to prevent the registration and deregistration of all VLANs but VLAN 1 between the two devices.

Figure 56 Network diagram

Configuration procedure

1. Configure Device A:

Enable GVRP globally.

```
<DeviceA> system-view
```

```
[DeviceA] gvrp
```

Configure port GigabitEthernet 1/0/1 as a trunk port, and assign it to all VLANs.

```
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan all
```

Enable GVRP on GigabitEthernet 1/0/1, and set the GVRP registration mode to forbidden on the port.

```
[DeviceA-GigabitEthernet1/0/1] gvrp
```

```
[DeviceA-GigabitEthernet1/0/1] gvrp registration forbidden
```

```
[DeviceA-GigabitEthernet1/0/1] quit
```

Create VLAN 2 (a static VLAN).

```
[DeviceA] vlan 2
```

```
[DeviceA-vlan2] quit
```

2. Configure Device B:

Enable GVRP globally.

```
<DeviceB> system-view
```

```
[DeviceB] gvrp
```

Configure port GigabitEthernet 1/0/1 as a trunk port, and assign it to all VLANs.

```
[DeviceB] interface gigabitethernet 1/0/1
```

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan all
```

Enable GVRP on GigabitEthernet 1/0/1, and set the GVRP registration mode to forbidden on the port.

```
[DeviceB-GigabitEthernet1/0/1] gvrp
```

```
[DeviceB-GigabitEthernet1/0/1] gvrp registration forbidden
```

```
[DeviceB-GigabitEthernet1/0/1] quit
```

Create VLAN 3 (a static VLAN).

```
[DeviceB] vlan 3
```

```
[DeviceB-vlan3] quit
```

3. Verify the configuration:

Use the **display gvrp local-vlan** command to display the local VLAN information that GVRP maintains on ports. For example:

Display the local VLAN information that GVRP maintains on port GigabitEthernet 1/0/1 of Device A.

```
[DeviceA] display gvrp local-vlan interface gigabitethernet 1/0/1
```

```
Following VLANs exist in GVRP local database:
```

```
1(default)
```

According to the output, information about VLAN 1 is registered through GVRP, but static VLAN information of VLAN 2 on the local device and dynamic VLAN information of VLAN 3 on Device B are not.

Display the local VLAN information that GVRP maintains on port GigabitEthernet 1/0/1 of Device B.

```
[DeviceB] display gvrp local-vlan interface gigabitethernet 1/0/1
```

Following VLANs exist in GVRP local database:

```
1(default)
```

According to the output, information about VLAN 1 is registered through GVRP, but static VLAN information of VLAN 3 on the local device and dynamic VLAN information of VLAN 2 on Device A are not.

Configuring QinQ

Throughout this document, customer network VLANs (CVLANs), also called inner VLANs, refer to the VLANs that a customer uses on the private network; and service provider network VLANs (SVLANs), also called outer VLANs, refer to the VLANs that a service provider uses to carry VLAN tagged traffic for customers.

Overview

802.1Q-in-802.1Q (QinQ) is a flexible, easy-to-implement Layer 2 VPN technology based on IEEE 802.1Q. QinQ enables the edge device on a service provider network to insert an outer VLAN tag in the Ethernet frames from customer networks, so that the Ethernet frames travel across the service provider network (public network) with double VLAN tags. QinQ enables a service provider to use a single SVLAN to serve customers who have multiple CVLANs.

Background and benefits

The IEEE 802.1Q VLAN tag uses 12 bits for VLAN IDs. A device supports a maximum of 4094 VLANs. This is far from enough for isolating users in actual networks, especially in metropolitan area networks (MANs).

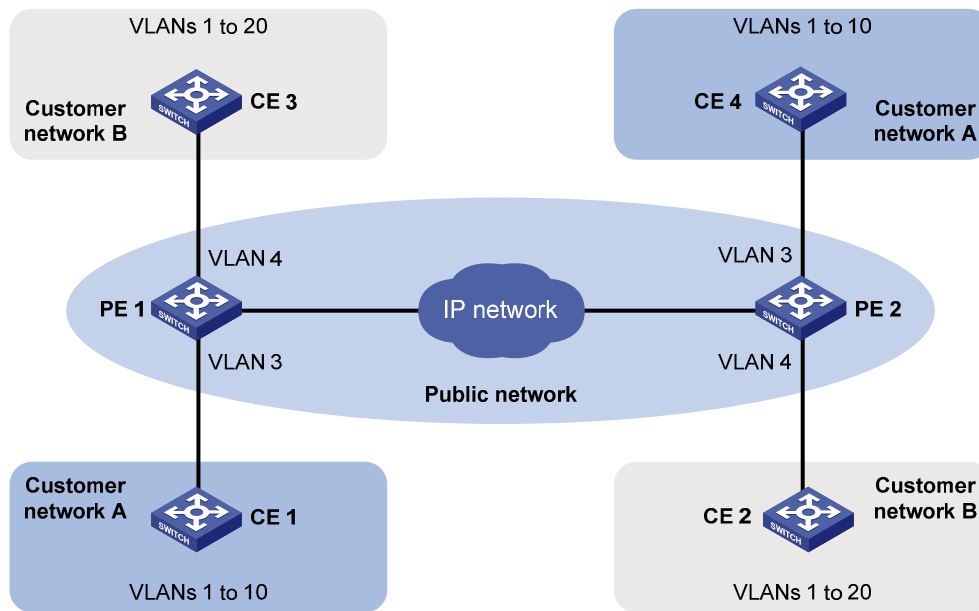

By tagging tagged frames, QinQ expands the available VLAN space from 4094 to 4094×4094 . QinQ delivers the following benefits:

- Releases the stress on the SVLAN resource.
- Enables customers to plan their CVLANs without conflicting with SVLANs.
- Provides an easy-to-implement Layer 2 VPN solution for small-sized MANs or intranets.
- Enables the customers to keep their VLAN assignment schemes unchanged when the service provider upgrades the service provider network.

How QinQ works

The devices in the public network forward a frame only according to its outer VLAN tag and obtain its source MAC address into the MAC address table of the outer VLAN. The inner VLAN tag of the frame is transmitted as the payload.

Figure 57 Typical QinQ application scenario

As shown in [Figure 57](#), customer network A has CVLANs 1 through 10, and customer network B has CVLANs 1 through 20. The service provider assigns SVLAN 3 for customer network A, and assigns SVLAN 4 for customer network B.

When a tagged Ethernet frame from customer network A arrives at a provider edge device (PE), the PE tags the frame with outer VLAN 3. When a tagged Ethernet frame from customer network B arrives at a PE, the PE tags the frame with outer VLAN 4. There is no overlap of VLAN IDs among customers, and traffic from different customers can be identified separately.

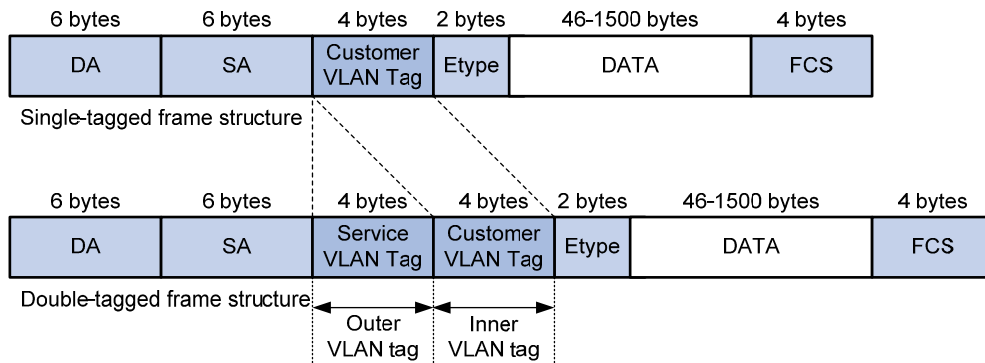

The double-tagged Ethernet frame is then transmitted over the service provider network and arrives at the other PE. The PE removes the SVLAN of the frame before sending it to the target customer edge device (CE).

QinQ frame structure

A QinQ frame is transmitted double-tagged over the service provider network. As shown in [Figure 58](#), the inner VLAN tag is the CVLAN tag, and the outer one is the SVLAN tag that the service provider has allocated to the customer.

QinQ uses CVLAN tags to transmit frames over the private network, and uses SVLAN tags to transmit frames over the public network. When a QinQ frame is transmitted over the public network, its CVLAN tag is transmitted as the payload.

Figure 58 Single-tagged Ethernet frame header and double-tagged Ethernet frame header

The default maximum transmission unit (MTU) of an interface is 1500 bytes. The size of an outer VLAN tag is 4 bytes. HP recommends you to increase the MTU of each interface on the service provider network to at least 1504 bytes.

Implementations of QinQ

HP provides the following QinQ implementations: basic QinQ and selective QinQ.

- Basic QinQ
 - Basic QinQ enables a port to tag any incoming frames with its port VLAN ID (PVID) tag, regardless of whether they have been tagged or not. If an incoming frame has been tagged, it becomes a double-tagged frame. If not, it becomes a frame tagged with the PVID tag.
- Selective QinQ
 - Selective QinQ is more flexible than basic QinQ. In addition to all the functions of basic QinQ, selective QinQ enables a port to perform the following per-CVLAN actions for incoming frames:
 - Tag frames from different CVLANs with different SVLAN tags.
 - Mark the outer VLAN 802.1p priority based on the existing inner VLAN 802.1p priority.
 - Modify the inner VLAN ID (available only on the 5500 EI).
 - Besides being able to separate the service provider network from the customer networks, selective QinQ provides abundant service features and enables more flexible networking.

Modifying the TPID in a VLAN tag

A VLAN tag uses the tag protocol identifier (TPID) field to identify the protocol type of the tag. The default value of this field, as defined in IEEE 802.1Q, is 0x8100.

Figure 59 shows the 802.1Q-defined tag structure of an Ethernet frame.

Figure 59 VLAN tag structure of an Ethernet frame

The device determines whether a received frame carries an SVLAN or CVLAN tag by checking the TPID value. For example, if a frame carries an SVLAN tag with TPID value 0x9100 and a CVLAN tag with TPID value 0x8100 and the configured TPID value of the SVLAN tag is 0x9100 and that of the CVLAN tag is 0x8200, the device considers that the frame carries only the SVLAN tag but not the CVLAN tag.

Devices of different vendors may set the TPID of the outer VLAN tag of QinQ frames to different values. For compatibility with these devices, modify the TPID value so that the QinQ frames, when sent to the public network, carry the TPID value identical to the value of a particular vendor, allowing interoperability with the devices of that vendor.

The TPID in an Ethernet frame has the same position as the protocol type field in a frame without a VLAN tag. To avoid problems in packet forwarding and handling in the network, do not set the TPID value to any of the reserved values.

Table 21 Reserved protocol type values

Protocol type	Value
ARP	0x0806
PUP	0x0200
RARP	0x8035
IP	0x0800
IPv6	0x86DD
PPPoE	0x8863/0x8864
MPLS	0x8847/0x8848
IPX/SPX	0x8137
IS-IS	0x8000
LACP	0x8809
802.1X	0x888E
Cluster	0x88A7
Reserved	0xFFFD/0xFFFE/0xFFFF

Protocols and standards

IEEE 802.1Q: *IEEE standard for local and metropolitan area networks: Virtual Bridged Local Area Networks*

QinQ configuration task list

When you configure QinQ, follow these guidelines:

- QinQ requires configurations only on the service provider network.
- QinQ configurations made in Ethernet interface view take effect on the current interface only. Those made in Layer 2 aggregate interface view take effect on the current aggregate interface and all the member ports in the aggregation group. Those made in port group view take effect on all member ports in the current port group.
- Do not configure QinQ on a reflector port. For more information about reflector ports, see *Network Management and Monitoring Configuration Guide*.

- On a port with basic QinQ enabled, you must configure the port to allow packets from its PVID to pass through. On a port with selective QinQ enabled, you must configure the port to allow packets from the inner and outer VLANs of QinQ packets to pass through.

Complete the follows tasks to configure QinQ:

Task	Remarks	
Configuring basic QinQ	Enabling basic QinQ	Required
	Configuring VLAN transparent transmission	Optional
Configuring selective QinQ	Configuring an outer VLAN tagging policy	Required Perform at least one of these tasks.
	Configuring an inner-outer VLAN 802.1p priority mapping	
	Configuring inner VLAN ID substitution (available only on the 5500 E1)	
Configuring the TPID value in VLAN tags	Optional	

Configuring basic QinQ

Enabling basic QinQ

A basic QinQ-enabled port tags an incoming packet with its PVID tag.

To enable basic QinQ:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable basic QinQ.	qinq enable	Disabled by default.

Configuring VLAN transparent transmission

When basic QinQ is enabled on a port, all packets passing through the port are tagged with the port's PVID tag. However, by configuring the VLAN transparent transmission function on a port, you can specify the port not to add its PVID tag to packets carrying specific inner VLAN tags when they pass through it, so that these packets are transmitted in the service provider network with single tags.

Configuration restrictions and guidelines

- When you are configuring transparent transmission for a VLAN, you must configure all the devices on the transmission path to permit packets of this VLAN to pass through.

- For VLANs whose packets are to be transparently transmitted through a port, do not configure VLAN mapping for them on the port. For more information about VLAN mapping, see "[Configuring VLAN mapping \(available only on the 5500 EI\)](#)."

Configuration procedure

To configure VLAN transparent transmission:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> • Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Configure the link type of the ports.	port link-type { hybrid trunk }	N/A
4. Configure the ports to allow packets from the transparent VLANs, and inner and outer VLANs of QinQ packets to pass through.	<ul style="list-style-type: none"> • When the ports are hybrid ports: port hybrid vlan <i>vlan-id-list</i> { tagged untagged } • When the ports are trunk ports: port trunk permit vlan { <i>vlan-id-list</i> all } 	Use either command.
5. Enable basic QinQ on the ports.	qinq enable	By default, basic QinQ is disabled on ports.
6. Configure VLAN transparent transmission on the ports.	qinq transparent-vlan <i>vlan-list</i>	By default, VLAN transparent transmission is not configured.

Configuring selective QinQ

Configuring an outer VLAN tagging policy

Basic QinQ can only tag received frames with the PVID tag of the receiving port. Selective QinQ allows adding different outer VLAN tags based on different inner VLAN tags.

You can configure an outer VLAN tagging policy in one of the following approaches:

- Port-based approach
- QoS policy-based approach (available only on the 5500 EI)

If multiple outer VLAN tagging policies are configured in both approaches on the same port, the one in the QoS policy-based approach takes effect.

Configuring an outer VLAN tagging policy in the port-based approach

Before enabling selective QinQ on a port, enable basic QinQ on the port first. When both features are enabled on the port, frames that meet the selective QinQ condition are handled with selective QinQ on this port first, and the left frames are handled with basic QinQ.

To configure an outer VLAN tagging policy in the port-based approach:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable basic QinQ.	qinq enable	Disabled by default.
4. Enter QinQ view and configure the SVLAN tag for the port to add.	qinq vid <i>vlan-id</i>	By default, the SVLAN tag to be added is the PVID tag of the receiving port.
5. Tag frames of the specified CVLANs with the current SVLAN.	raw-vlan-id inbound { all <i>vlan-list</i> }	N/A

NOTE:

- An inner VLAN tag corresponds to only one outer VLAN tag.
- To change an outer VLAN tag, you must delete the old outer VLAN tag configuration and configure a new outer VLAN tag.

Configuring an outer VLAN tagging policy in the QoS policy-based approach (available only on the 5500 EI)

To enable the switch to tag tagged packets based on inner VLAN tags, follow these steps:

- Configure a class to match packets with certain tags.
- Configure a traffic behavior to tag packets with an outer VLAN tag.
- Create a QoS policy and associate the class with the behavior in the policy.
- Apply the QoS policy to the port that connects to the user.

To configure selective QinQ:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>classifier-name</i> [operator { and or }]	By default, the operator of a class is AND.
3. Specify the inner VLAN IDs of matching frames.	if-match customer-vlan-id <i>vlan-id-list</i>	N/A
4. Return to system view.	quit	N/A
5. Create a traffic behavior and enter traffic behavior view.	traffic behavior <i>behavior-name</i>	N/A
6. Specify an outer VLAN ID.	nest top-most vlan-id <i>vlan-id</i>	N/A
7. Return to system view.	quit	N/A
8. Create a QoS policy and enter QoS policy view.	qos policy <i>policy-name</i>	N/A

Step	Command	Remarks
9. Associate the traffic class with the traffic behavior defined earlier.	classifier classifier-name behavior behavior-name	N/A
10. Return to system view.	quit	N/A
11. Enter Ethernet interface view or port group view of the customer network-side port.	<ul style="list-style-type: none"> Enter Ethernet interface view: interface interface-type interface-number Enter port group view: port-group manual port-group-name 	Use either command.
12. Enable basic QinQ.	qinq enable	N/A
13. Apply the QoS policy to the incoming traffic.	qos apply policy policy-name inbound	N/A

NOTE:

Selective QinQ has higher priority than basic QinQ. A received frame is tagged with an outer VLAN ID based on basic QinQ only after it fails to match the match criteria defined in the traffic class.

Configuring an inner-outer VLAN 802.1p priority mapping

Through QoS policies, the 5500 SI&5500 EI switches achieve the following inner-outer VLAN 802.1p priority mapping modes:

- Marking the 802.1p priorities in outer VLAN tags according to the inner VLAN IDs or the 802.1p priorities in the inner VLAN tags.
- Copying the 802.1p priority in the inner VLAN tags to the outer VLAN tags.

To mark the 802.1p priorities in outer VLAN tags according to the inner VLAN IDs or the 802.1p priorities in the inner VLAN tags:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier classifier-name [operator { and or }]	By default, the operator of a class is AND.
3. Configure a match criterion.	<ul style="list-style-type: none"> Match the specified inner VLAN IDs: if-match customer-vlan-id vlan-id-list Match the specified inner VLAN tag priorities: if-match customer-dot1p 8021p-list 	Use either command.
4. Return to system view.	quit	N/A
5. Create a traffic behavior and enter traffic behavior view.	traffic behavior behavior-name	N/A

Step	Command	Remarks
6. Configure a marking action or an inner-to-outer tag priority copying action.	<ul style="list-style-type: none"> Mark the 802.1p priorities in outer VLAN tags: remark dot1p 8021p Copy the inner 802.1p priorities to outer 802.1p priorities: remark dot1p customer-dot1p-trust 	Use either command.
7. Return to system view.	quit	N/A
8. Create a QoS policy and enter QoS policy view.	qos policy policy-name	N/A
9. Associate the traffic class with the traffic behavior defined earlier.	classifier classifier-name behavior behavior-name	N/A
10. Return to system view.	quit	N/A
11. Enter Ethernet interface view or port group view of the customer network-side port.	<ul style="list-style-type: none"> Enter Ethernet interface view: interface interface-type interface-number Enter port group view: port-group manual port-group-name 	Use either command.
12. Enable basic QinQ.	qinq enable	N/A
13. Apply the QoS policy to the incoming traffic.	qos apply policy policy-name inbound	N/A

Configuring inner VLAN ID substitution (available only on the 5500 EI)

When you configure basic QinQ or an outer VLAN tagging policy for selective QinQ on a port connecting the device to the customer network, basic QinQ or the outer VLAN tagging policy can add outer VLAN tags to packets, but cannot modify the inner VLAN IDs of packets.

To modify the inner VLAN IDs of packets, follow these steps on the port connecting the device to the service provider network:

1. Configure a class to match the specified inner VLAN IDs and outer VLAN ID of packets.
2. Configure a behavior to modify the inner VLAN IDs of packets.
3. Associate the class with the behavior in a QoS policy.
4. Apply the QoS policy to the outgoing traffic of the port connecting the device to the service provider network.

To configure inner VLAN ID substitution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier classifier-name [operator and]	By default, the operator of a class is AND.
3. Configure a match criterion to match the specified inner VLAN IDs.	if-match customer-vlan-id vlan-id-list	N/A

Step	Command	Remarks
4.	Configure a match criterion to match the specified outer VLAN IDs. if-match service-vlan-id <i>vlan-id</i>	N/A
5.	Return to system view. quit	N/A
6.	Create a traffic behavior and enter traffic behavior view. traffic behavior <i>behavior-name</i>	N/A
7.	Configure the action of marking the inner VLAN IDs. remark customer-vlan-id <i>vlan-id</i>	N/A
8.	Return to system view. quit	N/A
9.	Create a QoS policy and enter QoS policy view. qos policy <i>policy-name</i>	N/A
10.	Associate the traffic class with the traffic behavior defined earlier. classifier <i>classifier-name</i> behavior <i>behavior-name</i>	N/A
11.	Return to system view. quit	N/A
12.	Enter Ethernet interface view or port group view of the service provider network-side ports. <ul style="list-style-type: none">• Enter Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i>• Enter port group view: port-group manual <i>port-group-name</i>	Use either command.
13.	Apply the QoS policy to the outgoing traffic. qos apply policy <i>policy-name</i> outbound	N/A

Configuring the TPID value in VLAN tags

Configuring the TPID value on the 5500 EI

To configure the TPID value:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Configure the TPID value. qinq ethernet-type { customer-tag service-tag } <i>hex-value</i>	Optional. By default, the TPID value is 0x8100. The configuration applies to all ports.

Configuring the TPID value on the 5500 SI

To configure the TPID value:

Step	Command	Remarks
1.	Enter system view. system-view	N/A

Step	Command	Remarks
2. Configure the TPID value.	qinq ethernet-type <i>hex-value</i>	Optional. By default, the TPID value is 0x8100. The configuration applies to all ports.

NOTE:

The TPID value configured on the 5500 SI Switch Series applies to both the CVLAN tags and the SVLAN tags.

QinQ configuration examples

Basic QinQ configuration example

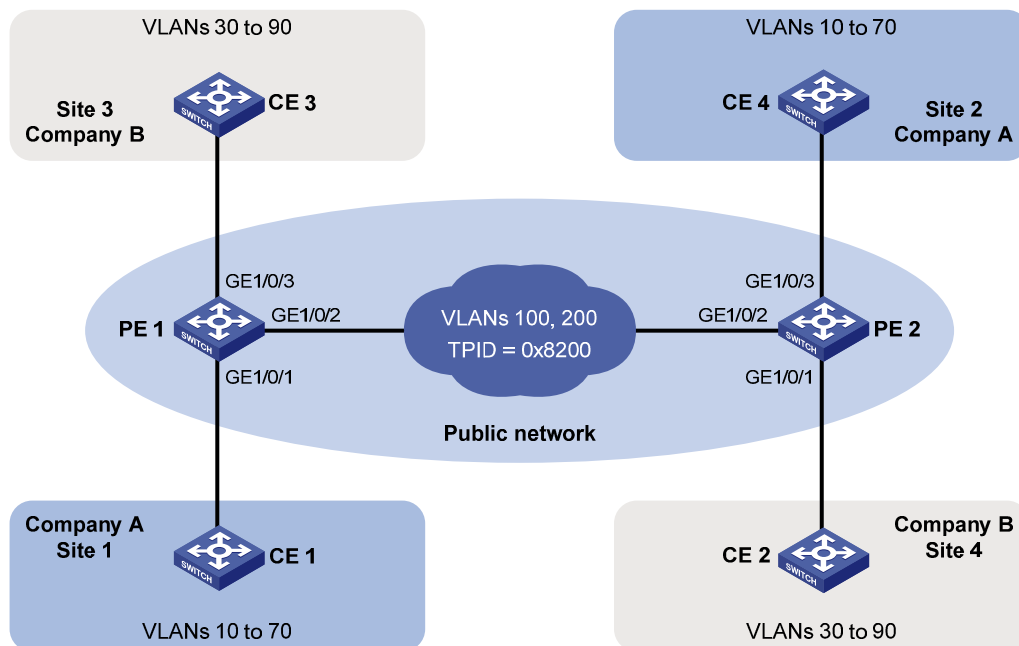

Network requirements

As shown in Figure 60:

- The two branches of Company A, Site 1 and Site 2, are connected through the service provider network and use CVLANs 10 through 70. The two branches of Company B, Site 3 and Site 4, are connected through the service provider network and use CVLANs 30 through 90.
- PE 1 and PE 2 are edge devices on the service provider network and are connected through third-party devices with a TPID value of 0x8200.

Configure the edge and third-party devices to enable communication between the branches of Company A through SVLAN 100, and communication between the branches of Company B through SVLAN 200.

Figure 60 Network diagram

Configuration procedure

! **IMPORTANT:**

Make sure that you have configured the devices in the service provider network to allow QinQ packets to pass through.

1. Configure PE 1:

- Configure GigabitEthernet 1/0/1:

Configure GigabitEthernet 1/0/1 as a trunk port and assign it to VLAN 100 and VLANs 10 through 70..

```
<PE1> system-view
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] port link-type trunk
[PE1-GigabitEthernet1/0/1] port trunk permit vlan 100 10 to 70
```

Configure VLAN 100 as the PVID for the port.

```
[PE1-GigabitEthernet1/0/1] port trunk pvid vlan 100
```

Enable basic QinQ on the port.

```
[PE1-GigabitEthernet1/0/1] qinq enable
[PE1-GigabitEthernet1/0/1] quit
```

- Configure GigabitEthernet 1/0/2:

Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLAN 100 and VLAN 200.

```
[PE1] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-type trunk
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 100 200
```

Set the TPID value in the outer VLAN tag to 0x8200 on the port.

```
[PE1-GigabitEthernet1/0/2] quit
[PE1] qinq ethernet-type service-tag 8200
```

NOTE:

The previous command is available only on the 5500 EI Switch Series. For how to configure the TPID value on the 5500 SI Switch Series, see "[Configuring the TPID value on the 5500 SI.](#)"

- Configure GigabitEthernet 1/0/3:

Configure GigabitEthernet 1/0/3 as a trunk port and assign it to VLAN 200 and VLANs 30 through 90..

```
[PE1] interface gigabitethernet 1/0/3
[PE1-GigabitEthernet1/0/3] port link-type trunk
[PE1-GigabitEthernet1/0/3] port trunk permit vlan 200 30 to 90
```

Configure VLAN 200 as the PVID for the port.

```
[PE1-GigabitEthernet1/0/3] port trunk pvid vlan 200
```

Enable basic QinQ on the port.

```
[PE1-GigabitEthernet1/0/3] qinq enable
[PE1-GigabitEthernet1/0/3] quit
```

2. Configure PE 2:

- Configure GigabitEthernet 1/0/1:

Configure GigabitEthernet 1/0/1 as a trunk port and assign it to VLAN 200 and VLANs 30 through 90..

```
<PE2> system-view
```

- ```
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] port link-type trunk
[PE2-GigabitEthernet1/0/1] port trunk permit vlan 200 30 to 90
Configure VLAN 200 as the PVID for the port.
[PE2-GigabitEthernet1/0/1] port trunk pvid vlan 200
Enable basic QinQ on the port.
[PE2-GigabitEthernet1/0/1] qinq enable
[PE2-GigabitEthernet1/0/1] quit
```
- Configure GigabitEthernet 1/0/2:
 

```
Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLAN 100 and VLAN 200.
[PE2] interface gigabitethernet 1/0/2
[PE2-GigabitEthernet1/0/2] port link-type trunk
[PE2-GigabitEthernet1/0/2] port trunk permit vlan 100 200
Set the TPID value in the outer VLAN tag to 0x8200 on the port.
[PE2-GigabitEthernet1/0/2] quit
[PE2] qinq ethernet-type service-tag 8200
```

---

**NOTE:**

The previous command is available only on the 5500 EI Switch Series. For how to configure the TPID value on the 5500 SI Switch Series, see "[Configuring the TPID value on the 5500 SI.](#)"

---

- Configure GigabitEthernet 1/0/3:
 

```
Configure GigabitEthernet 1/0/3 as a trunk port and assign it to VLAN 100 and VLANs 10 through 70..
[PE2] interface gigabitethernet 1/0/3
[PE2-GigabitEthernet1/0/3] port link-type trunk
[PE2-GigabitEthernet1/0/3] port trunk permit vlan 100 10 to 70
Configure VLAN 100 as the PVID for the port.
[PE2-GigabitEthernet1/0/3] port trunk pvid vlan 100
Enable basic QinQ on the port.
[PE2-GigabitEthernet1/0/3] qinq enable
[PE2-GigabitEthernet1/0/3] quit
```
- 3. Configure third-party devices:**
- On the third-party devices between PE 1 and PE 2, configure the port that connects to PE 1 and that connecting to PE 2 to allow tagged frames of VLAN 100 and VLAN 200 to pass through.

## Selective QinQ configuration example (configuring an outer VLAN tagging policy in port-based approach)

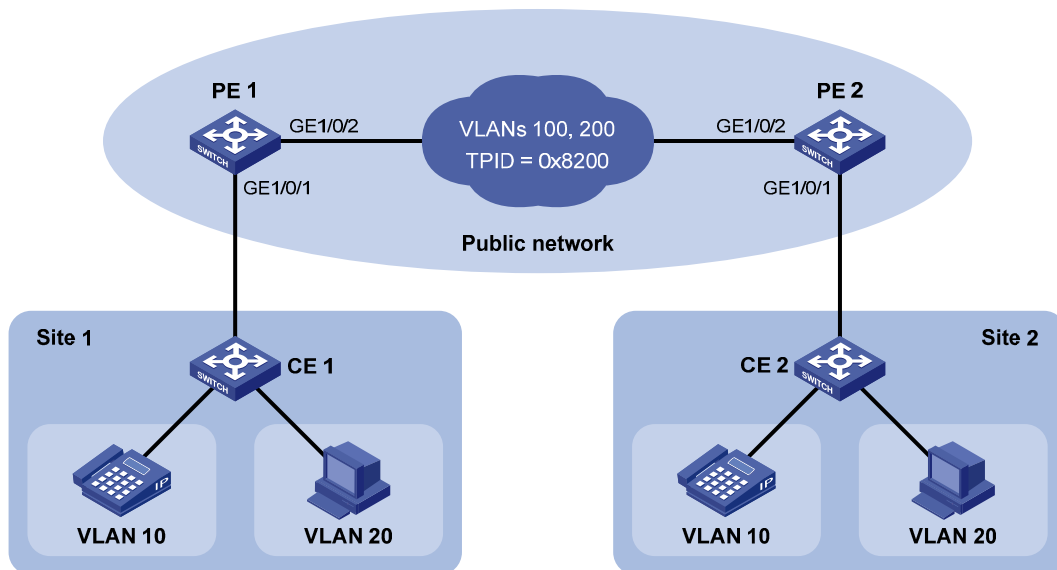

### Network requirements

As shown in [Figure 61](#):

- The two branches of a company, Site 1 and Site 2, are connected through the service provider network and use CVLAN 10 and CVLAN 20 to transmit voice traffic and data traffic separately.
- PE 1 and PE 2 are edge devices on the service provider network and are connected through third-party devices with a TPID value of 0x8200.

Configure the edge and third-party devices to allow frames from CVLAN 10 to be transmitted between the branches via SVLAN 100 and frames from CVLAN 20 to be transmitted between the branches via SVLAN 200.

**Figure 61 Network diagram**

## Configuration procedure

### ! IMPORTANT:

Make sure that you have configured the devices in the service provider network to allow QinQ packets to pass through.

#### 1. Configure PE 1:

- Configure GigabitEthernet 1/0/1:

# Configure GigabitEthernet 1/0/1 as a hybrid port to permit frames of VLAN 10 and VLAN 20 to pass through tagged, and frames of VLAN 100 and VLAN 200 to pass through untagged.

```
<PE1> system-view
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] port link-type hybrid
[PE1-GigabitEthernet1/0/1] port hybrid vlan 10 20 tagged
```

```
[PE1-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
```

# Enable basic QinQ on the port.

```
[PE1-GigabitEthernet1/0/1] qinq enable
```

# Configure the port to tag VLAN 10 frames with outer VLAN ID 100.

```
[PE1-GigabitEthernet1/0/1] qinq vid 100
[PE1-GigabitEthernet1/0/1-vid-100] raw-vlan-id inbound 10
[PE1-GigabitEthernet1/0/1-vid-100] quit
```

# Configure the port to tag VLAN 20 frames with outer VLAN ID 200.

```
[PE1-GigabitEthernet1/0/1] qinq vid 200
[PE1-GigabitEthernet1/0/1-vid-200] raw-vlan-id inbound 20
```

- ```
[PE1-GigabitEthernet1/0/1-vid-200] quit
[PE1-GigabitEthernet1/0/1] quit
```
- **Configure GigabitEthernet 1/0/2:**

Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLAN 100 and VLAN 200.

```
[PE1] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-type trunk
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 100 200
```

Set the TPID in the outer VLAN tags to 0x8200.

```
[PE1-GigabitEthernet1/0/2] quit
[PE1] qinq ethernet-type service-tag 8200
```

NOTE:

The previous command is available only on the 5500 EI Switch Series. For how to configure the TPID value on the 5500 SI Switch Series, see "[Configuring the TPID value on the 5500 SI.](#)"

2. Configure PE 2:

- **Configure GigabitEthernet 1/0/1:**

Configure GigabitEthernet 1/0/1 as a hybrid port to permit frames of VLAN 10 and VLAN 20 to pass through tagged, and frames of VLAN 100 and VLAN 200 to pass through untagged.

```
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] port link-type hybrid
[PE2-GigabitEthernet1/0/1] port hybrid vlan 10 20 tagged
[PE2-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
```

Enable basic QinQ on the port.

```
[PE2-GigabitEthernet1/0/1] qinq enable
```

Configure the port to tag VLAN 10 frames with outer VLAN ID 100.

```
[PE2-GigabitEthernet1/0/1] qinq vid 100
[PE2-GigabitEthernet1/0/1-vid-100] raw-vlan-id inbound 10
[PE2-GigabitEthernet1/0/1-vid-100] quit
```

Configure the port to tag VLAN 20 frames with outer VLAN ID 200.

```
[PE2-GigabitEthernet1/0/1] qinq vid 200
[PE2-GigabitEthernet1/0/1-vid-200] raw-vlan-id inbound 20
[PE2-GigabitEthernet1/0/1-vid-200] quit
[PE2-GigabitEthernet1/0/1] quit
```
- **Configure GigabitEthernet 1/0/2:**

Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLAN 100 and VLAN 200.

```
[PE2] interface gigabitethernet 1/0/2
[PE2-GigabitEthernet1/0/2] port link-type trunk
[PE2-GigabitEthernet1/0/2] port trunk permit vlan 100 200
```

Set the TPID in the outer VLAN tags to 0x8200.

```
[PE2-GigabitEthernet1/0/2] quit
[PE2] qinq ethernet-type service-tag 8200
```

NOTE:

The previous command is available only on the 5500 EI Switch Series. For how to configure the TPID value on the 5500 SI Switch Series, see "[Configuring the TPID value on the 5500 SI.](#)"

3. Configure third-party devices:

On the third-party devices between PE 1 and PE 2, configure the port that connects to PE 1 and that connecting to PE 2 to allow tagged frames of VLAN 100 and VLAN 200 to pass through.

Selective QinQ configuration example (configuring an outer VLAN tagging policy in QoS policy-based approach)

! IMPORTANT:

This configuration example is available only on the 5500 EI Switch Series.

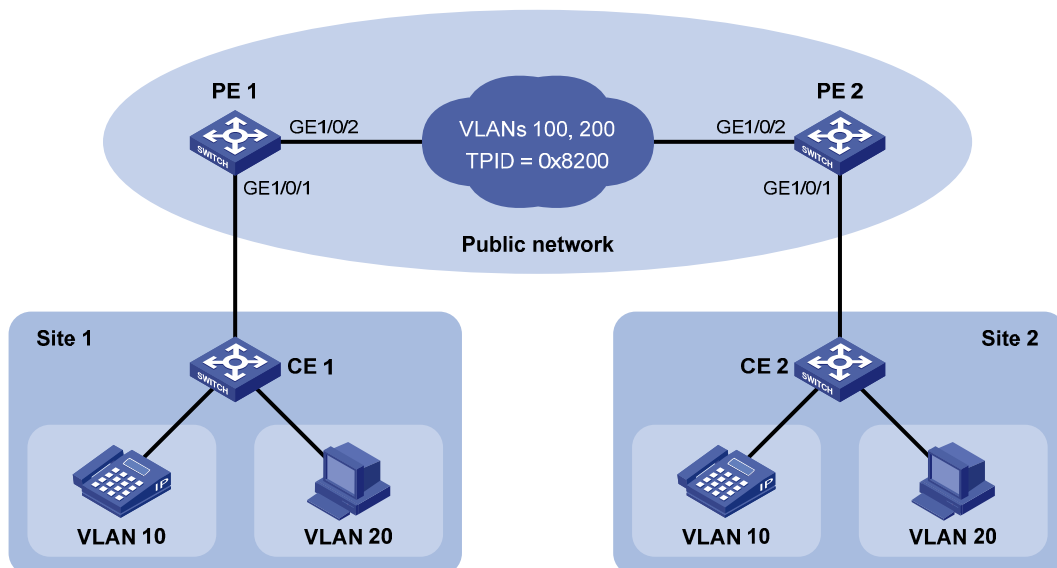

Network requirements

As shown in [Figure 61](#):

- The two branches of a company, Site 1 and Site 2, are connected through the service provider network and use CVLAN 10 and CVLAN 20 to transmit voice traffic and data traffic separately.
- PE 1 and PE 2 are edge devices on the service provider network and are connected through third-party devices with a TPID value of 0x8200.

Configure the edge and third-party devices to allow frames from CVLAN 10 to be transmitted between the branches via SVLAN 100 and frames from CVLAN 20 to be transmitted between the branches via SVLAN 200.

Figure 62 Network diagram

Configuration procedure

❗ **IMPORTANT:**

Make sure that you have configured the devices in the service provider network to allow QinQ packets to pass through.

1. Configure PE 1:

- Configure GigabitEthernet 1/0/1:

Configure GigabitEthernet 1/0/1 as a hybrid port to permit frames of VLAN 10 and VLAN 20 to pass through tagged, and frames of VLAN 100 and VLAN 200 to pass through untagged.

```
<PE1> system-view
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] port link-type hybrid
[PE1-GigabitEthernet1/0/1] port hybrid vlan 10 20 tagged
[PE1-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
[PE1-GigabitEthernet1/0/1] quit
```

Create class **A10** and configure the class to match frames from Site 1 with CVLAN 10.

```
[PE1] traffic classifier A10
[PE1-classifier-A10] if-match customer-vlan-id 10
[PE1-classifier-A10] quit
```

Create traffic behavior **P100** and add the action of inserting outer VLAN tag 100.

```
[PE1] traffic behavior P100
[PE1-behavior-P100] nest top-most vlan-id 100
[PE1-behavior-P100] quit
```

Create class **A20** and configure the class to match frames with CVLAN 20. Create traffic behavior **P200** and add the action of inserting outer VLAN tag 200.

```
[PE1] traffic classifier A20
[PE1-classifier-A20] if-match customer-vlan-id 20
[PE1-classifier-A20] quit
[PE1] traffic behavior P200
[PE1-behavior-P200] nest top-most vlan-id 200
[PE1-behavior-P200] quit
```

Create a QoS policy named **qinq**, associate traffic class **A10** with traffic behavior **P100**, and associate traffic class **A20** with traffic behavior **P200**.

```
[PE1] qos policy qinq
[PE1-qospolicy-qinq] classifier A10 behavior P100
[PE1-qospolicy-qinq] classifier A20 behavior P200
[PE1-qospolicy-qinq] quit
```

Enable basic QinQ on the port.

```
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] qinq enable
```

Apply QoS policy **qinq** to the incoming traffic on the port.

```
[PE1-GigabitEthernet1/0/1] qos apply policy qinq inbound
```

- Configure GigabitEthernet 1/0/2:

Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLAN 100 and VLAN 200.

```
[PE1] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-type trunk
```

```
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 100 200
# Set the TPID in the outer VLAN tags to 0x8200.
[PE1-GigabitEthernet1/0/2] quit
[PE1] qinq ethernet-type service-tag 8200
```

2. Configure PE 2:

- Configure GigabitEthernet 1/0/1:

Configure GigabitEthernet 1/0/1 as a hybrid port to permit frames of VLAN 10 and VLAN 20 to pass through tagged, and frames of VLAN 100 and VLAN 200 to pass through untagged.

```
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] port link-type hybrid
[PE2-GigabitEthernet1/0/1] port hybrid vlan 10 20 tagged
[PE2-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
[PE2-GigabitEthernet1/0/1] quit
```

Create class **A10** and configure the class to match frames from Site 2 with CVLAN 10.

```
[PE2] traffic classifier A10
[PE2-classifier-A10] if-match customer-vlan-id 10
[PE2-classifier-A10] quit
```

Create traffic behavior **P100** and add the action of inserting outer VLAN tag 100.

```
[PE2] traffic behavior P100
[PE2-behavior-P100] nest top-most vlan-id 100
[PE2-behavior-P100] quit
```

Create class **A20** and configure the class to match frames with CVLAN 20. Create traffic behavior **P200** and add the action of inserting outer VLAN tag 200.

```
[PE2] traffic classifier A20
[PE2-classifier-A20] if-match customer-vlan-id 20
[PE2-classifier-A20] quit
[PE2] traffic behavior P200
[PE2-behavior-P200] nest top-most vlan-id 200
[PE2-behavior-P200] quit
```

Create a QoS policy named **qinq**, associate traffic class **A10** with traffic behavior **P100**, and associate traffic class **A20** with traffic behavior **P200**.

```
[PE2] qos policy qinq
[PE2-qospolicy-qinq] classifier A10 behavior P100
[PE2-qospolicy-qinq] classifier A20 behavior P200
[PE2-qospolicy-qinq] quit
```

Enable basic QinQ on the port.

```
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] qinq enable
```

Apply QoS policy **qinq** to the incoming traffic on the port.

```
[PE2-GigabitEthernet1/0/1] qos apply policy qinq inbound
```

- Configure GigabitEthernet 1/0/2:

Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLAN 100 and VLAN 200.

```
[PE2] interface gigabitethernet 1/0/2
[PE2-GigabitEthernet1/0/2] port link-type trunk
[PE2-GigabitEthernet1/0/2] port trunk permit vlan 100 200
```

```
# Set the TPID in the outer VLAN tags to 0x8200.
```

```
[PE2-GigabitEthernet1/0/2] quit
```

```
[PE2] qinq ethernet-type service-tag 8200
```

3. Configure third-party devices:

On the third-party devices between PE 1 and PE 2, configure the port that connects to PE 1 and the port that connects to PE 2 to allow tagged frames of VLAN 100 and VLAN 200 to pass through.

Selective QinQ configuration example (inner VLAN ID substitution)

⚠ **IMPORTANT:**

This configuration example is available only on the 5500 EI Switch Series.

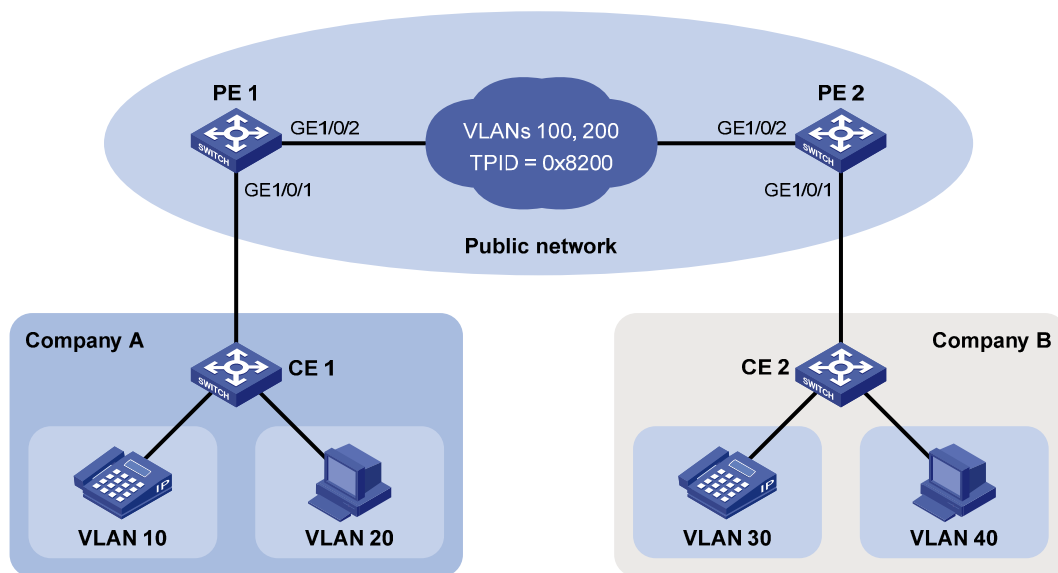

Network requirements

As shown in Figure 63:

- Company A uses CVLAN 10 and CVLAN 20 to transmit voice traffic and data traffic separately, and Company B uses CVLAN 30 and CVLAN 40 to transmit voice traffic and data traffic separately. The services of the two companies are integrated together.
- PE 1 and PE 2 are edge devices on the service provider network and are connected through third-party devices with a TPID value of 0x8200.

Configure the edge and third-party devices to allow the voice traffic and data traffic to be transmitted between the two companies via SVLAN 100 SVLAN 200 separately.

Figure 63 Network diagram

Configuration procedure

⚠ **IMPORTANT:**

Make sure that you have configured the devices in the service provider network to allow QinQ packets to pass through.

1. Configure PE 1:

o Configure GigabitEthernet 1/0/1:

Configure GigabitEthernet 1/0/1 as a hybrid port to permit frames of VLAN 10 and VLAN 20 to pass through tagged, and frames of VLAN 100 and VLAN 200 to pass through untagged.

```
<PE1> system-view
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] port link-type hybrid
[PE1-GigabitEthernet1/0/1] port hybrid vlan 10 20 tagged
[PE1-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
[PE1-GigabitEthernet1/0/1] quit
```

Create class **A10** and configure the class to match frames with CVLAN 10.

```
[PE1] traffic classifier A10
[PE1-classifier-A10] if-match customer-vlan-id 10
[PE1-classifier-A10] quit
```

Create traffic behavior **P100** and add the action of inserting outer VLAN tag 100.

```
[PE1] traffic behavior P100
[PE1-behavior-P100] nest top-most vlan-id 100
[PE1-behavior-P100] quit
```

Create class **A20** and configure the class to match frames with CVLAN 20. Create traffic behavior **P200** and add the action of inserting outer VLAN tag 200.

```
[PE1] traffic classifier A20
[PE1-classifier-A20] if-match customer-vlan-id 20
[PE1-classifier-A20] quit
[PE1] traffic behavior P200
[PE1-behavior-P200] nest top-most vlan-id 200
[PE1-behavior-P200] quit
```

Create a QoS policy named **qinq**, associate traffic class **A10** with traffic behavior **P100**, and associate traffic class **A20** with traffic behavior **P200**.

```
[PE1] qos policy qinq
[PE1-qospolicy-qinq] classifier A10 behavior P100
[PE1-qospolicy-qinq] classifier A20 behavior P200
[PE1-qospolicy-qinq] quit
```

Enable basic QinQ on the port.

```
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] qinq enable
```

Apply QoS policy **qinq** to the incoming traffic on the port.

```
[PE1-GigabitEthernet1/0/1] qos apply policy qinq inbound
```

o Configure GigabitEthernet 1/0/2:

Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLAN 100 and VLAN 200.

```
[PE1] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-type trunk
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 100 200
```

Create class **A100** and configure the class to match frames with CVLAN 10 and SVLAN 100.

```

[PE1] traffic classifier A100
[PE1-classifier-A100] if-match customer-vlan-id 10
[PE1-classifier-A100] if-match service-vlan-id 100
[PE1-classifier-A100] quit
# Configure traffic behavior T100 to mark matching packets with CVLAN 30.
[PE1] traffic behavior T100
[PE1-behavior-T100] remark customer-vlan-id 30
[PE1-behavior-T100] quit
# Create class A200 and configure the class to match frames with CVLAN 20 and SVLAN 200.
[PE1] traffic classifier A200
[PE1-classifier-A200] if-match customer-vlan-id 20
[PE1-classifier-A200] if-match service-vlan-id 200
[PE1-classifier-A200] quit
# Configure traffic behavior T200 to mark matching packets with CVLAN 40.
[PE1] traffic behavior T200
[PE1-behavior-T200] remark customer-vlan-id 40
[PE1-behavior-T200] quit
# Create a QoS policy named sqinq, associate traffic class A100 with traffic behavior T100, and associate traffic class A200 with traffic behavior T200.
[PE1] qos policy sqinq
[PE1-qospolicy-sqinq] classifier A100 behavior T100
[PE1-qospolicy-sqinq] classifier A200 behavior T200
[PE1-qospolicy-sqinq] quit
# Apply QoS policy sqinq to the outgoing traffic on the port.
[PE1-GigabitEthernet1/0/2] qos apply policy sqinq outbound
# Set the TPID value in the outer tag to 0x8200.
[PE1-GigabitEthernet1/0/2] quit
[PE1] qinq ethernet-type service-tag 8200

```

2. Configure PE 2:

- Configure GigabitEthernet 1/0/1:

```

# Configure GigabitEthernet 1/0/1 as a hybrid port to permit frames of VLAN 30 and VLAN 40 to pass through tagged, and frames of VLAN 100 and VLAN 200 to pass through untagged.
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] port link-type hybrid
[PE2-GigabitEthernet1/0/1] port hybrid vlan 30 40 tagged
[PE2-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
[PE2-GigabitEthernet1/0/1] quit
# Create class A30 and configure the class to match frames with CVLAN 30.
[PE2] traffic classifier A30
[PE2-classifier-A30] if-match customer-vlan-id 30
[PE2-classifier-A30] quit
# Create traffic behavior P100 and add the action of inserting outer VLAN tag 100.
[PE2] traffic behavior P100
[PE2-behavior-P100] nest top-most vlan-id 100

```

```

[PE2-behavior-P100] quit
# Create class A40 and configure the class to match frames with CVLAN 40. Create traffic
behavior P200 and add the action of inserting outer VLAN tag 200.
[PE2] traffic classifier A40
[PE2-classifier-A40] if-match customer-vlan-id 40
[PE2-classifier-A40] quit
[PE2] traffic behavior P200
[PE2-behavior-P200] nest top-most vlan-id 200
[PE2-behavior-P200] quit
# Create a QoS policy named qinq, associate traffic class A30 with traffic behavior P100, and
associate traffic class A40 with traffic behavior P200.
[PE2] qos policy qinq
[PE2-qospolicy-qinq] classifier A30 behavior P100
[PE2-qospolicy-qinq] classifier A40 behavior P200
[PE2-qospolicy-qinq] quit
# Enable basic QinQ on the port.
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] qinq enable
# Apply QoS policy qinq to the incoming traffic on the port.
[PE2-GigabitEthernet1/0/1] qos apply policy qinq inbound
o Configure GigabitEthernet 1/0/2:
# Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLAN 100 and VLAN 200.
[PE2] interface gigabitethernet 1/0/2
[PE2-GigabitEthernet1/0/2] port link-type trunk
[PE2-GigabitEthernet1/0/2] port trunk permit vlan 100 200
# Create class A100 and configure the class to match frames with CVLAN 30 and SVLAN
100.
[PE2] traffic classifier A100
[PE2-classifier-A100] if-match customer-vlan-id 30
[PE2-classifier-A100] if-match service-vlan-id 100
[PE2-classifier-A100] quit
# Configure traffic behavior T100 to mark matching packets with CVLAN 10.
[PE2] traffic behavior T100
[PE2-behavior-T100] remark customer-vlan-id 10
[PE2-behavior-T100] quit
# Create class A200 and configure the class to match frames with CVLAN 40 and SVLAN
200.
[PE2] traffic classifier A200
[PE2-classifier-A200] if-match customer-vlan-id 40
[PE2-classifier-A200] if-match service-vlan-id 200
[PE2-classifier-A200] quit
# Configure traffic behavior T200 to mark matching packets with CVLAN 20.
[PE2] traffic behavior T200
[PE2-behavior-T200] remark customer-vlan-id 20
[PE2-behavior-T200] quit

```

Create a QoS policy named **sqinq**, associate traffic class **A100** with traffic behavior **T100**, and associate traffic class **A200** with traffic behavior **T200**.

```
[PE2] qos policy sqinq
[PE2-qospolicy-sqinq] classifier A100 behavior T100
[PE2-qospolicy-sqinq] classifier A200 behavior T200
[PE2-qospolicy-sqinq] quit
```

Apply QoS policy **sqinq** to the outgoing traffic on the port.

```
[PE2] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] qos apply policy sqinq outbound
```

Set the TPID value in the outer tag to 0x8200.

```
[PE2-GigabitEthernet1/0/2] quit
[PE2] qinq ethernet-type service-tag 8200
```

3. Configure third-party devices:

On the third-party devices between PE 1 and PE 2, configure the port that connects to PE 1 and that connecting to PE 2 to allow tagged frames of VLAN 100 and VLAN 200 to pass through.

Configuring VLAN mapping (available only on the 5500 EI)

Overview

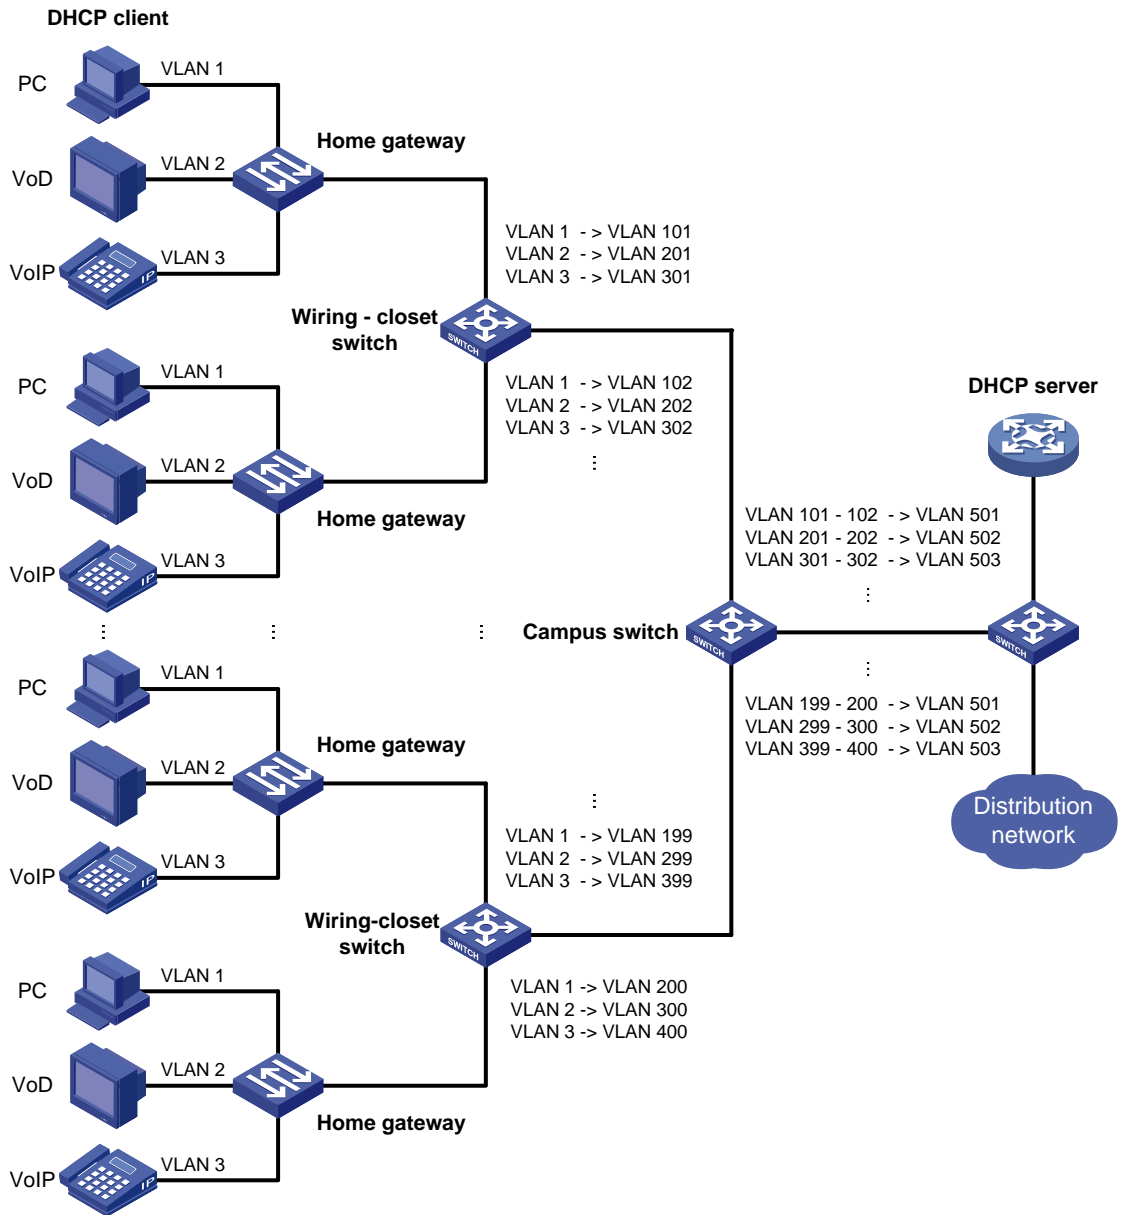

VLAN mapping re-marks VLAN tagged traffic with new VLAN IDs. HP provides the following types of VLAN mapping:

- **One-to-one VLAN mapping**—Replaces one VLAN tag with another. You can use one-to-one VLAN mapping to sub-classify traffic from a particular VLAN for granular QoS control.
- **Many-to-one VLAN mapping**—Replaces multiple VLAN tags with the same VLAN tag. You can use many-to-one VLAN mapping to aggregate traffic from different VLANs to regulate the aggregate traffic as a whole. Many-to-one VLAN mapping is usually used together with one-to-one VLAN mapping.
- **Two-to-two VLAN mapping**—Replaces the outer and inner VLAN IDs of double tagged traffic with a new pair of VLAN IDs. You can use two-to-two VLAN mapping to enable two remote sites in different VLANs to communicate at Layer 2 across two service provider networks that use different VLAN assignment schemes.

Application scenario of one-to-one and many-to-one VLAN mapping

Figure 64 shows a typical application scenario in which each home gateway uses different VLANs to transmit the PC, VoD, and VoIP services.

Figure 64 Application scenario of one-to-one and many-to-one VLAN mapping

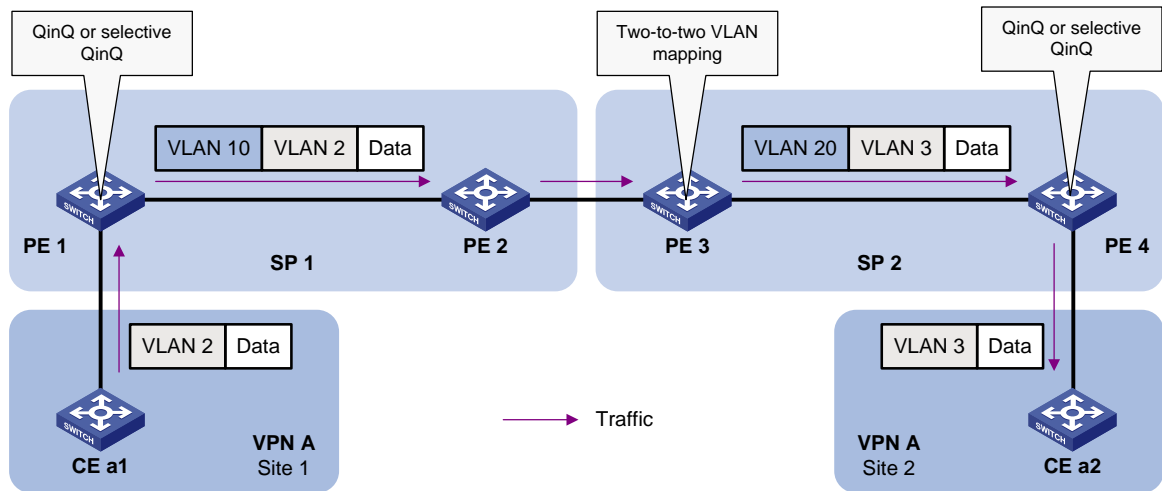

To further sub-classify each type of traffic by customer, perform one-to-one VLAN mapping on the wiring-closet switches, and assign a separate VLAN for each type of traffic from each customer. The required total number of VLANs in the network can be large. To prevent the maximum number of VLANs from being exceeded on the distribution layer device, perform many-to-one VLAN mapping on the campus switch to assign the same type of traffic from different customers to the same VLAN.

Application scenario of two-to-two VLAN mapping

Figure 65 shows a typical application scenario in which two remote sites of VPN A, Site 1 and Site 2, must communicate across two SP networks, SP 1 and SP 2.

Figure 65 Application scenario of two-to-two VLAN mapping

Site 1 and Site 2 are in VLAN 2 and VLAN 3, respectively. The VLAN assigned for VPN A is VLAN 10 in the SP 1 network and VLAN 20 in the SP 2 network.

If Site 1 sends a packet to Site 2, the packet is processed on the way to its destination using the following workflow:

1. When the packet tagged with VLAN 2 arrives at the edge of network SP 1, PE 1 tags the packet with outer VLAN 10 through basic QinQ or selective QinQ.
2. When the double-tagged packet enters the SP 2 network, PE 3 replaces the outer VLAN tag (VLAN 10) with VLAN 20. Because the packet is destined for Site 2 in VLAN 3, PE 3 also replaces the inner tag (VLAN 2) of the packet with VLAN 3. This process is two-to-two VLAN mapping.
3. When PE 4 receives the packet with the new VLAN tag pair, it removes the outer VLAN tag and forwards the packet to VLAN 3.

For more information about basic QinQ and selection QinQ configurations, see "[Configuring QinQ.](#)"

Concepts and terms

Figure 66 shows a simplified network to help explain the concepts and terms that you might encounter when you work with VLAN mapping.

Figure 66 Basic concepts of VLAN mapping

- **Uplink traffic**—Traffic transmitted from the customer network to the service provider network.

- **Downlink traffic**—Traffic transmitted from the service provider network to the customer network.
- **Network-side port**—A port connected to or closer to the service provider network.
- **Customer-side port**—A port connected to or closer to the customer network.
- **Uplink policy**—A QoS policy that defines VLAN mapping rules for uplink traffic.
- **Downlink policy**—A QoS policy that defines VLAN mapping rules for downlink traffic.
- **Customer VLANs (CVLANs)**—VLANs assigned for customers.
- **Service provider VLANs (SVLANs)**—VLANs assigned for transmitting traffic across the service provider network.

For more information about QoS policies, see *ACL and QoS Configuration Guide*.

VLAN mapping implementations

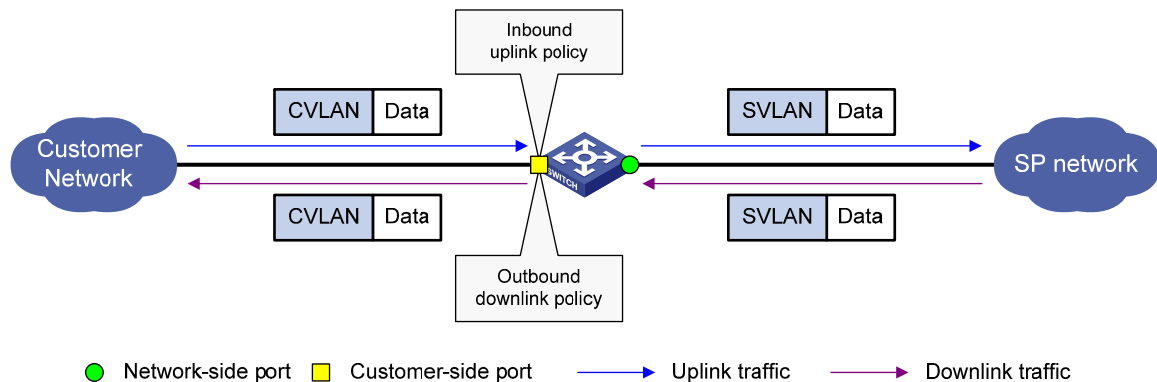

This section describes how VLAN mapping is implemented on your device.

One-to-one VLAN mapping

Implement one-to-one VLAN mapping on the customer-side port through the following configurations, as shown in [Figure 67](#):

- Apply an uplink policy to the incoming traffic, mapping each CVLAN ID to a unique SVLAN ID. When a packet arrives, the switch replaces its CVLAN ID with the matching SVLAN ID.
- Apply a downlink policy to the outgoing traffic, mapping each SVLAN ID back to its corresponding CVLAN ID. When forwarding a packet out of the port, the switch replaces its SVLAN ID with the matching CVLAN ID.

Figure 67 One-to-one VLAN mapping implementation

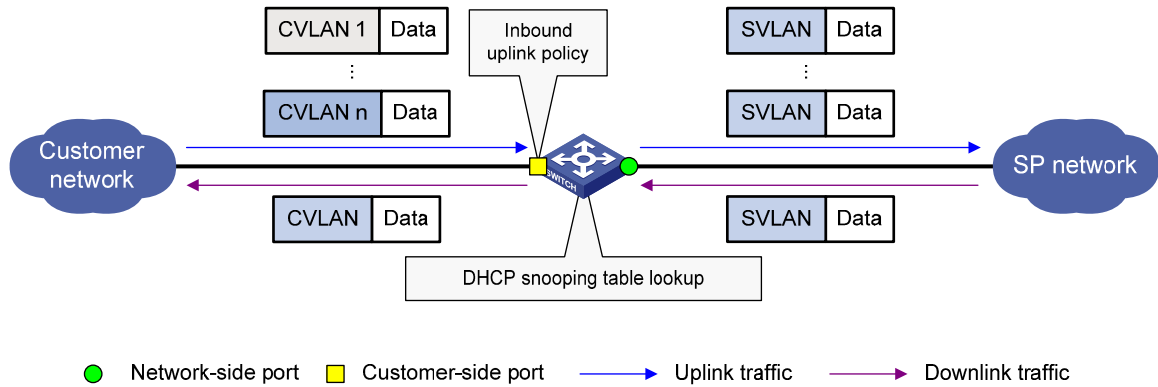

Many-to-one VLAN mapping

Implement many-to-one VLAN mapping through the following configurations, as shown in [Figure 68](#):

- Apply an uplink policy to the incoming traffic on the customer-side port to map different CVLAN IDs to one SVLAN ID. When a packet arrives, the switch replaces its CVLAN tag with the matching SVLAN tag.
- Configure the network-side port as a DHCP snooping trusted port. For downlink traffic, the switch looks through the DHCP snooping table, and replaces the SVLAN ID with the CVLAN ID found in the table.

Figure 68 Many-to-one VLAN mapping implementation

Each DHCP snooping entry contains information about one DHCP client, including its IP address, MAC address, and CVLAN. For more information about DHCP snooping, see *Layer 3—IP Services Configuration Guide*.

Two-to-two VLAN mapping

Implement two-to-two VLAN mapping through the following configurations, as shown in [Figure 69](#).

- For uplink traffic, apply an inbound policy on the customer-side port to replace the SVLAN with a new CVLAN, and apply an outbound policy on the network-side port to replace the CVLAN with a new SVLAN.
- For downlink traffic, apply an outbound policy on the customer-side port to replace the double tags with the original VLAN tag pair.

Figure 69 Two-to-two VLAN mapping implementation

VLAN mapping configuration tasks

Use the VLAN mapping methods as appropriate to the roles of your switches in the network, as described in this table:

Task	Switch role
Configuring one-to-one VLAN mapping	Wiring-closet switch
Configuring many-to-one VLAN mapping	Campus switch
Configuring two-to-two VLAN mapping	Edge switch between SP networks

Configuring one-to-one VLAN mapping

Perform one-to-one VLAN mapping on wiring-closet switches (see [Figure 64](#)) to isolate traffic by both user and traffic type.

Perform these tasks to configure one-to-one VLAN mapping:

Task	Description
Configuring an uplink policy	Creates CVLAN-to-SVLAN mappings (required).
Configuring a downlink policy	Creates SVLAN-to-CVLAN mappings (required).
Configuring the customer-side port	Configures settings required for one-to-one VLAN mapping (required).
Configuring the network-side port	Configures VLAN settings required for normal communication (required).

Configuration prerequisites

Create CVLANs and SVLANs, and plan CVLAN-SVLAN mappings.

Configuring an uplink policy

To configure an uplink policy to map each CVLAN to a unique SVLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator { and or }]	
3. Specify a CVLAN as the match criterion.	if-match customer-vlan-id <i>vlan-id</i>	Repeat these steps to configure one class for each CVLAN.
4. Return to system view.	quit	
5. Create a traffic behavior and enter traffic behavior view.	traffic behavior <i>behavior-name</i>	
6. Configure an SVLAN marking action.	remark service-vlan-id <i>vlan-id</i>	Repeat these steps to configure one behavior for each SVLAN.
7. Return to system view.	quit	
8. Create a QoS policy and enter QoS policy view.	qos policy <i>policy-name</i>	N/A
9. Associate the class with the behavior to map the CVLAN to the SVLAN.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	Repeat this step to create other CVLAN-to-SVLAN mappings.

Configuring a downlink policy

To configure a downlink policy to map SVLANs back to CVLANs:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator { and or }]	Repeat these steps to configure one class for each SVLAN.
3. Configure an SVLAN as the match criterion.	if-match service-vlan-id <i>vlan-id</i>	
4. Return to system view.	quit	
5. Create a traffic behavior and enter traffic behavior view.	traffic behavior <i>behavior-name</i>	Repeat these steps to configure a behavior for each CVLAN.
6. Configure a CVLAN marking action.	remark customer-vlan-id <i>vlan-id</i>	
7. Return to system view.	quit	
8. Create a QoS policy and enter QoS policy view.	qos policy <i>policy-name</i>	N/A
9. Associate the class with the behavior to map the SVLAN to the CVLAN.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	Repeat this step to create other CVLAN-to-SVLAN mappings.

Configuring the customer-side port

To configure the customer-side port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the port as a trunk port.	port link-type trunk	The default link type of an Ethernet port is access.
4. Assign the port to CVLANs and SVLANs.	port trunk permit vlan { <i>vlan-id-list</i> all }	By default, a trunk port is in only VLAN 1.
5. Enable basic QinQ.	qinq enable	By default, basic QinQ is disabled.
6. Apply the uplink policy to the incoming traffic.	qos apply policy <i>policy-name</i> inbound	N/A
7. Apply the downlink policy to the outgoing traffic.	qos apply policy <i>policy-name</i> outbound	N/A

Configuring the network-side port

To configure the network-side port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
3. Configure the port as a trunk port.	port link-type trunk	The default link type of ports is access.
4. Assign the port to SVLANs.	port trunk permit vlan { <i>vlan-id-list</i> all }	By default, a trunk port is in only VLAN 1.

Configuring many-to-one VLAN mapping

⚠ CAUTION:

Before changing VLAN mappings on a port, clear all DHCP snooping entries by using the **reset dhcp-snooping** command (see *Layer 3—IP Services Command Reference*).

Perform many-to-one VLAN mapping on campus switches (see [Figure 64](#)) to transmit the same type of traffic from different users in one VLAN.

Perform these tasks to configure many-to-one VLAN mapping:

Task	Description
Enabling DHCP snooping	Enables DHCP snooping globally (required).
Enabling ARP detection in SVLANs	Enables ARP detection in all SVLANs (required).
Configuring an uplink policy	Configures an uplink policy for the customer-side port (required).
Configuring the customer-side port	Configures VLAN and other settings required for many-to-one VLAN mapping (required).
Configuring the network-side port	Configures VLAN and other settings required for many-to-one VLAN mapping (required).

Configuration prerequisites

Before configuring many-to-one VLAN mapping:

- Make sure that all home users obtain IP addresses through DHCP. For how to assign IP addresses through DHCP, see *Layer 3—IP Services Configuration Guide*.
- Create CVLANs and SVLANs, and plan CVLANs-to-SVLAN mappings.

Enabling DHCP snooping

To enable DHCP snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable DHCP snooping.	dhcp-snooping	Disabled by default.

Enabling ARP detection in SVLANs

The ARP detection function enables a switch to modify the VLAN attributes of ARP packets, which is impossible under the normal ARP packet processing procedure. For more information about ARP detection, see *Security Configuration Guide*.

To enable ARP detection in all SVLANs:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Enable ARP detection.	arp detection enable	Disabled by default.

NOTE:

To defend against ARP attacks, enable ARP detection also in all CVLANs.

Configuring an uplink policy

To configure an uplink policy to map a group of CVLANs to one SVLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> operator or	
3. Configure multiple CVLANs as match criteria.	if-match customer-vlan-id { <i>vlan-id-list</i> <i>vlan-id1</i> to <i>vlan-id2</i> }	Repeat these steps to configure one class for each group of CVLANs.
4. Return to system view.	quit	
5. Create a traffic behavior and enter traffic behavior view.	traffic behavior <i>behavior-name</i>	
6. Configure an SVLAN marking action.	remark service-vlan-id <i>vlan-id</i>	Repeat these steps to configure one behavior for each SVLAN.
7. Return to system view.	quit	
8. Create a QoS policy and enter QoS policy view.	qos policy <i>policy-name</i>	N/A
9. Map the CVLANs to the SVLAN by associating the class with the behavior.	classifier <i>tcl-name</i> behavior <i>behavior-name</i> mode dot1q-tag-manipulation	Repeat this step to create other CVLANs-to-SVLAN mappings.

Configuring the customer-side port

△ CAUTION:

Before applying a QoS policy to the customer-side port, enable customer-side QinQ on the port. Before disabling customer-side QinQ on the customer-side port, remove the QoS policy from the port first.

To configure the customer-side port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the port as a trunk port.	port link-type trunk	The default link type of an Ethernet port is access.
4. Assign the port to CVLANs and SVLANs.	port trunk permit vlan { <i>vlan-id-list</i> all }	By default, a trunk port is in only VLAN 1.
5. Enable customer-side QinQ.	qinq enable downlink	By default, customer-side QinQ is disabled on all ports.
6. Apply the uplink policy to the incoming traffic.	qos apply policy <i>policy-name</i> inbound	N/A

Configuring the network-side port

To configure the network-side port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the port as a trunk port.	port link-type trunk	The default link type of an Ethernet port is access.
4. Assign the port to SVLANs.	port trunk permit vlan { <i>vlan-id-list</i> all }	By default, a trunk port is in only VLAN 1.
5. Configure the port as a DHCP snooping trusted port.	dhcp-snooping trust	By default, all ports are DHCP snooping untrusted ports.
6. Configure the port as an ARP trusted port.	arp detection trust	By default, all ports are ARP untrusted ports.
7. Enable network-side QinQ.	qinq enable uplink	By default, network-side QinQ is disabled on all ports.

Configuring two-to-two VLAN mapping

Perform two-to-two VLAN mapping on an edge device that connects two SP networks, for example, on PE 3 in [Figure 65](#). Two-to-two VLAN mapping enables two remote sites in different VLANs to communicate at Layer 2 across two service provider networks that use different VLAN assignment schemes.

For the ease of description, the VLAN tags of the double-tagged frames that arrive at the customer-side port are called foreign CVLANs and SVLANs, and the VLAN tags marked by the edge device are called local CVLANs and SVLANs.

Perform these tasks to configure two-to-two VLAN mapping:

Task	Description
Configuring an uplink policy for the customer-side port	Replaces foreign SVLANs with local SVLANs for uplink traffic (required).
Configuring an uplink policy for the network-side port	Replaces foreign CVLANs with local CVLANs for uplink traffic (required).
Configuring a downlink policy for the customer-side port	Replaces local SVLANs and CVLANs with foreign SVLANs and CVLANs (required).
Configuring the customer-side port	Configures VLAN and other settings required for two-to-two VLAN mapping (required).
Configuring the network-side port	Configures VLAN and other settings required for two-to-two VLAN mapping (required).

Configuring an uplink policy for the customer-side port

The uplink policy on the customer-side port modifies the SVLAN ID of incoming traffic.

To configure an uplink policy for the customer-side port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator and]	
3. Specify a foreign CVLAN as a match criterion.	if-match customer-vlan-id <i>vlan-id</i>	Repeat these steps to create one class for each foreign CVLAN and SVLAN pair.
4. Specify a foreign SVLAN as a match criterion.	if-match service-vlan-id <i>vlan-id</i>	
5. Return to system view.	quit	
6. Create a traffic behavior and enter traffic behavior view.	traffic behavior <i>behavior-name</i>	
7. Configure an SVLAN marking action to replace the foreign SVLAN ID with a local SVLAN ID.	remark service-vlan-id <i>vlan-id</i>	Repeat these steps to configure one SVLAN marking action for each CVLAN and SVLAN pair.
8. Return to system view.	quit	
9. Create a QoS policy and enter QoS policy view.	qos policy <i>policy-name</i>	N/A
10. Associate the class with the behavior.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	Repeat this step to create other class-behavior associations.

Configuring an uplink policy for the network-side port

The uplink policy on the network-side port modifies the CVLAN ID of incoming traffic.

To configure an uplink policy for the network-side port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator and]	
3. Specify a foreign CVLAN as a match criterion.	if-match customer-vlan-id <i>vlan-id</i>	Repeat these steps to create one class for each local SVLAN and foreign CVLAN pair.
4. Specify a local SVLAN as a match criterion.	if-match service-vlan-id <i>vlan-id</i>	
5. Return to system view.	quit	
6. Create a traffic behavior and enter traffic behavior view.	traffic behavior <i>behavior-name</i>	Repeat these steps to configure one CVLAN marking action for each local SVLAN and foreign CVLAN pair.
7. Configure a CVLAN marking action to replace the foreign CVLAN ID with a local CVLAN ID.	remark customer-vlan-id <i>vlan-id</i>	
8. Return to system view.	quit	
9. Create a QoS policy and enter QoS policy view.	qos policy <i>policy-name</i>	N/A
10. Associate the class with the behavior.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	Repeat this step to create other class-behavior associations.

Configuring a downlink policy for the customer-side port

The downlink policy on the customer-side port replaces local SVLAN and CVLAN pairs with foreign SVLAN and CVLAN pairs.

To configure a downlink policy for the customer-side port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator and]	
3. Specify a local CVLAN as a match criterion.	if-match customer-vlan-id <i>vlan-id</i>	Repeat these steps to create one class for each local CVLAN and SVLAN pair.
4. Specify a local SVLAN as a match criterion.	if-match service-vlan-id <i>vlan-id</i>	
5. Return to system view.	quit	
6. Create a traffic behavior and enter traffic behavior view.	traffic behavior <i>behavior-name</i>	Repeat these steps to create one VLAN marking behavior for each local CVLAN and SVLAN pair.
7. Configure a CVLAN marking action to replace the local CVLAN ID with a foreign CVLAN ID.	remark customer-vlan-id <i>vlan-id</i>	
8. Configure an SVLAN marking action to replace the local SVLAN ID with a foreign SVLAN ID.	remark service-vlan-id <i>vlan-id</i>	
9. Return to system view.	quit	

Step	Command	Remarks
10. Create a QoS policy and enter QoS policy view.	qos policy <i>policy-name</i>	N/A
11. Associate the class with the behavior.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	Repeat this step to create other class-behavior associations.

Configuring the customer-side port

To configure the customer-side port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the port as a trunk port.	port link-type trunk	The default link type of an Ethernet port is access.
4. Assign the port to the local SVLANs.	port trunk permit vlan { <i>vlan-id-list</i> all }	By default, a trunk port is in only VLAN 1.
5. Apply the uplink policy configured for the customer-side port to the incoming traffic.	qos apply policy <i>policy-name</i> inbound	N/A
6. Apply the downlink policy configured for the customer-side port to the outgoing traffic.	qos apply policy <i>policy-name</i> outbound	N/A

Configuring the network-side port

To configure the network-side port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the port as a trunk port.	port link-type trunk	The default link type of an Ethernet port is access.
4. Assign the port to local SVLANs.	port trunk permit vlan { <i>vlan-id-list</i> all }	By default, a trunk port is in only VLAN 1.
5. Apply the uplink policy for the network-side port to the outgoing traffic.	qos apply policy <i>policy-name</i> outbound	N/A

VLAN mapping configuration examples

One-to-one and many-to-one VLAN mapping configuration example

Network requirements

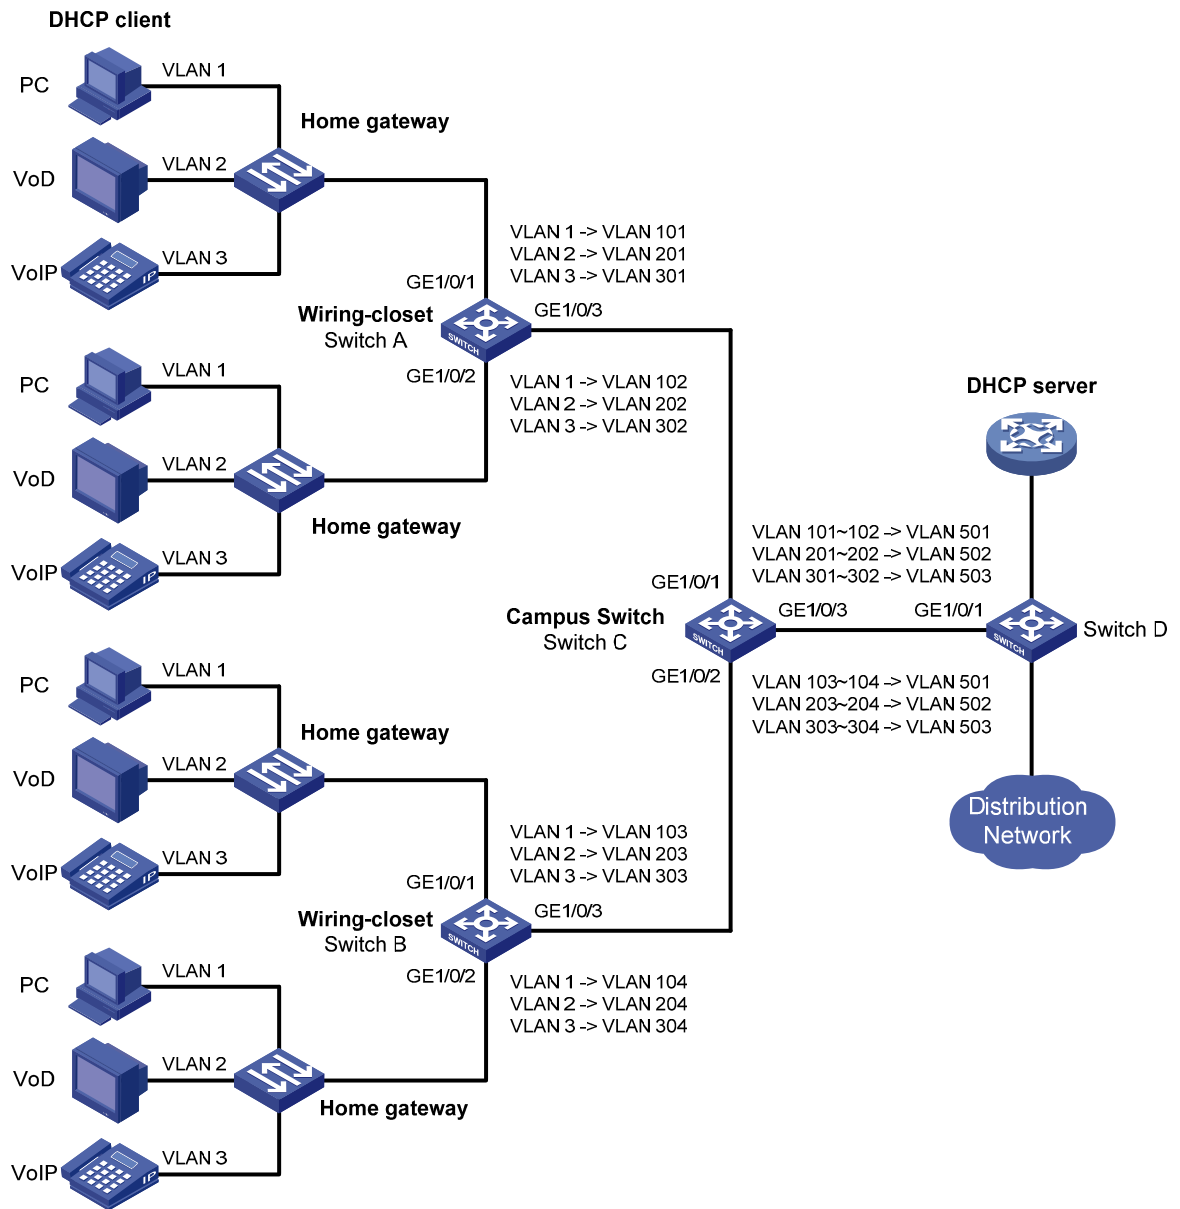

As shown in [Figure 70](#):

- Each home is offered PC, VoD, and VoIP services, connects to a wiring-closet switch through the home gateway, and obtains the IP address through DHCP.
- VLAN 1 is assigned for PC traffic, VLAN 2 is assigned for VoD traffic, and VLAN 3 is assigned for VoIP service traffic on the home gateways.

Assign one VLAN for each type of traffic from each user on the wiring-closet switches, so that traffic of the same service type from different homes is isolated.

Perform many-to-one VLAN mapping on the campus switch (Switch C) to transmit the same type of traffic from different homes in one VLAN: use VLAN 501 for PC traffic, VLAN 502 for VoD traffic, and VLAN 503 for VoIP traffic, so that the VLAN resources are saved.

Figure 70 Network diagram

Configuration procedure

1. Configure Switch A:

Create the CVLANs and the SVLANs.

```
<SwitchA> system-view
[SwitchA] vlan 2 to 3
[SwitchA] vlan 101 to 102
[SwitchA] vlan 201 to 202
[SwitchA] vlan 301 to 302
```

Configure uplink policies **p1** and **p2** to enable one SVLAN to transmit one service for one customer.

```
[SwitchA] traffic classifier c1
[SwitchA-classifier-c1] if-match customer-vlan-id 1
```

```

[SwitchA-classifier-c1] traffic classifier c2
[SwitchA-classifier-c2] if-match customer-vlan-id 2
[SwitchA-classifier-c2] traffic classifier c3
[SwitchA-classifier-c3] if-match customer-vlan-id 3
[SwitchA-classifier-c3] quit
[SwitchA] traffic behavior b1
[SwitchA-behavior-b1] remark service-vlan-id 101
[SwitchA-behavior-b1] traffic behavior b2
[SwitchA-behavior-b2] remark service-vlan-id 201
[SwitchA-behavior-b2] traffic behavior b3
[SwitchA-behavior-b3] remark service-vlan-id 301
[SwitchA-behavior-b3] traffic behavior b4
[SwitchA-behavior-b4] remark service-vlan-id 102
[SwitchA-behavior-b4] traffic behavior b5
[SwitchA-behavior-b5] remark service-vlan-id 202
[SwitchA-behavior-b5] traffic behavior b6
[SwitchA-behavior-b6] remark service-vlan-id 302
[SwitchA-behavior-b6] quit
[SwitchA] qos policy p1

```

4. Configure Switch D:

```

# Enable DHCP snooping.
<SwitchD> system-view
[SwitchD] dhcp-snooping
# Assign port GigabitEthernet 1/0/1 to SVLANs 501 to 503.
[SwitchD] interface gigabitethernet 1/0/1
[SwitchD-GigabitEthernet1/0/1] port link-type trunk
[SwitchD-GigabitEthernet1/0/1] port trunk permit vlan 501 502 503

```

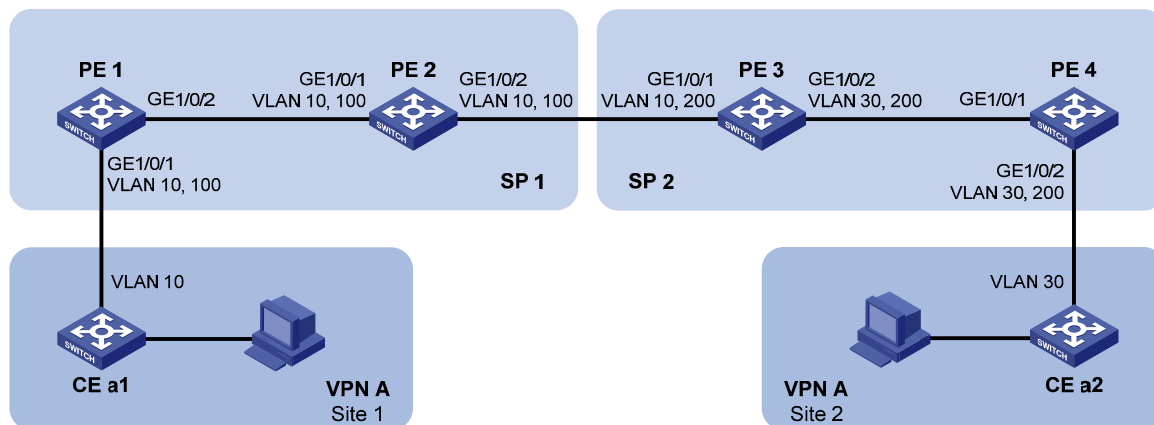

Two-to-two VLAN mapping configuration example

Network requirements

As shown in Figure 71, two VPN A branches, Site 1 and Site 2, are in VLAN 10 and VLAN 30, respectively. The two sites use different VPN access services of different service providers, SP 1 and SP 2. SP 1 assigns VLAN 100 for Site 1, and SP 2 assigns VLAN 200 for Site 2.

Configure two-to-two VLAN mappings to enable the two branches to communicate across networks SP 1 and SP 2.

Figure 71 Network diagram

Configuration procedure

1. Configure PE 1:

Configure QinQ function on GigabitEthernet 1/0/1 to add outer VLAN tag 100 to the traffic tagged with VLAN 10.

```
<PE1> system-view
[PE1] interface gigabitEthernet 1/0/1
[PE1-GigabitEthernet1/0/1] port access vlan 100
[PE1-GigabitEthernet1/0/1] qinq enable
[PE1-GigabitEthernet1/0/1] quit
# Configure the uplink port GigabitEthernet 1/0/2 to permit frames of VLAN 100 to pass through.
[PE1] interface gigabitEthernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-type trunk
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 100
```

2. Configure PE 2:

Set port GigabitEthernet 1/0/1 as a trunk port, and assign it to VLAN 100.

```
<PE2> system-view
[PE2] interface gigabitEthernet 1/0/1
[PE2-GigabitEthernet1/0/1] port link-type trunk
[PE2-GigabitEthernet1/0/1] port trunk permit vlan 100
[PE2-GigabitEthernet1/0/1] quit
# Set port GigabitEthernet 1/0/2 as a trunk port, and assign it to VLAN 100.
[PE2] interface gigabitEthernet 1/0/2
[PE2-GigabitEthernet1/0/2] port link-type trunk
[PE2-GigabitEthernet1/0/2] port trunk permit vlan 100
```

3. Configure PE 3:

Configure an uplink policy **down_uplink** for customer-side port GigabitEthernet 1/0/1 to substitute SVLAN ID 200 for the SVLAN ID in the incoming traffic tagged with CVLAN 10 and SVLAN 100.

```
<PE3> system-view
[PE3] traffic classifier down_uplink
[PE3-classifier-down_uplink] if-match customer-vlan-id 10
[PE3-classifier-down_uplink] if-match service-vlan-id 100
[PE3-classifier-down_uplink] quit
[PE3] traffic behavior down_uplink
[PE3-behavior-down_uplink] remark service-vlan-id 200
[PE3-behavior-down_uplink] quit
[PE3] qos policy down_uplink
[PE3-qospolicy-down_uplink] classifier down_uplink behavior down_uplink
[PE3-qospolicy-down_uplink] quit
```

Configure a downlink policy **down_downlink** for customer-side port GigabitEthernet 1/0/1 to substitute CVLAN 10 and SVLAN 100 for traffic tagged with CVLAN 30 and SVLAN 200.

```
[PE3] traffic classifier down_downlink
[PE3-classifier-down_downlink] if-match customer-vlan-id 30
[PE3-classifier-down_downlink] if-match service-vlan-id 200
[PE3-classifier-down_downlink] quit
[PE3] traffic behavior down_downlink
[PE3-behavior-down_downlink] remark customer-vlan-id 10
[PE3-behavior-down_downlink] remark service-vlan-id 100
[PE3-behavior-down_downlink] quit
[PE3] qos policy down_downlink
[PE3-qospolicy-down_downlink] classifier down_downlink behavior down_downlink
[PE3-qospolicy-down_downlink] quit
```

Configure an uplink policy **up_uplink** for network-side port GigabitEthernet 1/0/2 to substitute CVLAN 30 for the CVLAN ID of the outgoing traffic tagged with CVLAN 10 and SVLAN 200.

```
[PE3] traffic classifier up_uplink
[PE3-classifier-up_uplink] if-match customer-vlan-id 10

```

Configure GigabitEthernet 1/0/1 to permit frames of VLAN 200 to pass through.

```
[DeviceD] interface gigabitethernet 1/0/1
```

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 200
```

Configuring LLDP

Overview

Background

In a heterogeneous network, a standard configuration exchange platform ensures that different types of network devices from different vendors can discover one another and exchange configuration for the sake of interoperability and management.

The IETF drafted the Link Layer Discovery Protocol (LLDP) in IEEE 802.1AB. The protocol operates on the data link layer to exchange device information between directly connected devices. With LLDP, a device sends local device information (including its major functions, management IP address, device ID, and port ID) as TLV (type, length, and value) triplets in LLDP Data Units (LLDPDUs) to the directly connected devices. At the same time, the device stores the device information received in LLDPDUs sent from the LLDP neighbors in a standard management information base (MIB). For more information about MIBs, see *Network Management and Monitoring Configuration Guide*. LLDP enables a network management system to quickly detect and identify Layer 2 network topology changes.

Basic concepts

LLDPDU formats

LLDP sends device information in LLDPDUs. LLDPDUs are encapsulated in Ethernet II or Subnetwork Access Protocol (SNAP) frames.

1. Ethernet II-encapsulated LLDPDU format

Figure 72 Ethernet II-encapsulated LLDPDU format

Table 22 Fields in an Ethernet II-encapsulated LLDPDU

Field	Description
Destination MAC address	MAC address to which the LLDPDU is advertised. It is fixed to 0x0180-C200-000E, a multicast MAC address.

Field	Description
Source MAC address	MAC address of the sending port. If the port does not have a MAC address, the MAC address of the sending bridge is used.
Type	Ethernet type for the upper layer protocol. It is 0x88CC for LLDP.
Data	LLDPDU.
FCS	Frame check sequence, a 32-bit CRC value used to determine the validity of the received Ethernet frame.

2. SNAP-encapsulated LLDPDU format

Figure 73 SNAP-encapsulated LLDPDU format

Table 23 Fields in a SNAP-encapsulated LLDPDU

Field	Description
Destination MAC address	MAC address to which the LLDPDU is advertised. It is fixed at 0x0180-C200-000E, a multicast MAC address.
Source MAC address	MAC address of the sending port.
Type	SNAP type for the upper layer protocol. It is 0xAAAA-0300-0000-88CC for LLDP.
Data	LLDPDU.
FCS	Frame check sequence, a 32-bit CRC value used to determine the validity of the received Ethernet frame.

LLDPDU_s

LLDP uses LLDPDU_s to exchange information. An LLDPDU comprises multiple TLV sequences. Each TLV carries a type of device information, as shown in [Figure 74](#).

Figure 74 LLDPDU encapsulation format

An LLDPDU can carry up to 28 types of TLVs. Mandatory TLVs include Chassis ID TLV, Port ID TLV, Time To Live TLV, and End of LLDPDU TLV. Other TLVs are optional.

TLVs

TLVs are type, length, and value sequences that carry information elements. The type field identifies the type of information, the length field measures the length of the information field in octets, and the value field contains the information itself.

LLDPDU TLVs fall into the following categories:

- Basic management TLVs
- Organizationally (IEEE 802.1 and IEEE 802.3) specific TLVs
- LLDP-MED (media endpoint discovery) TLVs

Basic management TLVs are essential to device management. Organizationally specific TLVs and LLDP-MED TLVs are used for enhanced device management; they are defined by standardization or other organizations and are optional to LLDPDUs.

1. Basic management TLVs

Table 24 lists the basic management TLV types. Some of them are mandatory to LLDPDUs, that is, must be included in every LLDPDU.

Table 24 Basic management TLVs

Type	Description	Remarks
Chassis ID	Specifies the bridge MAC address of the sending device	
Port ID	Specifies the ID of the sending port If the LLDPDU carries LLDP-MED TLVs, the port ID TLV carries the MAC address of the sending port or the bridge MAC if the port does not have a MAC address. If the LLDPDU carries no LLDP-MED TLVs, the port ID TLV carries the port name.	Mandatory
Time To Live	Specifies the life of the transmitted information on the receiving device	
End of LLDPDU	Marks the end of the TLV sequence in the LLDPDU	
Port Description	Specifies the port description of the sending port	
System Name	Specifies the assigned name of the sending device	
System Description	Specifies the description of the sending device	
System Capabilities	Identifies the primary functions of the sending device and the enabled primary functions	Optional
Management Address	Specifies the management address, and the interface number and object identifier (OID) associated with the address	

2. IEEE 802.1 organizationally specific TLVs

Table 25 IEEE 802.1 organizationally specific TLVs

Type	Description
Port VLAN ID	Specifies the port's VLAN identifier (PVID). An LLDPDU carries only one TLV of this type.
Port And Protocol VLAN ID	Indicates whether the device supports protocol VLANs and, if so, what VLAN IDs these protocols will be associated with. An LLDPDU can carry multiple different TLVs of this type.

Type	Description
VLAN Name	Specifies the textual name of any VLAN to which the port belongs. An LLDPDU can carry multiple different TLVs of this type.
Protocol Identity	Indicates protocols supported on the port. An LLDPDU can carry multiple different TLVs of this type.

NOTE:

- HP devices support only receiving protocol identity TLVs.
- Layer 3 Ethernet ports do not support IEEE 802.1 organizationally specific TLVs.

3. IEEE 802.3 organizationally specific TLVs

Table 26 IEEE 802.3 organizationally specific TLVs

Type	Description
MAC/PHY Configuration/Status	Contains the bit-rate and duplex capabilities of the sending port, support for auto negotiation, enabling status of auto negotiation, and the current rate and duplex mode.
Power Via MDI	Contains the power supply capability of the port, including the Power over Ethernet (PoE) type, which can be Power Sourcing Equipment (PSE) or Powered Device (PD), PoE mode, whether PSE power supply is supported, whether PSE power supply is enabled, and whether the PoE mode is controllable.
Link Aggregation	Indicates the aggregation capability of the port (whether the link is capable of being aggregated), and the aggregation status (whether the link is in an aggregation).
Maximum Frame Size	Indicates the supported maximum frame size. It is now the maximum transmission unit (MTU) of the port.
Power Stateful Control	Indicates the power state control configured on the sending port, including the power type of the PSE or PD, PoE sourcing and receiving priority, and PoE sourcing and receiving power.

NOTE:

The Power Stateful Control TLV is defined in IEEE P802.3at D1.0. The later versions no longer support this TLV. HP devices send this type of TLVs only after receiving them.

LLDP-MED TLVs

LLDP-MED TLVs provide multiple advanced applications for voice over IP (VoIP), such as basic configuration, network policy configuration, and address and directory management. LLDP-MED TLVs provide a cost-effective and easy-to-use solution for deploying voice devices in Ethernet. LLDP-MED TLVs are shown in [Table 27](#).

Table 27 LLDP-MED TLVs

Type	Description
LLDP-MED Capabilities	Allows a network device to advertise the LLDP-MED TLVs that it supports.

Type	Description
Network Policy	Allows a network device or terminal device to advertise the VLAN ID of the specific port, the VLAN type, and the Layer 2 and Layer 3 priorities for specific applications.
Extended Power-via-MDI	Allows a network device or terminal device to advertise power supply capability. This TLV is an extension of the Power Via MDI TLV.
Hardware Revision	Allows a terminal device to advertise its hardware version.
Firmware Revision	Allows a terminal device to advertise its firmware version.
Software Revision	Allows a terminal device to advertise its software version.
Serial Number	Allows a terminal device to advertise its serial number.
Manufacturer Name	Allows a terminal device to advertise its vendor name.
Model Name	Allows a terminal device to advertise its model name.
Asset ID	Allows a terminal device to advertise its asset ID. The typical case is that the user specifies the asset ID for the endpoint to facilitate directory management and asset tracking.
Location Identification	Allows a network device to advertise the appropriate location identifier information for a terminal device to use in the context of location-based applications.

Management address

The network management system uses the management address of a device to identify and manage the device for topology maintenance and network management. The management address TLV encapsulates the management address.

How LLDP works

Operating modes of LLDP

LLDP can operate in one of the following modes:

- **TxRx mode**—A port in this mode sends and receives LLDPDUs.
- **Tx mode**—A port in this mode only sends LLDPDUs.
- **Rx mode**—A port in this mode only receives LLDPDUs.
- **Disable mode**—A port in this mode does not send or receive LLDPDUs.

Each time the LLDP operating mode of a port changes, its LLDP protocol state machine re-initializes. A re-initialization delay, which is user configurable, prevents LLDP from being initialized too frequently at times of frequent changes to the operating mode. With this delay configured, before a port can initialize LLDP, it must wait for the specified interval after the LLDP operating mode changes.

Transmitting LLDPDUs

An LLDP-enabled port operating in TxRx mode or Tx mode sends LLDPDUs to its directly connected devices both periodically and when the local configuration changes. To prevent LLDPDUs from overwhelming the network during times of frequent changes to local device information, an interval is introduced between two successive LLDPDUs.

This interval is shortened to 1 second in either of the following cases:

- A new neighbor is discovered. A new LLDPDU is received and carries device information new to the local device.
- The LLDP operating mode of the port changes from Disable or Rx to TxRx or Tx.

This is the fast sending mechanism of LLDP. With this mechanism, a specific number of LLDPDUs are sent successively at 1-second intervals, to help LLDP neighbors discover the local device as soon as possible. Then, the normal LLDPDU transmit interval resumes.

Receiving LLDPDUs

An LLDP-enabled port that is operating in TxRx mode or Rx mode checks the validity of TLVs carried in every received LLDPDU. If valid, the information is saved and an aging timer is set for it based on the time to live (TTL) value in the Time to Live TLV carried in the LLDPDU. If the TTL value is zero, the information ages out immediately.

Protocols and standards

- IEEE 802.1AB-2005, *Station and Media Access Control Connectivity Discovery*
- ANSI/TIA-1057, *Link Layer Discovery Protocol for Media Endpoint Devices*

LLDP configuration task list

When you configure LLDP, follow these guidelines:

- LLDP-related configurations made in Layer 2/Layer 3 Ethernet interface view take effect only on the current port, and those made in port group view take effect on all ports in the current port group.
- Layer 3 interfaces refer to route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see "[Configuring Ethernet interfaces](#)").
- The 5500 SI Switches Series does not support Layer 3 Ethernet interfaces.

Complete these tasks to configure LLDP:

Task	Remarks	
Enabling LLDP	Required	
Setting the LLDP operating mode	Optional	
Setting the LLDP re-initialization delay	Optional	
Performing basic LLDP configuration	Enabling LLDP polling	Optional
	Configuring the advertisable TLVs	Optional
	Configuring the management address and its encoding format	Optional
	Setting other LLDP parameters	Optional
	Setting an encapsulation format for LLDPDUs	Optional
Configuring CDP compatibility	Optional	
Enabling LLDP to automatically discover IP phones	Optional	
Configuring LLDP to advertise a specific voice VLAN	Optional	
Dynamically advertising server-assigned VLANs through LLDP	Optional	
Configuring LLDP trapping	Optional	

Performing basic LLDP configuration

Enabling LLDP

To make LLDP take effect on specific ports, you must enable LLDP both globally and on these ports.

To enable LLDP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable LLDP globally.	lldp enable	By default, LLDP is globally enabled.
3. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none">Enter Layer 2/Layer 3 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i>Enter port group view: port-group manual <i>port-group-name</i>	Use either command.
4. Enable LLDP.	lldp enable	Optional. By default, LLDP is enabled on a port.

Setting the LLDP operating mode

LLDP can operate in one of the following modes.

- **TxRx mode**—A port in this mode sends and receives LLDPDUs.
- **Tx mode**—A port in this mode only sends LLDPDUs.
- **Rx mode**—A port in this mode only receives LLDPDUs.
- **Disable mode**—A port in this mode does not send or receive LLDPDUs.

To set the LLDP operating mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none">Enter Layer 2/Layer 3 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i>Enter port group view: port-group manual <i>port-group-name</i>	Use either command.
3. Set the LLDP operating mode.	lldp admin-status { disable rx tx txrx }	Optional. TxRx by default.

Setting the LLDP re-initialization delay

When LLDP operating mode changes on a port, the port initializes the protocol state machines after a certain delay. By adjusting the LLDP re-initialization delay, you can avoid frequent initializations caused by frequent changes to the LLDP operating mode on a port.

To set the LLDP re-initialization delay for ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the LLDP re-initialization delay.	lldp timer reinit-delay <i>delay</i>	Optional. 2 seconds by default.

Enabling LLDP polling

With LLDP polling enabled, a device periodically searches for local configuration changes. On detecting a configuration change, the device sends LLDPDUs to inform neighboring devices of the change.

To enable LLDP polling:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2/Layer 3 Ethernet interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable LLDP polling and set the polling interval.	lldp check-change-interval <i>interval</i>	Disabled by default.

Configuring the advertisable TLVs

To configure the advertisable LLDPDU TLVs on the specified port or ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2/Layer 3 Ethernet interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Configure the advertisable TLVs (Layer 2 Ethernet interface view or port group view).	lldp tlv-enable { basic-tlv { all port-description system-capability system-description system-name } dot1-tlv { all port-vlan-id protocol-vlan-id [<i>vlan-id</i>] vlan-name [<i>vlan-id</i>] } dot3-tlv { all link-aggregation mac-physic max-frame-size power } med-tlv { all capability inventory location-id { civic-address <i>device-type country-code</i> { <i>ca-type ca-value</i> } &<1-10> elin-address <i>tel-number</i> } network-policy power-over-ethernet } }	Optional. By default, all types of LLDP TLVs except location identification TLVs are advertisable on a Layer 2 Ethernet port.

Step	Command	Remarks
4. Configure the advertisable TLVs (Layer 3 Ethernet interface view).	lldp tlv-enable { basic-tlv { all port-description system-capability system-description system-name } dot3-tlv { all link-aggregation mac-physic max-frame-size power } med-tlv { all capability inventory location-id { civic-address <i>device-type country-code</i> { <i>ca-type ca-value</i> }&<1-10> elin-address <i>tel-number</i> } power-over-ethernet } }	Optional. By default, all types of LLDP TLVs, except IEEE 802.1 organizationally specific TLVs, network policy TLVs, and location identification TLVs, are advertisable on a Layer 3 Ethernet port.

Configuring the management address and its encoding format

LLDP encodes management addresses in numeric or character string format in management address TLVs.

By default, management addresses are encoded in numeric format. If a neighbor encoded its management address in character string format, you must configure the encoding format of the management address as string on the connecting port to guarantee normal communication with the neighbor.

To configure a management address to be advertised and its encoding format on a port or group of ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2/Layer 3 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Allow LLDP to advertise the management address in LLDPDUs and configure the advertised management address.	lldp management-address-tlv [<i>ip-address</i>]	Optional. By default, the management address is sent through LLDPDUs. <ul style="list-style-type: none"> For a Layer 2 Ethernet port, the management address is the main IP address of the lowest-ID VLAN carried on the port. If none of the carried VLANs is assigned an IP address, no management address will be advertised. For a Layer 3 Ethernet port, the management address is its own IP address. If no IP address is configured for the Layer 3 Ethernet port, no management address will be advertised.

Step	Command	Remarks
4. Configure the encoding format of the management address as character string.	lldp management-address-format string	Optional. By default, the management address is encapsulated in the numeric format.

Setting other LLDP parameters

The Time to Live TLV carried in an LLDPDU determines how long the device information carried in the LLDPDU can be saved on a recipient device.

By setting the TTL multiplier, you can configure the TTL of locally sent LLDPDUs, which determines how long information about the local device can be saved on a neighboring device. The TTL is expressed by using the following formula:

$$\text{TTL} = \text{Min} (65535, (\text{TTL multiplier} \times \text{LLDPDU transmit interval}))$$

As the expression shows, the TTL can be up to 65535 seconds. TTLs greater than 65535 will be rounded down to 65535 seconds.

Configuration restrictions and guidelines

- To make sure that LLDP neighbors can receive LLDPDUs to update information about the current device before it ages out, configure both the LLDPDU transmit interval and delay to be less than the TTL.
- It is a good practice to set the LLDPDU transmit interval to be no less than four times the LLDPDU transmit delay.
- If the LLDPDU transmit delay is greater than the LLDPDU transmit interval, the device uses the LLDPDUs transmit delay as the transmit interval.

Configuration procedure

To change the TTL multiplier:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the TTL multiplier.	lldp hold-multiplier <i>value</i>	Optional. 4 by default.
3. Set the LLDPDU transmit interval.	lldp timer tx-interval <i>interval</i>	Optional. 30 seconds by default.
4. Set the LLDPDU transmit delay.	lldp timer tx-delay <i>delay</i>	Optional. 2 seconds by default.
5. Set the number of LLDPDUs sent each time fast LLDPDU transmission is triggered.	lldp fast-count <i>count</i>	Optional. 3 by default.

Setting an encapsulation format for LLDPDUs

LLDPDUs can be encapsulated in the following formats: Ethernet II or SNAP frames.

- With Ethernet II encapsulation configured, an LLDP port sends LLDPDUs in Ethernet II frames and processes only incoming, Ethernet II encapsulated LLDPDUs.
- With SNAP encapsulation configured, an LLDP port sends LLDPDUs in SNAP frames and processes only incoming, SNAP encapsulated LLDPDUs.

By default, Ethernet II frames encapsulate LLDPDUs. If the neighbor devices encapsulate LLDPDUs in SNAP frames, configure the encapsulation format for LLDPDUs as SNAP to guarantee normal communication with the neighbors.

To set the encapsulation format for LLDPDUs to SNAP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none"> • Enter Layer 2/Layer 3 Ethernet interface view: interface <i>interface-type interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Set the encapsulation format for LLDPDUs to SNAP.	lldp encapsulation snap	Ethernet II encapsulation format applies by default.

NOTE:

LLDP-CDP (Cisco Discovery Protocol) packets use only SNAP encapsulation.

Configuring CDP compatibility

To make your device work with Cisco IP phones, you must enable CDP compatibility.

If your LLDP-enabled device cannot recognize CDP packets, it does not respond to the requests of Cisco IP phones for the voice VLAN ID configured on the device. As a result, a requesting Cisco IP phone sends voice traffic without any tag to your device, and, as a result, your device cannot differentiate the voice traffic from other types of traffic.

With CDP compatibility enabled, your device can receive and recognize CDP packets from a Cisco IP phone and respond with CDP packets, which carry the voice VLAN configuration TLVs. According to the voice VLAN configuration TLVs, the IP phone automatically configures the voice VLAN. As a result, the voice traffic is confined in the configured voice VLAN, and differentiated from other types of traffic.

For more information about voice VLANs, see "[Configuring a voice VLAN](#)."

Configuration prerequisites

Before you configure CDP compatibility, complete the following tasks:

- Globally enable LLDP.
- Enable LLDP on the port connecting to an IP phone and configure the port to operate in TxRx mode.

Configuring CDP compatibility

CAUTION:

The maximum TTL value that CDP allows is 255 seconds. To make CDP-compatible LLDP work properly with Cisco IP phones, be sure that the product of the TTL multiplier and the LLDPDU transmit interval is less than 255 seconds.

CDP-compatible LLDP operates in one of the follows modes:

- **TxRx**—CDP packets can be transmitted and received.
- **Disable**—CDP packets cannot be transmitted or received.

To make CDP-compatible LLDP take effect on specific ports, first enable CDP-compatible LLDP globally, and then configure CDP-compatible LLDP to operate in TxRx mode.

To enable LLDP to be compatible with CDP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable CDP compatibility globally.	lldp compliance cdp	Disabled by default.
3. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none">• Enter Layer 2/Layer 3 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i>• Enter port group view: port-group manual <i>port-group-name</i>	Use either command.
4. Configure CDP-compatible LLDP to operate in TxRx mode.	lldp compliance admin-status cdp txrx	Disable mode by default.

Enabling LLDP to automatically discover IP phones

In a traditional voice VLAN network, the switch maps the source MAC addresses of IP phones to a limited number of OUI addresses to allow them to access the network. This method restricts the types of IP phones on the network, if the IP phones with the source MAC addresses match the same OUI address are categorized as a type.

To break the restriction, you can enable the switch to automatically discover IP phones through LLDP. With this function, the switch can automatically discover the peer, and exchange LLDP TLVs with the peer. If the LLDP System Capabilities TLV received on a port shows that the peer is phone capable, the switch determines that the peer is an IP phone and sends an LLDP TLV carrying the voice VLAN configuration to the peer.

When the IP phone discovery process is complete, the port will automatically join the voice VLAN and improve the transmission priority of the voice traffic for the IP phone. To ensure that the IP phone can pass authentication, the switch will add the MAC address of the IP phone to the MAC address table.

For more information about voice VLANs, see "[Configuring a voice VLAN.](#)"

Configuration prerequisites

Before you enable the switch to automatically discover IP phones through LLDP, complete the following tasks:

- Enable LLDP globally and on ports.
- Configure voice VLANs.

Configuration procedure

To enable LLDP to automatically discover IP phones:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable LLDP to automatically discover IP phones.	voice vlan track lldp	Disabled by default.

ⓘ IMPORTANT:

- When the switch is enabled to automatically discover IP phones through LLDP, you can connect at most five IP phones to each port of the switch.
- You cannot use this function together with CDP compatibility.

Configuring LLDP to advertise a specific voice VLAN

Voice VLAN advertisement through LLDP is available only for LLDP-enabled IP phones. If CDP-compatibility is enabled, this feature is also available for CDP-enabled IP phones. For more information about CDP compatibility, see "[Configuring CDP compatibility](#)." For more information about the voice VLANs, see "[Configuring a voice VLAN](#)."

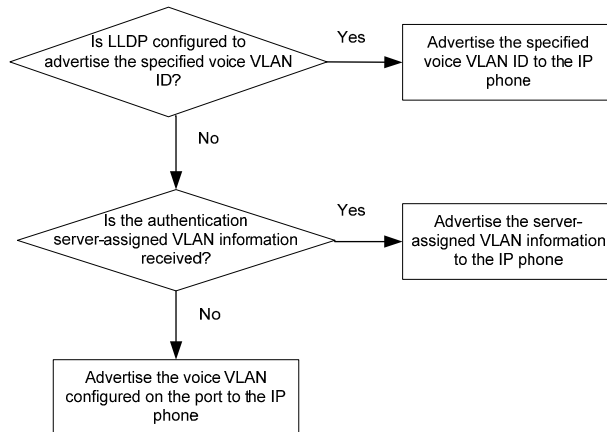

Configuration guidelines

Use this feature in one of the following scenarios:

- Decrease the voice VLAN processing delay in an IRF fabric.
On an LLDP-enabled port, LLDP advertises the voice VLAN information to the IP phone connected to the port. When a packet arrives on the port, the switch compares the source MAC address against its voice device OUI list. If a match is found, the switch learns the MAC address in the voice VLAN, and promotes the forwarding priority for the packet. Because this process is completed in software, in an IRF fabric, MAC address learning and synchronization of the learned MAC address entry to all member devices introduces an undesirable delay. Directly specifying the voice VLAN to be advertised by LLDP enables the IRF fabric to learn and synchronize MAC address entries faster in hardware.
- Avoid configuring the voice VLAN function on a port.

[Figure 75](#) shows the procedure of voice VLAN advertisement through LLDP.

Figure 75 Voice VLAN advertisement through LLDP

With the received voice VLAN information, the IP phone automatically completes the voice VLAN configuration, including the voice VLAN ID, tagging status, and priority. This voice VLAN can be the voice VLAN directly specified for LLDP advertisement, the voice VLAN configured on the port, or the voice VLAN assigned by a server, depending on your configuration.

To identify the voice VLAN advertised by LLDP, execute the **display lldp local-information** command, and examine the MED information fields in the command output.

Configuration procedure

To configure LLDP to advertise a specific voice VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable LLDP globally.	lldp enable	By default, LLDP is globally enabled.
3. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use one of the commands.
4. Enable LLDP.	lldp enable	Optional. By default, LLDP is enabled on a port.
5. Configure LLDP to advertise a specific voice VLAN.	lldp voice-vlan <i>vlan-id</i>	By default, LLDP advertises the voice VLAN configured on the port.

Dynamically advertising server-assigned VLANs through LLDP

Dynamic advertisement of server-assigned VLANs through LLDP must work with 802.1X or MAC authentication, and is available only for LLDP-enabled IP phones. If 802.1X authentication is used, make sure the IP phones also support 802.1X authentication.

To implement this function for an IP phone, perform the following configuration tasks:

- Enable LLDP globally and on the port connected to the IP phone.
- Configure 802.1X or MAC authentication to make sure the IP phone can pass security authentication. For more information about 802.1X authentication, MAC authentication, and VLAN assignment by servers, see *Security Configuration Guide*.
- Configure VLAN authorization for the IP phone on the authentication server.

After the IP phone passes authentication, LLDP advertises the server-assigned VLAN in the Network Policy TLV to the IP phone. The IP phone will send its traffic tagged with the assigned VLAN.

Configuring LLDP trapping

LLDP trapping notifies the network management system (NMS) of events such as newly-detected neighboring devices and link malfunctions.

LLDP traps are sent periodically, and the interval is configurable. To prevent excessive LLDP traps from being sent when the topology is unstable, set a trap transmit interval for LLDP.

To configure LLDP trapping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view or port group view.	<ul style="list-style-type: none">• Enter Layer 2/Layer 3 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i>• Enter port group view: port-group manual <i>port-group-name</i>	Use either command.
3. Enable LLDP trapping.	lldp notification remote-change enable	Disabled by default.
4. Return to system view.	quit	N/A
5. Set the LLDP trap transmit interval.	lldp timer notification-interval <i>interval</i>	Optional. 5 seconds by default.

Displaying and maintaining LLDP

Task	Command	Remarks
Display the global LLDP information or the information contained in the LLDP TLVs to be sent through a port.	display lldp local-information [global interface <i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information contained in the LLDP TLVs sent from neighboring devices.	display lldp neighbor-information [brief interface <i>interface-type interface-number</i> [brief] list [system-name <i>system-name</i>]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display LLDP statistics.	display lldp statistics [global interface <i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display LLDP status of a port.	display lldp status [interface <i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display types of advertisable optional LLDP TLVs.	display lldp tlv-config [interface <i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

LLDP configuration examples

Basic LLDP configuration example

Network requirements

As shown in [Figure 76](#), the NMS and Switch A are located in the same Ethernet. An MED device and Switch B are connected to GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 of Switch A.

Enable LLDP on the ports of Switch A and Switch B to monitor the link between Switch A and Switch B and the link between Switch A and the MED device on the NMS.

Figure 76 Network diagram

Configuration procedure

1. Configure Switch A:

```
# Enable LLDP globally.
<SwitchA> system-view
[SwitchA] lldp enable
```

Enable LLDP on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. (You can skip this step because LLDP is enabled on ports by default.) Set the LLDP operating mode to Rx.

```
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] lldp enable
[SwitchA-GigabitEthernet1/0/1] lldp admin-status rx
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] lldp enable
[SwitchA-GigabitEthernet1/0/2] lldp admin-status rx
[SwitchA-GigabitEthernet1/0/2] quit
```

2. Configure Switch B:

Enable LLDP globally.

```
<SwitchB> system-view
[SwitchB] lldp enable
```

Enable LLDP on GigabitEthernet1/0/1. (You can skip this step because LLDP is enabled on ports by default.) Set the LLDP operating mode to Tx.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] lldp enable
[SwitchB-GigabitEthernet1/0/1] lldp admin-status tx
[SwitchB-GigabitEthernet1/0/1] quit
```

3. Verify the configuration:

Display the global LLDP status and port LLDP status on Switch A.

```
[SwitchA] display lldp status
Global status of LLDP: Enable
The current number of LLDP neighbors: 2
The current number of CDP neighbors: 0
LLDP neighbor information last changed time: 0 days,0 hours,4 minutes,40 seconds
Transmit interval          : 30s
Hold multiplier            : 4
Reinit delay               : 2s
Transmit delay             : 2s
Trap interval              : 5s
Fast start times           : 3
```

```
Port 1 [GigabitEthernet1/0/1]:
Port status of LLDP        : Enable
Admin status                : Rx_Only
Trap flag                   : No
Polling interval           : 0s
```

```
Number of neighbors: 1
Number of MED neighbors : 1
Number of CDP neighbors : 0
Number of sent optional TLV : 0
Number of received unknown TLV : 0
```

```
Port 2 [GigabitEthernet1/0/2]:
```

```
Port status of LLDP          : Enable
Admin status                 : Rx_Only
Trap flag                    : No
Polling interval             : 0s
```

```
Number of neighbors:       1
Number of MED neighbors    : 0
Number of CDP neighbors    : 0
Number of sent optional TLV : 0
Number of received unknown TLV : 3
```

As the sample output shows, GigabitEthernet 1/0/1 of Switch A connects to an MED device, and GigabitEthernet 1/0/2 of Switch A connects to a non-MED device. Both ports operate in Rx mode, and they only receive LLDPDUs.

Remove the link between Switch A and Switch B and then display the global LLDP status and port LLDP status on Switch A.

```
[SwitchA] display lldp status
Global status of LLDP: Enable
The current number of LLDP neighbors: 1
The current number of CDP neighbors: 0
LLDP neighbor information last changed time: 0 days,0 hours,5 minutes,20 seconds
Transmit interval          : 30s
Hold multiplier            : 4
Reinit delay               : 2s
Transmit delay             : 2s
Trap interval              : 5s
Fast start times           : 3
```

```
Port 1 [GigabitEthernet1/0/1]:
Port status of LLDP          : Enable
Admin status                 : Rx_Only
Trap flag                    : No
Polling interval             : 0s
```

```
Number of neighbors        : 1
Number of MED neighbors    : 1
Number of CDP neighbors    : 0
Number of sent optional TLV : 0
Number of received unknown TLV : 5
```

```
Port 2 [GigabitEthernet1/0/2]:
Port status of LLDP          : Enable
Admin status                 : Rx_Only
Trap flag                    : No
Polling interval             : 0s
```

```
Number of neighbors        : 0
Number of MED neighbors    : 0
Number of CDP neighbors    : 0
```

```
Number of sent optional TLV      : 0
Number of received unknown TLV  : 0
```

As the sample output shows, GigabitEthernet 1/0/2 of Switch A does not connect to any neighboring devices.

CDP-compatible LLDP configuration example

Network requirements

As shown in [Figure 77](#), GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 of Switch A are each connected to a Cisco IP phone. The two IP phones send out tagged voice traffic.

Configure voice VLAN 2 on Switch A. Enable CDP compatibility of LLDP on Switch A to allow the Cisco IP phones to automatically configure the voice VLAN, confining their voice traffic within the voice VLAN and isolating the voice traffic from other types of traffic.

Figure 77 Network diagram

Configuration procedure

1. Configure a voice VLAN on Switch A:

```
# Create VLAN 2.
```

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] quit
```

```
# Set the link type of GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to trunk and enable voice VLAN on them.
```

```
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port link-type trunk
[SwitchA-GigabitEthernet1/0/1] voice vlan 2 enable
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] port link-type trunk
[SwitchA-GigabitEthernet1/0/2] voice vlan 2 enable
[SwitchA-GigabitEthernet1/0/2] quit
```

2. Configure CDP-compatible LLDP on Switch A:

```
# Enable LLDP globally and enable LLDP to be compatible with CDP globally.
```

```
[SwitchA] lldp enable
[SwitchA] lldp compliance cdp
```

```
# Enable LLDP (you can skip this step because LLDP is enabled on ports by default.), configure LLDP to operate in TxRx mode, and configure CDP-compatible LLDP to operate in TxRx mode on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.
```

```
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] lldp enable
[SwitchA-GigabitEthernet1/0/1] lldp admin-status txrx
[SwitchA-GigabitEthernet1/0/1] lldp compliance admin-status cdp txrx
```

```
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] lldp enable
[SwitchA-GigabitEthernet1/0/2] lldp admin-status txrx
[SwitchA-GigabitEthernet1/0/2] lldp compliance admin-status cdp txrx
[SwitchA-GigabitEthernet1/0/2] quit
```

3. Verify the configuration:

Display the neighbor information on Switch A.

```
[SwitchA] display lldp neighbor-information
```

```
CDP neighbor-information of port 1[GigabitEthernet1/0/1]:
```

```
  CDP neighbor index : 1
  Chassis ID         : SEP00141CBCDBFF
  Port ID            : Port 1
  Software version   : P0030301MFG2
  Platform           : Cisco IP Phone 7960
  Duplex             : Full
```

```
CDP neighbor-information of port 2[GigabitEthernet1/0/2]:
```

```
  CDP neighbor index : 2
  Chassis ID         : SEP00141CBCDBFF
  Port ID            : Port 1
  Software version   : P0030301MFG2
  Platform           : Cisco IP Phone 7960
  Duplex             : Full
```

As the sample output shows, Switch A has discovered the IP phones connected to GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, and has obtained their LLDP device information.

Configuring a service loopback group (available only on the 5500 EI)

Overview

To increase traffic redirecting throughput, you can bundle multiple Ethernet ports of a device together to increase bandwidth and implement load sharing. These ports that act as a logical link form a service loopback group. A service loopback group must contain at least one Ethernet port as its member port, called a service loopback port.

For example, by assigning three Ethernet ports of the same device to a service loopback group, you can create a logical link whose bandwidth can be as high as the total bandwidth of these three ports. In addition, service traffic is load balanced among these ports.

Service types of service loopback groups

A service loopback group is applicable to a specified service type. The service types supported by the service loopback group are:

- **Tunnel**—Supports unicast tunnel traffic

Requirements on service loopback ports

Before you assign a port to a service loopback group, ensure the following:

- The port supports the services type or types of the service loopback group.
- The port is not configured with multiple spanning tree protocol (MSTP), Link Layer Discovery Protocol (LLDP), Neighbor Discovery Protocol (NDP), 802.1X, MAC address authentication, port security mode, or IP source guard, or as the member port of an isolation group.
- The link type of the port is access.
- The port is not a member of any Ethernet link aggregation group or service loopback group.

States of service loopback ports

A member port in a service loopback group is a service loopback port, which can be in either of the following states:

- **Selected**—A selected port can loop back user traffic.
- **Unselected**—An unselected port cannot loop back user traffic.

The number of selected ports is limited in a service loopback group.

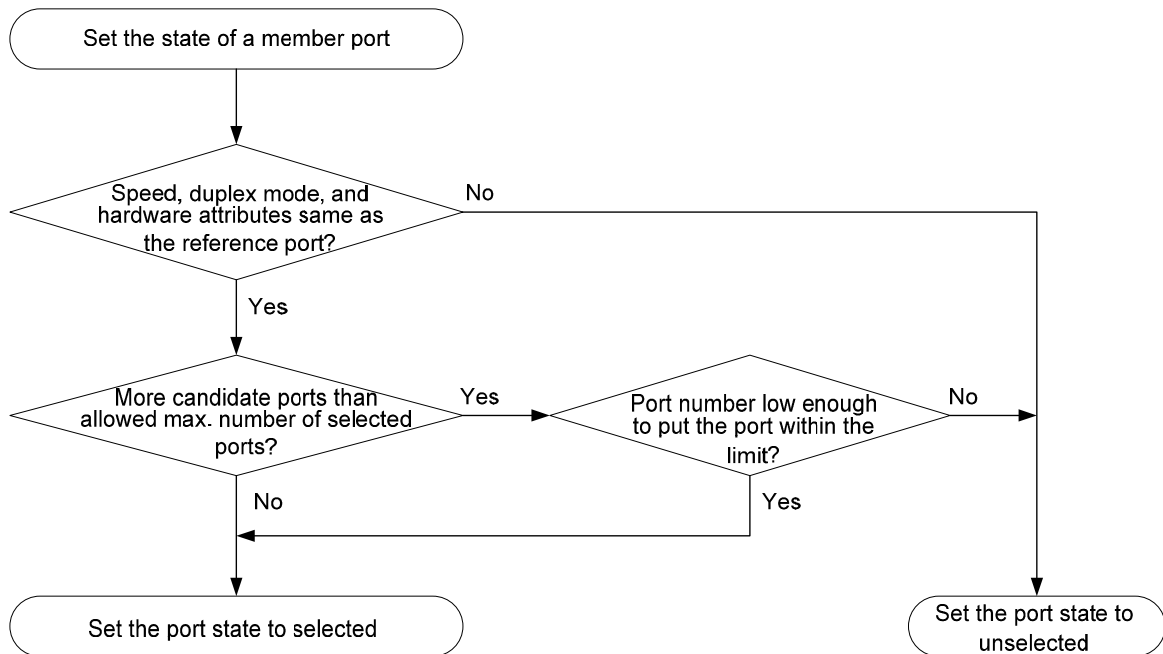

Setting the state of service loopback ports

The system sets the state of each member port in a service loopback group to selected or unselected by using the following workflow:

1. Select the full-duplex port with the highest rate as the reference port. If two ports have the same duplex mode and speed, the one with the lower port number wins.

- Set the state of each member port in the service loopback group.

Figure 78 Setting the state of each member port in a service loopback group

NOTE:

Every time a new port is assigned to a service loopback group, the system resets the state of the member ports in the service loopback group according to the process described previously.

Configuration restrictions and guidelines

- A service loopback group may be referenced by multiple features once it is created, and can process service traffic only after it is referenced.
- You can change the service type of an existing service loopback group. For the change to be successful, make sure that the service group has not been referenced, the attributes of all member ports (if any) do not conflict with the target service type, and no service loopback group has been created for the target service type, because only one service loopback group is allowed for a service type.
- You cannot remove a service loopback group that other features reference.

Configuration procedure

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a service loopback group and specify its service type.	service-loopback group <i>number</i> type tunnel	N/A

Step	Command	Remarks
3. Enter Layer 2 Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Assign the Ethernet interface to the specified service loopback group.	port service-loopback group <i>number</i>	By default, a port does not belong to any service loopback group. You can perform this command on different ports to assign multiple ports to a service loopback group.

Displaying and maintaining service loopback groups

Task	Command	Remarks
Display information about the specified service loopback group or all service loopback groups.	display service-loopback group [<i>number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Service loopback group configuration example

Network requirements

All the Ethernet ports of Device A support the tunnel service. Assign GigabitEthernet1/0/1 through GigabitEthernet1/0/3 to a service loopback group to increase bandwidth and achieve load sharing for tunnel traffic.

Configuration procedure

```
# Create service loopback group 1, and specify the service type as tunnel (unicast tunnel service).
<DeviceA> system-view
[DeviceA] service-loopback group 1 type tunnel

# Disable MSTP, LLDP, and NDP on GigabitEthernet1/0/1 through GigabitEthernet1/0/3 and then
assign them to service loopback group 1.
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo stp enable
[DeviceA-GigabitEthernet1/0/1] undo lldp enable
[DeviceA-GigabitEthernet1/0/1] undo ndp enable
[DeviceA-GigabitEthernet1/0/1] port service-loopback group 1
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] undo lldp enable
[DeviceA-GigabitEthernet1/0/2] undo ndp enable
[DeviceA-GigabitEthernet1/0/2] port service-loopback group 1
[DeviceA-GigabitEthernet1/0/2] quit
```

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] undo stp enable
[DeviceA-GigabitEthernet1/0/3] undo lldp enable
[DeviceA-GigabitEthernet1/0/3] undo ndp enable
[DeviceA-GigabitEthernet1/0/3] port service-loopback group 1
[DeviceA-GigabitEthernet1/0/3] quit

# Create logical interface Tunnel 1 and reference service loopback group 1 on Tunnel 1.
[DeviceA] interface tunnel 1
[DeviceA-Tunnel1] service-loopback-group 1
```

Configuring MVRP

Overview

Multiple Registration Protocol (MRP) is an attribute registration protocol and transmits attribute messages. Multiple VLAN Registration Protocol (MVRP) is a typical MRP application. MVRP propagates and learns VLAN configuration among devices. MVRP enables a device to propagate the local VLAN configuration to the other devices, receive VLAN configuration from other devices, and dynamically update the local VLAN configuration (including the active VLANs and the ports through which a VLAN can be reached). MVRP makes sure that all MVRP-enabled devices in a LAN maintain the same VLAN configuration, and reduces the VLAN configuration workload. When the network topology changes, MVRP can propagate and learn VLAN configuration information again according to the new topology, and real-time synchronize the network topology.

MRP is an enhanced version of Generic Attribute Registration Protocol (GARP) and improves the declaration efficiency. MVRP is an enhanced version of GARP VLAN Registration Protocol (GVRP). MVRP delivers the following benefits over GVRP:

- GVRP does not support the multiple spanning tree instance (MSTI). MVRP runs on a per-MSTI basis, and implements per-VLAN redundant link calculation and load sharing.
- MVRP decreases the number of packets transmitted for the same amount of VLAN configuration, and improves the declaration efficiency.

For more information about GVRP, see "[Configuring GVRP](#)." For more information about MSTI, see "[Configuring spanning tree protocols](#)."

Introduction to MRP

MRP allows participants in the same LAN to declare, propagate, and register information (for example, VLAN information) on a per Multiple Spanning Tree Instance (MSTI) basis.

MRP implementation

Each port that participates in an MRP application (for example, MVRP) is called an "MRP participant". Similarly, a port that participates in an MVRP application is called an "MVRP participant."

As shown in [Figure 79](#), an MRP participant registers and deregisters its attribute values on other MRP participants by sending declarations and withdrawals, and registers and deregisters the attribute values of other participants according to the received declarations and withdrawals. MRP rapidly propagates the configuration information of an MRP participant throughout the LAN.

Figure 79 MRP implementation

MVRP registers and deregisters VLAN attributes as follows:

- When a port receives the declaration of a VLAN attribute, the port registers the VLAN and joins the VLAN.
- When a port receives the withdrawal of a VLAN attribute, the port deregisters the VLAN and leaves the VLAN.

Figure 79 shows a simple MVRP implementation on an MSTI. In a network with multiple MSTIs, VLAN registration and deregistration are performed on a per-MSTI basis.

MRP messages

MRP exchanges information among MRP participants by advertising MRP messages, including Join, New, Leave, and LeaveAll. Join and New messages are declarations, and Leave and LeaveAll messages are withdrawals.

- Join message
 - An MRP participant sends Join messages when it wishes to declare the attribute values configured on it and receives Join messages from other MRP participants.
 - When receiving a Join message, an MRP participant sends a Join message to all participants except the sender.

Join messages fall into the following types:

- **JoinEmpty**—An MRP participant sends JoinEmpty messages to declare attribute values that it has not registered. For example, when a static VLAN exists on a device, the attribute of the VLAN on the device is not changed even if the device learns the VLAN again through MRP. In this case, the Join message for the VLAN attribute is a JoinEmpty message, because the VLAN attribute is not registered.
- **JoinIn**—An MRP participant sends JoinIn messages to declare attribute values that it has registered. For example, when the device learns a VLAN through MRP messages, and dynamically creates the VLAN, the Join message for the VLAN attribute is a JoinIn message.
- New message

Similar to a Join message, a New message enables MRP participants to register attributes.

 - When the Multiple Spanning Tree Protocol (MSTP) topology changes, an MRP participant sends New messages to declare the topology change.
 - On receiving a New message, an MRP participant sends a New message out of each port except the receiving port.
- Leave message
 - An MRP participant sends Leave messages when it wishes other participants to deregister the attributes that it has deregistered.
 - When receiving a Leave message, an MRP participant sends a Leave message to all participants except the sender.
- LeaveAll message
 - Each MRP participant is configured with an individual LeaveAll timer. When the timer expires, the MRP participant sends LeaveAll messages to the remote participants, so that the local participant and the remote participants deregister all attributes and re-register all attributes. This process periodically clears the useless attributes in the network.
 - On receiving a LeaveAll message, MRP determines whether to send a Join message to request the sender to re-register these attributes according to attribute status.

MRP timers

The implementation of MRP uses the following timers to control MRP message transmission.

- Periodic timer

On startup, an MRP participant starts its own Periodic timer to control MRP message transmission. The MRP participant collects the MRP messages to be sent before the Periodic timer expires, and sends the MRP messages in as few packets as possible when the Periodic timer expires and meanwhile restarts the Periodic timer. This mechanism reduces the number of MRP protocol packets periodically sent.

You can enable or disable the Periodic timer at the CLI. When you disable the Periodic timer, MRP will not periodically send MRP messages.

- Join timer

The Join timer controls the transmission of Join messages. To make sure that Join messages can be reliably transmitted to other participants, an MRP participant waits for a period of the Join timer after sending a Join message. If the participant receives JoinIn messages from other participants and the attributes in the JoinIn messages are the same as the sent Join messages before the Join timer expires, the participant does not re-send the Join message. When both the Join timer and the Periodic timer expire, the participant re-sends the Join message.

- Leave timer

The Leave timer controls the deregistration of attributes. When an MRP participant wishes other participants to deregister its attributes, it sends a Leave message. On receiving a Leave message, MRP starts the Leave timer, and deregisters the attributes if it does not receive any Join message for the attributes before the Leave timer expires. When an MRP participant sends or receives LeaveAll messages, it starts the Leave timer. MRP deregisters the attributes in the LeaveAll messages if it does not receive any Join message for the attributes before the Leave timer expires.

- LeaveAll timer

On startup, an MRP participant starts its own LeaveAll timer. When the LeaveAll timer expires, MRP sends out a LeaveAll message and restarts the LeaveAll timer. On receiving the LeaveAll message, other participants re-register all the attributes and re-start their LeaveAll timer.

When the LeaveAll timer of an MRP participant expires, the MRP participant sends LeaveAll messages to the remote participants. On receiving a LeaveAll message, a remote participant restarts its LeaveAll timer, and stops sending out LeaveAll messages. This mechanism effectively reduces the number of LeaveAll messages in the network.

To avoid the case that the LeaveAll timer of a fixed participant always first expires, the switch randomly changes the LeaveAll timer within a certain range when the MRP participant restarts its LeaveAll timer.

MVRP registration modes

The VLAN information propagated by MVRP includes not only locally, manually configured static VLAN information but also dynamic VLAN information from other devices.

VLANs created manually, locally are called "static VLANs", and VLANs learned through MVRP are called "dynamic VLANs". The following MVRP registration modes are available.

- Normal

An MVRP participant in normal registration mode performs dynamic VLAN registrations and deregistrations, and sends declarations and withdrawals for dynamic and static VLANs.

- Fixed

An MVRP participant in fixed registration mode disables deregistering dynamic VLANs, sends declarations for dynamic VLANs and static VLANs, and drops received MVRP protocol packets. As a result, an MVRP participant port in fixed registration mode does not deregister or register dynamic VLANs.

- Forbidden

An MVRP participant in forbidden registration mode disables registering dynamic VLANs, sends declarations for dynamic VLANs and static VLANs, and drops received MVRP protocol packets. As a result, an MVRP participant in forbidden registration mode does not register dynamic VLANs, and does not re-register a dynamic VLAN when the VLAN is deregistered.

Protocols and standards

IEEE 802.1ak *IEEE Standard for Local and Metropolitan Area Networks: Virtual Bridged Local Area Networks – Amendment 07: Multiple Registration Protocol*

MVRP configuration task list

Task	Remarks
Configuration prerequisites	Required.
Enabling MVRP	Required.
Configuring the MVRP registration mode	Optional.
Configuring MRP timers	Optional.
Enabling GVRP compatibility	Optional.

Configuration prerequisites

Before configuring MVRP, perform the following tasks:

- Make sure that all MSTIs in the network are effective and each MSTI is mapped to an existing VLAN on each device in the network, because MVRP runs on a per-MSTI basis.
- Configure the involved ports as trunk ports, because MVRP is available only on trunk ports.

Enabling MVRP

Configuration restrictions and guidelines

- MVRP can work with STP, RSTP, or MSTP, but not other link layer topology protocols, including service loopback, PVST, RRPP, and Smart Link. Ports blocked by STP, RSTP, or MSTP can receive and send MVRP protocol packets. For more information about service loopback, see "[Configuring a service loopback group \(available only on the 5500 EI\)](#)." For more information about STP, RSTP, MSTP, and PVST, see "[Configuring spanning tree protocols](#)." For more information about RRPP and Smart Link, see *High Availability Configuration Guide*.
- Do not enable both MVRP and remote port mirroring on a port. Otherwise, MVRP may register the remote probe VLAN to incorrect ports, which would cause the monitor port to receive undesired

duplicates. For more information about port mirroring, see *Network Management and Monitoring Configuration Guide*.

- Enabling MVRP on a Layer 2 aggregate interface enables both the aggregate interface and all Selected member ports in the link aggregation group to participate in dynamic VLAN registration and deregistration.

Configuration procedure

To enable MVRP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable MVRP globally.	mvrp global enable	By default, MVRP is globally disabled. To enable MVRP on a port, first enable MVRP globally.
3. Enter interface view.	<ul style="list-style-type: none"> • Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use one of the commands.
4. Configure the port to permit the specified VLANs.	port trunk permit vlan { <i>vlan-list</i> all }	By default, a trunk port permits only VLAN 1. Make sure that the trunk port permits all registered VLANs. For more information about the port trunk permit vlan { <i>vlan-list</i> all } command, see <i>Layer 2—LAN Switching Command Reference</i> .
5. Enable MVRP on the port.	mvrp enable	By default, MVRP is disabled on a port.

Configuring the MVRP registration mode

To configure the MVRP registration mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use one of the commands.
3. Configure the MVRP registration mode.	mvrp registration { fixed forbidden normal }	Optional. The default setting is normal registration mode.

Configuring MRP timers

⚠ CAUTION:

The MRP timers apply to all MRP applications, for example, MVRP, on a port. To avoid frequent VLAN registrations and deregistrations, use the same MRP timers throughout the network.

Each port maintains its own Periodic, Join, and LeaveAll timers, and each attribute of a port maintains a Leave timer.

To configure MRP timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use one of the commands.
3. Configure the LeaveAll timer.	mrp timer leaveall <i>timer-value</i>	Optional. The default setting is 1000 centiseconds.
4. Configure the Join timer.	mrp timer join <i>timer-value</i>	Optional. The default setting is 20 centiseconds.
5. Configure the Leave timer.	mrp timer leave <i>timer-value</i>	Optional. The default setting is 60 centiseconds.
6. Configure the Periodic timer.	mrp timer periodic <i>timer-value</i>	Optional. The default setting is 100 centiseconds.

Table 28 shows the value ranges for Join, Leave, and LeaveAll timers and their dependencies.

- If you set a timer to a value beyond the allowed value range, your configuration will fail. To do that, you can change the allowed value range by tuning the value of another related timer.
- To restore the default settings of the timers, restore the Join timer first, followed by the Leave and LeaveAll timers.

Table 28 Dependencies of the Join, Leave, and LeaveAll timers

Timer	Lower limit	Upper limit
Join	20 centiseconds	Half the Leave timer
Leave	Twice the Join timer	LeaveAll timer
LeaveAll	Leave timer on each port	32760 centiseconds

NOTE:

You can restore the Periodic timer to the default at any time.

Enabling GVRP compatibility

MVRP can be compatible with GVRP. When the peer device supports GVRP, you can enable GVRP compatibility on the local end, so that the local end can receive and send MVRP and GVRP protocol packets at the same time.

Configuration restrictions and guidelines

- MVRP with GVRP compatibility enabled can work together with STP or RSTP, but cannot work together with MSTP. When MVRP with GVRP compatibility enabled works with MSTP, the network might operate improperly.
- When GVRP compatibility is enabled for MVRP, HP recommends disabling the Period timer. Otherwise, the VLAN status might frequently change when the system is busy.

Configuration procedure

To enable GVRP compatibility:

Step	Command	Remarks
1. Enter system view	system-view	N/A
2. Enable GVRP compatibility	mvrp gvrp-compliance enable	By default, GVRP compatibility is disabled.

Displaying and maintaining MVRP

Task	Command	Remarks
Display the MVRP status of the specified port and each MVRP interface in the specified VLAN.	display mvrp state interface <i>interface-type interface-number</i> vlan <i>vlan-id</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the MVRP running status.	display mvrp running-status [interface <i>interface-list</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the MVRP statistics.	display mvrp statistics [interface <i>interface-list</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the dynamic VLAN operation information of the specified port.	display mvrp vlan-operation interface <i>interface-type interface-number</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear the MVRP statistics of the specified ports.	reset mvrp statistics [interface <i>interface-list</i>]	Available in user view

Configuration example for MVRP in normal registration mode

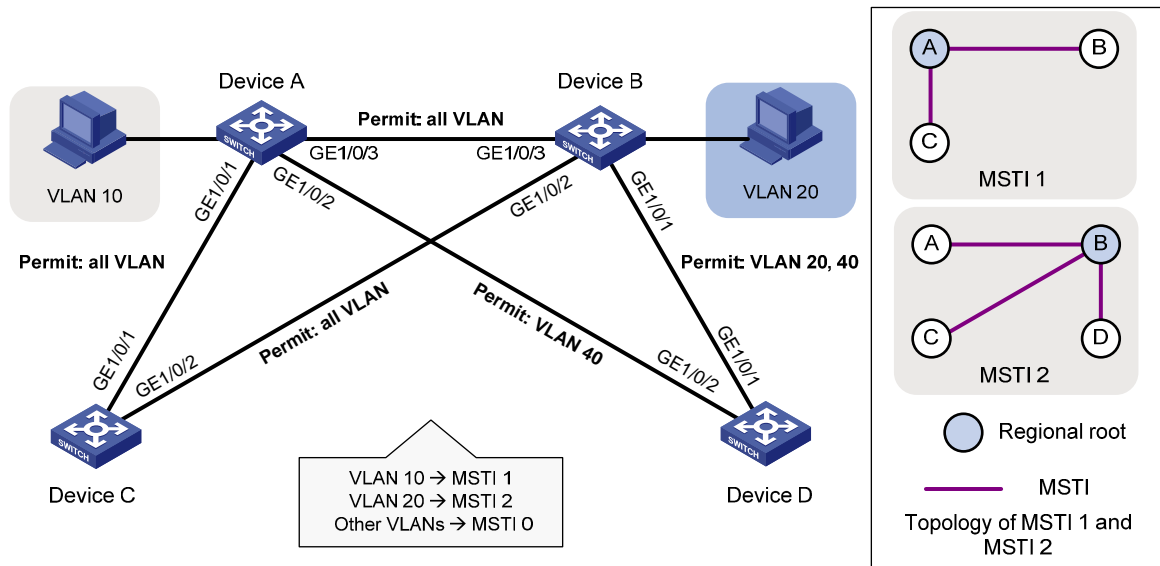

Network requirements

As shown in [Figure 80](#), configure MSTP, map VLAN 10 to MSTI 1, map VLAN 20 MST 2, and map the other VLANs to MSTI 0.

Configure MVRP and set the MVRP registration mode to normal, so that Device A, Device B, Device C, and Device D can register and deregister dynamic and static VLANs and keep identical VLAN configuration for each MSTI.

When the network is stable, set the MVRP registration mode to fixed on the port that connecting Device B to Device A, so that the dynamic VLANs on Device B are not de-registered.

Figure 80 Network diagram

Configuration procedure

Configuring Device A

```
# Enter MST region view.
<DeviceA> system-view
[DeviceA] stp region-configuration

# Configure the MST region name, VLAN-to-instance mappings, and revision level.
[DeviceA-mst-region] region-name example
[DeviceA-mst-region] instance 1 vlan 10
[DeviceA-mst-region] instance 2 vlan 20
[DeviceA-mst-region] revision-level 0

# Manually activate the MST region configuration.
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit

# Configure Device A as the primary root bridge of MSTI 1.
[DeviceA] stp instance 1 root primary

# Globally enable the spanning tree feature.
[DeviceA] stp enable

# Globally enable MVRP.
[DeviceA] mvrp global enable

# Configure port GigabitEthernet 1/0/1 as a trunk port, and configure it to permit all VLANs.
[DeviceA] interface gigabitEthernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan all

# Enable MVRP on port GigabitEthernet 1/0/1.
[DeviceA-GigabitEthernet1/0/1] mvrp enable
[DeviceA-GigabitEthernet1/0/1] quit
```

```

# Configure port GigabitEthernet1/0/2 as a trunk port, and configure it to permit VLAN 40.
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 40

# Enable MVRP on port GigabitEthernet1/0/2.
[DeviceA-GigabitEthernet1/0/2] mvrp enable
[DeviceA-GigabitEthernet1/0/2] quit

# Configure port GigabitEthernet 1/0/3 as a trunk port, and configure it to permit all VLANs.
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-type trunk
[DeviceA-GigabitEthernet1/0/3] port trunk permit vlan all

# Enable MVRP on port GigabitEthernet 1/0/3.
[DeviceA-GigabitEthernet1/0/3] mvrp enable
[DeviceA-GigabitEthernet1/0/3] quit

# Create VLAN 10.
[DeviceA] vlan 10
[DeviceA-vlan10] quit

```

Configuring Device B

```

# Enter MST region view.
<DeviceB> system-view
[DeviceB] stp region-configuration

# Configure the MST region name, VLAN-to-instance mappings, and revision level.
[DeviceB-mst-region] region-name example
[DeviceB-mst-region] instance 1 vlan 10
[DeviceB-mst-region] instance 2 vlan 20
[DeviceB-mst-region] revision-level 0

# Manually activate the MST region configuration.
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit

# Configure Device B as the primary root bridge of MSTI 2.
[DeviceB] stp instance 2 root primary

# Globally enable the spanning tree feature.
[DeviceB] stp enable

# Globally enable MVRP.
[DeviceB] mvrp global enable

# Configure port GigabitEthernet 1/0/1 as a trunk port, and configure it to permit VLANs 20 and 40.
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 20 40

# Enable MVRP on port GigabitEthernet 1/0/1.
[DeviceB-GigabitEthernet1/0/1] mvrp enable
[DeviceB-GigabitEthernet1/0/1] quit

# Configure port GigabitEthernet1/0/2 as a trunk port, and configure it to permit all VLANs.

```

```

[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan all
# Enable MVRP on port GigabitEthernet1/0/2.
[DeviceB-GigabitEthernet1/0/2] mvrp enable
[DeviceB-GigabitEthernet1/0/2] quit
# Configure port GigabitEthernet 1/0/3 as a trunk port, and configure it to permit all VLANs.
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan all
# Enable MVRP on port GigabitEthernet 1/0/3.
[DeviceB-GigabitEthernet1/0/3] mvrp enable
[DeviceB-GigabitEthernet1/0/3] quit
# Create VLAN 20.
[DeviceB] vlan 20
[DeviceB-vlan20] quit

```

Configuring Device C

```

# Enter MST region view.
<DeviceC> system-view
[DeviceC] stp region-configuration
# Configure the MST region name, VLAN-to-instance mappings, and revision level.
[DeviceC-mst-region] region-name example
[DeviceC-mst-region] instance 1 vlan 10
[DeviceC-mst-region] instance 2 vlan 20
[DeviceC-mst-region] revision-level 0
# Manually activate the MST region configuration.
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
# Globally enable the spanning tree feature.
[DeviceC] stp enable
# Globally enable MVRP.
[DeviceC] mvrp global enable
# Configure port GigabitEthernet 1/0/1 as a trunk port, and configure it to permit all VLANs.
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan all
# Enable MVRP on port GigabitEthernet 1/0/1.
[DeviceC-GigabitEthernet1/0/1] mvrp enable
[DeviceC-GigabitEthernet1/0/1] quit
# Configure port GigabitEthernet1/0/2 as a trunk port, and configure it to permit all VLANs.
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan all

```

```
# Enable MVRP on port GigabitEthernet1/0/2.
[DeviceC-GigabitEthernet1/0/2] mvrp enable
[DeviceC-GigabitEthernet1/0/2] quit
```

Configure Device D:

```
# Enter MST region view.
<DeviceD> system-view
[DeviceD] stp region-configuration

# Configure the MST region name, VLAN-to-instance mappings, and revision level.
[DeviceD-mst-region] region-name example
[DeviceD-mst-region] instance 1 vlan 10
[DeviceD-mst-region] instance 2 vlan 20
[DeviceD-mst-region] revision-level 0

# Manually activate the MST region configuration.
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit

# Globally enable the spanning tree feature.
[DeviceD] stp enable

# Globally enable MVRP.
[DeviceD] mvrp global enable

# Configure port GigabitEthernet 1/0/1 as a trunk port, and configure it to permit VLANs 20 and 40.
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 20 40

# Enable MVRP on port GigabitEthernet 1/0/1.
[DeviceD-GigabitEthernet1/0/1] mvrp enable
[DeviceD-GigabitEthernet1/0/1] quit

# Configure port GigabitEthernet1/0/2 as a trunk port, and configure it to permit VLAN 40.
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 40

# Enable MVRP on port GigabitEthernet1/0/2.
[DeviceD-GigabitEthernet1/0/2] mvrp enable
[DeviceD-GigabitEthernet1/0/2] quit
```

Verifying the configuration

1. Verify the normal registration mode configuration:

Use the **display mvrp running-status** command to display the local MVRP VLAN information to verify whether the configuration takes effect.

Check the local VLAN information on Device A.

```
[DeviceA] display mvrp running-status
-----[MVRP Global Info]-----
Global Status      : Enabled
Compliance-GVRP   : False
```

```

----[GigabitEthernet1/0/1]----
Config Status           : Enabled
Running Status          : Enabled
Join Timer               : 20 (centiseconds)
Leave Timer               : 60 (centiseconds)
Periodic Timer           : 100 (centiseconds)
LeaveAll Timer           : 1000 (centiseconds)
Registration Type        : Normal
Local VLANs :
  1(default),

```

```

----[GigabitEthernet1/0/2]----
Config Status           : Enabled
Running Status          : Enabled
Join Timer               : 20 (centiseconds)
Leave Timer               : 60 (centiseconds)
Periodic Timer           : 100 (centiseconds)
LeaveAll Timer           : 1000 (centiseconds)
Registration Type        : Normal
Local VLANs :
  1(default),

```

```

----[GigabitEthernet1/0/3]----
Config Status           : Enabled
Running Status          : Enabled
Join Timer               : 20 (centiseconds)
Leave Timer               : 60 (centiseconds)
Periodic Timer           : 100 (centiseconds)
LeaveAll Timer           : 1000 (centiseconds)
Registration Type        : Normal
Local VLANs :
  1(default), 20,

```

The output shows that:

- Ports GigabitEthernet 1/0/1 and GigabitEthernet1/0/2 have learned only VLAN 1 through MVRP.
- Port GigabitEthernet 1/0/3 has learned VLAN 1 and dynamic VLAN 20 created on Device B through MVRP.

Check the local VLAN information on Device B.

```
[DeviceB] display mvrp running-status
```

```

-----[MVRP Global Info]-----
Global Status           : Enabled
Compliance-GVRP        : False

```

```

----[GigabitEthernet1/0/1]----
Config Status           : Enabled
Running Status          : Enabled
Join Timer               : 20 (centiseconds)
Leave Timer               : 60 (centiseconds)

```

```

Periodic Timer                : 100 (centiseconds)
LeaveAll Timer                 : 1000 (centiseconds)
Registration Type             : Normal
Local VLANs :
  1(default),

```

----[GigabitEthernet1/0/2]----

```

Config Status                 : Enabled
Running Status               : Enabled
Join Timer                   : 20 (centiseconds)
Leave Timer                   : 60 (centiseconds)
Periodic Timer               : 100 (centiseconds)
LeaveAll Timer                : 1000 (centiseconds)
Registration Type            : Normal
Local VLANs :
  1(default),

```

----[GigabitEthernet1/0/3]----

```

Config Status                 : Enabled
Running Status               : Enabled
Join Timer                   : 20 (centiseconds)
Leave Timer                   : 60 (centiseconds)
Periodic Timer               : 100 (centiseconds)
LeaveAll Timer                : 1000 (centiseconds)
Registration Type            : Normal
Local VLANs :
  1(default), 10,

```

The output shows that:

- Ports GigabitEthernet 1/0/1 and GigabitEthernet1/0/2 have learned only VLAN 1 through MVRP.
- Port GigabitEthernet 1/0/3 has learned VLAN 1 and dynamic VLAN 10 created on Device A through MVRP.

Check the local VLAN information on Device C.

```
[DeviceC] display mvrp running-status
```

-----[MVRP Global Info]-----

```

Global Status      : Enabled
Compliance-GVRP   : False

```

----[GigabitEthernet1/0/1]----

```

Config Status                 : Enabled
Running Status               : Enabled
Join Timer                   : 20 (centiseconds)
Leave Timer                   : 60 (centiseconds)
Periodic Timer               : 100 (centiseconds)
LeaveAll Timer                : 1000 (centiseconds)
Registration Type            : Normal
Local VLANs :
  1(default), 10,

```

```
----[GigabitEthernet1/0/2]----
```

```
Config Status           : Enabled
Running Status          : Enabled
Join Timer               : 20 (centiseconds)
Leave Timer              : 60 (centiseconds)
Periodic Timer          : 100 (centiseconds)
LeaveAll Timer           : 1000 (centiseconds)
Registration Type       : Normal
Local VLANs :
  1(default), 20,
```

The output shows that:

- Port GigabitEthernet 1/0/1 has learned VLAN 1 and dynamic VLAN 10 created on Device A through MVRP.
- Port GigabitEthernet1/0/2 has learned VLAN 1 and dynamic VLAN 20 created on Device B through MVRP.

Check the local VLAN information on Device D.

```
[DeviceD] display mvrp running-status
```

```
-----[MVRP Global Info]-----
```

```
Global Status      : Enabled
Compliance-GVRP   : False
```

```
----[GigabitEthernet1/0/1]----
```

```
Config Status           : Enabled
Running Status          : Enabled
Join Timer               : 20 (centiseconds)
Leave Timer              : 60 (centiseconds)
Periodic Timer          : 100 (centiseconds)
LeaveAll Timer           : 1000 (centiseconds)
Registration Type       : Normal
Local VLANs :
  1(default), 20,
```

```
----[GigabitEthernet1/0/2]----
```

```
Config Status           : Enabled
Running Status          : Enabled
Join Timer               : 20 (centiseconds)
Leave Timer              : 60 (centiseconds)
Periodic Timer          : 100 (centiseconds)
LeaveAll Timer           : 1000 (centiseconds)
Registration Type       : Normal
Local VLANs :
  1(default),
```

The output shows that:

- Port GigabitEthernet 1/0/1 has learned VLAN 1 and dynamic VLAN 20 created on Device B through MVRP.
- Port GigabitEthernet1/0/2 has learned only VLAN 1 through MVRP.

2. Change the registration mode and verify the configuration:

Set the MVRP registration mode to fixed on GigabitEthernet 1/0/3 of Device B, so that the dynamic VLANs that Device B learns in VLAN 1 are not de-registered.

Set the MVRP registration mode to fixed on GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] mvrp registration fixed
[DeviceB-GigabitEthernet1/0/3] quit
```

Display the local MVRP VLAN information on GigabitEthernet 1/0/3.

```
[DeviceB] display mvrp running-status interface gigabitethernet 1/0/3
-----[MVRP Global Info]-----
Global Status      : Enabled
Compliance-GVRP   : False

----[GigabitEthernet1/0/3]----
Config Status      : Enabled
Running Status     : Enabled
Join Timer         : 20 (centiseconds)
Leave Timer        : 60 (centiseconds)
Periodic Timer     : 100 (centiseconds)
LeaveAll Timer     : 1000 (centiseconds)
Registration Type  : Fixed
Local VLANs :
  1(default), 10,
```

The output shows that the VLAN information on GigabitEthernet 1/0/3 is not changed after you set the MVRP registration mode to fixed on GigabitEthernet 1/0/3.

Delete VLAN 10 on Device A.

```
[DeviceA] undo vlan 10
```

Display the local MVRP VLAN information on GigabitEthernet 1/0/3.

```
[DeviceB] display mvrp running-status interface gigabitethernet 1/0/3
-----[MVRP Global Info]-----
Global Status      : Enabled
Compliance-GVRP   : False

----[GigabitEthernet1/0/3]----
Config Status      : Enabled
Running Status     : Enabled
Join Timer         : 20 (centiseconds)
Leave Timer        : 60 (centiseconds)
Periodic Timer     : 100 (centiseconds)
LeaveAll Timer     : 1000 (centiseconds)
Registration Type  : Fixed
Local VLANs :
  1(default), 10,
```

The output shows that the dynamic VLAN information on GigabitEthernet 1/0/3 is not changed after you set the MVRP registration mode to fixed on GigabitEthernet 1/0/3.

Configuring ARP

Only HP 5500 EI switches support Layer 3 Ethernet port configuration.

You can use the **port link-mode** command to set an Ethernet port to operate in bridge (Layer 2) or route mode (Layer 3) (see *Layer 2—LAN Switching Configuration Guide*).

Overview

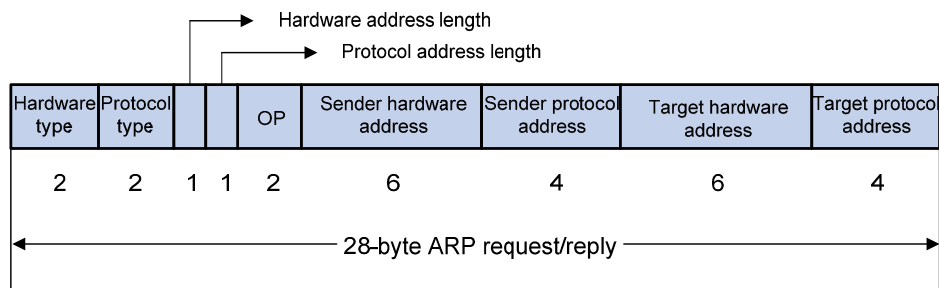

The Address Resolution Protocol (ARP) is used to resolve an IP address into a physical address (Ethernet MAC address, for example).

In an Ethernet LAN, a device uses ARP to resolve the IP address of the next hop to the corresponding MAC address.

ARP message format

ARP messages include ARP requests and ARP replies. Figure 1 shows the format of the ARP request/reply. Numbers in the figure refer to field lengths.

Figure 1 ARP message format

ARP message fields:

- **Hardware type**—The hardware address type. Value 1 represents Ethernet.
- **Protocol type**—The type of the protocol address to be mapped. The hexadecimal value 0x0800 represents IP.
- **Hardware address length and protocol address length**—Length, in bytes, of a hardware address and a protocol address. For an Ethernet address, the value of the hardware address length field is 6. For an IPv4 address, the value of the protocol address length field is 4.
- **OP**—Operation code, which describes type of the ARP message. Value 1 represents an ARP request, and value 2 represents an ARP reply.
- **Sender hardware address**—Hardware address of the device sending the message.
- **Sender protocol address**—Protocol address of the device sending the message.
- **Target hardware address**—Hardware address of the device to which the message is being sent.
- **Target protocol address**—Protocol address of the device to which the message is being sent.

ARP operation

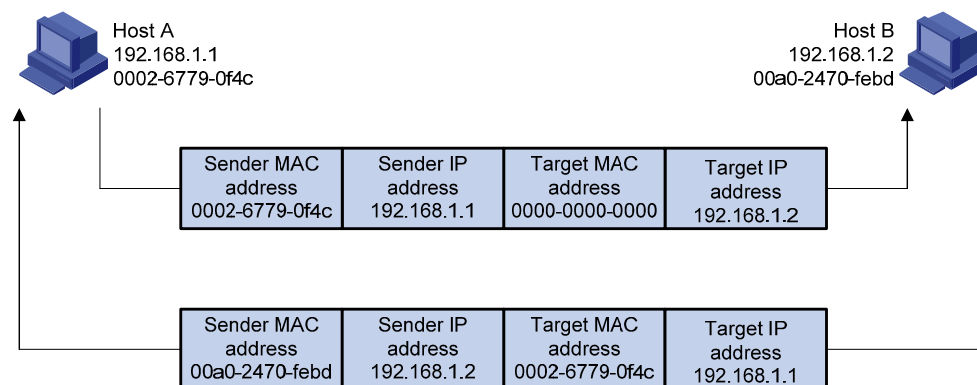

If Host A and Host B are on the same subnet and Host A sends a packet to Host B, as shown in [Figure 2](#), the resolution process is:

1. Host A looks in its ARP table to see whether there is an ARP entry for Host B. If yes, Host A uses the MAC address in the entry to encapsulate the IP packet into a data link layer frame and sends the frame to Host B.
2. If Host A finds no entry for Host B, Host A buffers the packet and broadcasts an ARP request using the following information:
 - **Source IP address and source MAC address**—Host A's own IP address and the MAC address
 - **Target IP address**—Host B's IP address
 - **Target MAC address**—An all-zero MAC address

All hosts on this subnet can receive the broadcast request, but only the requested host (Host B) processes the request.

3. Host B compares its own IP address with the target IP address in the ARP request. If they are the same, Host B:
 - a. Adds the sender IP address and sender MAC address into its ARP table.
 - b. Encapsulates its MAC address into an ARP reply.
 - c. Unicasts the ARP reply to Host A.
4. After receiving the ARP reply, Host A:
 - a. Adds the MAC address of Host B to its ARP table.
 - b. Encapsulates the MAC address into the packet and sends it to Host B.

Figure 2 ARP address resolution process

If Host A and Host B are on different subnets, the resolution process is as follows:

1. Host A sends an ARP request to the gateway. The target IP address in the ARP request is the IP address of the gateway.
2. After obtaining the MAC address of the gateway from an ARP reply, Host A sends the packet to the gateway.
3. If the gateway maintains the ARP entry of Host B, it forwards the packet to Host B directly; if not, it broadcasts an ARP request, in which the target IP address is the IP address of Host B.
4. After obtaining the MAC address of Host B, the gateway sends the packet to Host B.

ARP table

An ARP table stores dynamic and static ARP entries.

Dynamic ARP entry

ARP automatically creates and updates dynamic entries. A dynamic ARP entry is removed when its aging timer expires or the output interface goes down, and it can be overwritten by a static ARP entry.

Static ARP entry

A static ARP entry is manually configured and maintained. It does not age out, and cannot be overwritten by a dynamic ARP entry.

Static ARP entries protect communication between devices, because attack packets cannot modify the IP-to-MAC mapping in a static ARP entry.

Static ARP entries can be classified into long and short ARP entries.

- To configure a long static ARP entry, specify the IP address, MAC address, VLAN, and output interface. A long static ARP entry is directly used for forwarding matching packets. To allow communication with a host using a fixed IP-to-MAC mapping through a specific interface in a specific VLAN, configure a long static ARP entry for it.
- To configure a short static ARP entry, you only need to specify the IP address and MAC address.
 - If the output interface is a Layer 3 Ethernet port, the short ARP entry can be directly used for forwarding matching packets.
 - If the output interface is a VLAN interface, the device first sends an ARP request whose target IP address is the IP address of the short entry. If the sender IP and MAC addresses in the received ARP reply match the IP and MAC addresses of the short static ARP entry, the device adds the interface receiving the ARP reply to the short static ARP entry, and then uses the resolved entry to forward the matching IP packets.

To communicate with a host by using a fixed IP-to-MAC mapping, configure a short static ARP entry for it.

Configuring a static ARP entry

A static ARP entry is effective when the device it corresponds to works normally. However, when a VLAN or VLAN interface is deleted, any static ARP entry corresponding to it will also be deleted (if it is a long static ARP entry) or will become unresolved (if it is a short and resolved static ARP entry).

Follow these guidelines when you configure a long static ARP entry:

- The *vlan-id* argument must be the ID of an existing VLAN where the ARP entry resides. The specified Ethernet interface must belong to that VLAN. The VLAN interface of the VLAN must be created.
- The IP address of the VLAN interface of the VLAN specified by the *vlan-id* argument must belong to the same subnet as the IP address specified by the *ip-address* argument.

To configure a static ARP entry:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Configure a static ARP entry.	<ul style="list-style-type: none"> Configure a long static ARP entry: arp static <i>ip-address mac-address vlan-id interface-type interface-number</i> [vpn-instance <i>vpn-instance-name</i>] Configure a short static ARP entry: arp static <i>ip-address mac-address</i> [vpn-instance <i>vpn-instance-name</i>] 	<p>Use either command.</p> <p>Only HP 5500 EI Switch Series supports the vpn-instance <i>vpn-instance-name</i> option</p>

Configuring the maximum number of dynamic ARP entries for an interface

An interface can dynamically learn ARP entries, so it may hold too many ARP entries. To solve this problem, you can set the maximum number of dynamic ARP entries that an interface can learn. When the maximum number is reached, the interface stops learning ARP entries.

A Layer 2 interface can learn an ARP entry only when both its maximum number and the VLAN interface's maximum number are not reached.

To set the maximum number of dynamic ARP entries that an interface can learn:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type interface-number</i>	N/A
3. Set the maximum number of dynamic ARP entries that the interface can learn.	arp max-learning-number <i>number</i>	<p>Optional.</p> <p>By default, a Layer 2 interface does not limit the number of dynamic ARP entries. A Layer 3 interface can learn up to 2048 ARP entries for HP 5500 SI Switch Series, and up to 8192 ARP entries for HP 5500 EI Switch Series.</p> <p>If the value of the <i>number</i> argument is set to 0, the interface is disabled from learning dynamic ARP entries.</p>

Setting the aging timer for dynamic ARP entries

Each dynamic ARP entry in the ARP table has a limited lifetime, called aging timer. The aging timer of a dynamic ARP entry is reset each time the dynamic ARP entry is updated. Dynamic ARP entries that are not updated before their aging timers expire are deleted from the ARP table.

To set the age timer for dynamic ARP entries:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Set the age timer for dynamic ARP entries.	arp timer aging <i>aging-time</i>	Optional. 20 minutes by default.

Enabling dynamic ARP entry check

The dynamic ARP entry check function controls whether the device supports dynamic ARP entries with multicast MAC addresses.

When dynamic ARP entry check is enabled, the device cannot learn dynamic ARP entries containing multicast MAC addresses.

When dynamic ARP entry check is disabled, the device can learn dynamic ARP entries containing multicast MAC addresses.

To enable dynamic ARP entry check:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable dynamic ARP entry check.	arp check enable	Optional. Enabled by default.

Configuring ARP quick update

HP recommends enabling ARP quick update in WLANs only.

As shown in [Figure 3](#), the laptop frequently roams between AP 1 and AP 2. This affects the mapping between its MAC address and output interface on the switch. If the switch does not update its ARP table immediately after the output interface changes, it may fail to communicate with the laptop.

Figure 3 ARP quick update application scenario

With ARP quick update enabled, the switch updates the corresponding ARP entry immediately after the change of the mapping between a MAC address and an output interface to ensure nonstop data forwarding.

To enable ARP quick update:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable ARP quick update.	mac-address station-move quick-notify enable	Optional. Disabled by default.

Configuring multicast ARP

Microsoft Network Load Balancing (NLB) is a load balancing technology for server clustering developed on Windows Server.

NLB supports load sharing and redundancy among servers within a cluster. To implement fast failover, NLB requires that the switch forwards network traffic to all servers or specified servers in the cluster, and each server filters out unexpected traffic. In a medium or small data center that uses the Windows Server operating system, the proper cooperation of the switch and NLB is very important. For more information about NLB, see the related documents of Windows Sever.

Microsoft NLB provides the following packet sending modes to make the switch forward network traffic to all servers or specified servers:

- **Unicast mode**—NLB assigns each cluster member a common MAC address, which is the cluster MAC address, and changes the source MAC address of each sent packet. Thus, the switch cannot add the cluster MAC address to its MAC table. In addition, because the cluster MAC address is unknown to the switch, packets destined to it are forwarded on all the ports of the switch.
- **Multicast mode**—NLB uses a multicast MAC address that is a virtual MAC address for network communication, for example 0300-5e11-1111.
- **Internet Group Management Protocol (IGMP) multicast mode**—The switch sends packets only out of the ports that connect to the cluster members rather than all ports.

NOTE:

Multicast ARP is applicable to only multicast-mode NLB.

To configure multicast ARP:

Step	Command	Remarks
1. Disable the ARP entry check function.	undo arp check enable	N/A
2. Configure a static ARP entry.	arp static <i>ip-address mac-address vlan-id interface-type interface-number</i> [vpn-instance <i>vpn-instance-name</i>]	Optional. Only HP 5500 EI Switch Series supports the vpn-instance <i>vpn-instance-name</i> option.
3. Configure a static multicast MAC address entry.	mac-address multicast <i>mac-address interface interface-list vlan vlan-id</i>	See <i>IP Multicast Command Reference</i> .

Displaying and maintaining ARP

CAUTION:

- Clearing ARP entries from the ARP table may cause communication failures.
- The verbose keyword is available only on the HP 5500 EI Switch Series.

Task	Command	Remarks
Display ARP entries in the ARP table.	display arp [[all dynamic static] [slot <i>slot-number</i>] vlan <i>vlan-id</i> interface <i>interface-type interface-number</i>] [count verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the ARP entry for a specified IP address.	display arp <i>ip-address</i> [slot <i>slot-number</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the ARP entries for a specified VPN instance (only available on the HP 5500 EI).	display arp vpn-instance <i>vpn-instance-name</i> [count] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the age timer for dynamic ARP entries.	display arp timer aging [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear ARP entries from the ARP table.	reset arp { all dynamic static slot <i>slot-number</i> interface <i>interface-type interface-number</i> }	Available in user view

ARP configuration examples

Static ARP entry configuration example

Network requirements

As shown in [Figure 4](#), hosts are connected to the switch, which is connected to the router through interface GigabitEthernet 1/0/1 in VLAN 10. The IP and MAC addresses of the router are 192.168.1.1/24 and 00e0-fc01-0000 respectively.

To prevent malicious users from attacking the switch and enhance security for communications between the router and switch, configure a static ARP entry for the router on the switch.

Figure 4 Network diagram

Configuration procedure

Configure the switch:

Create VLAN 10.

```
<Switch> system-view
[Switch] vlan 10
[Switch-vlan10] quit
```

Add interface GigabitEthernet 1/0/1 to VLAN 10.

```
[Switch] interface GigabitEthernet 1/0/1
[Switch-GigabitEthernet1/0/1] port link-type trunk
[Switch-GigabitEthernet1/0/1] port trunk permit vlan 10
[Switch-GigabitEthernet1/0/1] quit
```

Create interface VLAN-interface 10 and configure its IP address.

```
[Switch] interface vlan-interface 10
[Switch-vlan-interface10] ip address 192.168.1.2 24
[Switch-vlan-interface10] quit
```

Configure a static ARP entry that has IP address 192.168.1.1, MAC address 00e0-fc01-0000, and output interface GigabitEthernet 1/0/1 in VLAN 10.

```
[Switch] arp static 192.168.1.1 00e0-fc01-0000 10 GigabitEthernet 1/0/1
```

Display information about static ARP entries.

```
[Switch] display arp static
```

IP Address	MAC Address	VLAN ID	Interface	Aging Type
192.168.1.1	00e0-fc01-0000	10	GE1/0/1	N/A S

Multicast ARP configuration example

Network requirements

As shown in [Figure 5](#), a small data center uses Microsoft multicast-mode NLB. To enable the switches to cooperate with NLB, configure the following:

- Add GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 into VLAN 1, and specify IP address 16.1.1.30/24 for VLAN-interface 1.
- Add GigabitEthernet 1/0/1 and GigabitEthernet 1/0/4 into VLAN 2, and specify IP address 17.1.1.1/24 for VLAN-interface 2.
- Specify 17.1.1.1/24 as the default gateway of Host A and Host B.
- Specify 16.1.1.30/24 as the default gateway of Server A and Server B.
- Disable the ARP entry check function so that the switch can learn dynamic ARP entries containing multicast MAC addresses.
- Configure a static multicast MAC address entry so that only interfaces GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 can receive multicast information.

Figure 5 Network diagram

Configuration procedure

This example only describes multicast ARP configuration on the switch, and is only applicable to multicast NLB. For NLB configuration on the servers, see the related documents of the Windows Server.

Specify an IP address for VLAN-interface 2.

```
<Switch> system-view
[Switch] vlan 2
[Switch-vlan2] port GigabitEthernet 1/0/4
[Switch-vlan2] port GigabitEthernet 1/0/1
[Switch-vlan2] quit
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 17.1.1.1 255.255.255.0
[Switch-Vlan-interface2] quit
```

Specify an IP address for VLAN-interface 1.

```
[Switch] interface vlan-interface 1
[Switch-Vlan-interface1] ip address 16.1.1.30 255.255.255.0
[Switch-Vlan-interface1] quit
```

Disable the ARP entry check function.

```
[Switch] undo arp check enable
```

Configure a static multicast MAC address entry.

```
[Switch] mac-address multicast 03bf-1001-0164 interface GigabitEthernet 1/0/2 GigabitEthernet 1/0/3 vlan 1
```

Verifying the configuration

- **NLB load sharing**—Enables the FTP server function of Server A and Server B. Host A and Host B send requests to the virtual IP address and each of them logs in to a different server.
- **NLB redundancy**—Disables the network interface card of Server A. Host A and Host B send requests to the virtual IP address and both log in to the FTP server on Server B.

Configuring gratuitous ARP

Overview

In a gratuitous ARP packet, the sender IP address and the target IP address are the IP address of the sending device.

A device sends a gratuitous ARP packet for either of the following purposes:

- Determine whether its IP address is already used by another device. If the IP address is already used, the device is informed of the conflict by an ARP reply.
- Inform other devices of a change of its MAC address.

Gratuitous ARP packet learning

This feature enables a device to create or update ARP entries by using the sender IP and MAC addresses in received gratuitous ARP packets.

With this feature disabled, the device uses received gratuitous ARP packets to update existing ARP entries only.

Periodic sending of gratuitous ARP packets

Enabling a device to periodically send gratuitous ARP packets helps downstream devices update their corresponding ARP entries or MAC entries in time. This feature can be used to:

- Prevent gateway spoofing.

When an attacker sends forged gratuitous ARP packets to the hosts on a network, the traffic destined for the gateway from the hosts is sent to the attacker instead. As a result, the hosts cannot access the external network.

To prevent gateway spoofing attacks, enable the gateway to send gratuitous ARP packets containing its primary IP address and manually configured secondary IP addresses at a specific interval, so hosts can learn correct gateway address information.
- Prevent ARP entries from aging out.

If network traffic is heavy or if a host's CPU usage is high on a host, received ARP packets may be discarded or not be processed in time. Eventually, the dynamic ARP entries on the receiving host age out, and the traffic between the host and the corresponding devices is interrupted until the host re-creates the ARP entries.

To prevent this problem, enable the gateway to send gratuitous ARP packets periodically. The gratuitous ARP packets contain the gateway's primary IP address or one of its manually configured secondary IP addresses, so the receiving host can update ARP entries in time, ensuring traffic continuity.
- Prevent the virtual IP address of a VRRP group from being used by a host.

The master router of a VRRP group can periodically send gratuitous ARP packets to the hosts on the local network, so that the hosts can update local ARP entries and avoid using the virtual IP address of the VRRP group.

If the virtual IP address of the VRRP group is associated with a virtual MAC address, the sender MAC address in the gratuitous ARP packet takes the virtual MAC address of the virtual router. If the virtual IP address of the VRRP group is associated with the real MAC address of an interface, the sender MAC address in the gratuitous ARP packet takes the MAC address of the interface on the master router in the VRRP group.

For more information about VRRP, see *High Availability Configuration Guide*.

Configuration guidelines

Follow these guidelines when you configure gratuitous ARP:

- You can enable periodic sending of gratuitous ARP packets in VLAN interface view or Layer 3 Ethernet port view.
- You can enable periodic sending of gratuitous ARP packets on a maximum of 1024 interfaces.
- Periodic sending of gratuitous ARP packets takes effect only when the link of the enabled interface goes up and an IP address has been assigned to the interface.
- If you change the interval for sending gratuitous ARP packets, the configuration is effective at the next sending interval.
- The frequency of sending gratuitous ARP packets may be much lower than is expected if this function is enabled on multiple interfaces, if each interface is configured with multiple secondary IP addresses, or if a small sending interval is configured in such cases.

Configuration procedure

To configure gratuitous ARP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable learning of gratuitous ARP packets.	gratuitous-arp-learning enable	Optional. Enabled by default.
3. Enable the device to send gratuitous ARP packets upon receiving ARP requests from another subnet.	gratuitous-arp-sending enable	By default, a device does not send gratuitous ARP packets upon receiving ARP requests from another subnet.
4. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
5. Enable periodic sending of gratuitous ARP packets and set the sending interval.	arp send-gratuitous-arp [interval <i>milliseconds</i>]	Disabled by default.

Configuring proxy ARP

Overview

Proxy ARP enables a device on a network to answer ARP requests for an IP address not on that network. With proxy ARP, hosts on different broadcast domains can communicate with each other as they do on the same network.

Proxy ARP includes common proxy ARP and local proxy ARP.

- **Common proxy ARP**—Allows communication between hosts that connect to different Layer-3 interfaces and reside in different broadcast domains.
- **Local proxy ARP**—Allows communication between hosts that connect to the same Layer-3 interface and reside in different broadcast domains.

Common proxy ARP

A proxy ARP enabled device allows hosts that reside on different subnets to communicate.

As shown in [Figure 6](#), Switch connects to two subnets through VLAN-interface 1 and VLAN-interface 2. The IP addresses of the two interfaces are 192.168.10.99/24 and 192.168.20.99/24. Host A and Host B are assigned the same prefix 192.168.0.0. Host A connects to VLAN-interface 1 and Host B connects to VLAN-interface 2.

Figure 6 Application environment of proxy ARP

Because Host A and Host B have the same prefix 192.168.0.0, Host A considers that Host B is on the same network, and it broadcasts an ARP request for the MAC address of Host B. However, Host B cannot receive this request because it is in a different broadcast domain.

You can enable proxy ARP on VLAN-interface 1 of the switch so that the switch can reply to the ARP request from Host A with the MAC address of VLAN-interface 1, and forward packets sent from Host A to Host B. In this case, the switch acts as a proxy of Host B.

A main advantage of proxy ARP is that you can enable it on a single switch without disturbing routing tables of other routers in the network. Proxy ARP acts as the gateway for hosts that are not configured with a default gateway or do not have routing capability.

Local proxy ARP

As shown in [Figure 7](#), Host A and Host B belong to VLAN 2, but are isolated at Layer 2. Host A connects to GigabitEthernet 1/0/3 while Host B connects to GigabitEthernet 1/0/1. Enable local proxy ARP on Switch A to allow Layer 3 communication between the two hosts.

Figure 7 Application environment of local proxy ARP

Enable local proxy ARP in one of the following cases:

- Hosts connecting to different isolated Layer 2 ports in the same VLAN need to communicate at Layer 3.
- If a super VLAN is configured, hosts in different sub VLANs of the super VLAN need to communicate at Layer 3.
- If an isolate-user-VLAN is configured, hosts in different secondary VLANs of the isolate-user-VLAN need to communicate at Layer 3.

Enabling common proxy ARP

To enable common proxy ARP in VLAN interface view/Layer 3 Ethernet port view/Layer 3 aggregate interface view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Enable proxy ARP.	proxy-arp enable	Disabled by default

Enabling local proxy ARP

To enable local proxy ARP in VLAN interface view/Layer 3 Ethernet port view/Layer 3 aggregate interface view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Enable local proxy ARP.	local-proxy-arp enable [ip-range <i>startIP to endIP</i>]	Disabled by default

Displaying and maintaining proxy ARP

Task	Command	Remarks
Display whether proxy ARP is enabled.	display proxy-arp [interface <i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display whether local proxy ARP is enabled.	display local-proxy-arp [interface <i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Proxy ARP configuration examples

Common proxy ARP configuration example

Network requirements

As shown in [Figure 8](#), Host A and Host D have the same IP prefix and mask (IP addresses of Host A and Host D are 192.168.10.100/16 and 192.168.20.200/16 respectively), but they are located on different subnets separated by the switch (Host A belongs to VLAN 1 while Host D belongs to VLAN 2). As a result, Host D cannot receive or respond to any ARP request from Host A.

You must configure proxy ARP on the switch to enable communication between the two hosts.

Figure 8 Network diagram

Configuration procedure

```
# Create VLAN 2.  
<Switch> system-view  
[Switch] vlan 2  
[Switch-vlan2] quit
```

```

# Specify the IP address of interface VLAN-interface 1.
[Switch] interface vlan-interface 1
[Switch-Vlan-interface1] ip address 192.168.10.99 255.255.255.0

# Enable proxy ARP on interface VLAN-interface 1.
[Switch-Vlan-interface1] proxy-arp enable
[Switch-Vlan-interface1] quit

# Specify the IP address of interface VLAN-interface 2.
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.20.99 255.255.255.0

# Enable proxy ARP on interface VLAN-interface 2.
[Switch-Vlan-interface2] proxy-arp enable

```

After completing preceding configurations, use the **ping** command to verify the connectivity between Host A and Host D.

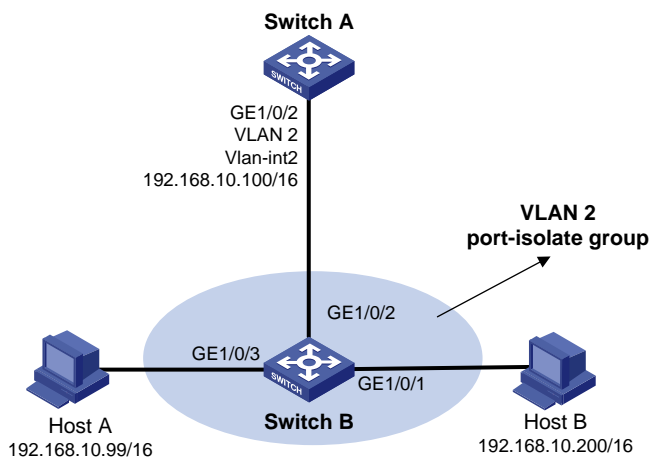

Local proxy ARP configuration example in case of port isolation

Network requirements

As shown in Figure 9, Host A and Host B belong to the same VLAN, and connect to Switch B via GigabitEthernet 1/0/3 and GigabitEthernet 1/0/1 respectively. Switch B connects to Switch A via GigabitEthernet 1/0/2.

Configure port isolation on GigabitEthernet 1/0/3 and GigabitEthernet 1/0/1 of Switch B to isolate Host A from Host B at Layer 2. Enable local proxy ARP on Switch A to allow communication between Host A and Host B at Layer 3.

Figure 9 Network diagram

Configuration procedure

1. Configure Switch B:
 - # Add GigabitEthernet 1/0/3, GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to VLAN 2. Configure port isolation on Host A and Host B.

```

<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port GigabitEthernet 1/0/3

```

```

[SwitchB-vlan2] port GigabitEthernet 1/0/1
[SwitchB-vlan2] port GigabitEthernet 1/0/2
[SwitchB-vlan2] quit
[SwitchB] interface GigabitEthernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] port-isolate enable
[SwitchB-GigabitEthernet1/0/3] quit
[SwitchB] interface GigabitEthernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port-isolate enable
[SwitchB-GigabitEthernet1/0/1] quit

```

2. Configure Switch A:

Create VLAN 2, and add GigabitEthernet 1/0/2 to VLAN 2.

```

<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port GigabitEthernet 1/0/2
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.10.100 255.255.0.0

```

From Host A, ping Host B. The ping operation is unsuccessful because they are isolated at Layer 2.

Configure local proxy ARP to allow communication between Host A and Host B at Layer 3.

```

[SwitchA-Vlan-interface2] local-proxy-arp enable

```

From Host A, ping Host B. The ping operation is successful after the configuration.

Local proxy ARP configuration example in super VLAN(only available on the HP 5500 EI)

Network requirements

Figure 10 shows a super VLAN, VLAN 10, with the interface IP address 192.168.10.100/16 and sub-VLANs (VLAN 2 and VLAN 3). GigabitEthernet 1/0/2 belongs to VLAN 2 and GigabitEthernet 1/0/1 belongs to VLAN 3. Host A belongs to VLAN 2 and connects to GigabitEthernet 1/0/2 of the switch. Host B belongs to VLAN 3 and connects to GigabitEthernet 1/0/1 of the switch.

As Host A and Host B belong to different Sub-VLANs, they are isolated at Layer 2. Configure local proxy ARP on the switch to allow Layer 3 communication between Host A and Host B.

Figure 10 Network diagram

Configuration procedure

Create the super VLAN and the sub-VLANs. Add GigabitEthernet 1/0/2 to VLAN 2 and GigabitEthernet 1/0/1 to VLAN 3. Configure the IP address 192.168.10.100/16 for the interface of VLAN 10.

```
<Switch> system-view
[Switch] vlan 2
[Switch-vlan2] port GigabitEthernet 1/0/2
[Switch-vlan2] quit
[Switch] vlan 3
[Switch-vlan3] port GigabitEthernet 1/0/1
[Switch-vlan3] quit
[Switch] vlan 10
[Switch-vlan10] supervlan
[Switch-vlan10] subvlan 2 3
[Switch-vlan10] quit
[Switch] interface vlan-interface 10
[Switch-Vlan-interface10] ip address 192.168.10.100 255.255.0.0
```

From Host A, ping Host B. The ping operation is unsuccessful because they are isolated at Layer 2.

Configure local proxy ARP to implement Layer 3 communication between sub-VLANs.

```
[Switch-Vlan-interface10] local-proxy-arp enable
```

From Host A, ping Host B. The ping operation is successful after the configuration.

Local proxy ARP configuration example in isolate-user-VLAN

Network requirements

As shown in [Figure 11](#), Switch B is attached to Switch A. VLAN 5 on Switch B is an isolate-user-VLAN, which includes uplink port GigabitEthernet 1/0/2 and two secondary VLANs, VLAN 2 and VLAN 3. GigabitEthernet 1/0/3 belongs to VLAN 2, and GigabitEthernet 1/0/1 belongs to VLAN 3.

Host A belongs to VLAN 2 and connects to GigabitEthernet 1/0/3 of Switch B. Host B belongs to VLAN 3 and connects to GigabitEthernet 1/0/1 of Switch B.

As Host A and Host B belong to different secondary VLANs, they are isolated at Layer 2. Configure local proxy ARP on Switch A to implement Layer 3 communication between Host A and Host B.

Figure 11 Network diagram

Configuration procedure

1. Configure Switch B:

Create VLAN 2, VLAN 3, and VLAN 5 on Switch B. Add GigabitEthernet 1/0/3 to VLAN 2, GigabitEthernet 1/0/1 to VLAN 3, and GigabitEthernet 1/0/2 to VLAN 5. Configure VLAN 5 as the isolate-user-VLAN, and VLAN 2 and VLAN 3 as secondary VLANs. Configure the mappings between isolate-user-VLAN and the secondary VLANs.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port GigabitEthernet 1/0/3
[SwitchB-vlan2] quit
[SwitchB] vlan 3
[SwitchB-vlan3] port GigabitEthernet 1/0/1
[SwitchB-vlan3] quit
[SwitchB] vlan 5
[SwitchB-vlan5] port GigabitEthernet 1/0/2
[SwitchB-vlan5] isolate-user-vlan enable
[SwitchB-vlan5] quit
[SwitchB] interface GigabitEthernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port isolate-user-vlan 5 promiscuous
[SwitchB-GigabitEthernet1/0/2] quit
[SwitchB] interface GigabitEthernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port isolate-user-vlan host
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface GigabitEthernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] port isolate-user-vlan host
[SwitchB-GigabitEthernet1/0/3] quit
[SwitchB] isolate-user-vlan 5 secondary 2 3
```

2. Configure Switch A:

Create VLAN 5 and add GigabitEthernet 1/0/2 to it.

```
<SwitchA> system-view
[SwitchA] vlan 5
```

```
[SwitchA-vlan5] port GigabitEthernet 1/0/2
[SwitchA-vlan5] quit
[SwitchA] interface vlan-interface 5
[SwitchA-Vlan-interface5] ip address 192.168.10.100 255.255.0.0
```

From Host A, ping Host B. The ping operation is unsuccessful because they are isolated at Layer 2.

Configure local proxy ARP to implement Layer 3 communication between Host A and Host B.

```
[SwitchA-Vlan-interface5] local-proxy-arp enable
```

From Host A, ping Host B. The ping operation is successful after the configuration.

Configuring ARP snooping

Overview

The ARP snooping feature is used in Layer 2 switching networks. It creates ARP snooping entries using ARP packets.

If ARP snooping is enabled on a VLAN of a device, ARP packets received by the interfaces of the VLAN are redirected to the CPU. The CPU uses ARP packets to create ARP snooping entries comprising source IP and MAC addresses, VLAN and receiving port information.

The aging time and valid period of an ARP snooping entry are 25 minutes and 15 minutes, respectively. If an ARP snooping entry is not updated within 15 minutes, it becomes invalid and cannot be used. After that, if an ARP packet whose source IP and MAC addresses correspond with the entry is received, the entry becomes valid, and its age timer restarts. If the age timer of an ARP entry expires, the entry is removed.

If the ARP snooping device receives an ARP packet that has the same sender IP address as but a different sender MAC address from a valid ARP snooping entry, it considers that an attack occurs. An ARP snooping entry conflict occurs in this case. As a result, the ARP snooping entry becomes invalid and is removed after 25 minutes.

Configuration procedure

To enable ARP snooping for a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Enable ARP snooping.	arp-snooping enable	Disabled by default

Displaying and maintaining ARP snooping

Task	Command	Remarks
Display ARP snooping entries.	display arp-snooping [ip <i>ip-address</i> vlan <i>vlan-id</i>] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Remove ARP snooping entries.	reset arp-snooping [ip <i>ip-address</i> vlan <i>vlan-id</i>]	Available in user view

Configuring IP addressing

Only the HP 5500 EI switches support Layer 3 Ethernet port configuration.

This chapter describes IP addressing basic and manual IP address assignment for interfaces. Dynamic IP address assignment (BOOTP and DHCP) are beyond the scope of this chapter.

The term "interface" in this chapter refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

Overview

This section describes the IP addressing basics.

IP addressing uses a 32-bit address to identify each host on a network. To make addresses easier to read, they are written in dotted decimal notation, each address being four octets in length. For example, address 000010000000000010000000100000001 in binary is written as 10.1.1.1.

IP address classes

Each IP address breaks down into two parts:

- **Net ID**—Identifies a network. The first several bits of a net ID, known as the class field or class bits, identify the class of the IP address.
- **Host ID**—Identifies a host on a network.

IP addresses are divided into five classes, shown in [Figure 12](#). The shaded areas represent the address class. The first three classes are widely used.

Figure 12 IP address classes

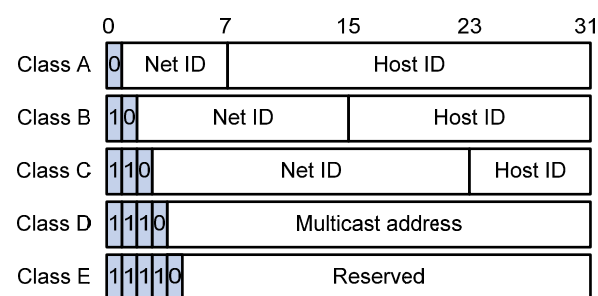

Table 1 IP address classes and ranges

Class	Address range	Remarks
A	0.0.0.0 to 127.255.255.255	The IP address 0.0.0.0 is used by a host at startup for temporary communication. This address is never a valid destination address. Addresses starting with 127 are reserved for loopback test. Packets destined to these addresses are processed locally as input packets rather than sent to the link.

Class	Address range	Remarks
B	128.0.0.0 to 191.255.255.255	N/A
C	192.0.0.0 to 223.255.255.255	N/A
D	224.0.0.0 to 239.255.255.255	Multicast addresses.
E	240.0.0.0 to 255.255.255.255	Reserved for future use except for the broadcast address 255.255.255.255.

Special IP addresses

The following IP addresses are for special use and cannot be used as host IP addresses.

- **IP address with an all-zero net ID**—Identifies a host on the local network. For example, IP address 0.0.0.16 indicates the host with a host ID of 16 on the local network.
- **IP address with an all-zero host ID**—Identifies a network.
- **IP address with an all-one host ID**—Identifies a directed broadcast address. For example, a packet with the destination address of 192.168.1.255 will be broadcast to all the hosts on the network 192.168.1.0.

Subnetting and masking

Subnetting divides a network down into smaller networks called subnets by using some bits of the host ID to create a subnet ID.

Masking identifies the boundary between the host ID and the combination of net ID and subnet ID. (When subnetting is not adopted, a mask identifies the boundary between the net ID and the host ID.)

Each subnet mask is made up of 32 bits that correspond to the bits in an IP address. In a subnet mask, consecutive ones represent the net ID and subnet ID, and consecutive zeros represent the host ID.

Before being subnetted, Class A, B, and C networks use the following default masks (also called natural masks): 255.0.0.0, 255.255.0.0, and 255.255.255.0 respectively.

Figure 13 shows how a Class B network is subnetted.

Figure 13 Subnetting a Class B network

Subnetting increases the number of addresses that cannot be assigned to hosts. After being subnetted, a network can accommodate fewer hosts.

For example, a Class B network without subnetting can accommodate 1022 more hosts than the same network subnetted into 512 subnets.

- **Without subnetting**—65,534 hosts ($2^{16} - 2$). (The two deducted addresses are the broadcast address, which has an all-one host ID, and the network address, which has an all-zero host ID.)
- **With subnetting**—Using the first 9 bits of the host-id for subnetting provides 512 (2^9) subnets. However, only 7 bits remain available for the host ID. This allows 126 ($2^7 - 2$) hosts in each subnet, a total of 64,512 hosts (512×126).

Assigning an IP address to an interface

You can assign an interface one primary address and multiple secondary addresses.

Generally, you only need to assign the primary address to an interface. In some cases, you need to assign secondary IP addresses to the interface. For example, if the interface connects to two subnets, to enable the device to communicate with all hosts on the LAN, you need to assign a primary IP address and a secondary IP address to the interface.

Configuration guidelines

Follow these guidelines when you assign an IP address to an interface:

- Each interface has only one primary IP address. A newly configured primary IP address overwrites the previous one.
- You cannot assign secondary IP addresses to an interface that obtains an IP address through BOOTP or DHCP.
- The primary and secondary IP addresses you assign to the interface can be located on the same network segment, but different interfaces on your device must reside on different network segments.
- You can manually assign an IP address to an interface, or configure the interface to obtain an IP address through BOOTP or DHCP. If you change the way an interface obtains an IP address, the new IP address overwrites the previous one.

Configuration procedure

To assign an IP address to an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Assign an IP address to the interface.	ip address <i>ip-address</i> { <i>mask-length</i> <i>mask</i> } [sub]	By default, no IP address is assigned to any interface.

Configuration example

Network requirements

As shown in [Figure 14](#), a port in VLAN 1 on a switch is connected to a LAN comprising two segments: 172.16.1.0/24 and 172.16.2.0/24.

To enable the hosts on the two subnets to communicate with the external network through the switch, and to enable the hosts on the two subnets to communicate with each other:

- Assign a primary IP address and a secondary IP address to VLAN-interface 1 on the switch.
- Set the primary IP address of VLAN-interface 1 as the gateway address of the hosts on subnet 172.16.1.0/24, and the secondary IP address of VLAN-interface 1 as the gateway address of the hosts on subnet 172.16.2.0/24.

Figure 14 Network diagram

Configuration procedure

Assign a primary IP address and a secondary IP address to VLAN-interface 1.

```
<Switch> system-view
[Switch] interface vlan-interface 1
[Switch-Vlan-interface1] ip address 172.16.1.1 255.255.255.0
[Switch-Vlan-interface1] ip address 172.16.2.1 255.255.255.0 sub
```

Set the gateway address to 172.16.1.1 on the hosts attached to subnet 172.16.1.0/24, and to 172.16.2.1 on the hosts attached to subnet 172.16.2.0/24.

From the switch, ping a host on subnet 172.16.1.0/24 to verify the connectivity.

```
<Switch> ping 172.16.1.2
PING 172.16.1.2: 56 data bytes, press CTRL_C to break
  Reply from 172.16.1.2: bytes=56 Sequence=1 ttl=255 time=25 ms
  Reply from 172.16.1.2: bytes=56 Sequence=2 ttl=255 time=27 ms
  Reply from 172.16.1.2: bytes=56 Sequence=3 ttl=255 time=26 ms
  Reply from 172.16.1.2: bytes=56 Sequence=4 ttl=255 time=26 ms
  Reply from 172.16.1.2: bytes=56 Sequence=5 ttl=255 time=26 ms
```

```
--- 172.16.1.2 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 25/26/27 ms
```

The output shows that the switch can communicate with the hosts on subnet 172.16.1.0/24.

From the switch, ping a host on subnet 172.16.2.0/24 to verify the connectivity.

```
<Switch> ping 172.16.2.2
PING 172.16.2.2: 56 data bytes, press CTRL_C to break
  Reply from 172.16.2.2: bytes=56 Sequence=1 ttl=255 time=25 ms
  Reply from 172.16.2.2: bytes=56 Sequence=2 ttl=255 time=26 ms
  Reply from 172.16.2.2: bytes=56 Sequence=3 ttl=255 time=26 ms
  Reply from 172.16.2.2: bytes=56 Sequence=4 ttl=255 time=26 ms
  Reply from 172.16.2.2: bytes=56 Sequence=5 ttl=255 time=26 ms

--- 172.16.2.2 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 25/25/26 ms
```

The output shows that the switch can communicate with the hosts on subnet 172.16.2.0/24.

From a host on subnet 172.16.2.0/24, ping a host on subnet 172.16.1.0/24 to verify the connectivity. Host B can be successfully pinged from Host A.

Configuring IP unnumbered(only available on the HP 5500 EI)

Overview

Logically, to enable IP on an interface, you must assign this interface a unique IP address. Yet, you can borrow an IP address already configured on one of other interfaces on your device instead. This is called "IP unnumbered" and the interface borrowing the IP address is called "IP unnumbered interface".

You can use IP unnumbered to save IP addresses either when available IP addresses are inadequate or when an interface is brought up only for occasional use.

Configuration guidelines

Follow these guidelines when you configure IP unnumbered on an interface:

- An interface cannot borrow an IP address from an unnumbered interface.
- Multiple interfaces can use the same unnumbered IP address.
- If an interface has multiple IP addresses, only the primary IP address can be borrowed.
- The IP address of the borrowing interface varies with that of the borrowed interface. If an IP address is configured for the borrowed interface, the IP address of the borrowing interface is the same as that of the borrowed interface; if no IP address is configured for the borrowed interface, no IP address is assigned for the borrowing interface.

Configuration prerequisites

Assign a primary IP address to the interface from which you want to borrow the IP address. Alternatively, you may configure the interface to obtain one through BOOTP or DHCP.

Configuration procedure

To configure IP unnumbered on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter tunnel interface view.	interface tunnel <i>number</i>	N/A
3. Specify the current interface to borrow the IP address of the specified interface.	ip address unnumbered interface <i>interface-type interface-number</i>	The interface does not borrow IP addresses from other interfaces by default.

Displaying and maintaining IP addressing

Task	Command	Remarks
Display IP configuration information for a specified Layer 3 interface or all Layer 3 interfaces.	display ip interface [<i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display brief IP configuration information for a specified Layer 3 interface or all Layer 3 interfaces.	display ip interface [<i>interface-type [interface-number]</i>] brief [{ begin exclude include } <i>regular-expression</i>]	Available in any view

DHCP overview

The Dynamic Host Configuration Protocol (DHCP) provides a framework to assign configuration information to network devices.

DHCP uses the client/server model.

Figure 15 A typical DHCP application

A DHCP client can obtain an IP address and other configuration parameters from a DHCP server on another subnet via a DHCP relay agent. For more information about the DHCP relay agent, see "[Configuring DHCP relay agent.](#)"

DHCP address allocation

DHCP supports the following mechanisms for IP address allocation.

- **Static allocation**—The network administrator assigns an IP address to a client like a WWW server, and DHCP conveys the assigned address to the client.
- **Automatic allocation**—DHCP assigns a permanent IP address to a client.
- **Dynamic allocation**—DHCP assigns an IP address to a client for a limited period of time, which is called a lease. Most DHCP clients obtain their addresses in this way.

Dynamic IP address allocation process

Figure 16 Dynamic IP address allocation process

1. The client broadcasts a DHCP-DISCOVER message to locate a DHCP server.
2. A DHCP server offers configuration parameters such as an IP address to the client, in a DHCP-OFFER message. The sending mode of the DHCP-OFFER is determined by the flag field in the DHCP-DISCOVER message. For related information, see "[DHCP message format](#)."
3. If several DHCP servers send offers to the client, the client accepts the first received offer, and broadcasts it in a DHCP-REQUEST message to formally request the IP address.
4. All DHCP servers receive the DHCP-REQUEST message, but only the server from which the client accepts the offered IP address returns either a DHCP-ACK message to the client, confirming that the IP address has been allocated to the client, or a DHCP-NAK message, denying the IP address allocation.

After the client receives the DHCP-ACK message, it broadcasts a gratuitous ARP packet to verify whether the IP address assigned by the server is already in use. If the client receives no response within the specified time, the client uses the assigned IP address. Otherwise, the client sends a DHCP-DECLINE message to the server to request an IP address again.

IP addresses offered by other DHCP servers are still assignable to other clients.

IP address lease extension

The IP address dynamically allocated by a DHCP server to a client has a lease. When the lease expires, the IP address is reclaimed by the DHCP server. To continue using the IP address, the client must extend the lease duration.

After half the lease duration, the DHCP client sends a DHCP-REQUEST unicast to the DHCP server to extend the lease. Depending on availability of the IP address, the DHCP server returns either a DHCP-ACK unicast confirming that the client's lease has been extended, or a DHCP-NAK unicast denying the request.

If the client receives no reply, it broadcasts another DHCP-REQUEST message for lease extension after 7/8 lease duration. Again, depending on availability of the IP address, the DHCP server returns either a DHCP-ACK unicast confirming that the client's lease has been extended, or a DHCP-NAK unicast denying the request.

DHCP message format

Figure 17 shows the DHCP message format, which is based on the BOOTP message format although DHCP uses some of the fields in significantly different ways. The numbers in parentheses indicate the size of each field in bytes.

Figure 17 DHCP message format

- **op**—Message type defined in option field. 1 = REQUEST, 2 = REPLY
- **htype, hlen**—Hardware address type and length of a DHCP client.
- **hops**—Number of relay agents a request message traveled.
- **xid**—Transaction ID, a random number chosen by the client to identify an IP address allocation.
- **secs**—Filled in by the client, the number of seconds elapsed since the client began address acquisition or renewal process. Currently this field is reserved and set to 0.
- **flags**—The leftmost bit is defined as the BROADCAST (B) flag. If this flag is set to 0, the DHCP server sent a reply back by unicast; if this flag is set to 1, the DHCP server sent a reply back by broadcast. The remaining bits of the flags field are reserved for future use.
- **ciaddr**—Client IP address if the client has an IP address that is valid and usable; otherwise, set to zero.
- **yiaddr**—'Your' (client) IP address, assigned by the server.
- **siaddr**—Server IP address, from which the client obtained configuration parameters.
- **giaddr**—(Gateway) IP address of the first relay agent a request message traveled.
- **chaddr**—Client hardware address.
- **sname**—Server host name, from which the client obtained configuration parameters.
- **file**—Bootfile name and path information, defined by the server to the client.
- **options**—Optional parameters field that is variable in length, which includes the message type, lease duration, subnet mask, domain name server IP address, WINS IP address, and other information.

DHCP options

DHCP uses the same message format as BOOTP, but DHCP uses the Option field to carry information for dynamic address allocation and to provide additional configuration information to clients.

Figure 18 DHCP option format

Common DHCP options

The following are common DHCP options:

- **Option 3**—Router option. It specifies the gateway address.
- **Option 6**—DNS server option. It specifies the DNS server’s IP address.
- **Option 33**—Static route option. It specifies a list of classful static routes (the destination addresses in these static routes are classful) that a client should add into its routing table. If both Option 33 and Option 121 exist, Option 33 is ignored.
- **Option 51**—IP address lease option.
- **Option 53**—DHCP message type option. It identifies the type of the DHCP message.
- **Option 55**—Parameter request list option. It is used by a DHCP client to request specified configuration parameters. The option contains values that correspond to the parameters requested by the client.
- **Option 60**—Vendor class identifier option. It is used by a DHCP client to identify its vendor, and by a DHCP server to distinguish DHCP clients by vendor class and assign specific IP addresses for the DHCP clients.
- **Option 66**—TFTP server name option. It specifies a TFTP server to be assigned to the client.
- **Option 67**—Bootfile name option. It specifies the bootfile name to be assigned to the client.
- **Option 121**—Classless route option. It specifies a list of classless static routes (the destination addresses in these static routes are classless) that the requesting client should add to its routing table. If both Option 33 and Option 121 exist, Option 33 is ignored.
- **Option 150**—TFTP server IP address option. It specifies the TFTP server IP address to be assigned to the client.

For more information about DHCP options, see RFC 2132 and RFC 3442.

Custom options

Some options, such as Option 43, Option 82, and Option 184, have no unified definitions in RFC 2132.

Vendor-specific option (Option 43)

DHCP servers and clients use Option 43 to exchange vendor-specific configuration information.

The DHCP client can obtain the following information through Option 43:

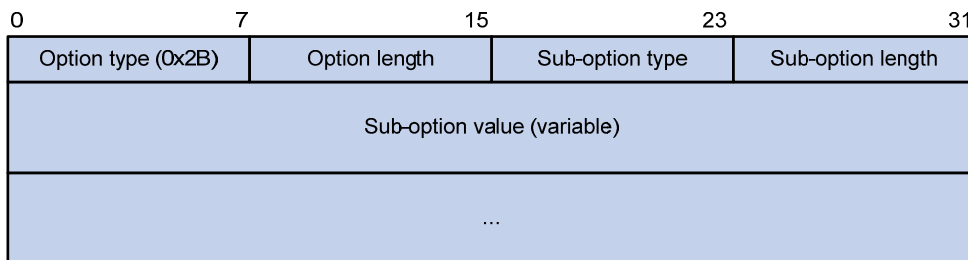

- Auto-Configuration Server (ACS) parameters, including the ACS URL, username, and password.

- Service provider identifier, which is acquired by the Customer Premises Equipment (CPE) from the DHCP server and sent to the ACS for selecting vender-specific configurations and parameters.
- Preboot Execution Environment (PXE) server address, which is used to obtain the bootfile or other control information from the PXE server.

1. Format of Option 43

Network configuration parameters are carried in different sub-options of Option 43 as shown in Figure 19.

Figure 19 Option 43 format

- **Sub-option type**—Type of a sub-option. The field value can be 0x01 (an ACS parameter sub-option), 0x02 (a service provider identifier sub-option), or 0x80 (a PXE server address sub-option).
 - **Sub-option length**—Length of a sub-option excluding the sub-option type and sub-option length fields.
 - **Sub-option value**—Value of a sub-option. The value format varies with sub-options.
2. Format of the sub-option value field of Option 43
- As shown in Figure 20, the value field of the ACS parameter sub-option contains variable ACS URL, ACS username, and ACS password separated by spaces (0x20):

Figure 20 ACS parameter sub-option value field

- The value field of the service provider identifier sub-option contains the service provider identifier.
- Figure 21 shows the format of the value field of the PXE server address sub-option. The value of the PXE server type can only be 0. The server number field indicates the number of PXE servers contained in the sub-option. The server IP addresses field contains the IP addresses of the PXE servers.

Figure 21 PXE server address sub-option value field

Relay agent option (Option 82)

Option 82 is the relay agent option in the option field of the DHCP message. It records the location information of the DHCP client. When a DHCP relay agent or DHCP snooping device receives a client's request, it adds Option 82 to the request message and sends it to the server.

The administrator can locate the DHCP client to further implement security control and accounting. The Option 82 supporting server can also use such information to define individual assignment policies of IP address and other parameters for the clients.

Option 82 involves at most 255 sub-options. At least one sub-option must be defined. The DHCP relay agent supports three sub-options: sub-option 1 (Circuit ID), sub-option 2 (Remote ID) and sub-option 9 (private padding format).

Option 82 has no unified definition. Its padding formats vary with vendors.

There are two methods for configuring Option 82:

- **User-defined method**—Manually specify the content of Option 82.
- **Non-user-defined method**—Pad Option 82 in the default normal format, verbose format, private format, or standard format.

If you choose normal format and verbose format, you can specify the code type for the sub-options as ASCII or HEX.

- Normal padding format
 - **Sub-option 1**—Contains the VLAN ID and interface number of the interface that received the client's request. The value of the sub-option type is 1, and that of the circuit ID type is 0.

Figure 22 Sub-option 1 in normal padding format

- **Sub-option 2**—Contains the MAC address of the DHCP relay agent interface or the MAC address of the DHCP snooping device that received the client's request. The value of the sub-option type is 2, and that of the remote ID type is 0.

Figure 23 Sub-option 2 in normal padding format

- Verbose padding format
 - **Sub-option 1**—Contains the user-specified access node identifier (ID of the device that adds Option 82 in DHCP messages), and the type, number, and VLAN ID of the interface that received the client’s request. The VLAN ID field has a fixed length of 2 bytes. All the other padding contents of sub-option 1 are length variable. See [Figure 24](#).

Figure 24 Sub-option 1 in verbose padding format

Sub-option type (0x01)	Length	Node identifier
Interface type		Interface number
VLAN ID		

- **Sub-option 2**—Contains the MAC address of the DHCP relay agent interface or the MAC address of the DHCP snooping device that received the client’s request. It has the same format as that in normal padding format. See [Figure 23](#).
- Private padding format
 - **Sub-option 1**—Contains the VLAN ID of the interface that received the client’s request, module (subcard number of the receiving port) and port (port number of the receiving port). The value of the sub-option type is 1.

Figure 25 Sub-option 1 in private padding format

0	7	15	23	31
Sub-option type (0x01)	Length (0x04)	VLAN ID		
Module		Port		

- **Sub-option 2**—Contains the MAC address of the DHCP relay agent interface or the MAC address of the DHCP snooping device that received the client’s request. The value of the sub-option type is 2.

Figure 26 Sub-option 2 in private padding format

0	7	15	23	31
Sub-option type (0x02)	Length (0x06)	MAC Address		

- **Sub-option 9**—Contains the sysname and the primary IP address of the Loopback0 interface. The value of the sub-option type is 9.

Figure 27 Sub-option 9 in private padding format

0	7	15	23	31
Sub-option type (0x09)	Length	Enterprise Number		
Enterprise Number		Information Length	Index (0x01)	
Index (0x00)	Index (0x02)	Length	Sysname	
Sysname		Index (0x03)	Index (0x04)	
LoopBack0 IP				

- Standard padding format

- **Sub-option 1**—Contains the VLAN ID of the interface that received the client’s request, module (subcard number of the receiving port) and port (port number of the receiving port). The value of the sub-option type is 1, and the value of the circuit ID type is 0.

Figure 28 Sub-option 1 in standard padding format

0	7	15	23	31
Sub-option type (0x01)		Length (0x06)		Circuit ID type (0x00)
VLAN ID		Module		Port

- **Sub-option 2**—Contains the MAC address of the DHCP relay agent interface or the MAC address of the DHCP snooping device that received the client’s request. It has the same format as sub-option 2 in normal padding format. See [Figure 23](#).

Option 184

Option 184 is a reserved option, and parameters in the option can be defined as needed. The device supports Option 184 carrying voice related parameters, so a DHCP client with voice functions can get an IP address along with specified voice parameters from the DHCP server.

Option 184 involves the following sub-options:

- **Sub-option 1**—IP address of the primary network calling processor, which serves as the network calling control source and provides program downloads.
- **Sub-option 2**—IP address of the backup network calling processor. DHCP clients contact the backup when the primary is unreachable.
- **Sub-option 3**—Voice VLAN ID and the result whether or not DHCP clients take this ID as the voice VLAN.
- **Sub-option 4**—Failover route that specifies the destination IP address and the called number. A Session Initiation Protocol (SIP) user uses this IP address and number to reach another SIP user when both the primary and backup calling processors are unreachable.

You must define sub-option 1 to make other sub-options take effect.

Protocols and standards

- RFC 2131, *Dynamic Host Configuration Protocol*
- RFC 2132, *DHCP Options and BOOTP Vendor Extensions*
- RFC 1542, *Clarifications and Extensions for the Bootstrap Protocol*
- RFC 3046, *DHCP Relay Agent Information Option*
- RFC 3442, *The Classless Static Route Option for Dynamic Host Configuration Protocol (DHCP) version 4*

Configuring DHCP server

The term "interface" in the DHCP features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see the *Layer 2—LAN Switching Configuration Guide*).

Only HP 5500 EI switches support Layer 3 Ethernet port configuration.

Overview

The DHCP server is well suited to networks where:

- Manual configuration and centralized management are difficult to implement.
- Many hosts need to acquire IP addresses dynamically. This may be because the number of hosts exceeds the number of assignable IP addresses, so it is impossible to assign a fixed IP address to each host. For example, an ISP has a limited number of host addresses.
- A few hosts need fixed IP addresses.

In addition to assigning IP addresses to DHCP clients on public networks, a multi-VPN-instance customer edge (MCE) serving as the DHCP server can also assign IP addresses to DHCP clients on private networks. Note that the IP address ranges of public and private networks or those of private networks on the DHCP server cannot overlap each other. For more information about MCE, see *Layer 3—IP Routing Configuration Guide*.

DHCP address pool

Address pool types

DHCP address pools include common and extended address pools.

- **Common address pool**—Supports both static binding and dynamic allocation.
- **Extended address pool**—Supports only dynamic allocation.

Common address pool structure

The common address pool database is organized as a tree. The root of the tree is the address pool for natural networks, branches are address pools for subnets, and leaves are addresses statically bound to clients. For the same level address pools, a previously configured pool has a higher selection priority than a new one.

At the very beginning, subnets inherit network parameters and clients inherit subnet parameters. Therefore, common parameters, for example a DNS server address, should be configured at the highest (network or subnet) level of the tree. IP address lease durations are not inherited.

The new configuration at the higher level (parent) of the tree will be:

- Inherited if the lower level (child) has no such configuration.
- Overridden if the lower level (child) has such configuration.

NOTE:

The extended address pools on a DHCP server are independent of each other and no inheritance relationship exists among them.

Principles for selecting an address pool

The DHCP server observes the following principles to select an address pool when assigning an IP address to a client:

1. If there is an address pool where an IP address is statically bound to the MAC address or ID of the client, the DHCP server will select this address pool and assign the statically bound IP address to the client. For the configuration of this address pool, see "[Configuring static address allocation](#)."
2. If the receiving interface has an extended address pool referenced, the DHCP server will assign an IP address from this address pool. If no IP address is available in the address pool, the DHCP server will fail to assign an address to the client. For the configuration of such an address pool, see "[Configuring dynamic address allocation for an extended address pool](#)."
3. Otherwise, the DHCP server will select the smallest common address pool that contains the IP address of the receiving interface (if the client and the server reside on the same subnet), or the smallest common address pool that contains the IP address specified in the giaddr field of the client's request (if a DHCP relay agent is in-between). If no IP address is available in the address pool, the DHCP server will fail to assign an address to the client because it cannot assign an IP address from the parent address pool to the client. For the configuration of such an address pool, see "[Configuring dynamic address allocation](#)."

For example, two common address pools, 1.1.1.0/24 and 1.1.1.0/25, are configured on the DHCP server. If the IP address of the interface receiving DHCP requests is 1.1.1.1/25, the DHCP server will select IP addresses for clients from address pool 1.1.1.0/25. If no IP address is available in the address pool, the DHCP server will fail to assign addresses to clients. If the IP address of the interface receiving DHCP requests is 1.1.1.130/25, the DHCP server will select IP addresses for clients from the 1.1.1.0/24 address pool.

NOTE:

To avoid wrong IP address allocation, keep the IP addresses for dynamic allocation within the subnet where the interface of the DHCP server or DHCP relay agent resides.

IP address allocation sequence

A DHCP server assigns an IP address to a client according to the following sequence:

1. The IP address statically bound to the client's MAC address or ID.
2. The IP address that was ever assigned to the client.
3. The IP address designated by the Option 50 field in a DHCP-DISCOVER message. Option 50 is the requested IP address field in DHCP-DISCOVER messages. It is padded by the client to specify the IP address that the client wants to obtain. The contents to be padded depend on the client.
4. The first assignable IP address found in an extended or common address pool.
5. The IP address that was a conflict or passed its lease duration.

If no IP address is assignable, the server will not respond.

DHCP server configuration task list

Task	Remarks
Configuring an address pool for the DHCP server	Required.
Enabling DHCP	Required.
Enabling the DHCP server on an interface	Required.
Applying an extended address pool on an interface	Required by the extended address pool configuration. When configuring a common address pool, ignore this task.
Configuring the DHCP server security functions	Optional.
Enabling client offline detection	Optional.
Enabling handling of Option 82	Optional.
Specifying a server's IP address for the DHCP client	Optional.
Specifying the threshold for sending trap messages	Optional.
Setting the DSCP value for DHCP packets	Optional.

Configuring an address pool for the DHCP server Configuration task list

Task	Remarks			
Creating a DHCP address pool	Required.			
Configuring address allocation mode for a common address pool	<table border="0"> <tr> <td>Configuring static address allocation</td> <td rowspan="2">Required to configure either of the two for the common address pool configuration.</td> </tr> <tr> <td>Configuring dynamic address allocation</td> </tr> </table>	Configuring static address allocation	Required to configure either of the two for the common address pool configuration.	Configuring dynamic address allocation
Configuring static address allocation	Required to configure either of the two for the common address pool configuration.			
Configuring dynamic address allocation				
Configuring dynamic address allocation for an extended address pool	Required for the extended address pool configuration.			
Configuring a domain name suffix for the client				
Configuring DNS servers for the client				
Configuring WINS servers and NetBIOS node type for the client				
Configuring BIMS server information for the client				
Configuring gateways for the client	Optional.			
Configuring Option 184 parameters for the client with voice service				
Configuring the TFTP server and bootfile name for the client				
Specifying a server's IP address for the DHCP client				
Configuring self-defined DHCP options				

Creating a DHCP address pool

When creating a DHCP address pool, specify it as a common address pool or an extended address pool.

A common address pool and an extended address pool are different in address allocation mode configuration. Configurations of other parameters (such as the domain name suffix and DNS server address) for them are the same.

To create a DHCP address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a DHCP address pool and enter its view.	dhcp server ip-pool <i>pool-name</i> [extended]	No DHCP address pool is created by default.

Configuring address allocation mode for a common address pool

IMPORTANT:

You can configure either a static binding or dynamic address allocation for a common address pool, but not both.

You need to specify a subnet for dynamic address allocation. A static binding is a special address pool containing only one IP address.

Configuring static address allocation

Some DHCP clients, such as a WWW server, need fixed IP addresses. To provide a fixed IP address, you can create a static binding of a client's MAC address or client ID to an IP address in the DHCP address pool. A static binding is a special address pool containing only one IP address.

When the client with that MAC address or client ID requests an IP address, the DHCP server will assign the IP address from the binding to the client.

Follow these guidelines when you configure a static binding in a common address pool:

- Use the `static-bind ip-address` command together with `static-bind mac-address` or `static-bind client-identifier` to accomplish a static binding configuration.
- In a DHCP address pool, if you execute the `static-bind mac-address` command before the `static-bind client-identifier` command, the latter will overwrite the former and vice versa.
- If you use the `static-bind ip-address`, `static-bind mac-address`, or `static-bind client-identifier` command repeatedly in the DHCP address pool, the new configuration will overwrite the previous one.
- The IP address of the static binding cannot be an interface address of the DHCP server. Otherwise, an IP address conflict may occur and the bound client cannot obtain an IP address correctly.
- The ID of the static binding must be identical to the ID displayed by using the `display dhcp client verbose` command on the client. Otherwise, the client cannot obtain an IP address.
- When the device serves as a DHCP client or BOOTP client, you must bind the DHCP client's ID to an IP address, or bind the BOOTP client's MAC address to an IP address on the DHCP server; otherwise, the DHCP or BOOTP client cannot obtain a static IP address.

- If the interfaces on a DHCP client share the same MAC address, you must specify the client ID, rather than MAC address, in a static binding to identify the requesting interface; otherwise, the client may fail to obtain an IP address.

To configure a static binding in a common address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter common address pool view.	dhcp server ip-pool <i>pool-name</i>	N/A
3. Specify the IP address.	static-bind ip-address <i>ip-address</i> [<i>mask-length</i> mask <i>mask</i>]	No IP addresses are statically bound by default.
4. Specify the MAC address or client ID.	<ul style="list-style-type: none"> • Specify the MAC address: static-bind mac-address <i>mac-address</i> • Specify the client ID: static-bind client-identifier <i>client-identifier</i> 	Use at least one command. Neither is bound statically by default.
5. Specify the lease duration for the IP address.	expired { day <i>day</i> [hour <i>hour</i> [minute <i>minute</i> [second <i>second</i>]]] } unlimited }	Optional. By default, the lease duration of the IP address is unlimited.

Configuring dynamic address allocation

For dynamic address allocation, you must configure a DHCP address pool. For each address pool, you must specify one and only one address range, and the lease duration. A DHCP address pool can have only one lease duration.

To avoid address conflicts, configure the DHCP server to exclude IP addresses used by the gateway or FTP server from dynamic allocation.

Follow these guidelines when you configure dynamic address allocation for a common address pool:

- In common address pool view, using the **network** or **network ip range** command repeatedly overwrites the previous configuration.
- After you exclude IP addresses from automatic allocation by using the **dhcp server forbidden-ip** command, neither a common address pool nor an extended address pool can assign these IP addresses through dynamic address allocation.
- Using the **dhcp server forbidden-ip** command repeatedly can exclude multiple IP address ranges from allocation.

To configure dynamic address allocation for a common address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter common address pool view.	dhcp server ip-pool <i>pool-name</i>	N/A
3. Specify a subnet.	network <i>network-address</i> [<i>mask-length</i> mask <i>mask</i>]	Not specified by default.

Step	Command	Remarks
4. Specify the IP address range on the subnet for dynamic allocation.	network ip range <i>min-address max-address</i>	Optional. Not specified by default.
5. Specify the address lease duration.	expired { day <i>day</i> [hour <i>hour</i> [minute <i>minute</i>] [second <i>second</i>]] unlimited }	Optional. One day by default.
6. Return to system view.	quit	N/A
7. Exclude IP addresses from automatic allocation.	dhcp server forbidden-ip <i>low-ip-address [high-ip-address]</i>	Optional. Except IP addresses of the DHCP server interfaces, all addresses in the DHCP address pool are assignable by default.

Configuring dynamic address allocation for an extended address pool

After the assignable IP address range and the mask are specified, the address pool becomes valid.

Extended address pools support dynamic address allocation only. Excluded IP addresses specified with the **forbidden-ip** command in DHCP address pool view are not assignable in the current extended address pool, but are assignable in other address pools.

To configure dynamic address allocation for an extended address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter extended address pool view.	dhcp server ip-pool <i>pool-name</i> extended	N/A
3. Specify the IP address range.	network ip range <i>min-address max-address</i>	Not specified by default.
4. Specify the IP address mask.	network mask <i>mask</i>	Not specified by default.
5. Specify the IP address range for the DHCP clients of a specified vendor.	vendor-class-identifier <i>hex-string</i> <1-255> ip range <i>min-address max-address</i>	Optional. Not configured by default.
6. Specify the address lease duration.	expired { day <i>day</i> [hour <i>hour</i> [minute <i>minute</i> [second <i>second</i>]]] unlimited }	Optional. One day by default.
7. Exclude IP addresses from dynamic allocation.	forbidden-ip <i>ip-address</i> <1-8>	Optional. Except IP addresses of the DHCP server interfaces, all addresses in the DHCP address pool are assignable by default.

Configuring a domain name suffix for the client

You can specify a domain name suffix in each DHCP address pool on the DHCP server to provide the clients with the domain name suffix. With this suffix assigned, the client only needs to input part of a domain name, and the system will add the domain name suffix for name resolution. For more information about DNS, see "Configuring IPv4 DNS."

To configure a domain name suffix in the DHCP address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter DHCP address pool view.	dhcp server ip-pool <i>pool-name</i> [extended]	N/A
3. Specify a domain name suffix.	domain-name <i>domain-name</i>	Not specified by default

Configuring DNS servers for the client

A DHCP client contacts a Domain Name System (DNS) server to resolve names. You can specify up to eight DNS servers in the DHCP address pool.

To configure DNS servers in the DHCP address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter DHCP address pool view.	dhcp server ip-pool <i>pool-name</i> [extended]	N/A
3. Specify DNS servers.	dns-list <i>ip-address&<1-8></i>	Not specified by default

Configuring WINS servers and NetBIOS node type for the client

A Microsoft DHCP client using NetBIOS protocol contacts a Windows Internet Naming Service (WINS) server for name resolution. Therefore, the DHCP server should assign a WINS server address when assigning an IP address to the client.

You can specify up to eight WINS servers in a DHCP address pool.

You must also specify a NetBIOS node type in a DHCP address pool. There are four NetBIOS node types:

- **b (broadcast)-node**—A b-node client sends the destination name in a broadcast message. The destination returns its IP address to the client after receiving the message.
- **p (peer-to-peer)-node**—A p-node client sends the destination name in a unicast message to the WINS server, and the WINS server returns the destination IP address.
- **m (mixed)-node**—An m-node client broadcasts the destination name. If it receives no response, it unicasts the destination name to the WINS server to get the destination IP address.
- **h (hybrid)-node**—An h-node client unicasts the destination name to the WINS server. If it receives no response, it broadcasts the destination name to get the destination IP address.

To configure WINS servers and NetBIOS node type in the DHCP address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter DHCP address pool view.	dhcp server ip-pool <i>pool-name</i> [extended]	N/A
3. Specify WINS server IP addresses.	nbns-list <i>ip-address</i> &<1-8>	Optional for b-node. No address is specified by default.
4. Specify the NetBIOS node type.	netbios-type { b-node h-node m-node p-node }	Not specified by default.

Configuring BIMS server information for the client

The DHCP server must provide DHCP clients with the branch intelligent management system (BIMS) server IP address, port number, shared key from the DHCP address pool, to enable DHCP clients to perform regular software update and backup by using configuration files obtained from a BIMS server.

To configure the BIMS server IP address, port number, and shared key in the DHCP address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter DHCP address pool view.	dhcp server ip-pool <i>pool-name</i> [extended]	N/A
3. Specify the BIMS server IP address, port number, and shared key.	bims-server ip <i>ip-address</i> [port <i>port-number</i>] sharekey [cipher simple] <i>key</i>	Not specified by default

Configuring gateways for the client

You can specify up to eight gateways in a DHCP address pool.

To configure the gateways in the DHCP address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter DHCP address pool view.	dhcp server ip-pool <i>pool-name</i> [extended]	N/A
3. Specify gateways.	gateway-list <i>ip-address</i> &<1-8>	No gateway is specified by default.

Configuring Option 184 parameters for the client with voice service

To assign voice calling parameters along with an IP address to DHCP clients with voice service, you must configure Option 184 on the DHCP server. For more information about Option 184, see "[DHCP overview](#)."

To configure option 184 parameters in the DHCP address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter DHCP address pool view.	dhcp server ip-pool <i>pool-name</i> [extended]	N/A
3. Specify the IP address of the primary network calling processor.	voice-config ncp-ip <i>ip-address</i>	Not specified by default. After you configure this command, the other Option 184 parameters take effect.
4. Specify the IP address of the backup network calling processor.	voice-config as-ip <i>ip-address</i>	Optional. Not specified by default.
5. Configure the voice VLAN.	voice-config voice-vlan <i>vlan-id</i> { disable enable }	Optional. Not configured by default.
6. Specify the failover IP address and dialer string.	voice-config fail-over <i>ip-address dialer-string</i>	Optional. No failover IP address or dialer string is specified by default.

Configuring the TFTP server and bootfile name for the client

For the DHCP server to support client auto-configuration, you must specify the IP address or name of a TFTP server and the bootfile name in the DHCP address pool. You do not need to perform any configuration on the DHCP client.

The DHCP client uses these parameters to contact the TFTP server and request the configuration file used for system initialization.

1. When a switch starts up without loading any configuration file, the system sets an active interface (such as the interface of the default VLAN) as the DHCP client to request from the DHCP server for parameters, such as an IP address and name of a TFTP server, and the bootfile name.
2. After getting related parameters, the DHCP client will send a TFTP request to obtain the configuration file from the specified TFTP server for system initialization. If the client cannot get such parameters, it will perform system initialization without loading any configuration file.

To configure the IP address and name of the TFTP server and the bootfile name in the DHCP address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter DHCP address pool view.	dhcp server ip-pool <i>pool-name</i> [extended]	N/A
3. Specify the IP address or name of the TFTP server.	<ul style="list-style-type: none"> Specify the TFTP server: tftp-server ip-address <i>ip-address</i> Specify the name of the TFTP server: tftp-server domain-name <i>domain-name</i> 	Use either command. Not specified by default.
4. Specify the bootfile name.	bootfile-name <i>bootfile-name</i>	Not specified by default.

Specifying a server's IP address for the DHCP client

Some DHCP clients need to obtain configuration information from a server, such as a TFTP server. You can specify the IP address of that server in each address pool of the DHCP server. The DHCP server sends the server's IP address to DHCP clients along with other configuration information.

To specify the IP address of a server:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter DHCP address pool view.	dhcp server ip-pool <i>pool-name</i> [extended]	N/A
3. Specify the IP address of a server.	next-server <i>ip-address</i>	Not specified by default

Configuring self-defined DHCP options

△ CAUTION:

Be cautious when configuring self-defined DHCP options because such configuration may affect the DHCP operation process.

By configuring self-defined DHCP options, you can

- Define new DHCP options. New configuration options will come out with DHCP development. To support these new options, you can add them into the attribute list of the DHCP server.
- Define existing DHCP options. Vendors use Option 43 to define options that have no unified definitions in RFC 2132. The self-defined DHCP option enables DHCP clients to obtain vendor-specific information.
- Extend existing DHCP options. When the current DHCP options cannot meet the customers' requirements (for example, you cannot use the **dns-list** command to configure more than eight DNS server addresses), you can configure a self-defined option for extension.

To configure a self-defined DHCP option in the DHCP address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter DHCP address pool view.	dhcp server ip-pool <i>pool-name</i> [extended]	N/A

Step	Command	Remarks
3. Configure a self-defined DHCP option.	option code { ascii <i>ascii-string</i> hex <i>hex-string</i> &<1-16> ip-address <i>ip-address</i> &<1-8> }	No DHCP option is configured by default.

Table 2 Description of common options

Option	Option name	Corresponding command	Command parameter
3	Router Option	gateway-list	ip-address
6	Domain Name Server Option	dns-list	ip-address
15	Domain Name	domain-name	ascii
44	NetBIOS over TCP/IP Name Server Option	nbns-list	ip-address
46	NetBIOS over TCP/IP Node Type Option	netbios-type	hex
66	TFTP server name	tftp-server	ascii
67	Bootfile name	bootfile-name	ascii
43	Vendor Specific Information	N/A	hex

Enabling DHCP

Enable DHCP before performing other configurations.

To enable DHCP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable DHCP.	dhcp enable	Disabled by default

Enabling the DHCP server on an interface

With the DHCP server enabled on an interface, upon receiving a client's request, the DHCP server will assign an IP address from its address pool to the DHCP client.

Configuration guidelines

Follow these guidelines when you enable the DHCP server on an interface:

- If a DHCP relay agent exists between the DHCP server and client, the DHCP server, regardless of whether the **subaddress** keyword is used, will select an IP address from the address pool containing the primary IP address of the DHCP relay agent's interface (connected to the client) for a requesting client.
- When the DHCP server and client are on the same subnet:
 - With the keyword **subaddress** specified, the DHCP server will preferably assign an IP address from an address pool that resides on the same subnet as the primary IP address of the server

interface (connecting to the client). If the address pool contains no assignable IP address, the server assigns an IP address from an address pool that resides on the same subnet as the secondary IP addresses of the server interface. If the interface has multiple secondary IP addresses, each address pool is tried in turn for address allocation. If the interface has no secondary IP addresses, the server is unable to assign an IP address to the client.

- Without the keyword **subaddress** specified, the DHCP server can only assign an IP address from the address pool that resides on the same subnet as the primary IP address of the server interface.

Configuration procedure

To enable the DHCP server on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the DHCP server on an interface.	dhcp select server global-pool [subaddress]	Optional. Enabled by default.

Applying an extended address pool on an interface

After you create an extended address pool and apply it on an interface, the DHCP server, upon receiving a client's request on the interface, attempts to assign the client the statically bound IP address first and then an IP address from the specified address pool. If no IP address is available in this address pool, address allocation fails, and the DHCP server will not assign the client any IP address from other address pools.

Only an extended address pool can be applied on the interface. The address pool to be referenced must already exist.

To apply an extended address pool on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Apply an extended address pool on the interface.	dhcp server apply ip-pool <i>pool-name</i>	Optional. By default, the DHCP server has no extended address pool applied on its interface, and assigns an IP address from a common address pool to a requesting client.

Configuring the DHCP server security functions

Configuration prerequisites

Before you configure the DHCP server security functions, complete the following tasks on the DHCP server:

- Enable DHCP.
- Configure the DHCP address pool.

Enabling unauthorized DHCP server detection

Unauthorized DHCP servers on a network may assign wrong IP addresses to DHCP clients.

With unauthorized DHCP server detection enabled, the DHCP server checks whether a DHCP request contains Option 54 (Server Identifier Option). If yes, the DHCP server records the IP address of each detected DHCP server that assigned an IP address to a requesting DHCP client in the option, and records the receiving interface. The administrator can use this information to check for unauthorized DHCP servers.

With the unauthorized DHCP server detection enabled, the switch logs each detected DHCP server once. The administrator can use the log information to find unauthorized DHCP servers.

To enable unauthorized DHCP server detection:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable unauthorized DHCP server detection.	dhcp server detect	Disabled by default

Configuring IP address conflict detection

With IP address conflict detection enabled, before assigning an IP address, the DHCP server pings that IP address by using ICMP. If the server receives a response within the specified period, it selects and pings another IP address. If it receives no response, the server continues to ping the IP address until the specified number of ping packets are sent. If still no response is received, the server assigns the IP address to the requesting client. (The DHCP client probes the IP address by sending gratuitous ARP packets.)

To configure IP address conflict detection:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify the number of ping packets.	dhcp server ping packets <i>number</i>	Optional. One ping packet by default. The value 0 indicates that no ping operation is performed.

Step	Command	Remarks
3. Configure a timeout waiting for ping responses.	dhcp server ping timeout <i>milliseconds</i>	Optional. 500 ms by default. The value 0 indicates that no ping operation is performed.

Enabling client offline detection

With this feature enabled, the DHCP server considers a DHCP client goes offline when the ARP entry for the client ages out. In addition, it removes the client's IP-to-MAC binding entry.

Removing an ARP entry manually does not remove the corresponding client's IP-to-MAC binding.

To enable offline detection:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable offline detection.	dhcp server client-detect enable	Disabled by default

Enabling handling of Option 82

With Option 82 handling enabled, when the DHCP server receives a request with Option 82, it adds Option 82 into the response.

If the server is configured to ignore Option 82, it will assign an IP address to the client without adding Option 82 in the response message.

Configuration prerequisites

Before you enable Option 82 handling, complete the following tasks:

- **Configure the DHCP server**—Enable DHCP and configure the DHCP address pool.
- **Configure the relay agent or the device enabled with DHCP snooping**—For more information, see "[Configuring DHCP relay agent](#)" and "[Configuring DHCP snooping](#)."

Enabling Option 82 handling

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the server to handle Option 82.	dhcp server relay information enable	Optional. Enabled by default.

Specifying the threshold for sending trap messages

Configuration prerequisites

Before you perform the configuration, use the **snmp-agent target-host** command to specify the destination address of the trap messages. For more information about the command, see the *Network Management and Monitoring Command Reference*.

Configuration procedure

A DHCP server sends trap messages to the network management server when one of the following items reaches the specified threshold:

- The ratio of successfully allocated IP addresses to received DHCP requests
- The average IP address utilization of the address pool
- The maximum IP address utilization of the address pool

Trap messages help network administrators know the latest usage information of the DHCP server.

To specify the threshold for sending trap messages:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify the threshold for sending trap messages to the network management server.	dhcp server threshold { allocated-ip <i>threshold-value</i> average-ip-use <i>threshold-value</i> max-ip-use <i>threshold-value</i> }	Optional. Disabled by default.

Setting the DSCP value for DHCP packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for DHCP packets sent by the DHCP server.	dhcp dscp <i>dscp-value</i>	Optional. By default, the DSCP value is 56.

Displaying and maintaining the DHCP server

⚠ IMPORTANT:

A restart of the DHCP server or execution of the **reset dhcp server ip-in-use** command deletes all lease information. The DHCP server denies any DHCP request for lease extension, and the client must request an IP address again.

Task	Command	Remarks
Display information about IP address conflicts.	display dhcp server conflict { all ip <i>ip-address</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display information about lease expiration.	display dhcp server expired { all ip ip-address pool [<i>pool-name</i>] } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about assignable IP addresses.	display dhcp server free-ip [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IP addresses excluded from automatic allocation in the DHCP address pool.	display dhcp server forbidden-ip [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about bindings.	display dhcp server ip-in-use { all ip ip-address pool [<i>pool-name</i>] } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about DHCP server statistics.	display dhcp server statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display tree organization information of address pool(s).	display dhcp server tree { all pool [<i>pool-name</i>] } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear information about IP address conflicts.	reset dhcp server conflict { all ip ip-address }	Available in user view
Clear information about dynamic bindings.	reset dhcp server ip-in-use { all ip ip-address pool [<i>pool-name</i>] }	Available in user view
Clear information about DHCP server statistics.	reset dhcp server statistics	Available in user view

DHCP server configuration examples

DHCP networking involves the following two types:

- The DHCP server and client are on the same subnet and exchange messages directly.
- The DHCP server and client are not on the same subnet and they communicate with each other via a DHCP relay agent.

The DHCP server configuration for the two types is the same.

Static IP address assignment configuration example

Network requirements

As shown in [Figure 29](#), Switch B (DHCP client) and Switch C (BOOTP client) obtain the static IP address, DNS server address, and gateway address from Switch A (DHCP server).

The client ID of VLAN-interface 2 on Switch B is:

3030-3066-2e65-3234-392e-3830-3530-2d56-6c61-6e2d-696e-7465-7266-6163-6532.

The MAC address of VLAN-interface 2 on Switch C is 000f-e249-8050.

Figure 29 Network diagram

Configuration procedure

1. Configure the IP address of VLAN-interface 2 on Switch A.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 10.1.1.1 25
[SwitchA-Vlan-interface2] quit
```

2. Configure the DHCP server:

Enable DHCP.

```
[SwitchA] dhcp enable
```

Enable the DHCP server on VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] dhcp select server global-pool
[SwitchA-Vlan-interface2] quit
```

Create DHCP address pool 0, configure a static binding, DNS server and gateway in it.

```
[SwitchA] dhcp server ip-pool 0
[SwitchA-dhcp-pool-0] static-bind ip-address 10.1.1.5
[SwitchA-dhcp-pool-0] static-bind client-identifier
3030-3066-2e65-3234-392e-3830-3530-2d56-6c61-6e2d-696e-7465-7266-6163-6532
[SwitchA-dhcp-pool-0] dns-list 10.1.1.2
[SwitchA-dhcp-pool-0] gateway-list 10.1.1.126
[SwitchA-dhcp-pool-0] quit
```

Create DHCP address pool 1, configure a static binding, DNS server and gateway in it.

```
[SwitchA] dhcp server ip-pool 1
[SwitchA-dhcp-pool-1] static-bind ip-address 10.1.1.6
[SwitchA-dhcp-pool-1] static-bind mac-address 000f-e249-8050
[SwitchA-dhcp-pool-1] dns-list 10.1.1.2
[SwitchA-dhcp-pool-1] gateway-list 10.1.1.126
```

Verifying the configuration

After the preceding configuration is complete, Switch B can obtain IP address 10.1.1.5 and other network parameters, and Switch C can obtain IP address 10.1.1.6 and other network parameters from Switch A. You can use the **display dhcp server ip-in-use** command on the DHCP server to view the IP addresses assigned to the clients.

Dynamic IP address assignment configuration example

Network requirements

- As shown in Figure 30, the DHCP server (Switch A) assigns IP addresses to clients in subnet 10.1.1.0/24, which is subnetted into 10.1.1.0/25 and 10.1.1.128/25.
- The IP addresses of VLAN-interfaces 1 and 2 on Switch A are 10.1.1.1/25 and 10.1.1.129/25 respectively.
- In address pool 10.1.1.0/25, configure the address lease duration as ten days and twelve hours, domain name suffix aabbcc.com, DNS server address 10.1.1.2/25, gateway 10.1.1.126/25, and WINS server 10.1.1.4/25.
- In address pool 10.1.1.128/25, configure the address lease duration as five days, domain name suffix aabbcc.com, DNS server address 10.1.1.2/25, and gateway address 10.1.1.254/25, and there is no WINS server address.
- The domain name and DNS server address on subnets 10.1.1.0/25 and 10.1.1.128/25 are the same. Therefore, the domain name suffix and DNS server address can be configured only for subnet 10.1.1.0/24. Subnet 10.1.1.128/25 can inherit the configuration of subnet 10.1.1.0/24.

Figure 30 Network diagram

Configuration procedure

1. Specify IP addresses for VLAN interfaces. (Details not shown.)
2. Configure the DHCP server:

Enable DHCP.

```
<SwitchA> system-view
[SwitchA] dhcp enable
```

Enable the DHCP server on VLAN-interface 1 and VLAN-interface 2.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] dhcp select server global-pool
[SwitchA-Vlan-interface1] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] dhcp select server global-pool
[SwitchA-Vlan-interface2] quit
```

Exclude IP addresses (addresses of the DNS server, WINS server and gateways).

```
[SwitchA] dhcp server forbidden-ip 10.1.1.2
[SwitchA] dhcp server forbidden-ip 10.1.1.4
```

```

[SwitchA] dhcp server forbidden-ip 10.1.1.126
[SwitchA] dhcp server forbidden-ip 10.1.1.254
# Configure DHCP address pool 0 (subnet, client domain name suffix, and DNS server address).
[SwitchA] dhcp server ip-pool 0
[SwitchA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
[SwitchA-dhcp-pool-0] domain-name aabbcc.com
[SwitchA-dhcp-pool-0] dns-list 10.1.1.2
[SwitchA-dhcp-pool-0] quit
# Configure DHCP address pool 1 (subnet, gateway, lease duration, and WINS server).
[SwitchA] dhcp server ip-pool 1
[SwitchA-dhcp-pool-1] network 10.1.1.0 mask 255.255.255.128
[SwitchA-dhcp-pool-1] gateway-list 10.1.1.126
[SwitchA-dhcp-pool-1] expired day 10 hour 12
[SwitchA-dhcp-pool-1] nbns-list 10.1.1.4
[SwitchA-dhcp-pool-1] quit
# Configure DHCP address pool 2 (subnet, gateway, and lease duration).
[SwitchA] dhcp server ip-pool 2
[SwitchA-dhcp-pool-2] network 10.1.1.128 mask 255.255.255.128
[SwitchA-dhcp-pool-2] expired day 5
[SwitchA-dhcp-pool-2] gateway-list 10.1.1.254

```

Verifying the configuration

After the preceding configuration is complete, clients on networks 10.1.1.0/25 and 10.1.1.128/25 can obtain IP addresses on the corresponding network and other network parameters from Switch A. You can use the **display dhcp server ip-in-use** command on the DHCP server to view the IP addresses assigned to the clients.

Self-defined option configuration example

Network requirements

As shown in [Figure 31](#), the DHCP client (Switch B) obtains an IP address and PXE server addresses from the DHCP server (Switch A). The IP address belongs to subnet 10.1.1.0/24. The PXE server addresses are 1.2.3.4 and 2.2.2.2.

The DHCP server assigns PXE server addresses to DHCP clients through Option 43, a self-defined option. The format of Option 43 and that of the PXE server address sub-option are shown in [Figure 19](#) and [Figure 21](#), respectively. The value of Option 43 configured on the DHCP server in this example is 80 0B 00 00 02 01 02 03 04 02 02 02 02. The number 80 is the value of the sub-option type. The number 0B is the value of the sub-option length. The numbers 00 00 are the value of the PXE server type. The number 02 indicates the number of servers. The numbers 01 02 03 04 02 02 02 02 indicate that the PXE server addresses are 1.2.3.4 and 2.2.2.2.

Figure 31 Network diagram

Configuration procedure

1. Specify IP addresses for the interfaces. (Details not shown.)
2. Configure the DHCP server:

```
# Enable DHCP.
<SwitchA> system-view
[SwitchA] dhcp enable

# Enable the DHCP server on VLAN-interface 2.
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] dhcp select server global-pool
[SwitchA-Vlan-interface2] quit

# Configure DHCP address pool 0.
[SwitchA] dhcp server ip-pool 0
[SwitchA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
[SwitchA-dhcp-pool-0] option 43 hex 80 0B 00 00 02 01 02 03 04 02 02 02
```

Verifying the configuration

After the preceding configuration is complete, Switch B can obtain its IP address on 10.1.1.0/24 and PXE server addresses from the Switch A. You can use the **display dhcp server ip-in-use** command on the DHCP server to view the IP addresses assigned to the clients.

Troubleshooting DHCP server configuration

Symptom

A client's IP address obtained from the DHCP server conflicts with another IP address.

Analysis

A host on the subnet may have the same IP address.

Solution

1. Disable the client's network adapter or disconnect the client's network cable. Ping the IP address of the client from another host to check whether there is a host using the same IP address.
2. If a ping response is received, the IP address has been manually configured on a host. Execute the **dhcp server forbidden-ip** command on the DHCP server to exclude the IP address from dynamic allocation.
3. Enable the network adapter or connect the network cable. For example, to release the IP address and obtain another one on a Windows XP client:
 - a. Run **cmd** to enter DOS window.
 - b. Type **ipconfig/release** to relinquish the IP address.
 - c. Type **ipconfig/renew** to obtain another IP address.

Configuring DHCP relay agent

The DHCP relay agent configuration is supported only on Layer 3 Ethernet ports, Layer 3 aggregate interfaces, and VLAN interfaces.

The term "interface" in the DHCP features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see the *Layer 2—LAN Switching Configuration Guide*).

Only HP 5500 EI switches support Layer 3 Ethernet port configuration.

Overview

Via a relay agent, DHCP clients can communicate with a DHCP server on another subnet to obtain configuration parameters. DHCP clients on different subnets can contact the same DHCP server rather than having a DHCP server on each subnet. This centralizes management and reduces cost reduction.

An MCE device serving as the DHCP relay agent can forward DHCP packets not only between a DHCP server and clients on a public network, but also between a DHCP server and clients on a private network. Note that the IP address ranges of the public and private networks or those of private networks cannot overlap each other. For more information about MCE, see *Layer 3—IP Routing Configuration Guide*.

Fundamentals

Figure 32 DHCP relay agent application

The DHCP server and client interact with each other in the same way with or without a relay agent (see "[DHCP overview](#)").

Figure 33 DHCP relay agent work process

1. After receiving a DHCP-DISCOVER or DHCP-REQUEST broadcast message from a DHCP client, the DHCP relay agent fills the giaddr field of the message with its IP address and forwards the message to the designated DHCP server in unicast mode.
2. Based on the giaddr field, the DHCP server returns an IP address and other configuration parameters to the relay agent, and the relay agent conveys them to the client.

DHCP relay agent support for Option 82

Option 82 records location information of the DHCP client, letting the administrator locate the DHCP client for security control and accounting purposes. For more information, see "[DHCP overview](#)"

If the DHCP relay agent supports Option 82, it handles a client's request according to the contents defined in Option 82, if any. The handling strategies are described in [Table 3](#).

If a reply returned by the DHCP server contains Option 82, the DHCP relay agent removes the Option 82 before forwarding the reply to the client.

Table 3 Handling strategies of the DHCP relay agent

If a client's requesting message has...	Handling strategy	Padding format	The DHCP relay agent will...
	Drop	Random	Drop the message.
	Keep	Random	Forward the message without changing Option 82.
Option 82		normal	Forward the message after replacing the original Option 82 with the Option 82 padded in normal format.
	Replace	verbose	Forward the message after replacing the original Option 82 with the Option 82 padded in verbose format.
		user-defined	Forward the message after replacing the original Option 82 with the user-defined Option 82.
no Option 82	N/A	normal	Forward the message after adding the Option 82 padded in normal format.

If a client's requesting message has...	Handling strategy	Padding format	The DHCP relay agent will...
	N/A	verbose	Forward the message after adding the Option 82 padded in verbose format.
	N/A	user-defined	Forward the message after adding the user-defined Option 82.

DHCP relay agent configuration task list

Task	Remarks
Enabling DHCP	Required
Enabling the DHCP relay agent on an interface	Required
Correlating a DHCP server group with a relay agent interface	Required
Configuring the DHCP relay agent security functions	Optional
Enabling offline detection	Optional
Configuring the DHCP relay agent to release an IP address	Optional
Configuring the DHCP relay agent to support Option 82	Optional
Setting the DSCP value for DHCP packets	Optional

Enabling DHCP

Enable DHCP before performing other configurations related to the DHCP relay agent.

To enable DHCP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable DHCP.	dhcp enable	Disabled by default

Enabling the DHCP relay agent on an interface

With the DHCP relay agent enabled, an interface forwards incoming DHCP requests to a DHCP server for address allocation.

The IP address pool containing the IP address of the DHCP relay agent enabled interface must be configured on the DHCP server. Otherwise, the DHCP clients connected to the relay agent cannot obtain correct IP addresses.

To enable the DHCP relay agent on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the DHCP relay agent on the current interface.	dhcp select relay	With DHCP enabled, interfaces operate in the DHCP server mode.

Correlating a DHCP server group with a relay agent interface

To improve reliability, you can specify several DHCP servers as a group on the DHCP relay agent and correlate a relay agent interface with the server group. When the interface receives request messages from clients, the relay agent will forward them to all the DHCP servers of the group.

Configuration guidelines

Follow these guidelines when you correlate a DHCP server group with a relay agent interface:

- You can specify up to twenty DHCP server groups on the relay agent.
- By executing the **dhcp relay server-group** command repeatedly, you can specify up to eight DHCP server addresses for each DHCP server group.
- The IP addresses of DHCP servers and those of relay agent's interfaces that connect DHCP clients cannot be on the same subnet. Otherwise, the client cannot obtain an IP address.
- A DHCP server group can correlate with one or multiple DHCP relay agent interfaces, while a relay agent interface can only correlate with one DHCP server group. Using the **dhcp relay server-select** command repeatedly overwrites the previous configuration. However, if the specified DHCP server group does not exist, the interface still uses the previous correlation.
- The *group-id* argument in the **dhcp relay server-select** command is configured by using the **dhcp relay server-group** command.

Configuration procedure

To correlate a DHCP server group with a relay agent interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a DHCP server group and add a server into the group.	dhcp relay server-group <i>group-id</i> ip <i>ip-address</i>	Not created by default.
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Correlate the DHCP server group with the current interface.	dhcp relay server-select <i>group-id</i>	By default, no interface is correlated with any DHCP server group.

Configuring the DHCP relay agent security functions

Configuring address check

Address check can block illegal hosts from accessing external networks.

With this feature enabled, the DHCP relay agent can dynamically record clients' IP-to-MAC bindings after they obtain IP addresses through DHCP. This feature also supports static bindings. You can also configure static IP-to-MAC bindings on the DHCP relay agent, so users can access external networks using fixed IP addresses.

Upon receiving a packet from a host, the DHCP relay agent checks the source IP and MAC addresses in the packet against the recorded dynamic and static bindings. If no match is found, the DHCP relay agent does not learn the ARP entry of the host, and will not forward any reply to the host, so the host cannot access external networks via the DHCP relay agent.

Configuration guidelines

Follow these guidelines when you create a static binding and enable address check:

- The **dhcp relay address-check enable** command can be executed only on Layer 3 Ethernet ports and VLAN interfaces.
- Before enabling address check on an interface, you must enable the DHCP service, and enable the DHCP relay agent on the interface; otherwise, the address check configuration is ineffective.
- The **dhcp relay address-check enable** command only checks IP and MAC addresses but not interfaces.
- When using the **dhcp relay security static** command to bind an interface to a static binding entry, make sure that the interface is configured as a DHCP relay agent; otherwise, address entry conflicts may occur.

Configuration procedure

To create a static binding and enable address check:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a static binding.	dhcp relay security static <i>ip-address mac-address</i> [interface <i>interface-type interface-number</i>]	Optional. No static binding is created by default.
3. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
4. Enable address check.	dhcp relay address-check enable	Disabled by default.

Configuring periodic refresh of dynamic client entries

A DHCP client unicasts a DHCP-RELEASE message to the DHCP server to release its IP address. The DHCP relay agent simply conveys the message to the DHCP server and does not remove the IP-to-MAC entry of the client.

When this feature is enabled, the DHCP relay agent uses the IP address of a client and the MAC address of the DHCP relay interface to send a DHCP-REQUEST message to the DHCP server at specified intervals.

- If the server returns a DHCP-ACK message or does not return any message within a specified interval, the DHCP relay agent ages out the entry.
- If the server returns a DHCP-NAK message, the relay agent keeps the entry.

To configure periodic refresh of dynamic client entries:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable periodic refresh of dynamic client entries.	dhcp relay security refresh enable	Optional. Enabled by default.
3. Configure the refresh interval.	dhcp relay security tracker { <i>interval</i> auto }	Optional. auto by default. (auto interval is calculated by the relay agent according to the number of client entries.)

Enabling unauthorized DHCP server detection

Unauthorized DHCP servers may assign wrong IP addresses to DHCP clients.

With unauthorized DHCP servers detection enabled, the DHCP relay agent checks whether a request contains Option 54 (Server Identifier Option). If yes, the DHCP relay agent records the IP address of each detected DHCP server that assigned an IP address to a requesting DHCP client in the option, and records the receiving interface. The administrator can use this information to check for unauthorized DHCP servers.

The relay agent logs a DHCP server only once.

To enable unauthorized DHCP server detection:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable unauthorized DHCP server detection.	dhcp relay server-detect	Disabled by default

Enabling DHCP starvation attack protection

A DHCP starvation attack occurs when an attacker constantly sends forged DHCP requests using different MAC addresses in the chaddr field to a DHCP server. This exhausts the IP address resources of the DHCP server so legitimate DHCP clients cannot obtain IP addresses. The DHCP server may also fail to work because of exhaustion of system resources.

- To relieve a DHCP starvation attack that uses DHCP packets encapsulated with different source MAC addresses, you can limit the number of ARP entries that a Layer 3 interface can learn or MAC addresses that a Layer 2 port can learn. You can also configure an interface that has learned the maximum MAC addresses to discard packets whose source MAC addresses are not in the MAC address table.

- To prevent a DHCP starvation attack that uses DHCP requests encapsulated with the same source MAC address, enable MAC address check on the DHCP relay agent. With this function enabled, the DHCP relay agent compares the chaddr field of a received DHCP request with the source MAC address field of the frame. If they are the same, the DHCP relay agent decides this request as valid and forwards it to the DHCP server; if not, it discards the DHCP request.

To enable MAC address check:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable MAC address check.	dhcp relay check mac-address	Disabled by default

NOTE:

DHCP relay agents change the source MAC addresses when forwarding DHCP packets. Therefore, you can enable MAC address check only on a DHCP relay agent directly connected to DHCP clients. Otherwise, valid DHCP packets may be discarded and clients cannot obtain IP addresses.

Enabling offline detection

The DHCP relay agent checks whether a user is online by learning the ARP entry. When an ARP entry is aged out, the corresponding client is considered to be offline.

With this function enabled on an interface, the DHCP relay agent removes a client's IP-to-MAC entry when it is aged out, and sends a DHCP-RELEASE message to the DHCP server to release the IP address of the client. Removing an ARP entry manually does not remove the corresponding client's IP-to-MAC binding. When the client goes offline, use the **undo dhcp relay security** command to remove the IP-to-MAC binding manually.

To enable offline detection:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable offline detection.	dhcp relay client-detect enable	Disabled by default

Configuring the DHCP relay agent to release an IP address

You can configure the relay agent to release a client's IP address. The relay agent sends a DHCP-RELEASE message that contains the IP address. Upon receiving the DHCP-RELEASE message, the DHCP server releases the IP address; meanwhile, the client entry is removed from the DHCP relay agent. Dynamic client entries can be generated after you enable address check or IP source guard on the DHCP relay agent. For more information about IP source guard, see the *Security Configuration Guide*.

To configure the DHCP relay agent to send DHCP-RELEASE messages:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the DHCP relay agent to release an IP address.	dhcp relay release ip <i>client-ip</i>	The IP address must be in a dynamic client entry.

Configuring the DHCP relay agent to support Option 82

Configuration prerequisites

Before you perform this configuration, complete the following tasks:

- Enable DHCP.
- Enable the DHCP relay agent on the specified interface.
- Correlate a DHCP server group with relay agent interfaces.

Configuration guidelines

- To support Option 82, perform related configuration on both the DHCP server and relay agent. See "[Configuring DHCP server](#)" for DHCP server configuration of this kind.
- If the handling strategy of the DHCP relay agent is configured as **replace**, you must configure a padding format for Option 82. If the handling strategy is **keep** or **drop**, you need not configure any padding format.
- If sub-option 1 (node identifier) of Option 82 is padded with the device name (sysname) of a node, the device name must contain no spaces. Otherwise, the DHCP relay agent will drop the message.

Configuration procedure

To configure the DHCP relay agent to support Option 82:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the relay agent to support Option 82.	dhcp relay information enable	Disabled by default.
4. Configure the handling strategy for requesting messages containing Option 82.	dhcp relay information strategy { drop keep replace }	Optional. replace by default.

Step	Command	Remarks
5. Configure non-user-defined Option 82.	<ul style="list-style-type: none"> Configure the padding format for Option 82: dhcp relay information format { normal verbose [node-identifier { mac sysname user-defined node-identifier }] } Configure the code type for the circuit ID sub-option: dhcp relay information circuit-id format-type { ascii hex } Configure the code type for the remote ID sub-option: dhcp relay information remote-id format-type { ascii hex } 	<p>Optional.</p> <p>By default,</p> <ul style="list-style-type: none"> The padding format for Option 82 is normal. The code type for the circuit ID sub-option depends on the padding format of Option 82. Each field has its own code type. The code type for the remote ID sub-option is hex. <p>The code type configurations for the circuit ID sub-option and remote ID sub-option apply to non-user-defined Option 82 only.</p>
6. Configure user-defined Option 82.	<ul style="list-style-type: none"> Configure the padding content for the circuit ID sub-option: dhcp relay information circuit-id string <i>circuit-id</i> Configure the padding content for the remote ID sub-option: dhcp relay information remote-id string { <i>remote-id</i> sysname } 	<p>Optional.</p> <p>By default, the padding content depends on the padding format of Option 82.</p>

Setting the DSCP value for DHCP packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for DHCP packets sent by the DHCP relay agent.	dhcp dscp <i>dscp-value</i>	<p>Optional.</p> <p>By default, the DSCP value is 56.</p>

Displaying and maintaining the DHCP relay agent

Task	Command	Remarks
Display information about DHCP server groups correlated to a specified interface or all interfaces.	display dhcp relay { all interface <i>interface-type interface-number</i> } [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display Option 82 configuration information on the DHCP relay agent.	display dhcp relay information { all interface <i>interface-type interface-number</i> } [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display information about bindings of DHCP relay agents.	display dhcp relay security [<i>ip-address</i> dynamic static] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view

Task	Command	Remarks
Display statistics about bindings of DHCP relay agents.	display dhcp relay security statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the refreshing interval for entries of dynamic IP-to-MAC bindings.	display dhcp relay security tracker [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the configuration of a specified DHCP server group or all DHCP server groups.	display dhcp relay server-group { <i>group-id</i> all } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display packet statistics on relay agent.	display dhcp relay statistics [server-group { <i>group-id</i> all }] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear packet statistics from relay agent.	reset dhcp relay statistics [server-group <i>group-id</i>]	Available in user view

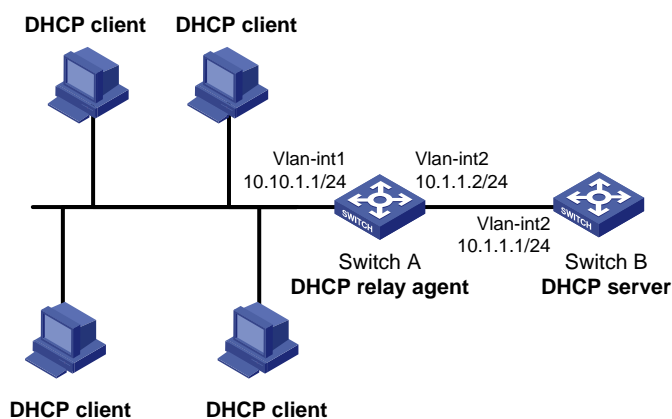

DHCP relay agent configuration examples

DHCP relay agent configuration example

Network requirements

As shown in [Figure 34](#), DHCP clients reside on network 10.10.1.0/24. The IP address of the DHCP server is 10.1.1.1/24. Because the DHCP clients reside on a different network than the DHCP server, a DHCP relay agent is deployed to forward messages between DHCP clients and the DHCP server. VLAN-interface 1 on the DHCP relay agent (Switch A) connects to the network where DHCP clients reside. The IP address of VLAN-interface 1 is 10.10.1.1/24 and the IP address of VLAN-interface 2 is 10.1.1.2/24.

Figure 34 Network diagram

Configuration procedure

The DHCP relay agent and server are on different subnets, so configure a static route or dynamic routing protocol to make them reachable to each other.

Configurations on the DHCP server are also required to guarantee the client-server communication via the DHCP relay agent. For DHCP server configuration information, see "[Configuring DHCP server.](#)"

Specify IP addresses for the interfaces. (Details not shown.)

Enable DHCP.

```
<SwitchA> system-view
```

```
[SwitchA] dhcp enable
```

Add DHCP server 10.1.1.1 into DHCP server group 1.

```
[SwitchA] dhcp relay server-group 1 ip 10.1.1.1
```

Enable the DHCP relay agent on VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
```

```
[SwitchA-Vlan-interface1] dhcp select relay
```

Correlate VLAN-interface 1 to DHCP server group 1.

```
[SwitchA-Vlan-interface1] dhcp relay server-select 1
```

After the preceding configuration is complete, DHCP clients can obtain IP addresses and other network parameters through the DHCP relay agent from the DHCP server. You can use the **display dhcp relay statistics** command to view statistics of DHCP packets forwarded by DHCP relay agents. After you enable address check of the DHCP relay agents with the **dhcp relay address-check enable** command, use the **display dhcp relay security** command to view bindings of DHCP relay agents

DHCP relay agent Option 82 support configuration example

Network requirements

- As shown in [Figure 34](#), enable Option 82 on the DHCP relay agent (Switch A).
- Configure the handling strategy for DHCP requests containing Option 82 as **replace**.
- Configure the padding content for the circuit ID sub-option as **company001** and for the remote ID sub-option as **device001**.
- Switch A forwards DHCP requests to the DHCP server (Switch B) after replacing Option 82 in the requests, so that the DHCP clients can obtain IP addresses.

Configuration procedure

Configurations on the DHCP server are also required to make the Option 82 configurations function normally.

Specify IP addresses for the interfaces. (Details not shown.)

Enable DHCP.

```
<SwitchA> system-view
```

```
[SwitchA] dhcp enable
```

Add DHCP server 10.1.1.1 into DHCP server group 1.

```
[SwitchA] dhcp relay server-group 1 ip 10.1.1.1
```

Enable the DHCP relay agent on VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
```

```
[SwitchA-Vlan-interface1] dhcp select relay
```

Correlate VLAN-interface 1 to DHCP server group 1.

```
[SwitchA-Vlan-interface1] dhcp relay server-select 1
```

Enable the DHCP relay agent to support Option 82, and perform Option 82-related configurations.

```
[SwitchA-Vlan-interface1] dhcp relay information enable
[SwitchA-Vlan-interface1] dhcp relay information strategy replace
[SwitchA-Vlan-interface1] dhcp relay information circuit-id string company001
[SwitchA-Vlan-interface1] dhcp relay information remote-id string device001
```

Troubleshooting DHCP relay agent configuration

Symptom

DHCP clients cannot obtain any configuration parameters via the DHCP relay agent.

Analysis

Problems may occur with the DHCP relay agent or server configuration.

Solution

To locate the problem, enable debugging and execute the **display** command on the DHCP relay agent to view the debugging information and interface state information.

Verify that:

- The DHCP is enabled on the DHCP server and relay agent.
- The address pool on the same subnet where DHCP clients reside is available on the DHCP server.
- The DHCP server and DHCP relay agent are reachable to each other.
- The relay agent interface connected to DHCP clients is correlated with a correct DHCP server group and the IP addresses of the group members are correct.

Configuring DHCP client

With DHCP client enabled, an interface uses DHCP to obtain configuration parameters such as an IP address from the DHCP server.

Configuration restrictions

- The DHCP client configuration is supported only on Layer 3 Ethernet ports, Layer 3 aggregate interfaces, and VLAN interfaces.
- When multiple VLAN interfaces with the same MAC address use DHCP for IP address acquisition via a relay agent, the DHCP server cannot be a Windows Server 2000 or Windows Server 2003.
- You cannot configure an interface of an aggregation group as a DHCP client.
- Only HP 5500 EI switches support Layer 3 Ethernet port configuration.

Enabling the DHCP client on an interface

Follow these guidelines when you enable the DHCP client on an interface:

- An interface can be configured to acquire an IP address in multiple ways. The latest configuration overwrites the previous one.
- Secondary IP addresses cannot be configured on an interface that is enabled with the DHCP client.
- If the IP address that interface A obtains from the DHCP server is on the same network segment as the IP address of interface B, interface A neither uses the IP address nor requests any IP address from the DHCP server unless you do the following: Delete the IP address of interface B and bring up interface A again by first executing the **shutdown** command and then the **undo shutdown** command, or, re-enable the DHCP client on interface A by executing the **undo ip address dhcp-alloc** command and then the **ip address dhcp-alloc** command.

To enable the DHCP client on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Enable the DHCP client on the interface.	ip address dhcp-alloc [client-identifier mac <i>interface-type interface-number</i>]	Disabled by default

Setting the DSCP value for DHCP packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for DHCP packets sent by the DHCP client.	dhcp client dscp <i>dscp-value</i>	Optional. By default, the DSCP value is 56.

Displaying and maintaining the DHCP client

Task	Command	Remarks
Display specified configuration information.	display dhcp client [verbose] [interface <i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

DHCP client configuration example

Network requirements

As shown in [Figure 35](#), on a LAN, Switch B contacts the DHCP server via VLAN-interface 2 to obtain an IP address, DNS server address, and static route information. The IP address resides on network 10.1.1.0/24. The DNS server address is 20.1.1.1. The next hop of the static route to network 20.1.1.0/24 is 10.1.1.2.

The DHCP server uses Option 121 to assign static route information to DHCP clients. The destination descriptor field comprises two parts, subnet mask length and destination network address. In this example, the value of the destination descriptor field takes 18 14 01 01, a hexadecimal number indicating that the subnet mask length is 24 and destination network address is 20.1.1.0. The value of the next hop address field takes 0A 01 01 02, a hexadecimal number indicating that the next hop is 10.1.1.2.

Figure 35 Network diagram

Configuration procedure

1. Configure Switch A:

Specify the IP address of VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 10.1.1.1 24
[SwitchA-Vlan-interface2] quit
```

Enable the DHCP service.

```
[SwitchA] dhcp enable
```

Exclude an IP address from automatic allocation.

```
[SwitchA] dhcp server forbidden-ip 10.1.1.2
```

Configure DHCP address pool 0 and specify the subnet, lease duration, DNS server address, and a static route to subnet 20.1.1.0/24.

```
[SwitchA] dhcp server ip-pool 0
[SwitchA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
[SwitchA-dhcp-pool-0] expired day 10
[SwitchA-dhcp-pool-0] dns-list 20.1.1.1
[SwitchA-dhcp-pool-0] option 121 hex 18 14 01 01 0A 01 01 02
```

2. Configure Switch B:

Enable the DHCP client on VLAN-interface 2.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address dhcp-alloc
```

Verifying the configuration

Use the **display dhcp client** command to view the IP address and other network parameters assigned to Switch B.

```
[SwitchB-Vlan-interface2] display dhcp client verbose
Vlan-interface2 DHCP client information:
Current machine state: BOUND
Allocated IP: 10.1.1.3 255.255.255.0
Allocated lease: 864000 seconds, T1: 432000 seconds, T2: 756000 seconds
Lease from 2009.02.20 11:06:35 to 2009.03.02 11:06:35
DHCP server: 10.1.1.1
Transaction ID: 0x410090f0
Classless static route:
  Destination: 20.1.1.0, Mask: 255.255.255.0, NextHop: 10.1.1.2
DNS server: 20.1.1.1
Client ID: 3030-3066-2e65-3230-
          302e-3030-3032-2d45-
          7468-6572-6e65-7430-
          2f30
T1 will timeout in 4 days 23 hours 59 minutes 50 seconds.
```

Use the **display ip routing-table** command to view the route information on Switch B. A static route to network 20.1.1.0/24 is added to the routing table.

```
[SwitchB-Vlan-interface2] display ip routing-table
Routing Tables: Public
          Destinations : 5          Routes : 5

Destination/Mask    Proto  Pre  Cost           NextHop         Interface
-----
10.1.1.0/24         Direct  0    0              10.1.1.3         Vlan2
10.1.1.3/32         Direct  0    0              127.0.0.1        InLoop0
20.1.1.0/24         Static  70   0              10.1.1.2         Vlan2
127.0.0.0/8         Direct  0    0              127.0.0.1        InLoop0
127.0.0.1/32        Direct  0    0              127.0.0.1        InLoop0
```

Configuring DHCP snooping

The DHCP snooping-enabled device must be either between the DHCP client and relay agent, or between the DHCP client and server. It does not work if it is between the DHCP relay agent and DHCP server.

DHCP snooping functions

DHCP snooping can:

1. Ensure that DHCP clients obtain IP addresses from authorized DHCP servers.
2. Record IP-to-MAC mappings of DHCP clients.

Ensuring that DHCP clients obtain IP addresses from authorized DHCP servers

With DHCP snooping, the ports of a switch can be configured as trusted or untrusted to make sure that clients obtain IP addresses only from authorized DHCP servers.

- **Trusted**—A trusted port forwards DHCP messages normally to ensure the clients get IP addresses from an authorized DHCP server.
- **Untrusted**—An untrusted port discards received DHCP-ACK and DHCP-OFFER messages to avoid IP address allocation from any unauthorized server.

Configure ports that connect to authorized DHCP servers or other DHCP snooping devices as trusted, and configure other ports as untrusted.

Recording IP-to-MAC mappings of DHCP clients

DHCP snooping reads DHCP-REQUEST messages and DHCP-ACK messages from trusted ports to record DHCP snooping entries. A DHCP snooping entry includes the MAC and IP addresses of the client, the port that connects to the DHCP client, and the VLAN of the port. Using DHCP snooping entries, DHCP snooping can implement the following functions:

- **ARP detection**—Whether ARP packets are sent from an authorized client is determined based on DHCP snooping entries. This feature prevents ARP attacks from unauthorized clients. For more information, see the *Security Configuration Guide*.
- **IP source guard**—IP source guard uses dynamic binding entries generated by DHCP snooping to filter packets on a per-port basis. This prevents unauthorized packets from traveling through. For more information, see the *Security Configuration Guide*.
- **VLAN mapping**—The device replaces service provider VLANs (SVLANs) in packets with customer VLANs (CVLANs) by searching corresponding DHCP snooping entries for DHCP client information including IP addresses, MAC addresses, and CVLANs, before sending the packets to clients. For more information, see *Layer 2—LAN Switching Configuration Guide*.

Application environment of trusted ports

Configuring a trusted port connected to a DHCP server

As shown in Figure 36, the DHCP snooping device port that is connected to an authorized DHCP server should be configured as a trusted port. The trusted port forwards reply messages from the authorized DHCP server to the client, but the untrusted port does not forward reply messages from the unauthorized DHCP server. This ensures that the DHCP client obtains an IP address from the authorized DHCP server.

Figure 36 Configuring trusted and untrusted ports

Configuring trusted ports in a cascaded network

In a cascaded network involving multiple DHCP snooping devices, the ports connected to other DHCP snooping devices should be configured as trusted ports.

To save system resources, you can disable the trusted ports, which are indirectly connected to DHCP clients, from recording client IP-to-MAC bindings upon receiving DHCP requests.

Figure 37 Configuring trusted ports in a cascaded network

Table 4 Roles of ports

Device	Untrusted port	Trusted port disabled from recording binding entries	Trusted port enabled to record binding entries
Switch A	GigabitEthernet 1/0/1	GigabitEthernet 1/0/3	GigabitEthernet 1/0/2
Switch B	GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4	GigabitEthernet 1/0/1	GigabitEthernet 1/0/2
Switch C	GigabitEthernet 1/0/1	GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4	GigabitEthernet 1/0/2

DHCP snooping support for Option 82

Option 82 records the location information of the DHCP client so the administrator can locate the DHCP client for security control and accounting purposes. For more information, see "[Configuring DHCP relay agent.](#)"

If DHCP snooping supports Option 82, it handles a client's request according to the contents defined in Option 82, if any. The handling strategies are described in [Table 5](#).

If a reply returned by the DHCP server contains Option 82, the DHCP snooping device removes the Option 82 before forwarding the reply to the client. If the reply contains no Option 82, the DHCP snooping device forwards it directly.

Table 5 Handling strategies of DHCP snooping

If a client's requesting message has...	Handling strategy	Padding format	The DHCP snooping device will...
Option 82	Drop	N/A	Drop the message.
	Keep	Random	Forward the message without changing Option 82.

If a client's requesting message has...	Handling strategy	Padding format	The DHCP snooping device will...	
	Replace	normal	Forward the message after replacing the original Option 82 with the Option 82 padded in normal format.	
		verbose	Forward the message after replacing the original Option 82 with the Option 82 padded in verbose format.	
		user-defined	Forward the message after replacing the original Option 82 with the user-defined Option 82.	
	Append	normal	Forward the message without changing Option 82.	
		verbose	Forward the message without changing Option 82.	
		private	Forward the message after adding sub-option 9 to option 82 or adding content to sub-option 9 that option 82 contains.	
		standard	Forward the message without changing Option 82.	
		user-defined	Forward the message without changing Option 82.	
	no Option 82	N/A	normal	Forward the message after adding the Option 82 padded in normal format.
		N/A	private	Forward the message after adding the Option 82 padded in private format.
N/A		standard	Forward the message after adding the Option 82 padded in standard format.	
N/A		verbose	Forward the message after adding the Option 82 padded in verbose format.	
N/A		user-defined	Forward the message after adding the user-defined Option 82.	

The handling strategy and padding format for Option 82 on the DHCP snooping device are the same as those on the relay agent.

DHCP snooping configuration task list

Task	Remarks
Configuring DHCP snooping basic functions	Required
Configuring DHCP snooping to support Option 82	Optional
Configuring DHCP snooping entries backup	Optional
Enabling DHCP starvation attack protection	Optional

Task	Remarks
Enabling DHCP-REQUEST message attack protection	Optional
Configuring DHCP packet rate limit	Optional

Configuring DHCP snooping basic functions

Configuration guidelines

Follow these guidelines when configure DHCP snooping basic functions:

- You must specify the ports connected to the authorized DHCP servers as trusted to make sure that DHCP clients can obtain valid IP addresses. The trusted port and the port connected to the DHCP client must be in the same VLAN.
- You can specify Layer 2 Ethernet ports and Layer 2 aggregate interfaces as trusted ports. For more information about aggregate interfaces, see the *Layer 2—LAN Switching Configuration Guide*.
- If a Layer 2 Ethernet port is added to an aggregation group, the DHCP snooping configuration of the interface will not take effect. After the interface quits the aggregation group, the configuration will be effective.
- DHCP snooping can work with basic QinQ or flexible QinQ. When receiving a packet without any VLAN tag from the DHCP client to the DHCP server, the DHCP snooping device adds a VLAN tag to the packet. If the packet has one VLAN tag, the device adds another VLAN tag to the packet and records the two VLAN tags in a DHCP snooping entry. The newly added VLAN tag is the outer tag. If the packet has two VLAN tags, the device directly forwards the packet to the DHCP server without adding any tag.
- If you need to add a new VLAN tag and meanwhile modify the original VLAN tag for the packet, DHCP snooping cannot work with flexible QinQ.

Configuration procedure

To configure DHCP snooping basic functions:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable DHCP snooping.	dhcp-snooping	Disabled by default.
3. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	The interface connects to the DHCP server.
4. Specify the port as a trusted port that records the IP-to-MAC bindings of clients.	dhcp-snooping trust	After DHCP snooping is enabled, a port is an untrusted port by default
5. Return to system view.	quit	N/A
6. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	The interface indirectly connects to the DHCP client.
7. Specify the port as a trusted port that does not record the IP-to-MAC bindings of clients.	dhcp-snooping trust no-user-binding	Optional. After DHCP snooping is enabled, a port is an untrusted port by default.

Configuring DHCP snooping to support Option 82

Configuration guidelines

Follow these guidelines when configure DHCP snooping to support Option 82:

- You can only enable DHCP snooping to support Option 82 on Layer 2 Ethernet ports, and Layer 2 aggregate interfaces.
- If a Layer 2 Ethernet port is added to an aggregation group, enabling DHCP snooping to support Option 82 on the interface will not take effect. After the interface quits the aggregation group, the configuration will be effective.
- Option 82 support requires configuration on both the DHCP server and the device enabled with DHCP snooping. See "[Configuring DHCP server](#)" for DHCP server configuration of this kind.
- If the handling strategy of the DHCP-snooping-enabled device is configured as **replace**, you need to configure a padding format for Option 82. If the handling strategy is **keep** or **drop**, you need not configure any padding format.
- If the Option 82 is padded with the device name, the device name must contain no spaces. Otherwise, the DHCP-snooping device will drop the message. You can use the **sysname** command to specify the device name. For more information about this command, see the *Fundamentals Command Reference*.
- If DHCP snooping and QinQ work together or the DHCP snooping device receives a DHCP packet with two VLAN tags, and the normal or verbose padding format is adopted for Option 82, DHCP snooping fills the VLAN ID field of sub-option 1 with outer VLAN tag.inter VLAN tag. For example, if the outer VLAN tag is 10 (a in hexadecimal) and the inner VLAN tag is 20 (14 in hexadecimal), the VLAN ID is 000a.0014.

Configuration procedure

To configure DHCP snooping to support Option 82:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable DHCP snooping to support Option 82.	dhcp-snooping information enable	Disabled by default.
4. Configure the handling strategy for requests containing Option 82.	dhcp-snooping information strategy { append drop keep replace }	Optional. replace by default.

Step	Command	Remarks
5.	<p>Configure Option 82 in the non-user-defined padding format.</p> <ul style="list-style-type: none"> Configure the padding format for Option 82: dhcp-snooping information format { normal private <1-1> standard verbose [node-identifier { mac sysname user-defined node-identifier }] } Configure the code type for the circuit ID sub-option: dhcp-snooping information circuit-id format-type { ascii hex } Configure the code type for the remote ID sub-option: dhcp-snooping information remote-id format-type { ascii hex } Enable sub-option 9: dhcp-snooping information [vlan <i>vlan-id</i>] sub-option <i>sub-option-code</i> 	<p>Optional.</p> <p>By default,</p> <ul style="list-style-type: none"> The padding format for Option 82 is normal. The code type for the circuit ID sub-option depends on the padding format of Option 82. Each field has its own code type. The code type for the remote ID sub-option is hex. Sub-option 9 is not enabled <p>Hex configuration applies to private padding format only.</p> <p>The code type configuration for the circuit ID sub-option and remote ID sub-option apply to non-user-defined Option 82 only.</p> <p>For sub-option 9, when append strategy is adopted, the sysname and the primary IP address of the Loopback0 interface are padded. When some other strategy is adopted, only the sysname is padded.</p>
6.	<p>Configure user-defined Option 82.</p> <ul style="list-style-type: none"> Configure the padding content for the circuit ID sub-option: dhcp-snooping information [vlan <i>vlan-id</i>] circuit-id string <i>circuit-id</i> Configure the padding content for the remote ID sub-option: dhcp-snooping information [vlan <i>vlan-id</i>] remote-id string { <i>remote-id</i> sysname } Configure the padding content for the sub-option 9: dhcp-snooping information [vlan <i>vlan-id</i>] sub-option <i>sub-option-code</i> [string <i>user-string</i>&<1-8>] 	<p>Optional.</p> <p>By default,</p> <ul style="list-style-type: none"> The padding content for the circuit ID sub-option depends on the padding format of Option 82. The padding content for the remote ID sub-option depends on the padding format of Option 82. Sub-option 9 is not padded.

Configuring DHCP snooping entries backup

DHCP snooping entries cannot survive a reboot. If the DHCP snooping device is rebooted, security modules (such as IP source guard) that use DHCP snooping entries to authenticate users will reject requests from clients until new entries are learned.

The DHCP snooping entries backup feature enables you to store DHCP snooping entries in a file. When the DHCP snooping device reboots, it reads DHCP snooping entries from this file.

After DHCP snooping is disabled with the **undo dhcp-snooping** command, the device will delete all DHCP snooping entries, including those stored in the file.

To configure DHCP snooping entries backup:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify the name of the file for storing DHCP snooping entries.	dhcp-snooping binding database filename <i>filename</i>	Not specified by default. DHCP snooping entries are stored immediately after this command is used and then updated at the interval set by the dhcp-snooping binding database update interval command.
3. Back up DHCP snooping entries to the file.	dhcp-snooping binding database update now	Optional. DHCP snooping entries will be stored to the file each time this command is used.
4. Set the interval at which the DHCP snooping entry file is refreshed.	dhcp-snooping binding database update interval <i>minutes</i>	Optional. By default, the file is not refreshed periodically.

Enabling DHCP starvation attack protection

A DHCP starvation attack occurs when an attacker constantly sends forged DHCP requests using different MAC addresses in the chaddr field to a DHCP server. This exhausts the IP address resources of the DHCP server so legitimate DHCP clients cannot obtain IP addresses. The DHCP server may also fail to work because of exhaustion of system resources. You can protect against starvation attacks in the following ways:

- To relieve a DHCP starvation attack that uses DHCP packets encapsulated with different source MAC addresses, you can limit the number of MAC addresses that a Layer 2 port can learn.
- To prevent a DHCP starvation attack that uses DHCP requests encapsulated with the same source MAC address, enable MAC address check on the DHCP snooping device. With this function enabled, the DHCP snooping device compares the chaddr field of a received DHCP request with the source MAC address field of the frame. If they are the same, the request is considered valid and forwarded to the DHCP server; if not, the request is discarded.

Enable MAC address check only on Layer 2 Ethernet ports and Layer 2 aggregate interfaces.

To enable MAC address check:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable MAC address check.	dhcp-snooping check mac-address	Disabled by default

Enabling DHCP-REQUEST message attack protection

Attackers may forge DHCP-REQUEST messages to renew the IP address leases for legitimate DHCP clients that no longer need the IP addresses. These forged messages keep a victim DHCP server renewing the leases of IP addresses instead of releasing the IP addresses. This wastes IP address resources.

To prevent such attacks, you can enable DHCP-REQUEST message check on DHCP snooping devices. With this feature enabled, upon receiving a DHCP-REQUEST message, a DHCP snooping device looks up local DHCP snooping entries for the corresponding entry of the message. If an entry is found, the DHCP snooping device compares the entry with the message information. If they are consistent, the DHCP-REQUEST message is considered a valid lease renewal request and forwarded to the DHCP server. If they are not consistent, the message is considered a forged lease renewal request and discarded. If no corresponding entry is found, the message is considered valid and forwarded to the DHCP server.

Enable DHCP-REQUEST message check only on Layer 2 Ethernet ports, and Layer 2 aggregate interfaces.

To enable DHCP-REQUEST message check:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable DHCP-REQUEST message check.	dhcp-snooping check request-message	Disabled by default

Configuring DHCP packet rate limit

Configuration guidelines

- You can configure DHCP packet rate limit only on Layer 2 Ethernet ports and Layer 2 aggregate interfaces.
- If a Layer 2 Ethernet port belongs to an aggregation group, it uses the DHCP packet maximum rate configured on the corresponding Layer 2 aggregate interface.
- To identify DHCP packets from unauthorized DHCP servers, DHCP snooping delivers all incoming DHCP packets to the CPU. If a malicious user sends a large number of DHCP requests to the DHCP snooping device, the CPU of the device will be overloaded, and the device may even crash. To solve this problem, you can configure DHCP packet rate limit on relevant interfaces.

Configuration procedure

To configure DHCP packet rate limit:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet port view or Layer 2 aggregate interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
3. Configure the maximum rate of incoming DHCP packets.	dhcp-snooping rate-limit <i>rate</i>	Not configured by default

Displaying and maintaining DHCP snooping

Task	Command	Remarks
Display DHCP snooping entries.	display dhcp-snooping [<i>ip ip-address</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display Option 82 configuration information on the DHCP snooping device.	display dhcp-snooping information { all <i>interface interface-type</i> <i>interface-number</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display DHCP packet statistics on the DHCP snooping device.	display dhcp-snooping packet statistics [<i>slot slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about trusted ports.	display dhcp-snooping trust [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the DHCP snooping entry file information.	display dhcp-snooping binding database [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear DHCP snooping entries.	reset dhcp-snooping { all <i>ip ip-address</i> }	Available in user view
Clear DHCP packet statistics on the DHCP snooping device.	reset dhcp-snooping packet statistics [<i>slot slot-number</i>]	Available in user view

DHCP snooping configuration examples

DHCP snooping configuration example

Network requirements

As shown in [Figure 38](#), Switch B is connected to a DHCP server through GigabitEthernet 1/0/1, and to two DHCP clients through GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3. GigabitEthernet 1/0/1 forwards DHCP server responses while the other two do not.

Switch B records clients' IP-to-MAC address bindings in DHCP-REQUEST messages and DHCP-ACK messages received from trusted ports.

Figure 38 Network diagram

Configuration procedure

```
# Enable DHCP snooping.
<SwitchB> system-view
[SwitchB] dhcp-snooping

# Specify GigabitEthernet 1/0/1 as trusted.
[SwitchB] interface GigabitEthernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] dhcp-snooping trust
[SwitchB-GigabitEthernet1/0/1] quit
```

DHCP snooping Option 82 support configuration example

Network requirements

As shown in Figure 38, enable DHCP snooping and Option 82 support on Switch B.

- Configure the handling strategy for DHCP requests containing Option 82 as **replace**.
- On GigabitEthernet 1/0/2, configure the padding content for the circuit ID sub-option as **company001** and for the remote ID sub-option as **device001**.
- On GigabitEthernet 1/0/3, configure the padding format as **verbose**, access node identifier as **sysname**, and code type as **ascii** for Option 82.
- Switch B forwards DHCP requests to the DHCP server (Switch A) after replacing Option 82 in the requests, so that the DHCP clients can obtain IP addresses.

Configuration procedure

```
# Enable DHCP snooping.
<SwitchB> system-view
[SwitchB] dhcp-snooping

# Specify GigabitEthernet 1/0/1 as trusted.
[SwitchB] interface GigabitEthernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] dhcp-snooping trust
[SwitchB-GigabitEthernet1/0/1] quit

# Configure GigabitEthernet 1/0/2 to support Option 82.
[SwitchB] interface GigabitEthernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] dhcp-snooping information enable
[SwitchB-GigabitEthernet1/0/2] dhcp-snooping information strategy replace
```

```
[SwitchB-GigabitEthernet1/0/2] dhcp-snooping information circuit-id string company001
[SwitchB-GigabitEthernet1/0/2] dhcp-snooping information remote-id string device001
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 to support Option 82.

```
[SwitchB] interface GigabitEthernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] dhcp-snooping information enable
[SwitchB-GigabitEthernet1/0/3] dhcp-snooping information strategy replace
[SwitchB-GigabitEthernet1/0/3] dhcp-snooping information format verbose node-identifier
sysname
[SwitchB-GigabitEthernet1/0/3] dhcp-snooping information circuit-id format-type ascii
[SwitchB-GigabitEthernet1/0/3] dhcp-snooping information remote-id format-type ascii
```

Configuring BOOTP client

Overview

BOOTP application

After you specify an interface of a device as a BOOTP client, the interface can use BOOTP to get information (such as IP address) from the BOOTP server.

To use BOOTP, an administrator must configure a BOOTP parameter file for each BOOTP client on the BOOTP server. The parameter file contains information such as MAC address and IP address of a BOOTP client. When a BOOTP client sends a request to the BOOTP server, the BOOTP server searches for the BOOTP parameter file and returns the corresponding configuration information.

BOOTP is usually used in relatively stable environments. In network environments that change frequently, DHCP is more suitable.

Because a DHCP server can interact with a BOOTP client, you can use the DHCP server to configure an IP address for the BOOTP client, without any BOOTP server.

Obtaining an IP address dynamically

A BOOTP client dynamically obtains an IP address from a BOOTP server in the following steps:

1. The BOOTP client broadcasts a BOOTP request, which contains its own MAC address.
2. The BOOTP server receives the request and searches the configuration file for the corresponding IP address and other information according to the MAC address of the BOOTP client. The BOOTP server then returns a BOOTP response to the BOOTP client.
3. The BOOTP client obtains the IP address from the received response.

A DHCP server can take the place of the BOOTP server in the above mentioned dynamic IP address acquisition.

Protocols and standards

- RFC 951, *Bootstrap Protocol (BOOTP)*
- RFC 2132, *DHCP Options and BOOTP Vendor Extensions*
- RFC 1542, *Clarifications and Extensions for the Bootstrap Protocol*

Configuration restrictions

- BOOTP client configuration only applies to Layer 3 Ethernet ports, Layer 3 aggregate interfaces and VLAN interfaces.
- If several VLAN interfaces sharing the same MAC address obtain IP addresses through a BOOTP relay agent, the BOOTP server cannot be a Windows Server 2000 or Windows Server 2003.
- You cannot configure an interface of an aggregation group as a BOOTP client.

Configuring an interface to dynamically obtain an IP address through BOOTP

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an interface to dynamically obtain an IP address through BOOTP.	ip address bootp-alloc	By default, an interface does not use BOOTP to obtain an IP address.

Displaying and maintaining BOOTP client configuration

Task	Command	Remarks
Display BOOTP client information.	display bootp client [interface <i>interface-type</i> <i>interface-number</i>] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view

BOOTP client configuration example

Network requirements

As shown in [Figure 30](#), Switch B's port belonging to VLAN 1 is connected to the LAN. VLAN-interface 1 obtains an IP address from the DHCP server by using BOOTP.

Configuration procedure

The following describes only the configuration on Switch B serving as a client.

Configure VLAN-interface 1 to dynamically obtain an IP address from the DHCP server.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address bootp-alloc
```

Use the **display bootp client** command to view the IP address assigned to the BOOTP client.

To make the BOOTP client obtain an IP address from the DHCP server, you must perform additional configurations on the DHCP server. For more information, see "[Configuring DHCP server.](#)"

Configuring IPv4 DNS

Overview

Domain Name System (DNS) is a distributed database used by TCP/IP applications to translate domain names into corresponding IP addresses. With DNS, you can use easy-to-remember domain names in some applications and let the DNS server translate them into correct IP addresses.

DNS services can be static or dynamic. After a user specifies a name, the device checks the local static name resolution table for an IP address. If no IP address is available, it contacts the DNS server for dynamic name resolution, which takes more time than static name resolution. To improve efficiency, you can put frequently queried name-to-IP address mappings in the local static name resolution table.

Static domain name resolution

Static domain name resolution means setting up mappings between domain names and IP addresses. IP addresses of the corresponding domain names can be found in the static domain resolution table when you use applications such as Telnet.

Dynamic domain name resolution

1. A user program sends a name query to the resolver of the DNS client.
2. The DNS resolver looks up the local domain name cache for a match. If the resolver finds a match, it sends the corresponding IP address back. If not, it sends a query to the DNS server.
3. The DNS server looks up the corresponding IP address of the domain name in its DNS database. If no match is found, the server sends a query to a higher level DNS server. This process continues until a result, whether successful or not, is returned.
4. After receiving a response from the DNS server, the DNS client returns the resolution result to the application.

Figure 39 Dynamic domain name resolution

Figure 39 shows the relationship between the user program, DNS client, and DNS server.

The DNS client is made up of the resolver and cache. The user program and DNS client can run on the same device or different devices, but the DNS server and the DNS client usually run on different devices.

Dynamic domain name resolution allows the DNS client to store latest mappings between domain names and IP addresses in the dynamic domain name cache. The DNS client does not need to send a request to the DNS server for a repeated query next time. The aged mappings are removed from the cache after some time, and latest entries are required from the DNS server. The DNS server decides how long a mapping is valid, and the DNS client gets the aging information from DNS messages.

DNS suffixes

The DNS client holds a list of suffixes which the user sets. The resolver can use the list to supply the missing part of incomplete names.

For example, a user can configure com as the suffix for aabbcc.com. The user only needs to type aabbcc to obtain the IP address of aabbcc.com because the resolver adds the suffix and delimiter before passing the name to the DNS server.

- If there is no dot (.) in the domain name (for example, aabbcc), the resolver considers this a host name and adds a DNS suffix before the query. If no match is found after all the configured suffixes are used, the original domain name (for example, aabbcc) is used for the query.
- If there is a dot (.) in the domain name (for example, www.aabbcc), the resolver directly uses this domain name for the query. If the query fails, the resolver adds a DNS suffix for another query.
- If the dot (.) is at the end of the domain name (for example, aabbcc.com.), the resolver considers it a Fully Qualified Domain Name (FQDN) and returns the query result, successful or failed. The dot (.) is considered a terminating symbol.

The device supports static and dynamic DNS client services.

NOTE:

If an alias is configured for a domain name on the DNS server, the device can resolve the alias into the IP address of the host.

DNS proxy

A DNS proxy forwards DNS requests and replies between DNS clients and a DNS server.

As shown in [Figure 40](#), a DNS client sends a DNS request to the DNS proxy, which forwards the request to the designated DNS server, and conveys the reply from the DNS server to the client.

The DNS proxy simplifies network management. When the DNS server address is changed, you can change the configuration on only the DNS proxy instead of on each DNS client.

Figure 40 DNS proxy networking application

A DNS proxy operates as follows:

1. A DNS client considers the DNS proxy as the DNS server, and sends a DNS request to the DNS proxy. The destination address of the request is the IP address of the DNS proxy.
2. The DNS proxy searches the local static domain name resolution table and dynamic domain name resolution table after receiving the request. If the requested information is found, the DNS proxy returns a DNS reply to the client.
3. If the requested information is not found, the DNS proxy sends the request to the designated DNS server for domain name resolution.
4. After receiving a reply from the DNS server, the DNS proxy records the IP address-to-domain name mapping and forwards the reply to the DNS client.

With no DNS server or route to a DNS server specified, the DNS proxy does not forward DNS requests, or answer requests from the DNS clients.

DNS spoofing

DNS spoofing is applied to the dial-up network, as shown in [Figure 41](#).

- The device connects to the PSTN/ISDN network through a dial-up interface and triggers the establishment of a dial-up connection only when packets are to be forwarded through the dial-up interface.
- The device serves as a DNS proxy and is specified as a DNS server on the hosts. After the dial-up connection is established through the dial-up interface, the device dynamically obtains the DNS server address through DHCP or other autoconfiguration mechanisms.

Figure 41 Application of DNS spoofing

Without DNS spoofing enabled, the device forwards the DNS requests received from the hosts to the DNS server, if it cannot find a match in the local domain name resolution table. However, without any dial-up connection established, the device cannot obtain the DNS server address, so it cannot forward or answer the requests from the clients. The domain name cannot be resolved and no traffic triggers the establishment of a dial-up connection.

DNS spoofing can solve this problem. DNS spoofing enables the device to reply the DNS client with a configured IP address when the device does not have a DNS server address or route to a DNS server. Subsequent packets sent by the DNS client trigger the establishment of a dial-up connection with the network.

In the network of [Figure 41](#), a host accesses the HTTP server in following these steps:

1. The host sends a DNS request to the device to resolve the domain name of the HTTP server into an IP address.
2. Upon receiving the request, the device searches the local static and dynamic DNS entries for a match. If no match is found and the device does know the DNS server address, the device spoofs the host by replying a configured IP address. The TTL of the DNS reply is 0. The device must have a route to the IP address with the dial-up interface as the outgoing interface.
3. Upon receiving the reply, the host sends an HTTP request to the replied IP address.
4. When forwarding the HTTP request through the dial-up interface, the device establishes a dial-up connection with the network and dynamically obtains the DNS server address through DHCP or other autoconfiguration mechanisms.
5. When the DNS reply ages out, the host sends a DNS request to the device again.
6. Then the device operates the same as a DNS proxy. For more information, see "[A DNS proxy operates as follows:](#)"
7. After obtaining the IP address of the HTTP server, the host can access the HTTP server.

Because the IP address configured with DNS spoofing is not the actual IP address of the requested domain name, the TTL of the DNS reply is set to 0 to prevent the DNS client from generating incorrect domain name-to-IP address mappings.

Configuring the IPv4 DNS client

Configuring static domain name resolution

Configuring static domain name resolution refers to specifying the mappings between host names and IPv4 addresses. Static domain name resolution allows applications such as Telnet to contact hosts by using host names instead of IPv4 addresses.

Follow these guidelines when you configure static domain name resolution:

- The IPv4 address you last assign to the host name will overwrite the previous one if there is any.
- You may create up to 50 static mappings between domain names and IPv4 addresses.

To configure static domain name resolution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a mapping between a host name and an IPv4 address.	ip host <i>hostname ip-address</i>	Not configured by default

Configuring dynamic domain name resolution

To send DNS queries to a correct server for resolution, dynamic domain name resolution needs to be enabled and a DNS server needs to be configured.

In addition, you can configure a DNS suffix that the system will automatically add to the provided domain name for resolution.

Configuration restrictions and guidelines

- You can configure up to six DNS servers, including those with IPv6 addresses, in system view, and up to six DNS servers on all interfaces of a device.
- A DNS server configured in system view has a higher priority than one configured in interface view. A DNS server configured earlier has a higher priority than one configured later in the same view. A DNS server manually configured has a higher priority than one dynamically obtained through DHCP. A name query request is first sent to the DNS server that has the highest priority. If no reply is received, it is sent to the DNS server that has the second highest priority, and thus in turn.
- You can specify up to ten DNS suffixes.

Configuration procedure

To configure dynamic domain name resolution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable dynamic domain name resolution.	dns resolve	Disabled by default.
3. Specify a DNS server.	<ul style="list-style-type: none">• (Approach 1) In System view: dns server ip-address• (Approach 2) In interface view:<ul style="list-style-type: none">a. interface interface-type interface-numberb. dns server ip-addressc. quit	Use either approach. Not specified by default.
4. Configure a DNS suffix.	dns domain domain-name	Optional. Not configured by default. Only the provided domain name is resolved.

Configuring the DNS proxy

You can specify multiple DNS servers by using the **dns server** command repeatedly. Upon receiving a name query request from a client, the DNS proxy forwards the request to the DNS server that has the highest priority. If having not received a reply, it forwards the request to a DNS server that has the second highest priority, and thus in turn.

To configure the DNS proxy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable DNS proxy.	dns proxy enable	Disabled by default.

Step	Command	Remarks
3. Specify a DNS server.	<ul style="list-style-type: none"> (Approach 1) In system view: dns server <i>ip-address</i> (Approach 2) In interface view: <ul style="list-style-type: none"> a. interface <i>interface-type</i> <i>interface-number</i> b. dns server <i>ip-address</i> 	<p>Use either approach.</p> <p>No DNS server is specified by default.</p>

Configuring DNS spoofing

DNS spoofing is effective only when:

- The DNS proxy is enabled on the device.
- No DNS server or route to any DNS server is specified on the device.

To configure DNS spoofing:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable DNS spoofing and specify the translated IP address.	dns spoofing <i>ip-address</i>	Disabled by default

Setting the DSCP value for DNS packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for DNS packets.	dns dscp <i>dscp-value</i>	<p>Optional.</p> <p>By default, the DSCP value for DNS packets is 0.</p>

Specifying the source interface for DNS packets

By default, the device uses the primary IP address of the output interface of the matching route as the source IP address of a DNS request. Therefore, the source IP address of the DNS packets may vary with DNS servers. In some scenarios, the DNS server only responds to DNS requests sourced from a specific IP address. In such cases, you must specify the source interface for the DNS packets so that the device can always use the primary IP address of the specified source interface as the source IP address of DNS packets.

To specify the source interface for DNS packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Set the DSCP value for DNS packets.	dns source-interface <i>interface-type interface-number</i>	By default, no source interface for DNS packets is specified. The device uses the primary IP address of the output interface of the matching route as the source IP address of a DNS request.

Displaying and maintaining IPv4 DNS

Task	Command	Remarks
Display the static IPv4 domain name resolution table.	display ip host [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv4 DNS server information.	display dns server [dynamic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display DNS suffixes.	display dns domain [dynamic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information of the dynamic IPv4 domain name cache.	display dns host ip [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear the information of the dynamic IPv4 domain name cache.	reset dns host ip	Available in user view

Static domain name resolution configuration example

Network requirements

As shown in [Figure 42](#), the device wants to access the host by using an easy-to-remember domain name rather than an IP address.

Configure static domain name resolution on the device so that the device can use the domain name `host.com` to access the host whose IP address is `10.1.1.2`.

Figure 42 Network diagram

Configuration procedure

Configure a mapping between host name `host.com` and IP address `10.1.1.2`.

```

<Sysname> system-view
[Sysname] ip host host.com 10.1.1.2
# Use the ping host.com command to verify that the device can use static domain name resolution to
resolve domain name host.com into IP address 10.1.1.2.
[Sysname] ping host.com
  PING host.com (10.1.1.2):
  56 data bytes, press CTRL_C to break
    Reply from 10.1.1.2: bytes=56 Sequence=1 ttl=128 time=1 ms
    Reply from 10.1.1.2: bytes=56 Sequence=2 ttl=128 time=4 ms
    Reply from 10.1.1.2: bytes=56 Sequence=3 ttl=128 time=3 ms
    Reply from 10.1.1.2: bytes=56 Sequence=4 ttl=128 time=2 ms
    Reply from 10.1.1.2: bytes=56 Sequence=5 ttl=128 time=3 ms

--- host.com ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 1/2/4 ms

```

Dynamic domain name resolution configuration example

Network requirements

As shown in [Figure 43](#), the device wants to access the host by using an easy-to-remember domain name rather than an IP address, and to request the DNS server on the network for an IP address by using dynamic domain name resolution. The IP address of the DNS server is 2.1.1.2/16 and the DNS server has a com domain, which stores the mapping between domain name host and IP address 3.1.1.1/16.

Configure dynamic domain name resolution and the domain name suffix com on the device that serves as a DNS client so that the device can use domain name host to access the host with the domain name host.com and the IP address 3.1.1.1/16.

Figure 43 Network diagram

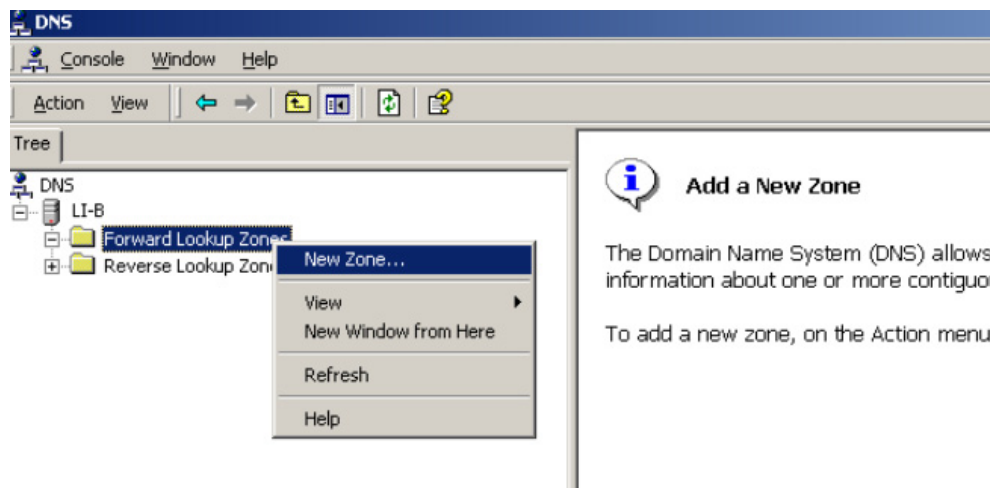

Configuration procedure

Before performing the following configuration, make sure that the device and the host are accessible to each other via available routes, and that the IP addresses of the interfaces are configured as shown [Figure 43](#).

This configuration may vary with DNS servers. The following configuration is performed on a PC running Windows Server 2000.

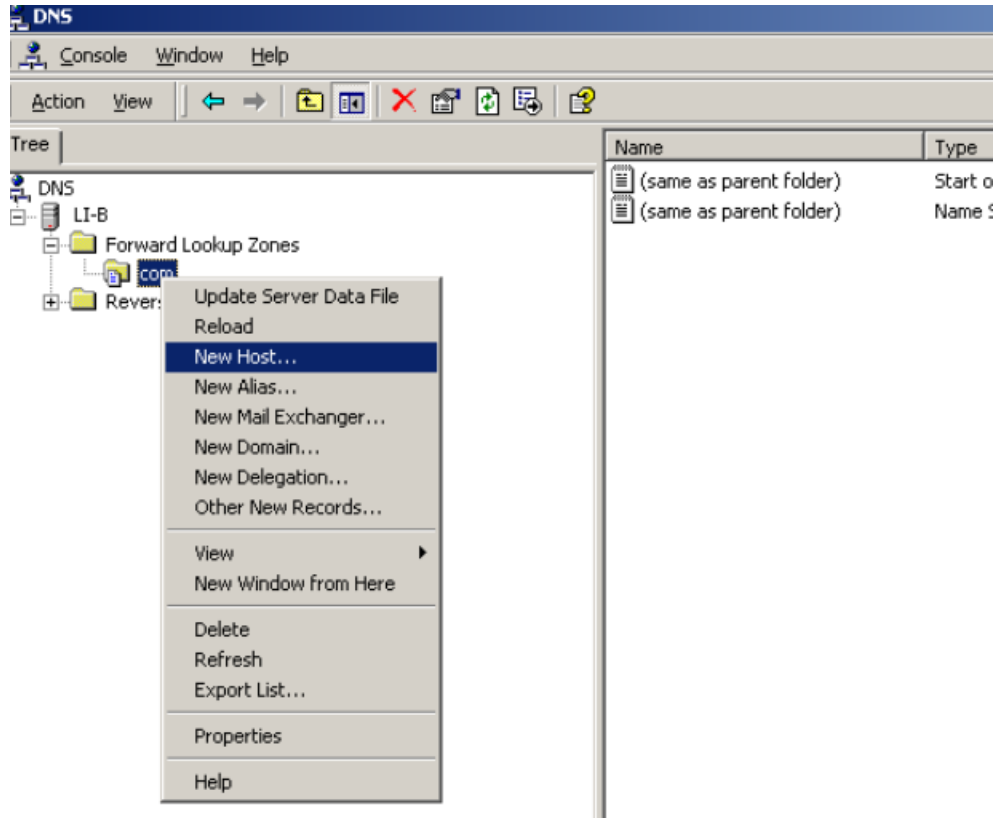

1. Configure the DNS server:
 - a. Select **Start > Programs > Administrative Tools > DNS**.
The DNS server configuration page appears, as shown in [Figure 44](#).
 - b. Right click **Forward Lookup Zones**, select **New Zone**, and then follow the steps to create a new zone named **com**.

Figure 44 Creating a zone

- a. On the DNS server configuration page, right click zone **com**, and select **New Host**.

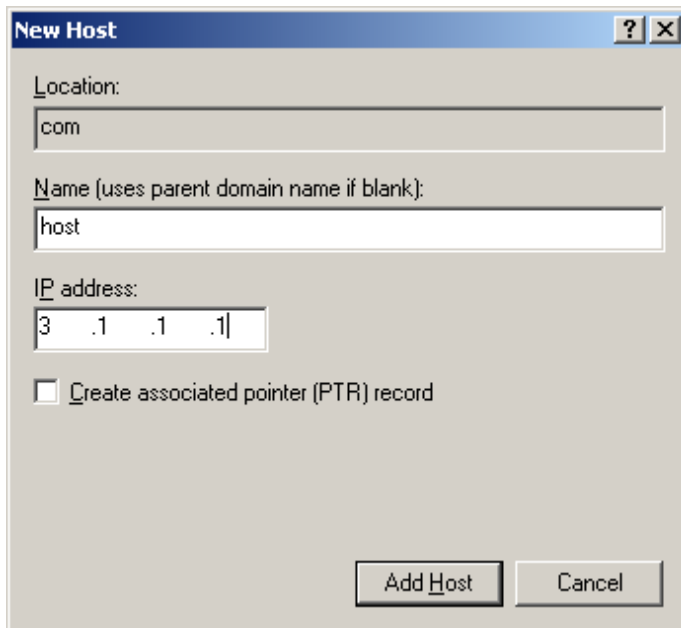

Figure 45 Adding a host

- d. On the page that appears, enter host name **host** and IP address **3.1.1.1**.
- e. Click **Add Host**.

The mapping between the IP address and host name is created.

Figure 46 Adding a mapping between domain name and IP address

- 2. Configure the DNS client:

```
# Enable dynamic domain name resolution.
<Sysname> system-view
[Sysname] dns resolve
# Specify the DNS server 2.1.1.2.
[Sysname] dns server 2.1.1.2
# Configure com as the name suffix.
[Sysname] dns domain com
```

Verifying the configuration

Use the **ping host** command on the device to verify that the communication between the device and the host is normal and that the corresponding destination IP address is 3.1.1.1.

```
[Sysname] ping host
Trying DNS resolve, press CTRL_C to break
Trying DNS server (2.1.1.2)
PING host.com (3.1.1.1):
56 data bytes, press CTRL_C to break
  Reply from 3.1.1.1: bytes=56 Sequence=1 ttl=126 time=3 ms
  Reply from 3.1.1.1: bytes=56 Sequence=2 ttl=126 time=1 ms
  Reply from 3.1.1.1: bytes=56 Sequence=3 ttl=126 time=1 ms
  Reply from 3.1.1.1: bytes=56 Sequence=4 ttl=126 time=1 ms
  Reply from 3.1.1.1: bytes=56 Sequence=5 ttl=126 time=1 ms

--- host.com ping statistics ---
 5 packet(s) transmitted
 5 packet(s) received
 0.00% packet loss
 round-trip min/avg/max = 1/1/3 ms
```

DNS proxy configuration example

Network requirements

When the IP address of the DNS server changes, you must configure the new IP address of the DNS server on each device on the LAN. To simplify network management, you can use the DNS proxy function.

As shown in [Figure 47](#):

- Specify Device A as the DNS server of Device B (the DNS client). Device A acts as a DNS proxy. The IP address of the real DNS server is 4.1.1.1.
- Configure the IP address of the DNS proxy on Device B. DNS requests of Device B are forwarded to the real DNS server through the DNS proxy.

Figure 47 Network diagram

Configuration procedure

Before performing the following configuration, assume that Device A, the DNS server, and the host are reachable to each other and the IP addresses of the interfaces are configured as shown in [Figure 47](#).

1. Configure the DNS server:
This configuration may vary with different DNS servers. When a PC running Windows Server 2000 acts as the DNS server, see "[Dynamic domain name resolution configuration example](#)" for related configuration information.

2. Configure the DNS proxy:
Specify the DNS server 4.1.1.1.
<DeviceA> system-view
[DeviceA] dns server 4.1.1.1
Enable DNS proxy.
[DeviceA] dns proxy enable

3. Configure the DNS client:
Enable the domain name resolution function.
<DeviceB> system-view
[DeviceB] dns resolve
Specify the DNS server 2.1.1.2.
[DeviceB] dns server 2.1.1.2

Verifying the configuration

Execute the **ping host.com** command on Device B to verify that the communication between the device and the host is normal and that the corresponding destination IP address is 3.1.1.1.

```
[DeviceB] ping host.com
Trying DNS resolve, press CTRL_C to break
Trying DNS server (2.1.1.2)
PING host.com (3.1.1.1):
56 data bytes, press CTRL_C to break
```

```
Reply from 3.1.1.1: bytes=56 Sequence=1 ttl=126 time=3 ms
Reply from 3.1.1.1: bytes=56 Sequence=2 ttl=126 time=1 ms
Reply from 3.1.1.1: bytes=56 Sequence=3 ttl=126 time=1 ms
Reply from 3.1.1.1: bytes=56 Sequence=4 ttl=126 time=1 ms
Reply from 3.1.1.1: bytes=56 Sequence=5 ttl=126 time=1 ms

--- host.com ping statistics ---
 5 packet(s) transmitted
 5 packet(s) received
 0.00% packet loss
round-trip min/avg/max = 1/1/3 ms
```

Troubleshooting IPv4 DNS configuration

Symptom

After enabling dynamic domain name resolution, the user cannot get the correct IP address.

Solution

1. Use the **display dns host ip** command to verify that the specified domain name is in the cache.
2. If the specified domain name does not exist, verify that dynamic domain name resolution is enabled and that the DNS client can communicate with the DNS server.
3. If the specified domain name is in the cache, but the IP address is incorrect, verify that the DNS client has the correct IP address of the DNS server.
4. Verify that the mapping between the domain name and IP address is correct on the DNS server.

Configuring IRDP

Overview

As an extension of the Internet Control Message Protocol (ICMP), the ICMP Router Discovery Protocol (IRDP) enables hosts to discover the IP addresses of their neighboring routers and set their default routes.

NOTE:

The hosts in this chapter support IRDP.

Background

Before a host can send packets to another network, it must know the IP address of at least one router on the local subnet. The host can obtain this information either through manual configuration, or from routing protocol packets sent by routers on the local subnet.

Both methods have disadvantages. The first method requires the administrator to manually configure and maintain router address information on hosts, and cannot track dynamic changes. The second method requires hosts to recognize various routing protocols, and will fail to work if no routing protocol runs on the local subnet.

IRDP was introduced to solve the problem. IRDP uses two new types of ICMP messages to allow hosts to discover neighboring routers. IRDP adapts to dynamic changes, requires less manual configuration, and does not rely on any routing protocols.

Working mechanism

IRDP uses the following types of ICMP messages.

- **Router advertisement (RA)**—Sent by a router to advertise its IP address and preference.
- **Router solicitation (RS)**—Sent by a host to voluntarily request the IP addresses of routers on the subnet.

IRDP operates in the following steps:

1. A router periodically broadcasts or multicasts an RA, which contains the IP addresses (including the primary IP address and manually configured secondary IP addresses) of interfaces. Hosts listen for RAs to obtain the IP addresses of neighboring routers.
2. Rather than wait for RAs, a newly attached host can voluntarily send an RS to request immediate RAs for the IP addresses of routers on the subnet. If no response to the RS is received, the host retransmits the RS several times. If the host still receives no RAs, it will obtain the IP addresses of routers from periodic RAs.
3. Upon receiving an RA, a host adds the IP addresses in the RA to its routing table. The host selects the IP address with the highest preference among all obtained IP addresses as the default gateway.

IRDP allows hosts to locate routers, but does not suggest the best route to a specific destination. If a host selects a router that is not the best next hop to a specific destination, the router will send back an ICMP redirect message to provide a better next hop.

Concepts

Preference of an IP address

Every IP address advertised in RAs has a preference value. The IP address with the highest preference is selected as the default router address.

You can configure the preference for IP addresses advertised on a router interface.

The bigger the preference value, the higher the preference. The minimum preference value (-2147483648) is used to indicate that the address, even though it may be advertised, is not to be used by neighboring hosts as a default router address.

Lifetime of an IP address

An RA contains a lifetime field that specifies the lifetime of advertised IP addresses. If no new RA for an IP address is received within the lifetime of the IP address, the host removes the corresponding route information.

All the IP addresses advertised by an interface have the same lifetime.

Advertising interval

A router interface with IRDP enabled sends out RAs at a random interval between the minimum advertising interval and the maximum advertising interval. This mechanism prevents the local link from being overloaded by a large number of RAs sent simultaneously from routers.

HP recommends shortening the advertising interval on a link that suffers high packet loss rates.

Destination address of RAs

An RA uses either of the two destination IP addresses:

- broadcast address 255.255.255.255.
- Multicast address 224.0.0.1, which identifies all the hosts on the local subnet.

By default, the destination IP address of an RA is the broadcast address. If the interface that sends RAs supports multicast, configure 224.0.0.1 as the destination IP address.

Proxy-advertised IP addresses

By default, an interface advertises its primary IP address and manually configured secondary IP addresses. You can configure other IP addresses for an interface to proxy-advertise.

Protocols and standards

RFC 1256, *ICMP Router Discovery Messages*

Configuration procedure

IRDP configuration takes effect only when IRDP is enabled.

To configure IRDP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	The interface can be a Layer 3 Ethernet port or VLAN interface.
3. Enable IRDP on the interface.	ip irdp	Disabled by default.
4. Configure the preference of advertised IP addresses.	ip irdp preference <i>preference-value</i>	Optional. The preference defaults to 0. The specified preference applies to all advertised IP addresses, including the primary IP address and the manually configured secondary IP addresses of the interface.
5. Set the lifetime of advertised IP addresses.	ip irdp lifetime <i>life-number</i>	Optional. 1800 seconds by default. The specified lifetime applies to all advertised IP addresses, including the IP address of the interface and proxy-advertised IP addresses on the interface.
6. Set the minimum advertising interval.	ip irdp minadvinterval <i>min-value</i>	Optional. 450 seconds by default.
7. Set the maximum advertising interval.	ip irdp maxadvinterval <i>max-value</i>	Optional. 600 seconds by default.
8. Configure the multicast address (224.0.0.1) as the destination IP address of RAs.	ip irdp multicast	Optional. By default, RAs use the broadcast address 255.255.255.255 as the destination IP address.
9. Specify a proxy-advertised IP address and its preference.	ip irdp address <i>ip-address</i> <i>preference</i>	Optional.

IRDP configuration example

Network requirements

Host A and Host B that run Linux operating systems reside in the internal network of a company. Switch A and Switch B serve as the egress routers and connect to external networks 192.168.1.0/24 and 192.168.2.0/24 respectively.

Configure Switch A as the default gateway of the hosts. The packets to the external networks can be properly routed.

Figure 48 Network diagram

Configuration procedure

1. Configure Switch A:

Specify the IP address for VLAN-interface 100.

```
<SwitchA> system-view
[SwitchA] interface Vlan-interface 100
[SwitchA-Vlan-interface100] ip address 10.154.5.1 24
```

Enable IRDP on VLAN-interface 100.

```
[SwitchA-Vlan-interface100] ip irdp
```

Specify preference 1000 for the IP address of VLAN-interface 100.

```
[SwitchA-Vlan-interface100] ip irdp preference 1000
```

Configure the multicast address 224.0.0.1 as the destination IP address for RAs sent by VLAN-interface 100.

```
[SwitchA-Vlan-interface100] ip irdp multicast
```

Specify the IP address 192.168.1.0 and preference 400 for VLAN-interface 100 to proxy-advertise.

```
[SwitchA-Vlan-interface100] ip irdp address 192.168.1.0 400
```

2. Configure Switch B:

Specify the IP address of VLAN-interface 100.

```
<SwitchB> system-view
[SwitchB] interface Vlan-interface 100
[SwitchB-Vlan-interface100] ip address 10.154.5.2 24
```

Enable IRDP on VLAN-interface 100.

```
[SwitchB-Vlan-interface100] ip irdp
```

Specify preference 500 for the IP address of VLAN-interface 100.

```
[SwitchB-Vlan-interface100] ip irdp preference 500
```

Configure the multicast address 224.0.0.1 as the destination IP address for RAs sent by VLAN-interface 100.

```
[SwitchB-Vlan-interface100] ip irdp multicast
```

Specify the IP address 192.168.2.0 and preference 400 for VLAN-interface 100 to proxy-advertise.

```
[SwitchB-Vlan-interface100] ip irdp address 192.168.2.0 400
```

Verifying the configuration

After enabling IRDP on Host A and Host B, display the routing table for the hosts (Host A for example).

```
[HostA@localhost ~]$ netstat -rne
```

```
Kernel IP routing table
```

Destination	Gateway	Genmask	Flags	Metric	Ref	Use	Iface
10.154.5.0	0.0.0.0	255.255.255.0	U	0	0	0	eth1
192.168.1.0	0.0.0.0	255.255.255.0	U	0	0	0	eth1
192.168.2.0	0.0.0.0	255.255.255.0	U	0	0	0	eth1
0.0.0.0	10.154.5.1	0.0.0.0	UG	0	0	0	eth1

The output shows that the default route on Host A points to IP address 10.154.5.1, and Host A has routes to 192.168.1.0/24 and 192.168.2.0/24.

Configuring IP performance optimization

Only the HP 5500 EI switch series supports configuring IP performance optimization on Layer 3 Ethernet interfaces.

The term "interface" in this chapter refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

Enabling receiving and forwarding of directed broadcasts to a directly connected network

Directed broadcast packets are broadcast on a specific network. In the destination IP address of a directed broadcast, the network ID identifies the target network, and the host ID is made up of all ones. If a device is allowed to forward directed broadcasts to a directly connected network, hackers may mount attacks to the network. However, you can enable the feature by using the UDP Helper function to convert broadcasts to unicasts and forward them to a specified server.

Enabling receiving of directed broadcasts to a directly connected network

If the switch is enabled to receive directed broadcasts, the switch determines whether to forward them according to the configuration on the outgoing interface.

To enable the device to receive directed broadcasts:

Step	Command
1. Enter system view.	system-view
2. Enable the device to receive directed broadcasts.	ip forward-broadcast

Enabling forwarding of directed broadcasts to a directly connected network

Follow these guidelines when you enable the device to forward directed broadcasts:

- If an ACL is referenced in the **ip forward-broadcast** command, only packets permitted by the ACL can be forwarded.
- If you repeatedly execute the **ip forward-broadcast** command on an interface, only the last command takes effect. If the command executed last does not include **acl acl-number**, the ACL configured previously is removed.

To enable the device to forward directed broadcasts:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Enable the interface to forward directed broadcasts.	ip forward-broadcast [acl <i>acl-number</i>]	Disabled by default

Configuration example

Network requirements

As shown in Figure 49, the host's interface and VLAN-interface 3 of the switch are on the same network segment (1.1.1.0/24). VLAN-interface 2 of Switch and the server are on another network segment (2.2.2.0/24). The default gateway of the host is VLAN-interface 3 (IP address 1.1.1.2/24) of Switch.

Configure the switch so that the server can receive directed broadcasts from the host to IP address 2.2.2.255.

Figure 49 Network diagram

Configuration procedure

Enable the switch to receive directed broadcasts.

```
<Switch> system-view
[Switch] ip forward-broadcast
```

Configure IP addresses for VLAN-interface 3 and VLAN-interface 2.

```
[Switch] interface vlan-interface 3
[Switch-Vlan-interface3] ip address 1.1.1.2 24
[Switch-Vlan-interface3] quit
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 2.2.2.2 24
```

Enable VLAN-interface 2 to forward directed broadcasts.

```
[Switch-Vlan-interface2] ip forward-broadcast
```

Configuring TCP attributes

Configuring TCP path MTU discovery

ⓘ IMPORTANT:

All the devices on the TCP path must be enabled to send ICMP error messages by using the **ip unreachable enable** command.

TCP path MTU discovery (in RFC 1191) discovers the path MTU between the source and destination ends of a TCP connection. It works as follows:

1. A TCP source device sends a packet with the Don't Fragment (DF) bit set.
2. A router that fails to forward the packet because it exceeds the MTU on the outgoing interface discards the packet and returns an ICMP error message, which contains the MTU of the outgoing interface.
3. Upon receiving the ICMP message, the TCP source device calculates the current path MTU of the TCP connection.
4. The TCP source device sends subsequent TCP segments that each are smaller than the MSS (MSS = path MTU - IP header length - TCP header length).

If the TCP source device still receives ICMP error messages when the MSS is smaller than 32 bytes, the TCP source device will fragment packets.

An ICMP error message received from a router that does not support RFC 1191 has the MTU of the outgoing interface set to 0. Upon receiving the ICMP message, the TCP source device selects the path MTU smaller than the current path MTU from the MTU table as described in RFC 1191 to calculate the TCP MSS. The MTU table contains MTUs of 68, 296, 508, 1006, 1280, 1492, 2002, 4352, 8166, 17914, 32000, and 65535 bytes. Because the minimum TCP MSS specified by the system is 32 bytes, the actual minimum MTU is 72 bytes.

After you enable TCP path MTU discovery, all new TCP connections will detect the path MTU. The device uses the path MTU to calculate the MSS to avoid IP fragmentation.

The path MTU uses an aging mechanism to make sure that the source device can increase the path MTU when the minimum link MTU on the path increases.

- When the TCP source device receives an ICMP error message, it reduces the path MTU and starts an age timer for the path MTU.
- After the age timer expires, the source device uses a larger MSS in the MTU table as described in RFC 1191.
- If no ICMP error message is received within two minutes, the source device increases the MSS again until the MSS is as large as the MSS negotiated during TCP three-way handshake.

To enable TCP path MTU discovery:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable TCP path MTU discovery.	tcp path-mtu-discovery [aging <i>minutes</i> no-aging]	Optional. Disabled by default.

Configuring the TCP send/receive buffer size

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the size of TCP send/receive buffer.	tcp window <i>window-size</i>	Optional. 8 KB by default.

Configuring TCP timers

You can configure the following TCP timers:

- **synwait timer**—When sending a SYN packet, TCP starts the synwait timer. If no response packet is received within the synwait timer interval, the TCP connection cannot be created.
- **finwait timer**—When a TCP connection is changed into FIN_WAIT_2 state, the finwait timer is started. If no FIN packet is received within the timer interval, the TCP connection is terminated. If a FIN packet is received, the TCP connection state changes to TIME_WAIT. If a non-FIN packet is received, the system restarts the timer upon receiving the last non-FIN packet. The connection is broken after the timer expires.

The actual length of the finwait timer is determined by the following formula:

Actual length of the finwait timer = (Configured length of the finwait timer – 75) + configured length of the synwait timer

To configure TCP timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the TCP synwait timer.	tcp timer syn-timeout <i>time-value</i>	Optional. 75 seconds by default.
3. Configure the TCP finwait timer.	tcp timer fin-timeout <i>time-value</i>	Optional. 675 seconds by default.

Configuring ICMP to send error packets

Sending error packets is a major function of ICMP. In case of network abnormalities, error packets are usually sent by the network or transport layer protocols to notify corresponding devices so as to facilitate control and management.

Advantages of sending ICMP error packets

ICMP error packets include the following types:

- ICMP redirect packets

A host may have only a default route to the default gateway in its routing table after startup. If the following conditions are satisfied, the default gateway will send ICMP redirect packets to the source host, telling it to reselect a correct next hop to send the subsequent packets:

- The receiving and forwarding interfaces are the same.
- The selected route has not been created or modified by an ICMP redirect packet.
- The selected route is not the default route of the device.
- There is no source route option in the packet.

The ICMP redirect packets function simplifies host administration and enables a host to gradually establish a sound routing table to find the best route.

- ICMP timeout packets

If the device receives an IP packet with a timeout error, it drops the packet and sends an ICMP timeout packet to the source.

The device sends an ICMP timeout packet under the following conditions:

- If the device finds that the destination of a packet is not itself and the TTL field of the packet is 1, it will send a "TTL timeout" ICMP error message.
- When the device receives the first fragment of an IP datagram whose destination is the device itself, it starts a timer. If the timer times out before all the fragments of the datagram are received, the device will send a "reassembly timeout" ICMP error packet.
- ICMP destination unreachable packets

If the device receives an IP packet with the destination unreachable, it will drop the packet and send an ICMP destination unreachable error packet to the source.

Conditions for sending an ICMP destination unreachable packet:

 - If neither a route nor the default route for forwarding a packet is available, the device will send a "network unreachable" ICMP error packet.
 - If the destination of a packet is local but the transport layer protocol of the packet is not supported by the local device, the device sends a "protocol unreachable" ICMP error packet to the source.
 - When receiving a packet with the destination being local and transport layer protocol being UDP, if the packet's port number does not match the running process, the device will send the source a "port unreachable" ICMP error packet.
 - If the source uses "strict source routing" to send packets, but the intermediate device finds that the next hop specified by the source is not directly connected, the device will send the source a "source routing failure" ICMP error packet.
 - When forwarding a packet, if the MTU of the sending interface is smaller than the packet, but the packet has been set as "Don't Fragment," the device will send the source a "fragmentation needed and Don't Fragment (DF)-set" ICMP error packet.

Disadvantages of sending ICMP error packets

Sending ICMP error packets facilitates network control and management, but it has the following disadvantages:

- Increases network traffic.
- A device's performance degrades if it receives a lot of malicious packets that cause it to respond with ICMP error packets.
- A host's performance degrades if the redirection function increases the size of its routing table.
- End users are affected because of receiving ICMP destination unreachable packets caused by malicious users.

To prevent such problems, disable the device from sending ICMP error packets.

Configuration procedure

The device stops sending "TTL timeout" ICMP error packets after sending ICMP timeout packets is disabled. However, "reassembly timeout" error packets will be sent normally.

To enable sending of ICMP error packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable sending of ICMP redirect packets.	ip redirects enable	Disabled by default

Step	Command	Remarks
3. Enable sending of ICMP timeout packets.	ip ttl-expires enable	Disabled by default
4. Enable sending of ICMP destination unreachable packets.	ip unreachable enable	Disabled by default

Displaying and maintaining IP performance optimization

Task	Command	Remarks
Display TCP connection statistics.	display tcp statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display UDP statistics.	display udp statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display statistics of IP packets.	display ip statistics [<i>slot slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display ICMP statistics.	display icmp statistics [<i>slot slot-number</i>] [{ begin exclude include } <i>regular-expression</i>] <i>regular-expression</i>]	Available in any view
Display socket information.	display ip socket [<i>socktype sock-type</i>] [<i>task-id socket-id</i>] [<i>slot slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Configuring UDP helper

Only the HP 5500 EI switches support configuring UDP helper on Layer 3 Ethernet interfaces.

The term "interface" in this chapter refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

Overview

UDP helper functions as a relay agent that converts UDP broadcast packets into unicast packets and forwards them to a specified destination server. This is helpful when a host cannot obtain network configuration information or request device names through broadcasting because the server or host to be requested is located on another broadcast domain.

With UDP helper enabled, a device decides whether to forward a received UDP broadcast packet according to the UDP destination port number of the packet.

- If the destination port number of the packet matches the one pre-configured on the device, the device modifies the destination IP address in the IP header, and then sends the packet to the specified destination server.
- If the destination port number of the packet does not match the one pre-configured on the device, the device sends the packet to the upper layer protocol for processing.

Configuration restrictions and guidelines

- The receiving of directed broadcasts to a directly connected network is disabled by default on the switch. As a result, UDP helper is available only when the **ip forward-broadcast** command is configured in system view. For more information about reception and forwarding of directed broadcasts to a directly connected network, see "Configuring IP performance optimization."
- A UDP helper enabled device must not forward DHCP broadcast packets that use destination port 67 or 68. Therefore, the UDP port numbers set with the **udp-helper port** command must not include 67 or 68.
- You can specify a port number or the corresponding parameter for a UDP port to forward packets. For example, **udp-helper port 53** and **udp-helper port dns** specify the same UDP port number.
- The configuration of all UDP ports is removed if you disable UDP helper.
- You can configure up to 256 UDP port numbers to enable the forwarding of packets with these UDP port numbers.
- You can configure up to 20 destination servers on an interface.

Configuration procedure

To configure UDP helper:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enable UDP helper.	udp-helper enable	Disabled by default.
3. Enable the forwarding of packets with the specified UDP destination port number(s).	udp-helper port { <i>port-number</i> dns netbios-ds netbios-ns tacacs ftpp time }	No UDP port number is specified by default.
4. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
5. Specify the destination server to which UDP packets are to be forwarded.	udp-helper server <i>ip-address</i>	No destination server is specified by default.

Displaying and maintaining UDP helper

Task	Command	Remarks
Displays information about forwarded UDP packets.	display udp-helper server [interface <i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear statistics about packets forwarded.	reset udp-helper packet	Available in user view

UDP helper configuration example

Network requirements

As shown in Figure 50, the IP address of VLAN-interface 1 of Switch A is 10.110.1.1/16, and the interface connects to the subnet 10.110.0.0/16.

Configure UDP helper to forward broadcast packets with UDP destination port number 55 and destination IP address 255.255.255.255 or 10.110.255.255 to the destination server 10.2.1.1/16 in public network.

Figure 50 Network diagram

Configuration procedure

Verify that a route from Switch A to the subnet 10.2.0.0/16 is available.

```
# Enable Switch A to receive directed broadcasts.
<SwitchA> system-view
[SwitchA] ip forward-broadcast

# Enable UDP helper.
[SwitchA] udp-helper enable

# Enable the forwarding broadcast packets with the UDP destination port 55.
[SwitchA] udp-helper port 55

# Specify the destination server 10.2.1.1 on VLAN-interface 1 in public network.
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interfacel] ip address 10.110.1.1 16
[SwitchA-Vlan-interfacel] udp-helper server 10.2.1.1
```

Configuring IPv6 basics

Only the HP 5500 EI switches support configuring IPv6 basics on Layer 3 Ethernet interfaces.

The term "interface" in this chapter refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

Overview

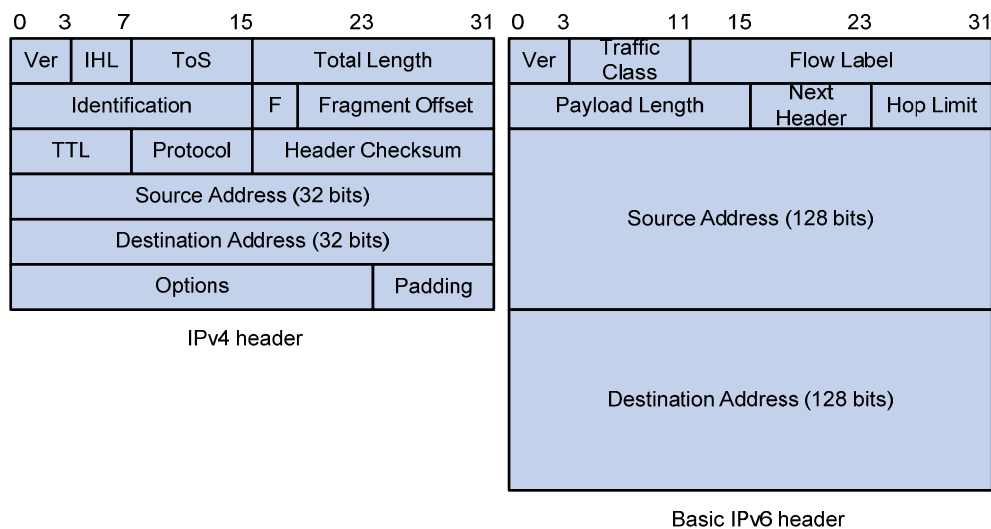

Internet Protocol Version 6 (IPv6), also called IP next generation (IPng), was designed by the Internet Engineering Task Force (IETF) as the successor to Internet Protocol version 4 (IPv4). The significant difference between IPv6 and IPv4 is that IPv6 increases the IP address size from 32 bits to 128 bits.

IPv6 features

Header format simplification

IPv6 removes several IPv4 header fields or moves them to the IPv6 extension headers to reduce the length of the basic IPv6 packet header. The basic IPv6 packet header has a fixed length of 40 bytes to simplify IPv6 packet handling and to improve forwarding efficiency. Although IPv6 address size is four times larger than IPv4 address size, the basic IPv6 packet header size is only twice the size of the option-less IPv4 packet header.

Figure 51 IPv4 packet header format and basic IPv6 packet header format

Larger address space

The source and destination IPv6 addresses are 128 bits (or 16 bytes) long. IPv6 can provide 3.4×10^{38} addresses to meet the requirements of hierarchical address division and the allocation of public and private addresses.

Hierarchical address structure

IPv6 uses hierarchical address structure to speed up route lookups and reduce the IPv6 routing table size through route aggregation.

Address autoconfiguration

To simplify host configuration, IPv6 supports stateful and stateless address autoconfiguration.

- Stateful address autoconfiguration enables a host to acquire an IPv6 address and other configuration information from a server (for example, a DHCP server).
- Stateless address autoconfiguration enables a host to automatically generate an IPv6 address and other configuration information by using its link-layer address and the prefix information advertised by a router.

To communicate with other hosts on the same link, a host automatically generates a link-local address based on its link-layer address and the link-local address prefix (FE80::/10).

Built-in security

IPv6 defines extension headers to support IPsec. IPsec provides end-to-end security for network security solutions and enhances interoperability among different IPv6 applications.

QoS support

The Flow Label field in the IPv6 header allows the device to label the packets and facilitates the special handling of a flow.

Enhanced neighbor discovery mechanism

The IPv6 neighbor discovery protocol is implemented through a group of Internet Control Message Protocol version 6 (ICMPv6) messages to manage the information exchange among neighboring nodes on the same link. The group of ICMPv6 messages replaces Address Resolution Protocol (ARP) messages, Internet Control Message Protocol version 4 (ICMPv4) Router Discovery messages, and ICMPv4 Redirect messages and provides a series of other functions.

Flexible extension headers

IPv6 eliminates the Options field in the header and introduces optional extension headers to provide scalability and improve efficiency. The Options field in the IPv4 packet header contains a maximum of 40 bytes, whereas the IPv6 extension headers are restricted to the maximum size of IPv6 packets only.

IPv6 addresses

IPv6 address format

An IPv6 address is represented as a set of 16-bit hexadecimal numbers separated by colons. An IPv6 address is divided into eight groups, and each 16-bit group is represented by four hexadecimal numbers, for example, 2001:0000:130F:0000:0000:09C0:876A:130B.

To simplify the representation of IPv6 addresses, you can handle zeros in IPv6 addresses by using the following methods:

- The leading zeros in each group can be removed. For example, the previous address can be represented in a shorter format as 2001:0:130F:0:0:9C0:876A:130B.
- If an IPv6 address contains two or more consecutive groups of zeros, they can be replaced by a double colon (::). For example, the previous address can be represented in the shortest format as 2001:0:130F::9C0:876A:130B.

A double colon may appear once or not at all in an IPv6 address. This limit allows the device to determine how many zeros the double colon represents, and correctly convert it to zeros to restore a 128-bit IPv6 address.

An IPv6 address consists of an address prefix and an interface ID, both of which are equivalent to the network ID and the host ID of an IPv4 address, respectively.

An IPv6 address prefix is written in IPv6-address/prefix-length notation where the IPv6-address is represented in any of the formats previously mentioned and the prefix-length is a decimal number indicating how many leftmost bits of the IPv6 address comprises the address prefix.

IPv6 address types

IPv6 addresses fall into the following types:

- **Unicast address**—An identifier for a single interface, similar to an IPv4 unicast address. A packet sent to a unicast address is delivered to the interface identified by that address.
- **Multicast address**—An identifier for a set of interfaces (typically belonging to different nodes), similar to an IPv4 multicast address. A packet sent to a multicast address is delivered to all interfaces identified by that address.
- **Anycast address**—An identifier for a set of interfaces (typically belonging to different nodes). A packet sent to an anycast address is delivered to the nearest one of the interfaces identified by that address. The nearest interface is chosen according to the routing protocols' measure of distance.

NOTE:

There are no broadcast addresses in IPv6. Their function is replaced by multicast addresses.

The type of an IPv6 address is designated by the first several bits, the format prefix. [Table 6](#) lists the mappings between address types and format prefixes.

Table 6 Mappings between address types and format prefixes

Type	Format prefix (binary)	IPv6 prefix ID	
Unicast address	Unspecified address	00...0 (128 bits)	::/128
	Loopback address	00...1 (128 bits)	::1/128
	Link-local address	1111111010	FE80::/10
	Site-local address	1111111011	FECO::/10
	Global unicast address	Other forms	N/A
Multicast address		11111111	FF00::/8
Anycast address	Anycast addresses use the unicast address space and have the identical structure of unicast addresses.		

Unicast addresses

Unicast addresses comprise global unicast addresses, link-local unicast addresses, site-local unicast addresses, the loopback address, and the unspecified address.

- Global unicast addresses, equivalent to public IPv4 addresses, are provided for network service providers. This type of address allows efficient prefix aggregation to restrict the number of global routing entries.

- Link-local addresses are used for communication among link-local nodes for neighbor discovery and stateless autoconfiguration. Packets with link-local source or destination addresses are not forwarded to other links.
- Site-local unicast addresses are similar to private IPv4 addresses. Packets with site-local source or destination addresses are not forwarded out of the local site (or a private network).
- A loopback address is 0:0:0:0:0:0:0:1 (or ::1). It cannot be assigned to any physical interface and can be used by a node to send an IPv6 packet to itself in the same way as the loopback address in IPv4.
- An unspecified address is 0:0:0:0:0:0:0:0 (or ::). It cannot be assigned to any node. Before acquiring a valid IPv6 address, a node fills this address in the source address field of IPv6 packets. The unspecified address cannot be used as a destination IPv6 address.

Multicast addresses

IPv6 multicast addresses listed in [Table 7](#) are reserved for special purposes.

Table 7 Reserved IPv6 multicast addresses

Address	Application
FF01::1	Node-local scope all-nodes multicast address
FF02::1	Link-local scope all-nodes multicast address
FF01::2	Node-local scope all-routers multicast address
FF02::2	Link-local scope all-routers multicast address
FF05::2	Site-local scope all-routers multicast address

Multicast addresses also include solicited-node addresses. A node uses a solicited-node multicast address to acquire the link-layer address of a neighboring node on the same link and to detect duplicate addresses. Each IPv6 unicast or anycast address has a corresponding solicited-node address. The format of a solicited-node multicast address is: FF02:0:0:0:0:1:FFXX:XXXX where FF02:0:0:0:0:1:FF is fixed and consists of 104 bits, and XX:XXXX is the last 24 bits of an IPv6 unicast address or anycast address.

EUI-64 address-based interface identifiers

An interface identifier is 64 bits and uniquely identifies an interface on a link.

Interfaces generate EUI-64 address-based interface identifiers differently.

- On an IEEE 802 interface (such as a VLAN interface)

The interface identifier is derived from the link-layer address (typically a MAC address) of the interface. The MAC address is 48 bits long. To obtain an EUI-64 address-based interface identifier, you must insert the hexadecimal number FFFE (16 bits of 1111111111111110) into the MAC address (behind the 24th high-order bit), and set the universal/local (U/L) bit (which is the seventh high-order bit) to 1, to make sure that the obtained EUI-64 address-based interface identifier is globally unique.

[Figure 52](#) shows how an EUI-64 address-based interface identifier is generated from a MAC address.

Figure 52 Converting a MAC address into an EUI-64 address-based interface identifier

- On a tunnel interface
The lower 32 bits of the EUI-64 address-based interface identifier are the source IPv4 address of the tunnel interface. The higher 32 bits of the EUI-64 address-based interface identifier of an ISATAP tunnel interface are 0000:5EFE, whereas those of other tunnel interfaces are all zeros. For more information about tunnels, see "Configuring tunneling."
- On an interface of another type
The EUI-64 address-based interface identifier is generated randomly by the device.

IPv6 neighbor discovery protocol

The IPv6 Neighbor Discovery (ND) protocol uses five types of ICMPv6 messages to implement the following functions:

- Address resolution
- Neighbor reachability detection
- Duplicate address detection
- Router/prefix discovery and address autoconfiguration
- Redirection

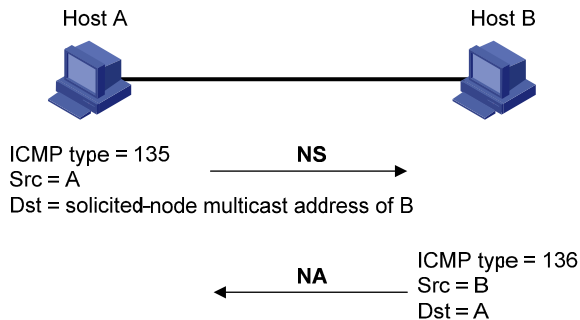

Table 8 ICMPv6 messages used by ND

ICMPv6 message	Type	Function
Neighbor Solicitation (NS) message	135	Acquires the link-layer address of a neighbor.
		Verifies whether a neighbor is reachable.
		Detects duplicate addresses.
Neighbor Advertisement (NA) message	136	Responds to an NS message.
		Notifies the neighboring nodes of link layer changes.
Router Solicitation (RS) message	133	Requests an address prefix and other configuration information for autoconfiguration after startup.
Router Advertisement (RA) message	134	Responds to an RS message.
		Advertises information such as the Prefix Information options and flag bits.
Redirect message	137	Informs the source host of a better next hop on the path to a particular destination when certain conditions are satisfied.

Address resolution

This function is similar to the ARP function in IPv4. An IPv6 node acquires the link-layer addresses of neighboring nodes on the same link through NS and NA message exchanges. Figure 53 shows how Host A acquires the link-layer address of Host B on a single link.

Figure 53 Address resolution

The address resolution operates in the following steps:

1. Host A multicasts an NS message. The source address of the NS message is the IPv6 address of the sending interface of Host A and the destination address is the solicited-node multicast address of Host B. The NS message contains the link-layer address of Host A.
2. After receiving the NS message, Host B determines whether the destination address of the packet is its solicited-node multicast address. If yes, Host B learns the link-layer address of Host A, and then unicasts an NA message containing its link-layer address.
3. Host A acquires the link-layer address of Host B from the NA message.

Neighbor reachability detection

After Host A acquires the link-layer address of its neighbor Host B, Host A can use NS and NA messages to check whether Host B is reachable.

1. Host A sends an NS message whose destination address is the IPv6 address of Host B.
2. If Host A receives an NA message from Host B, Host A decides that Host B is reachable. Otherwise, Host B is unreachable.

Duplicate address detection

After Host A acquires an IPv6 address, it performs Duplicate Address Detection (DAD) to check whether the address is being used by any other node (similar to the gratuitous ARP function in IPv4). DAD is accomplished through NS and NA message exchanges. Figure 54 shows the DAD process.

Figure 54 Duplicate address detection

1. Host A sends an NS message whose source address is the unspecified address and whose destination address is the corresponding solicited-node multicast address of the IPv6 address to be detected. The NS message contains the IPv6 address.
2. If Host B uses this IPv6 address, Host B returns an NA message. The NA message contains the IPv6 address of Host B.
3. Host A learns that the IPv6 address is being used by Host B after receiving the NA message from Host B. If receiving no NA message, Host A decides that the IPv6 address is not in use and uses this address.

Router/prefix discovery and address autoconfiguration

Router/prefix discovery enables a node to locate the neighboring routers and to learn from the received RA message configuration parameters such as the prefix of the network where the node is located.

Stateless address autoconfiguration enables a node to generate an IPv6 address automatically according to the information obtained through router/prefix discovery.

Router/prefix discovery is implemented through RS and RA messages in the following steps:

1. At startup, a node sends an RS message to request the address prefix and other configuration information for autoconfiguration.
2. A router returns an RA message containing information such as Prefix Information options. (The router also periodically sends an RA message. In addition to an address prefix, the Prefix Information option also contains the preferred lifetime and valid lifetime of the address prefix. Nodes update the preferred lifetime and valid lifetime accordingly through periodic RA messages.)
3. The node automatically generates an IPv6 address and other configuration information according to the address prefix and other configuration parameters in the RA message. (The automatically generated address is applicable within the valid lifetime and is removed when the valid lifetime expires.)

Redirection

A newly started host may contain only a default route to the gateway in its routing table. When certain conditions are satisfied, the gateway sends an ICMPv6 Redirect message to the source host, so the host can select a better next hop to forward packets (similar to the ICMP redirection function in IPv4).

The gateway sends an ICMPv6 Redirect message when the following conditions are satisfied.

- The receiving interface is the forwarding interface.
- The selected route itself is not created or modified by an ICMPv6 Redirect message.
- The selected route is not the default route.
- The IPv6 packet to be forwarded does not contain any routing header.

IPv6 path MTU discovery

The links that a packet passes from a source to a destination may have different MTUs. In IPv6, when the packet size exceeds the path MTU of a link, the packet is fragmented at the source end of the link to reduce the processing pressure on intermediate devices and to use network resources effectively.

The path MTU discovery mechanism is designed to find the minimum MTU of all links in the path between a source and a destination. [Figure 55](#) shows how a source host discovers the path MTU to a destination host.

Figure 55 Path MTU discovery process

1. The source host compares its MTU with the packet to be sent, performs necessary fragmentation, and sends the resulting packet to the destination host.
2. If the MTU supported by a forwarding interface is smaller than the packet, the device discards the packet and returns an ICMPv6 error packet containing the interface MTU to the source host.
3. After receiving the ICMPv6 error packet, the source host uses the returned MTU to limit the packet size, performs fragmentation, and sends the resulting packet to the destination host.
4. Step 2 and step 3 are repeated until the destination host receives the packet. In this way, the source host decides the minimum MTU of all links in the path to the destination host.

IPv6 transition technologies

Before IPv6 dominates the Internet, high-efficient and seamless IPv6 transition technologies are needed to enable communication between IPv4 and IPv6 networks. Several IPv6 transition technologies can be used in different environments and periods, such as dual stack (RFC 2893) and tunneling (RFC 2893).

Dual stack

Dual stack is the most direct transition approach. A network node that supports both IPv4 and IPv6 is a dual stack node. A dual stack node configured with an IPv4 address and an IPv6 address can forward both IPv4 and IPv6 packets. For an upper layer application that supports both IPv4 and IPv6, either TCP or UDP can be selected at the transport layer, whereas the IPv6 stack is preferred at the network layer. Dual stack is suitable for communication between IPv4 nodes or between IPv6 nodes. It is the basis of all transition technologies. However, it does not solve the IPv4 address depletion issue because each dual stack node must have a globally unique IP address.

Tunneling

Tunneling is an encapsulation technology that utilizes one network protocol to encapsulate packets of another network protocol and transfer them over the network. For more information about tunneling, see "Configuring tunneling."

Protocols and standards

Protocols and standards related to IPv6 include:

- RFC 1881, *IPv6 Address Allocation Management*
- RFC 1887, *An Architecture for IPv6 Unicast Address Allocation*
- RFC 1981, *Path MTU Discovery for IP version 6*
- RFC 2375, *IPv6 Multicast Address Assignments*

- RFC 2460, *Internet Protocol, Version 6 (IPv6) Specification*
- RFC 2461, *Neighbor Discovery for IP Version 6 (IPv6)*
- RFC 2462, *IPv6 Stateless Address Autoconfiguration*
- RFC 2463, *Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification*
- RFC 2464, *Transmission of IPv6 Packets over Ethernet Networks*
- RFC 2526, *Reserved IPv6 Subnet Anycast Addresses*
- RFC 2894, *Router Renumbering for IPv6*
- RFC 3307, *Allocation Guidelines for IPv6 Multicast Addresses*
- RFC 3513, *Internet Protocol Version 6 (IPv6) Addressing Architecture*

IPv6 basics configuration task list

Task	Remarks	
Configuring basic IPv6 functions	Enabling IPv6	Required
	Configuring an IPv6 global unicast address	Required to configure one
	Configuring an IPv6 link-local address	
	Configure an IPv6 anycast address	
Configuring IPv6 ND	Configuring a static neighbor entry	Optional
	Configuring the maximum number of neighbors dynamically learned	Optional
	Setting the age timer for ND entries in stale state	Optional
	Configuring parameters related to RA messages	Optional
	Configuring the maximum number of attempts to send an NS message for DAD	Optional
	Configuring ND snooping	Optional
	Enabling ND proxy	Optional
Configuring path MTU discovery	Configuring a static path MTU for a specified IPv6 address	Optional
	Configuring the aging time for dynamic path MTUs	Optional
Configuring IPv6 TCP properties		Optional
Configuring ICMPv6 packet sending	Configuring the maximum ICMPv6 error packets sent in an interval	Optional
	Enabling replying to multicast echo requests	Optional
	Enabling sending of ICMPv6 time exceeded messages	Optional
	Enabling sending of ICMPv6 destination unreachable messages	Optional

Configuring basic IPv6 functions

Enabling IPv6

Enable IPv6 before you perform any IPv6-related configuration. Without IPv6 enabled, an interface cannot forward IPv6 packets even if it has an IPv6 address configured.

To enable IPv6:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6.	ipv6	Disabled by default

Configuring an IPv6 global unicast address

Configure an IPv6 global unicast address by using the following options:

- **EUI-64 IPv6 addressing**—The IPv6 address prefix of an interface is manually configured, and the interface identifier is generated automatically by the interface.
- **Manual configuration**—The IPv6 global unicast address is configured manually.
- **Stateless address autoconfiguration**—The IPv6 global unicast address is generated automatically based on the address prefix information contained in the RA message.

Follow these guidelines when you configure an IPv6 global unicast address:

- You can configure multiple IPv6 global unicast addresses with different prefixes on an interface.
- A manually configured global unicast address takes precedence over an automatically generated one. If a global unicast address has been automatically generated on an interface when you manually configure another one with the same address prefix, the latter overwrites the previous. The overwritten automatic global unicast address will not be restored even if the manual one is removed. Instead, a new global unicast address will be automatically generated based on the address prefix information in the RA message that the interface receives at the next time.

EUI-64 IPv6 addressing

To configure an interface to generate an EUI-64 IPv6 address:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the interface to generate an EUI-64 IPv6 address.	ipv6 address <i>ipv6-address/prefix-length</i> eui-64	By default, no IPv6 global unicast address is configured on an interface.

Manual configuration

To specify an IPv6 address manually for an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an IPv6 address manually.	ipv6 address { <i>ipv6-address</i> <i>prefix-length</i> <i>ipv6-address/prefix-length</i> }	By default, no IPv6 global unicast address is configured on an interface.

Stateless address autoconfiguration

To configure an interface to generate an IPv6 address by using stateless address autoconfiguration:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an IPv6 address to be generated through stateless address autoconfiguration.	ipv6 address auto	By default, no IPv6 global unicast address is configured on an interface.

NOTE:

Using the **undo ipv6 address auto** command on an interface removes all IPv6 global unicast addresses automatically generated on the interface.

With stateless address autoconfiguration enabled on an interface, the device automatically generates an IPv6 global unicast address by using the address prefix information in the received RA message and the interface ID. On an IEEE 802 interface (such as a VLAN interface), the interface ID is generated based on the MAC address of the interface, and is globally unique. As a result, the interface ID portion of the IPv6 global address remains unchanged and exposes the sender. An attacker can further exploit communication details such as the communication peer and time.

To fix the vulnerability, configure the temporary address function that enables the system to generate and use temporary IPv6 addresses with different interface ID portions on an interface. With this function configured on an IEEE 802 interface, the system can generate two addresses, public IPv6 address and temporary IPv6 address.

- **Public IPv6 address**—Comprises an address prefix provided by the RA message, and a fixed interface ID generated based on the MAC address of the interface.
- **Temporary IPv6 address**—Comprises an address prefix provided by the RA message, and a random interface ID generated through MD5.

Before sending a packet, the system preferably uses the temporary IPv6 address of the sending interface as the source address of the packet to be sent. When this temporary IPv6 address expires, the system removes it and generates a new one. This enables the system to send packets with different source addresses through the same interface. If the temporary IPv6 address cannot be used because of a DAD conflict, the public IPv6 address is used.

The preferred lifetime and valid lifetime for temporary IPv6 addresses are specified as follows:

- The preferred lifetime of a temporary IPv6 address takes the value of the smaller of the following values:
 - The preferred lifetime of the address prefix in the RA message.

- The preferred lifetime configured for temporary IPv6 addresses minus DESYNC_FACTOR (which is a random number ranging 0 to 600, in seconds).
- The valid lifetime of a temporary IPv6 address takes the value of the smaller of the following values:
 - The valid lifetime of the address prefix.
 - The valid lifetime configured for temporary IPv6 addresses.

To configure the temporary address function:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the system to generate and preferably use the temporary IPv6 address of the sending interface as the source address of the packet to be sent.	ipv6 prefer temporary-address [<i>valid-lifetime preferred-lifetime</i>]	By default, the system does not generate or use a temporary IPv6 address.

You must also enable stateless address autoconfiguration on an interface if you need temporary IPv6 addresses to be generated on that interface. Temporary IPv6 addresses do not override public IPv6 addresses. Therefore, an interface may have multiple IPv6 addresses with the same address prefix but different interface ID portions.

If the public IPv6 address fails to be generated on an interface because of a prefix conflict or other reasons, no temporary IPv6 address will be generated on the interface.

Configuring an IPv6 link-local address

IPv6 link-local addresses can be configured in either of the following ways:

- **Automatic generation**—The device automatically generates a link-local address for an interface according to the link-local address prefix (FE80::/10) and the link-layer address of the interface.
- **Manual assignment**—IPv6 link-local addresses can be assigned manually.

An interface can have only one link-local address. To avoid link-local address conflicts, use the automatic generation method.

Manual assignment takes precedence over automatic generation.

- If you first use automatic generation and then manual assignment, the manually assigned link-local address will overwrite the automatically generated one.
- If you first use manual assignment and then automatic generation, the automatically generated link-local address will not take effect and the link-local address is still the manually assigned one. If you delete the manually assigned address, the automatically generated link-local address is validated.

To configure automatic generation of an IPv6 link-local address for an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
3.	Configure the interface to automatically generate an IPv6 link-local address. ipv6 address auto link-local	Optional. By default, no link-local address is configured on an interface. After an IPv6 global unicast address is configured on the interface, a link-local address is generated automatically.

To configure an IPv6 link-local address manually:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter interface view. interface <i>interface-type</i> <i>interface-number</i>	N/A
3.	Configure an IPv6 link-local address manually. ipv6 address <i>ipv6-address</i> link-local	Optional. By default, no link-local address is configured on an interface. After an IPv6 global unicast address is configured on the interface, a link-local address is generated automatically.

After an IPv6 global unicast address is configured for an interface, a link-local address is generated automatically.

- The automatically generated link-local address is the same as the one generated by using the **ipv6 address auto link-local** command.
- If a link-local address is manually assigned to an interface, this manual link-local address takes effect. If the manually assigned link-local address is removed, the automatically generated link-local address takes effect.

The **undo ipv6 address auto link-local** command can only remove the link-local addresses generated through the **ipv6 address auto link-local** command.

- If an IPv6 global unicast address is already configured for an interface, the interface still has a link-local address because the system automatically generates one for the interface.
- If no IPv6 global unicast address is configured, the interface has no link-local address.

Configure an IPv6 anycast address

To configure an IPv6 anycast address for an interface:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter interface view. interface <i>interface-type</i> <i>interface-number</i>	N/A
3.	Configure an IPv6 anycast address. ipv6 address <i>ipv6-address/prefix-length</i> anycast	Optional. By default, no IPv6 anycast address is configured on an interface.

Configuring IPv6 ND

Configuring a static neighbor entry

The IPv6 address of a neighboring node can be resolved into a link-layer address dynamically through NS and NA messages or through a manually configured static neighbor entry.

The device uniquely identifies a static neighbor entry by the neighbor's IPv6 address and the local Layer 3 interface number. You can configure a static neighbor entry by using either of the following methods:

- **Method 1**—Associate a neighbor IPv6 address and link-layer address with the Layer 3 interface of the local node.
- **Method 2**—Associate a neighbor IPv6 address and link-layer address with a port in a VLAN containing the local node.

You can use either of the previous configuration methods to configure a static neighbor entry for a VLAN interface.

- After a static neighbor entry is configured by using the first method, the device must resolve the corresponding Layer 2 port information of the VLAN interface.
- If you use the second method, make sure that the corresponding VLAN interface exists and that the Layer 2 port specified by *port-type port-number* belongs to the VLAN specified by *vlan-id*. After a static neighbor entry is configured, the device associates the VLAN interface with the IPv6 address to identify the static neighbor entry uniquely.

To configure a static neighbor entry:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a static neighbor entry.	ipv6 neighbor <i>ipv6-address</i> <i>mac-address</i> { <i>vlan-id port-type</i> <i>port-number</i> interface <i>interface-type interface-number</i> } [vpn-instance <i>vpn-instance-name</i>]	Only HP 5500 EI Switch Series supports the vpn-instance <i>vpn-instance-name</i> option.

Configuring the maximum number of neighbors dynamically learned

The device can dynamically acquire the link-layer address of a neighboring node through NS and NA messages and add it into the neighbor table. A large table can reduce the forwarding performance of the device. You can restrict the size of the neighbor table by setting the maximum number of neighbors that an interface can dynamically learn. When the number of dynamically learned neighbors reaches the threshold, the interface will stop learning neighbor information.

To configure the maximum number of neighbors dynamically learned:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the maximum number of neighbors dynamically learned by an interface.	ipv6 neighbors max-learning-num <i>number</i>	Optional. By default, a Layer 2 interface does not limit the number of neighbors dynamically learned. A Layer 3 interface can learn up to 1024 neighbors dynamically for HP 5500 SI Switch Series, and up to 4096 neighbors dynamically for HP 5500 EI Switch Series.

Setting the age timer for ND entries in stale state

ND entries in stale state have an age timer. If an ND entry in stale state is not refreshed before the timer expires, it transits to the delay state. If it is still not refreshed in five seconds, the ND entry transits to the probe state, and the device sends an NS message for detection. If no response is received, the device removes the ND entry.

To set the age timer for ND entries in stale state:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the age timer for ND entries in stale state.	ipv6 neighbor stale-aging <i>aging-time</i>	Optional. Four hours by default.

Configuring parameters related to RA messages

You can enable an interface to send RA messages, and configure the interval for sending RA messages and parameters in RA messages. After receiving an RA message, a host can use these parameters to perform corresponding operations. [Table 9](#) lists and describes the configurable parameters in an RA message.

The maximum interval for sending RA messages should be less than (or equal to) the router lifetime in RA messages, so the router can be updated through an RA message before expiration.

The values of the NS retransmission timer and the reachable time configured for an interface are sent to hosts via RA messages. Furthermore, this interface sends NS messages at the interval of the NS retransmission timer and considers a neighbor reachable within the reachable time.

Table 9 Parameters in an RA message and their descriptions

Parameters	Description
Cur Hop Limit	When sending an IPv6 packet, a host uses the value to fill the Hop Limit field in IPv6 headers. The value is also filled into the Hop Limit field in the response packet of a device.
Prefix Information options	After receiving the prefix information, the hosts on the same link can perform stateless autoconfiguration.

Parameters	Description
MTU	Make sure that all nodes on a link use the same MTU value.
M flag	Determines whether hosts use the stateful autoconfiguration to acquire IPv6 addresses. If the M flag is set to 1, hosts use the stateful autoconfiguration (for example, through a DHCP server) to acquire IPv6 addresses. Otherwise, hosts use the stateless autoconfiguration to acquire IPv6 addresses and generate IPv6 addresses according to their own link-layer addresses and the obtained prefix information.
O flag	Determines whether hosts use stateful autoconfiguration to acquire other configuration information. If the O flag is set to 1, hosts use stateful autoconfiguration (for example, through a DHCP server) to acquire other configuration information. Otherwise, hosts use stateless autoconfiguration to acquire other configuration information.
Router Lifetime	Tells the receiving hosts how long the advertising device can live
Retrans Timer	If the device fails to receive a response message within the specified time after sending an NS message, it will retransmit the NS message.
Reachable Time	If the neighbor reachability detection shows that a neighbor is reachable, the device considers the neighbor reachable within the specified reachable time. If the device must send a packet to the neighbor after the specified reachable time expires, the device will reconfirm whether the neighbor is reachable.

To allow sending of RA messages:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Disable RA message suppression.	undo ipv6 nd ra halt	By default, RA messages are suppressed.
4. Configure the maximum and minimum intervals for sending RA messages.	ipv6 nd ra interval <i>max-interval-value</i> <i>min-interval-value</i>	Optional. By default, the maximum interval for sending RA messages is 600 seconds, and the minimum interval is 200 seconds. The device sends RA messages at random intervals between the maximum interval and the minimum interval. The minimum interval should be less than or equal to 0.75 times the maximum interval.

To configure parameters related to RA messages:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the hop limit.	ipv6 nd hop-limit <i>value</i>	Optional. 64 by default.

Step	Command	Remarks
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Configure the prefix information in RA messages.	ipv6 nd ra prefix { <i>ipv6-prefix</i> <i>prefix-length</i> <i>ipv6-prefix/prefix-length</i> } <i>valid-lifetime preferred-lifetime</i> [no-autoconfig off-link] *	Optional. By default, no prefix information is configured for RA messages, and the IPv6 address of the interface sending RA messages is used as the prefix information with valid lifetime 2592000 seconds (30 days) and preferred lifetime 604800 seconds (seven days).
5. Turn off the MTU option in RA messages.	ipv6 nd ra no-advlinkmtu	Optional. By default, RA messages contain the MTU option.
6. Set the M flag bit to 1.	ipv6 nd autoconfig managed-address-flag	Optional. By default, the M flag bit is set to 0 and hosts acquire IPv6 addresses through stateless autoconfiguration.
7. Set the O flag bit to 1.	ipv6 nd autoconfig other-flag	Optional. By default, the O flag bit is set to 0 and hosts acquire other configuration information through stateless autoconfiguration.
8. Configure the router lifetime in RA messages.	ipv6 nd ra router-lifetime <i>value</i>	Optional. 1800 seconds by default.
9. Set the NS retransmission timer.	ipv6 nd ns retrans-timer <i>value</i>	Optional. By default, the local interface sends NS messages at 1000 millisecond intervals, and the value of the Retrans Timer field in RA messages sent by the local interface is 0. The interval for retransmitting an NS message is determined by the receiving device.
10. Set the reachable time.	ipv6 nd nud reachable-time <i>value</i>	Optional. By default, the neighbor reachable time on the local interface is 30000 milliseconds, and the value of the Reachable Time field in the RA messages sent by the local interface is 0. The neighbor reachable time is determined by the receiving device.

Configuring the maximum number of attempts to send an NS message for DAD

An interface sends an NS message for DAD after acquiring an IPv6 address. If the interface does not receive a response within a specified time (determined by the **ipv6 nd ns retrans-timer** command), it

continues to send an NS message. If the interface still does not receive a response after the number of sent attempts reaches the threshold (specified with the **ipv6 nd dad attempts** command), the acquired address is considered usable.

To configure the attempts to send an NS message for DAD:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the number of attempts to send an NS message for DAD.	ipv6 nd dad attempts <i>value</i>	Optional. 1 by default. When the <i>value</i> argument is set to 0, DAD is disabled.

Configuring ND snooping

Introduction

The ND snooping feature is used in Layer 2 switching networks. It creates ND snooping entries using DAD NS messages.

ND snooping entries are used to do the following:

- Cooperate with the ND detection function. For more information about ND detection, see *Security Configuration Guide*.
- Cooperate with the IP Source Guard function. For more information about IP source guard, see *Security Configuration Guide*.
- Work in all SAVI scenarios. For more information about SAVI, see *Security Configuration Guide*.

After you enable ND snooping on a VLAN of a device, ND packets received by the interfaces of the VLAN are redirected to the CPU. When ND snooping is enabled globally, the CPU uses the ND packets to create or update ND snooping entries comprising source IPv6 address, source MAC address, receiving VLAN, and receiving port information.

The following items describe how an ND snooping entry is created, updated, and aged out.

1. Create an ND snooping entry

The device only uses received DAD NS messages to create ND snooping entries.

2. Update an ND snooping entry

Upon receiving an ND packet, the device searches the ND snooping table for an entry containing the source IPv6 address of the packet. If the entry was refreshed within one second, the device does not update the entry. If the entry is not refreshed for more than one second, the device matches the MAC address of the ND packet and the receiving port against that in the entry.

- If both of them match those in the entry, the device updates the aging time of the ND snooping entry.
- If neither of them matches the entry and the received packet is a DAD NS message, the message is ignored.
- If neither of them matches the entry and the received packet is not a DAD NS message, the device performs active acknowledgement.

The active acknowledgement is performed in the following steps.

- The device checks the validity of the existing ND snooping entry. The device sends out a DAD NS message including the IPv6 address of the ND snooping entry. If a corresponding NA message (whose source IPv6 address, source MAC address, receiving port, and source VLAN are consistent with those of the existing entry) is received, the device updates the aging time of the existing entry. If no corresponding NA message is received within one second after the DAD NS message is sent, the device starts to check the validity of the received ND packet.
 - To check the validity of the received ND packet (packet A for example), the device sends out a DAD NS message including the source IPv6 address of packet A. If a corresponding NA message (whose source IPv6 address, source MAC address, receiving port, and source VLAN are consistent with those of packet A) is received, the device updates the aging time of the entry. If no corresponding NA message is received within one second after the DAD NS message is sent, the device does not update the entry.
- 3. Age out an ND snooping entry**
- An ND snooping entry is aged out after 25 minutes. If an ND snooping entry is not updated within 15 minutes, the device performs active acknowledgement.
- The device sends out a DAD NS message including the IPv6 address of the ND snooping.
- If a corresponding NA message is received (the source IPv6 address, source MAC address, receiving port, and source VLAN are consistent with those of the existing entry), the device updates the aging time of the existing entry.
 - If no corresponding NA message is received within one second after the DAD NS message is sent out, the device removes the entry when the timer expires.

Configuration procedure

To configure ND snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure ND snooping.	<ul style="list-style-type: none"> • Enable ND snooping based on global unicast addresses (the devices use DAD NS messages containing global unicast addresses to create ND snooping entries): ipv6 nd snooping enable global • Enable ND snooping based on link local addresses (the devices use DAD NS messages containing link local addresses to create ND snooping entries): ipv6 nd snooping enable link-local 	<p>Use either approach.</p> <p>By default, ND snooping is disabled.</p>
3. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
4. Enable ND snooping.	ipv6 nd snooping enable	Disabled by default.
5. Return to system view.	quit	N/A
6. Enter Layer 2 Ethernet port view/Layer 2 aggregate interface view.	interface <i>interface-type interface-number</i>	N/A

Step	Command	Remarks
7. Configure the maximum number of ND snooping entries the interface can learn.	<code>ipv6 nd snooping max-learning-num number</code>	Optional. By default, the number of ND snooping entries an interface can learn is unlimited.
8. Configure the interface as an uplink interface and disable it from learning ND snooping entries.	<code>ipv6 nd snooping uplink</code>	Optional. By default, when ND snooping is enabled on the device, an interface is allowed to learn ND snooping entries.

Enabling ND proxy

ND proxy supports the NS and NA messages only.

Introduction

If a host sends an NS message requesting the hardware address of another host that is isolated from the sending host at Layer 2, the device between the hosts must be able to forward the NS message to allow Layer 3 communication between the two hosts. This process is achieved by ND proxy.

Depending on application scenarios, ND proxy falls into common ND proxy and local ND proxy.

- Common ND proxy

As shown in [Figure 56](#), VLAN-interface 1 with IPv6 address 4:1::99/64 and VLAN-interface 2 with IPv6 address 4:2::99/64 belong to different subnets. Host A and Host B reside on the same network but in different broadcast domains.

Figure 56 Application environment of common ND proxy

Because Host A's IPv6 address is on the same subnet as Host B's, Host A directly sends an NS message to obtain Host B's MAC address. However, Host B cannot receive the NS message because they belong to different broadcast domains.

To solve this problem, enable common ND proxy on VLAN-interface 1 and VLAN-interface 2 of the switch. The switch finds the matching forwarding entry according to the destination IPv6 address of the NS message and sends the message through the output interface of that entry. Upon receiving the NS message, Host B sends an NA message to the switch, which forwards it to Host A.

- Local ND proxy

As shown in [Figure 57](#), both Host A and Host B belong to VLAN 2, but they connect to GigabitEthernet 1/0/3 and GigabitEthernet 1/0/1 respectively, which are isolated at Layer 2.

Figure 57 Application environment of local ND proxy

Because Host A's IPv6 address is on the same subnet as Host B's, Host A directly sends an NS message to obtain Host B's MAC address. However, Host B cannot receive the NS message because they are isolated at Layer 2.

To solve this problem, enable local ND proxy on VLAN-interface 2 of the switch A so that the switch A can forward messages between Host A and Host B.

Local ND proxy implements Layer 3 communication for two hosts in the following cases:

- The two hosts must connect to different isolated Layer 2 ports of a VLAN.
- If super VLAN is used, the two hosts must belong to different sub VLANs.
- If isolate-user-VLAN is used, the two hosts must belong to different secondary VLANs.

Configuration procedure

You can enable common ND proxy and local ND proxy in VLAN interface view, Layer 3 Ethernet port view.

To enable common ND proxy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable common ND proxy.	proxy-nd enable	Disabled by default

To enable local ND proxy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable local ND proxy.	local-proxy-nd enable	Optional. Disabled by default.

Configuring path MTU discovery

Configuring a static path MTU for a specified IPv6 address

You can configure a static path MTU for a specified destination IPv6 address. When a source host sends a packet through an interface, it compares the interface MTU with the static path MTU of the specified destination IPv6 address. If the packet size is larger than the smaller one of the two values, the host fragments the packet according to the smaller value.

To configure a static path MTU for a specified IPv6 address:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a static path MTU for a specified IPv6 address.	ipv6 pathmtu [vpn-instance <i>vpn-instance-name</i>] <i>ipv6-address</i> [<i>value</i>]	Not configured by default Only HP 5500 EI Switch Series supports the vpn-instance <i>vpn-instance-name</i> option

Configuring the aging time for dynamic path MTUs

After the path MTU from a source host to a destination host is dynamically determined (see "[IPv6 path MTU discovery](#)"), the source host sends subsequent packets to the destination host based on this MTU. After the aging time expires, the dynamic path MTU is removed and the source host re-determines a dynamic path MTU through the path MTU mechanism.

The aging time is invalid for a static path MTU.

To configure the aging time for dynamic path MTUs:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the aging time for dynamic path MTUs.	ipv6 pathmtu age <i>age-time</i>	Optional. 10 minutes by default.

Configuring IPv6 TCP properties

You can configure the following IPv6 TCP properties:

- **synwait timer**—When a SYN packet is sent, the synwait timer is triggered. If no response packet is received before the synwait timer expires, the IPv6 TCP connection establishment fails.
- **finwait timer**—When the IPv6 TCP connection status is FIN_WAIT_2, the finwait timer is triggered. If no packet is received before the finwait timer expires, the IPv6 TCP connection is terminated. If a FIN packet is received, the IPv6 TCP connection status becomes TIME_WAIT. If non-FIN packets are received, the finwait timer is reset upon receipt of the last non-FIN packet and the connection is terminated after the finwait timer expires.
- **Size of the IPv6 TCP sending/receiving buffer**

To configure IPv6 TCP properties:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the synwait timer.	tcp ipv6 timer syn-timeout <i>wait-time</i>	Optional. 75 seconds by default.
3. Set the finwait timer.	tcp ipv6 timer fin-timeout <i>wait-time</i>	Optional. 675 seconds by default.
4. Set the size of the IPv6 TCP sending/receiving buffer.	tcp ipv6 window <i>size</i>	Optional. 8 KB by default.

Configuring ICMPv6 packet sending

Configuring the maximum ICMPv6 error packets sent in an interval

If too many ICMPv6 error packets are sent within a short time in a network, network congestion may occur. To avoid network congestion, you can control the maximum number of ICMPv6 error packets sent within a specified time by adopting the token bucket algorithm.

You can set the capacity of a token bucket to determine the number of tokens in the bucket. In addition, you can set the update interval of the token bucket, the interval for restoring the configured capacity. One token allows one ICMPv6 error packet to be sent. Each time an ICMPv6 error packet is sent, the number of tokens in a token bucket decreases by one. If the number of ICMPv6 error packets successively sent exceeds the capacity of the token bucket, the additional ICMPv6 error packets cannot be sent out until the capacity of the token bucket is restored.

To configure the capacity and update interval of the token bucket:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the capacity and update interval of the token bucket.	ipv6 icmp-error { bucket <i>bucket-size</i> ratelimit <i>interval</i> } *	Optional. By default, the capacity of a token bucket is 10 and the update interval is 100 milliseconds. A maximum of 10 ICMPv6 error packets can be sent within 100 milliseconds. The update interval "0" indicates that the number of ICMPv6 error packets sent is not restricted.

Enabling replying to multicast echo requests

If hosts are configured to answer multicast echo requests, an attacker can use this mechanism to attack a host. For example, if Host A (an attacker) sends an echo request with the source being Host B to a multicast address, all the hosts in the multicast group will send echo replies to Host B. To prevent such an attack, disable a device from answering multicast echo requests by default. In some application scenarios, however, you must enable the device to answer multicast echo requests.

To enable replying to multicast echo requests:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable replying to multicast echo requests.	ipv6 icmpv6 multicast-echo-reply enable	Not enabled by default

Enabling sending of ICMPv6 time exceeded messages

A device sends out an ICMPv6 Time Exceeded message in the following situations:

- If a received IPv6 packet's destination IP address is not a local address and its hop limit is 1, the device sends an ICMPv6 Hop Limit Exceeded message to the source.
- Upon receiving the first fragment of an IPv6 datagram with the destination IP address being the local address, the device starts a timer. If the timer expires before all the fragments arrive, an ICMPv6 Fragment Reassembly Timeout message is sent to the source.

If large quantities of malicious packets are received, the performance of a device degrades greatly because it must send back ICMP Time Exceeded messages. You can disable sending of ICMPv6 Time Exceeded messages.

To enable sending of ICMPv6 time exceeded messages:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable sending of ICMPv6 Time Exceeded messages.	ipv6 hoplimit-expires enable	Optional. Enabled by default.

Enabling sending of ICMPv6 destination unreachable messages

If the device fails to forward a received IPv6 packet because of one of the following reasons, it drops the packet and sends a corresponding ICMPv6 Destination Unreachable error message to the source.

- If no route is available for forwarding the packet, the device sends a "no route to destination" ICMPv6 error message to the source.
- If the device fails to forward the packet because of an administrative prohibition (such as a firewall filter or an ACL), the device sends the source a "destination network administratively prohibited" ICMPv6 error message.
- If the device fails to deliver the packet because the destination is beyond the scope of the source IPv6 address (for example, the source IPv6 address of the packet is a link-local address whereas the destination IPv6 address of the packet is a global unicast address), the device sends the source a "beyond scope of source address" ICMPv6 error message.
- If the device fails to resolve the corresponding link layer address of the destination IPv6 address, the device sends the source an "address unreachable" ICMPv6 error message.
- If the packet with the destination being local and transport layer protocol being UDP and the packet's destination port number does not match the running process, the device sends the source a "port unreachable" ICMPv6 error message.

If an attacker sends abnormal traffic that causes the device to generate ICMPv6 destination unreachable messages, end users may be affected. To prevent such attacks, you can disable the device from sending ICMPv6 destination unreachable messages.

To enable sending of ICMPv6 destination unreachable messages:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable sending of ICMPv6 destination unreachable messages.	ipv6 unreachable enable	Disabled by default

Displaying and maintaining IPv6 basics configuration

Task	Command	Remarks
Display the IPv6 FIB entries.	display ipv6 fib [vpn-instance <i>vpn-instance-name</i>] [acl6 <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view Only HP 5500 EI Switch Series supports the vpn-instance <i>vpn-instance-name</i> option.
Display the IPv6 FIB entry of a specified destination IPv6 address.	display ipv6 fib [vpn-instance <i>vpn-instance-name</i>] <i>ipv6-address</i> [<i>prefix-length</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view Only HP 5500 EI Switch Series supports the vpn-instance <i>vpn-instance-name</i> option.
Display the IPv6 information of the interface.	display ipv6 interface [<i>interface-type</i> [<i>interface-number</i>]] [brief] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display neighbor information.	display ipv6 neighbors { { <i>ipv6-address</i> all dynamic static } [<i>slot slot-number</i>] interface <i>interface-type interface-number</i> vlan <i>vlan-id</i> } [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view Only HP 5500 EI Switch Series supports the verbose keyword.
Display the total number of neighbor entries satisfying the specified conditions.	display ipv6 neighbors { { all dynamic static } [<i>slot slot-number</i>] interface <i>interface-type interface-number</i> vlan <i>vlan-id</i> } count [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the neighbor information of a specified VPN(only available on the HP 5500 EI).	display ipv6 neighbors vpn-instance <i>vpn-instance-name</i> [count] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display the IPv6 path MTU information.	display ipv6 pathmtu [vpn-instance <i>vpn-instance-name</i>] { <i>ipv6-address</i> all dynamic static } [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view Only HP 5500 EI Switch Series supports the vpn-instance <i>vpn-instance-name</i> option.
Display socket information.	display ipv6 socket [socket-type <i>socket-type</i>] [<i>task-id</i> <i>socket-id</i>] [slot <i>slot-number</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display the statistics of IPv6 packets and ICMPv6 packets.	display ipv6 statistics [slot <i>slot-number</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display the IPv6 TCP connection statistics.	display tcp ipv6 statistics [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display the IPv6 TCP connection status information.	display tcp ipv6 status [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display the IPv6 UDP connection statistics.	display udp ipv6 statistics [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display ND snooping entries.	display ipv6 nd snooping [<i>ipv6-address</i> vlan <i>vlan-id</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Clear IPv6 neighbor information.	reset ipv6 neighbors { all dynamic interface <i>interface-type</i> <i>interface-number</i> slot <i>slot-number</i> static }	Available in user view
Clear the path MTU values.	reset ipv6 pathmtu { all static dynamic }	Available in user view
Clear the statistics of IPv6 and ICMPv6 packets.	reset ipv6 statistics [slot <i>slot-number</i>]	Available in user view
Clear all IPv6 TCP connection statistics.	reset tcp ipv6 statistics	Available in user view
Clear the statistics of all IPv6 UDP packets.	reset udp ipv6 statistics	Available in user view
Clear ND snooping entries.	reset ipv6 nd snooping [<i>ipv6-address</i> vlan <i>vlan-id</i>]	Available in user view

IPv6 basics configuration example

Network requirements

As shown in [Figure 58](#), a host, Switch A and Switch B are connected through Ethernet ports. Add the Ethernet ports into corresponding VLANs, configure IPv6 addresses for the VLAN interfaces and verify that they are connected.

- The global unicast addresses of VLAN-interface 1 and VLAN-interface 2 on Switch A are 2001::1/64 and 3001::1/64, respectively.
- The global unicast address of VLAN-interface 2 on Switch B is 3001::2/64, and a route to Host is available.

- IPv6 is enabled for the host to automatically obtain an IPv6 address through IPv6 ND, and a route to Switch B is available.

Figure 58 Network diagram

The VLAN interfaces have been created on the switch.

Configuration procedure

1. Configure Switch A:

Enable IPv6.

```
<SwitchA> system-view
[SwitchA] ipv6
```

Specify a global unicast address for VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address 3001::1/64
[SwitchA-Vlan-interface2] quit
```

Specify a global unicast address for VLAN-interface 1, and allow it to advertise RA messages (no interface advertises RA messages by default).

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipv6 address 2001::1/64
[SwitchA-Vlan-interface1] undo ipv6 nd ra halt
[SwitchA-Vlan-interface1] quit
```

2. Configure Switch B:

Enable IPv6.

```
<SwitchB> system-view
[SwitchB] ipv6
```

Configure a global unicast address for VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address 3001::2/64
[SwitchB-Vlan-interface2] quit
```

Configure an IPv6 static route with destination IP address 2001::/64 and next hop address 3001::1.

```
[SwitchB] ipv6 route-static 2001:: 64 3001::1
```

3. Configure the host:

Enable IPv6 for Host to automatically obtain an IPv6 address through IPv6 ND.

Display the neighbor information of GigabitEthernet 1/0/2 on Switch A.

```
[SwitchA] display ipv6 neighbors interface GigabitEthernet 1/0/2
```

```

Type: S-Static      D-Dynamic
IPv6 Address          Link-layer      VID  Interface  State T Age
FE80::215:E9FF:FEA6:7D14  0015-e9a6-7d14  1    GE1/0/2    STALE D 1238
2001::15B:E0EA:3524:E791  0015-e9a6-7d14  1    GE1/0/2    STALE D 1248

```

The output shows that the IPv6 global unicast address that the host obtained is 2001::15B:E0EA:3524:E791.

Verifying the configuration

Display the IPv6 interface settings on Switch A. All of the IPv6 global unicast addresses configured on the interface are displayed.

```
[SwitchA] display ipv6 interface vlan-interface 2
Vlan-interface2 current state :UP
Line protocol current state :UP

  OutDiscards:                   0
```

Ping Switch A and Switch B on the host, and ping Switch A and the host on Switch B to verify that they are connected.

❗ **IMPORTANT:**

When you ping a link-local address, you should use the **-i** parameter to specify an interface for the link-local address.

```
[SwitchB] ping ipv6 -c 1 3001::1
PING 3001::1 : 56 data bytes, press CTRL_C to break
  Reply from 3001::1
    bytes=56 Sequence=1 hop limit=64  time = 2 ms

--- 3001::1 ping statistics ---
  1 packet(s) transmitted
  1 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 2/2/2 ms
[SwitchB-Vlan-interface2] ping ipv6 -c 1 2001::15B:E0EA:3524:E791
PING 2001::15B:E0EA:3524:E791 : 56 data bytes, press CTRL_C to break
  Reply from 2001::15B:E0EA:3524:E791
    bytes=56 Sequence=1 hop limit=63  time = 3 ms

--- 2001::15B:E0EA:3524:E791 ping statistics ---
  1 packet(s) transmitted
  1 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 3/3/3 ms
```

The output shows that Switch B can ping Switch A and the host.

Troubleshooting IPv6 basics configuration

Symptom

The peer IPv6 address cannot be pinged.

Solution

1. Use the **display current-configuration** command in any view or the **display this** command in system view to verify that IPv6 is enabled.
2. Use the **display ipv6 interface** command in any view to verify that the IPv6 address of the interface is correct and the interface is up.
3. Use the **debugging ipv6 packet** command in user view to enable the debugging for IPv6 packets to help locate the cause.

DHCPv6 overview

Introduction to DHCPv6

The Dynamic Host Configuration Protocol for IPv6 (DHCPv6) was designed based on IPv6 addressing scheme and is used for assigning IPv6 prefixes, IPv6 addresses and other configuration parameters to hosts.

Compared with other IPv6 address allocation methods (such as manual configuration and stateless address autoconfiguration), DHCPv6 can:

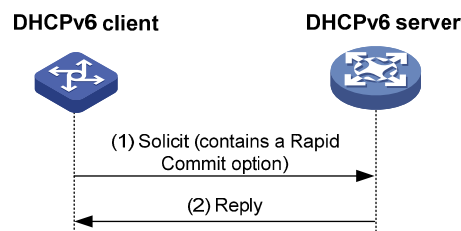

- Record addresses assigned to hosts and assign specific addresses to hosts, thus facilitating network management.
- Assign prefixes to devices, facilitating automatic configuration and management of the entire network.
- Assign other configuration parameters, such as DNS server addresses and domain names.

DHCPv6 address/prefix assignment

A process of DHCPv6 address/prefix assignment involves two or four messages. The following describe the detailed processes.

Rapid assignment involving two messages

Figure 59 Rapid assignment involving two messages

As shown in [Figure 59](#), the rapid assignment involving two messages operates in the following steps.

1. The DHCPv6 client sends out a Solicit message that contains a Rapid Commit option, requesting that rapid assignment of address/prefix and other configuration parameters should be preferred.
2. If the DHCPv6 server supports rapid assignment, it responds with a Reply message containing the assigned IPv6 address/prefix and other configuration parameters. If the DHCPv6 server does not support rapid assignment, [Assignment involving four messages](#) is implemented.

Assignment involving four messages

[Figure 60](#) shows the process of IPv6 address/prefix assignment involving four messages.

Figure 60 Assignment involving four messages

The assignment involving four messages operates in the following steps:

1. The DHCPv6 client sends out a Solicit message, requesting an IPv6 address/prefix and other configuration parameters.
2. If the Solicit message does not contain a Rapid Commit option, or if the DHCPv6 server does not support rapid assignment even though the Solicit message contains a Rapid Commit option, the DHCPv6 server responds with an Advertise message, informing the DHCPv6 client of the assignable address/prefix and other configuration parameters.
3. The DHCPv6 client may receive multiple Advertise messages offered by different DHCPv6 servers. It then selects an offer according to the receiving sequence and server priority, and sends a Request message to the selected server for the confirmation of assignment.
4. The DHCPv6 server sends a Reply message to the client, confirming that the address/prefix and other configuration parameters are assigned to the client.

Address/prefix lease renewal

The IPv6 address/prefix assigned by the DHCPv6 server has a lease time, which depends on the valid lifetime. When the valid lifetime of the IPv6 address/prefix expires, the DHCPv6 client cannot use the IPv6 address/prefix any longer. To continue using the IPv6 address/prefix, the DHCPv6 client has to renew the lease time.

As shown in [Figure 61](#), at T1, the DHCPv6 client unicasts a Renew message to the DHCPv6 server that assigned the IPv6 address/prefix to the DHCPv6 client. The recommended value of T1 is half the preferred lifetime. Then the DHCPv6 server responds with a Reply message, informing the client about whether or not the lease is renewed.

Figure 61 Using the Renew message for address/prefix lease renewal

As shown in [Figure 62](#), if the DHCPv6 client receives no response from the DHCPv6 server after sending out a Renew message at T1, it multicasts a Rebind message to all DHCPv6 servers at T2 (that is, when 80% preferred lifetime expires). Then the DHCPv6 server responds with a Reply message, informing the client about whether or not the lease is renewed.

If the DHCPv6 client receives no response from the DHCPv6 servers, the client stops using the address/prefix when the valid lifetime expires. For more information about the valid lifetime and the preferred lifetime, see "Configuring IPv6 basics."

Figure 62 Using the Rebind message for address/prefix lease renewal

Configuring stateless DHCPv6

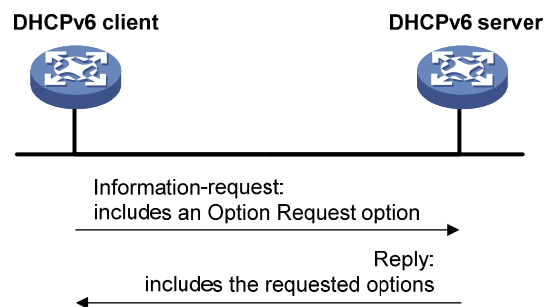

After obtaining an IPv6 address/prefix, a device can use stateless DHCPv6 to obtain other configuration parameters from a DHCPv6 server. This application is called stateless DHCPv6 configuration.

With an IPv6 address obtained through stateless address autoconfiguration, a device automatically enables the stateless DHCPv6 function after it receives an RA message with the managed address configuration flag (M flag) set to 0 and with the other stateful configuration flag (O flag) set to 1.

Stateless address autoconfiguration means that a node automatically generates an IPv6 address based on the information obtained through router/prefix discovery. For more information, see "Configuring IPv6 basics."

Operation

Figure 63 Operation of stateless DHCPv6

As shown in [Figure 63](#), stateless DHCPv6 operates in the following steps:

1. The DHCPv6 client multicasts an Information-request message to the multicast address of all DHCPv6 servers and DHCPv6 relay agents. The Information-request message contains an Option Request option, specifying the configuration parameters that the client requests from the DHCPv6 server.
2. After receiving the Information-request message, the DHCPv6 server returns the client a Reply message containing the requested configuration parameters.
3. The client checks the Reply message. If the obtained configuration parameters match those requested in the Information-request message, the client performs network configuration with the

parameters. If not, the client ignores the configuration parameters. If multiple replies are received, the first received reply will be used.

Protocols and standards

- RFC 3736, *Stateless Dynamic Host Configuration Protocol (DHCP) Service for IPv6*
- RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*
- RFC 2462, *IPv6 Stateless Address Autoconfiguration*
- RFC 3633, *IPv6 Prefix Options for Dynamic Host Configuration Protocol (DHCP) version 6*

Configuring DHCPv6 server

Overview

As shown in [Figure 64](#), the DHCPv6 server assigns the DHCPv6 client an IPv6 prefix to facilitate IPv6 address management and network configuration. After obtaining the IPv6 prefix, the DHCPv6 client sends an RA message containing the prefix information to the subnet where it resides, so that hosts on the subnet can automatically configure their IPv6 addresses by using the prefix.

A device serving as a DHCPv6 server assigns DHCPv6 clients IPv6 prefixes, but not IPv6 addresses, and supports DHCPv6 stateless configuration to assign other configuration parameters.

Figure 64 Typical DHCPv6 server application

Concepts

DHCPv6 multicast address

The multicast address FF05::1:3 identifies all DHCPv6 servers on the site-local network. The multicast address FF02::1:2 identifies all DHCPv6 servers and relay agents on the link-local link.

DUID

A DHCP unique identifier (DUID) uniquely identifies a DHCPv6 device (DHCPv6 client, server, or relay agent).

Figure 65 DUID-LL format

A DUID based on link-layer address (DUID-LL) defined in RFC 3315 is used to identify a DHCPv6 device. [Figure 65](#) shows the DUID-LL format, where:

- **DUID type**—The device supports DUID-LL as the DUID type with the value of 0x0003.
- **Hardware type**—The device supports Ethernet as the hardware type with the value of 0x0001.
- **Link layer address**—Its value is the bridge MAC address of the device.

IA

Identified by an IAID, an Identity Association (IA) provides a construct through which the obtained addresses, prefixes, and other configuration parameters assigned from a server to a client are managed. A client can maintain multiple IAs, each of which is configured on an interface to manage the addresses, prefixes, and other configuration parameters obtained by that interface.

IAID

An IAID uniquely identifies an IA. It is chosen by the client and must be unique among the IAIDs on the client.

PD

The Prefix Delegation (PD) is the lease record created by the DHCPv6 server for each assigned prefix. The PD contains information such as the IPv6 prefix, client DUID, IAID, valid lifetime, preferred lifetime, lease expiration time, and the IPv6 address of the requesting client.

Prefix selection process

Upon receiving a request, the DHCPv6 server selects the prefix and other configuration parameters from the address pool that is applied to the interface receiving the request. An address pool may contain the static prefixes configured for specific clients, or have a prefix pool referenced for dynamic assignment from the specific prefix range.

A DHCPv6 server selects a prefix from the address pool according to the following sequence:

1. The desired static prefix with the DUID and IAID matching those of the client
2. The static prefix with the DUID and IAID matching those of the client
3. The desired static prefix with the DUID matching the client's DUID and with no client IAID specified
4. The static prefix with the DUID matching the client's DUID and with no client IAID specified
5. The desired idle prefix in the prefix pool
6. An idle prefix in the prefix pool

DHCPv6 server configuration task list

Before you configure the DHCPv6 server, enable IPv6 by using the **ipv6** command.

Task	Remarks
Enabling the DHCPv6 server	Required
Creating a prefix pool	Required
Configuring a DHCPv6 address pool	Required
Applying the address pool to an interface	Required
Setting the DSCP value for DHCPv6 packets	Optional

Enabling the DHCPv6 server

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the DHCPv6 server function.	ipv6 dhcp server enable	Disabled by default

Creating a prefix pool

A prefix pool specifies a range of prefixes.

To create a prefix pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a prefix pool.	ipv6 dhcp prefix-pool <i>prefix-pool-number</i> prefix <i>prefix/prefix-len</i> assign-len <i>assign-len</i>	Not configured by default

Configuring a DHCPv6 address pool

You can configure prefixes and other configuration parameters, such as the DNS server address, domain name, SIP server address, domain name of the SIP server, and address family translation router (AFTR) in a DHCPv6 address pool, for the DHCPv6 server to assign them to DHCPv6 clients.

Configuration restrictions and guidelines

- Only one prefix pool can be referenced by an address pool.
- A non-existing prefix pool can be referenced by an address pool. However, no prefix is available in the prefix pool for dynamic prefix assignment until the prefix pool is created.
- You cannot modify the prefix pool referenced by an address pool, or the preferred lifetime or valid lifetime by using the **prefix-pool** command. You must remove the configuration before you can have another prefix pool referenced by the address pool, or modify the preferred lifetime and valid lifetime.
- You can configure up to eight DNS server addresses, one domain name, eight SIP server addresses, and eight SIP server domain names in an address pool.

Configuration procedure

To configure a DHCPv6 address pool:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a DHCPv6 address pool and enter DHCPv6 address pool view.	ipv6 dhcp pool <i>pool-number</i>	Not configured by default.

Step	Command	Remarks
3. Configure a DHCPv6 address pool.	<ul style="list-style-type: none"> Configure a static prefix: static-bind prefix <i>prefix/prefix-len</i> duid <i>duid</i> [iaid <i>iaid</i>] [preferred-lifetime <i>preferred-lifetime</i> valid-lifetime <i>valid-lifetime</i>] Apply a prefix pool to the address pool: prefix-pool <i>prefix-pool-number</i> [preferred-lifetime <i>preferred-lifetime</i> valid-lifetime <i>valid-lifetime</i>] 	Use either command. No prefix is specified by default.
4. Configure a DNS server address.	dns-server <i>ipv6-address</i>	Optional. Not configured by default.
5. Configure a domain name.	domain-name <i>domain-name</i>	Optional. Not configured by default.
6. Configure the IPv6 address or domain name of a SIP server.	sip-server { address <i>ipv6-address</i> domain-name <i>domain-name</i> }	Optional. Not configured by default.
7. Specify the AFTR address.	ds-lite address <i>ipv6-address</i>	Optional. Not specified by default.

Applying the address pool to an interface

After an address pool is applied to an interface, a prefix and other configuration parameters can be selected from the address pool and assigned to the DHCPv6 client requesting through the interface.

Follow these guidelines when you apply an address pool to an interface:

- An interface cannot serve as a DHCPv6 server and DHCPv6 relay agent at the same time.
- It is not recommended that you enable DHCPv6 server and DHCPv6 client on the same interface.
- Only one address pool can be applied to an interface.
- A non-existing address pool can be applied to an interface. However, the server cannot assign any prefix or other configuration information from the address pool until the address pool is created.
- You cannot modify the address pool applied to an interface or parameters such as the server priority by using the **ipv6 dhcp server apply pool** command. You must remove the applied address pool before you can apply another address pool to the interface or modify parameters such as the server priority.

To apply an address pool to an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Apply the DHCPv6 address pool to the interface.	ipv6 dhcp server apply pool <i>pool-number</i> [allow-hint preference <i>preference-value</i> rapid-commit] *	Not configured by default

Setting the DSCP value for DHCPv6 packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for DHCPv6 packets sent by the DHCPv6 server.	ipv6 dhcp dscp <i>dscp-value</i>	Optional. By default, the DSCP value in DHCPv6 packets is 56.

Displaying and maintaining the DHCPv6 server

Task	Command	Remarks
Display the DUID of the local device.	display ipv6 dhcp duid [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the DHCPv6 address pool information.	display ipv6 dhcp pool [<i>pool-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the prefix pool information.	display ipv6 dhcp prefix-pool [<i>prefix-pool-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the DHCPv6 server configuration information.	display ipv6 dhcp server [<i>interface interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the PD information.	display ipv6 dhcp server pd-in-use { all pool <i>pool-number</i> prefix <i>prefix/prefix-len</i> prefix-pool <i>prefix-pool-number</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display packet statistics on the DHCPv6 server.	display ipv6 dhcp server statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear PD information on the DHCPv6 server.	reset ipv6 dhcp server pd-in-use { all pool <i>pool-number</i> prefix <i>prefix/prefix-len</i> }	Available in user view
Clear packets statistics on the DHCPv6 server.	reset ipv6 dhcp server statistics	Available in user view

DHCPv6 server configuration example

Network requirements

As shown in [Figure 66](#), the switch serves as a DHCPv6 server, and assigns the IPv6 prefix, DNS server address, domain name, SIP server address, and SIP server domain name to the DHCPv6 clients. The IPv6 address of the switch is 1::1/64.

The switch assigns prefix 2001:0410:0201::/48 to the client whose DUID is 00030001CA0006A40000, and assigns prefixes ranging from 2001:0410::/48 to 2001:0410:FFFF::/48 (excluding 2001:0410:0201::/48) to other clients. The DNS server address is 2::2:3. The DHCPv6 clients reside in domain aaa.com. The SIP server address is 2:2::4, and the domain name of the SIP server is bbb.com.

Configuration considerations

To configure the DHCPv6 server:

- Enable IPv6 and DHCPv6 server.
- Create a prefix pool containing prefix 2001:0410::/32 with the length of the assigned prefix being 48, so that the server assigns clients the prefixes ranging 2001:0410::/48 to 2001:0410:FFFF::/48.
- Create an address pool. Configure a static prefix in the address pool and have the prefix pool referenced by the address pool. Configure other configuration parameters.
- Apply the address pool to the interface through which the server is connected to the clients.

Figure 66 Network diagram

Configuration procedure

Enable IPv6 and DHCPv6 server.

```
<Switch> system-view
[Switch] ipv6
[Switch] ipv6 dhcp server enable
```

Configure the IPv6 address of VLAN-interface 2.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ipv6 address 1::1/64
[Switch-Vlan-interface2] quit
```

Create and configure prefix pool 1.

```
[Switch] ipv6 dhcp prefix-pool 1 prefix 2001:0410::/32 assign-len 48
```

Create address pool 1.

```
[Switch] ipv6 dhcp pool 1
```

Apply prefix pool 1 to address pool 1, and set the preferred lifetime to one day, the valid lifetime to three days.

```
[Switch-ipv6-dhcp-pool-1] prefix-pool 1 preferred-lifetime 86400 valid-lifetime 259200
```

Configure static prefix 2001:0410:0201::/48 in address pool 1, and set the client DUID as 00030001CA0006A40000, the preferred lifetime to one day, and the valid lifetime to three days.

```
[Switch-ipv6-dhcp-pool-1] static-bind prefix 2001:0410:0201::/48 duid
00030001CA0006A40000 preferred-lifetime 86400 valid-lifetime 259200
```

Configure the DNS server address as 2:2::3.

```

[Switch-ipv6-dhcp-pool-1] dns-server 2:2::3

2001:410::/48	Auto(C)	1	Jul 10 2009 20:44:05

Configuring DHCPv6 relay agent

Overview

A DHCPv6 client usually uses a multicast address to contact the DHCPv6 server on the local link to obtain an IPv6 address and other configuration parameters. As shown in [Figure 67](#), if the DHCPv6 server resides on another subnet, the DHCPv6 client can contact the server via a DHCPv6 relay agent, so you do not need to deploy a DHCPv6 server on each subnet.

Figure 67 Typical DHCPv6 relay agent application

DHCPv6 relay agent operation

[Figure 68](#) shows how the DHCPv6 client obtains an IPv6 address and other network configuration parameters from the DHCPv6 server through the DHCPv6 relay agent, using the process of rapid assignment involving two messages.

Figure 68 Operating process of a DHCPv6 relay agent

The operation process is as follows:

1. The DHCPv6 client sends a Solicit message containing the Rapid Commit option to the multicast address FF02::1:2 of all the DHCPv6 servers and relay agents.

2. After receiving the Solicit message, the DHCPv6 relay agent encapsulates the message into the Relay Message option of a Relay-forward message, and sends the message to the DHCPv6 server.
3. After obtaining the Solicit message from the Relay-forward message, the DHCPv6 server selects an IPv6 address and other required parameters, and adds them to the reply which is encapsulated within the Relay Message option of a Relay-reply message. The DHCPv6 server then sends the Relay-reply message to the DHCPv6 relay agent.
4. The DHCPv6 relay agent obtains the reply from the Relay-reply message and sends the reply to the DHCPv6 client.

The DHCPv6 client uses the IPv6 address and other network parameters assigned by the DHCPv6 server to perform network configuration.

Configuring the DHCPv6 relay agent

Upon receiving a Solicit message from a DHCPv6 client, the interface that operates as a DHCPv6 relay agent encapsulates the request into a Relay-forward message and forwards the message to the specified DHCPv6 server, which then assigns an IPv6 address and other configuration parameters to the DHCPv6 client.

Configuration guidelines

Follow these guidelines when you configure the DHCPv6 relay agent:

- Before you configure the DHCPv6 relay agent, enable IPv6 by using the **ipv6** command in system view.
- Executing the **ipv6 dhcp relay server-address** command repeatedly can specify multiple DHCPv6 servers. Up to eight DHCPv6 servers can be specified for an interface. After receiving requests from DHCPv6 clients, the DHCPv6 relay agent forwards the requests to all the specified DHCPv6 servers.
- If the DHCPv6 server address is a link-local address or link-scoped multicast address on the local link, you must specify an outgoing interface using the **interface** keyword in the **ipv6 dhcp relay server-address** command. Otherwise, DHCPv6 packets may fail to be forwarded to the DHCPv6 server.
- After you remove all the specified DHCPv6 servers from an interface with the **undo ipv6 dhcp relay server-address** command, DHCPv6 relay agent is disabled on the interface.
- An interface cannot serve as a DHCPv6 relay agent and DHCPv6 server at the same time.
- HP does not recommend enabling the DHCPv6 relay agent and DHCPv6 client on the same interface

Configuration procedure

To configure the DHCPv6 relay agent:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
3. Enable DHCPv6 relay agent on the interface and specify a DHCPv6 server.	ipv6 dhcp relay server-address <i>ipv6-address [interface interface-type interface-number]</i>	By default, DHCPv6 relay agent is disabled and no DHCPv6 server is specified on the interface.

Setting the DSCP value for DHCPv6 packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for DHCPv6 packets sent by the DHCPv6 relay agent.	ipv6 dhcp dscp <i>dscp-value</i>	Optional. By default, the DSCP value in DHCPv6 packets is 56.

Displaying and maintaining the DHCPv6 relay agent

Task	Command	Remarks
Display the DUID of the local device.	display ipv6 dhcp duid [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display DHCPv6 server addresses specified on the DHCPv6 relay agent.	display ipv6 dhcp relay server-address { all interface <i>interface-type interface-number</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display packet statistics on the DHCPv6 relay agent.	display ipv6 dhcp relay statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear packets statistics on the DHCPv6 relay agent.	reset ipv6 dhcp relay statistics	Available in user view

DHCPv6 relay agent configuration example

Network requirements

As shown in [Figure 69](#), the network address prefix of DHCPv6 clients is 1::/64, and the IPv6 address of the DHCPv6 server is 2::2/64. The DHCPv6 client and server need to communicate via a DHCPv6 relay agent (Switch A).

Switch A acts as the gateway of network 1::/64. It sends RA messages to notify the hosts to obtain IPv6 addresses and other configuration parameters through DHCPv6.

Figure 69 Network diagram

Configuration procedure

1. Configure Switch A as a DHCPv6 relay agent:

Enable the IPv6 packet forwarding function.

```
<SwitchA> system-view
[SwitchA] ipv6
```

Configure the IPv6 addresses of VLAN-interface 2 and VLAN-interface 3 respectively.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address 2::1 64
[SwitchA-Vlan-interface2] quit
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ipv6 address 1::1 64
```

Enable DHCPv6 relay agent and specify the DHCPv6 server address on VLAN-interface 3.

```
[SwitchA-Vlan-interface3] ipv6 dhcp relay server-address 2::2
```

2. Configure Switch A as a gateway:

Enable Switch A to send RA messages and turn on the M and O flags.

```
[SwitchA-Vlan-interface3] undo ipv6 nd ra halt
[SwitchA-Vlan-interface3] ipv6 nd autoconfig managed-address-flag
[SwitchA-Vlan-interface3] ipv6 nd autoconfig other-flag
```

Verifying the configuration

Display DHCPv6 server address information on Switch A.

```
[SwitchA-Vlan-interface3] display ipv6 dhcp relay server-address all
Interface: Vlan3
Server address(es)                               Output Interface
2::2
```

Display packet statistics on the DHCPv6 relay agent.

```
[SwitchA-Vlan-interface3] display ipv6 dhcp relay statistics
Packets dropped           : 0
Error                     : 0
Excess of rate limit     : 0
Packets received         : 14
```

Configuring DHCPv6 client

Overview

Serving as a DHCPv6 client, the device only supports stateless DHCPv6 configuration, that is, the device can only obtain other network configuration parameters, except the IPv6 address and prefix from the DHCPv6 server.

With an IPv6 address obtained through stateless address autoconfiguration, the device automatically enables the stateless DHCPv6 function after it receives an RA message with the M flag set to 0 and the O flag set to 1.

Configuring the DHCPv6 client

Configuration prerequisites

To make the DHCPv6 client successfully obtain configuration parameters through stateless DHCPv6 configuration, make sure that the DHCPv6 server is available.

Configuration guidelines

- For more information about the **ipv6 address auto** command, see the *Layer 3—IP Services Command Reference*.
- HP does not recommend enabling the DHCPv6 client and DHCPv6 server, or the DHCPv6 client and DHCPv6 relay agent on the same interface at the same time.

Configuration procedure

To configure the DHCPv6 client:

Step	Command
1. Enter system view.	system-view
2. Enable the IPv6 packet forwarding function.	ipv6
3. Enter interface view.	interface <i>interface-type interface-number</i>
4. Enable IPv6 stateless address autoconfiguration.	ipv6 address auto

Setting the DSCP value for DHCPv6 packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Set the DSCP value for the DHCPv6 packets sent by the DHCPv6 client.	<code>ipv6 dhcp client dscp dscp-value</code>	Optional. By default, the DSCP value in DHCPv6 packets is 56.

Displaying and maintaining the DHCPv6 client

Task	Command	Remarks
Display DHCPv6 client information.	<code>display ipv6 dhcp client [interface interface-type interface-number] [{ begin exclude include } regular-expression]</code>	Available in any view
Display DHCPv6 client statistics.	<code>display ipv6 dhcp client statistics [interface interface-type interface-number] [{ begin exclude include } regular-expression]</code>	Available in any view
Display the DUID of the local device.	<code>display ipv6 dhcp duid [{ begin exclude include } regular-expression]</code>	Available in any view
Clear DHCPv6 client statistics.	<code>reset ipv6 dhcp client statistics [interface interface-type interface-number]</code>	Available in user view

Stateless DHCPv6 configuration example

Network requirements

As shown in [Figure 70](#), through stateless DHCPv6, Switch A obtains the DNS server address, domain name, and other information from the server.

Switch B acts as the gateway to send RA messages periodically.

Figure 70 Network diagram

Configuration procedure

- Configure Switch B:
 - # Enable the IPv6 packet forwarding function.
 - <SwitchB> system-view
 - [SwitchB] ipv6
 - # Configure the IPv6 address of VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address 1::1 64
# Set the O flag in the RA messages to 1.
[SwitchB-Vlan-interface2] ipv6 nd autoconfig other-flag
# Enable Switch B to send RA messages.
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
```

2. Configure Switch A:

Enable the IPv6 packet forwarding function.

```
<SwitchA> system-view
[SwitchA] ipv6
```

Enable stateless IPv6 address autoconfiguration on VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address auto
```

With this command executed, if VLAN-interface 2 has no IPv6 address configured, Switch A will automatically generate a link-local address, and send an RS message, requesting the gateway (Switch B) to reply with an RA message immediately.

Verifying the configuration

After receiving an RA message with the M flag set to 0 and the O flag set to 1, Switch A automatically enables the stateless DHCPv6 function.

Use the **display ipv6 dhcp client** command to view the current client configuration information. If the client successfully obtains configuration information from the server, the following information will be displayed.

```
[SwitchA-Vlan-interface2] display ipv6 dhcp client interface vlan-interface 2
Vlan-interface2 is in stateless DHCPv6 client mode
State is OPEN
Preferred Server:
  Reachable via address      : FE80::213:7FFF:FEF6:C818
  DUID                       : 0003000100137ff6c818
  DNS servers                : 1:2:3:5
                             1:2:4:7
  Domain names               : abc.com
                             Sysname.com
```

Use the **display ipv6 dhcp client statistics** command to view the current client statistics.

```
[SwitchA-Vlan-interface2] display ipv6 dhcp client statistics
Interface                : Vlan-interface2

Configuring DHCPv6 snooping

A DHCPv6 snooping device does not work if it is between a DHCPv6 relay agent and a DHCPv6 server. The DHCPv6 snooping device works when it is between a DHCPv6 client and a DHCPv6 relay agent or between a DHCPv6 client and a DHCPv6 server.

You can configure only Layer 2 Ethernet ports or Layer 2 aggregate interfaces as DHCPv6 snooping trusted ports. For more information about aggregate interfaces, see *Layer 2—LAN Switching Configuration Guide*.

Overview

DHCPv6 snooping is security feature with the following functions:

- Ensure that DHCPv6 clients obtain IPv6 addresses from authorized DHCPv6 servers.
- Record IP-to-MAC mappings of DHCPv6 clients.

Ensuring that DHCPv6 clients obtain IPv6 addresses from authorized DHCPv6 servers

If DHCPv6 clients obtain invalid IPv6 addresses and network configuration parameters from an unauthorized DHCP server, they will be unable to communicate normally with other network devices. With DHCPv6 snooping, the ports of a device can be configured as trusted or untrusted to make sure that the clients obtain IPv6 addresses only from authorized DHCPv6 servers.

- **Trusted**—A trusted port forwards DHCPv6 messages normally.
- **Untrusted**—An untrusted port discards reply messages from any DHCPv6 server.

Figure 71 Trusted and untrusted ports

A DHCPv6 snooping device's port that is connected to an authorized DHCPv6 server, DHCPv6 relay agent, or another DHCPv6 snooping device should be configured as a trusted port. The trusted port forwards reply messages from the authorized DHCPv6 server. Other ports are configured as untrusted so

that they do not forward reply messages from any DHCPv6 servers. This ensures that the DHCPv6 client can obtain an IPv6 address from the authorized DHCPv6 server only.

As shown in [Figure 71](#), configure the port that connects to the DHCPv6 server as a trusted port, and other ports as untrusted.

Recording IP-to-MAC mappings of DHCPv6 clients

DHCPv6 snooping reads DHCPv6 messages to create and update DHCPv6 snooping entries, including MAC addresses of clients, IPv6 addresses obtained by the clients, ports that connect to DHCPv6 clients, and VLANs to which the ports belong. You can use the **display ipv6 dhcp snooping user-binding** command to view the IPv6 address obtained by each client, so you can manage and monitor the clients' IPv6 addresses.

Enabling DHCPv6 snooping

To allow clients to obtain IPv6 addresses from an authorized DHCPv6 server, enable DHCPv6 snooping globally and configure trusted and untrusted ports properly. To record DHCPv6 snooping entries for a VLAN, enable DHCPv6 snooping for the VLAN.

To enable DHCPv6 snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable DHCPv6 snooping globally.	ipv6 dhcp snooping enable	Disabled by default.
3. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
4. Enable DHCPv6 snooping for the VLAN.	ipv6 dhcp snooping vlan enable	Optional. Disabled by default.

Configuring a DHCPv6 snooping trusted port

After enabling DHCPv6 snooping globally, you can specify trusted and untrusted ports for a VLAN as needed. A DHCPv6 snooping trusted port normally forwards received DHCPv6 packets. A DHCPv6 snooping untrusted port discards any DHCPv6 reply message received from a DHCPv6 server. Upon receiving a DHCPv6 request from a client in the VLAN, the DHCPv6 snooping device forwards the packet through trusted ports rather than any untrusted port in the VLAN, reducing network traffic.

You must specify a port connected to an authorized DHCPv6 server as trusted to make sure that DHCPv6 clients can obtain valid IPv6 addresses. The trusted port and the ports connected to the DHCPv6 clients must be in the same VLAN.

If a Layer 2 Ethernet port is added to an aggregation group, the DHCPv6 snooping configuration of the interface will not take effect until the interface quits from the aggregation group.

To configure a DHCPv6 snooping trusted port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the port as trusted.	ipv6 dhcp snooping trust	By default, all ports of the device with DHCPv6 snooping globally enabled are untrusted.

Configuring the maximum number of DHCPv6 snooping entries an interface can learn

Perform this optional task to prevent an interface from learning too many DHCPv6 snooping entries and to save system resources.

To configure the maximum number of DHCPv6 snooping entries an interface can learn:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the maximum number of DHCPv6 snooping entries that the interface can learn.	ipv6 dhcp snooping max-learning-num <i>number</i>	Optional. By default, the number of DHCPv6 snooping entries learned by an interface is not limited.

Displaying and maintaining DHCPv6 snooping

Task	Command	Remarks
Display DHCPv6 snooping trusted ports.	display ipv6 dhcp snooping trust [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display DHCPv6 snooping entries.	display ipv6 dhcp snooping user-binding { <i>ipv6-address</i> dynamic } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear DHCPv6 snooping entries.	reset ipv6 dhcp snooping user-binding { <i>ipv6-address</i> dynamic }	Available in user view

DHCPv6 snooping configuration example

Network requirements

As shown in [Figure 72](#), Switch is connected to a DHCPv6 server through GigabitEthernet 1/0/1, and is connected to DHCPv6 clients through GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3. These three interfaces belong to VLAN 2. Configure Switch to forward DHCPv6 reply messages received on GigabitEthernet 1/0/1 only and record the IP-to-MAC mappings for DHCPv6 clients.

Figure 72 Network diagram

Configuration procedure

Enable DHCPv6 snooping globally.

```
<Switch> system-view
```

```
[Switch] ipv6 dhcp snooping enable
```

Add GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to VLAN 2.

```
[Switch] vlan 2
```

```
[Switch-vlan2] port GigabitEthernet 1/0/1 GigabitEthernet 1/0/2 GigabitEthernet 1/0/3
```

Enable DHCPv6 snooping for VLAN 2.

```
[Switch-vlan2] ipv6 dhcp snooping vlan enable
```

```
[Switch] quit
```

Configure GigabitEthernet 1/0/1 as a DHCPv6 snooping trusted port.

```
[Switch] interface GigabitEthernet 1/0/1
```

```
[Switch-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
```

Verifying the configuration

Connect GigabitEthernet 1/0/2 to a DHCPv6 client, GigabitEthernet 1/0/1 to a DHCPv6 server, and GigabitEthernet 1/0/3 to an unauthorized DHCPv6 server. The DHCPv6 client obtains an IPv6 address from DHCPv6 server, but cannot obtain any IPv6 address from the unauthorized DHCPv6 server. You can use the **display ipv6 dhcp snooping user-binding** command to view the DHCPv6 snooping entries on Switch.

Configuring IPv6 DNS

Overview

IPv6 Domain Name System (DNS) is responsible for translating domain names into IPv6 addresses. Like IPv4 DNS, IPv6 DNS includes static domain name resolution and dynamic domain name resolution. The functions and implementations of the two types of domain name resolution are the same as those of IPv4 DNS. For more information, see "Configuring IPv4 DNS."

Configuring the IPv6 DNS client

Configuring static domain name resolution

Configuring static domain name resolution refers to specifying the mappings between host names and IPv6 addresses. Static domain name resolution allows applications such as Telnet to contact hosts by using host names instead of IPv6 addresses.

Follow these guidelines when you configure static domain name resolution:

- A host name can be mapped to one IPv6 address only. If you map a host name to different IPv6 addresses, the last configuration takes effect.
- You can configure up to 50 mappings between domain name and IPv6 address on the switch.

To configure static domain name resolution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a mapping between a host name and an IPv6 address.	ipv6 host <i>hostname ipv6-address</i>	Not configured by default

Configuring dynamic domain name resolution

To send DNS queries to a correct server for resolution, dynamic domain name resolution needs to be enabled and a DNS server needs to be configured.

In addition, you can configure a DNS suffix that the system automatically adds to the provided domain name for resolution.

Follow these guidelines when you configure dynamic domain name resolution:

- You can configure up to six DNS servers, including those with IPv4 addresses on the switch.
- You can specify up to ten DNS suffixes on the switch.

To configure dynamic domain name resolution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable dynamic domain name resolution.	dns resolve	Disabled by default.
3. Specify a DNS server.	dns server ipv6 <i>ipv6-address</i> [<i>interface-type interface-number</i>]	Not specified by default. If the IPv6 address of a DNS server is a link-local address, you must specify the <i>interface-type</i> and <i>interface-number</i> arguments.
4. Configure a DNS suffix.	dns domain <i>domain-name</i>	Optional. Not configured by default. Only the provided domain name is resolved.

Setting the DSCP value for IPv6 DNS packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for IPv6 DNS packets.	dns ipv6 dscp <i>dscp-value</i>	Optional. By default, the DSCP value in IPv6 DNS packets is 0.

Displaying and maintaining IPv6 DNS

Task	Command	Remarks
Display the static IPv6 domain name resolution table.	display ipv6 host [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 DNS server information.	display dns ipv6 server [dynamic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display DNS suffixes.	display dns domain [dynamic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about dynamic IPv6 domain name cache.	display dns host ipv6 [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear information about dynamic IPv6 domain name cache.	reset dns host ipv6	Available in user view

Static domain name resolution configuration example

Network requirements

As shown in [Figure 73](#), the device wants to access the host by using an easy-to-remember domain name rather than an IPv6 address. Configure static domain name resolution on the device so that the device can use the domain name `host.com` to access the host whose IPv6 address is `1::2`.

Figure 73 Network diagram

Configuration procedure

Configure a mapping between host name `host.com` and IPv6 address `1::2`.

```
<Device> system-view
[Device] ipv6 host host.com 1::2
```

Enable IPv6 packet forwarding.

```
[Device] ipv6
```

Use the **ping ipv6 host.com** command to verify that the device can use static domain name resolution to resolve domain name `host.com` into IPv6 address `1::2`.

```
[Device] ping ipv6 host.com
PING host.com (1::2):
 56 data bytes, press CTRL_C to break
  Reply from 1::2
  bytes=56 Sequence=1 hop limit=128 time = 3 ms
  Reply from 1::2
  bytes=56 Sequence=2 hop limit=128 time = 1 ms
  Reply from 1::2
  bytes=56 Sequence=3 hop limit=128 time = 1 ms
  Reply from 1::2
  bytes=56 Sequence=4 hop limit=128 time = 2 ms
  Reply from 1::2
  bytes=56 Sequence=5 hop limit=128 time = 2 ms
--- host.com ping statistics ---
 5 packet(s) transmitted
 5 packet(s) received
 0.00% packet loss
 round-trip min/avg/max = 1/1/3 ms
```

Dynamic domain name resolution configuration example

Network requirements

As shown in [Figure 74](#), the device wants to access the host by using an easy-to-remember domain name rather than an IPv6 address. The IPv6 address of the DNS server is `2::2/64` and the server has a `com` domain, which stores the mapping between domain name `host` and IPv6 address `1::1/64`.

Configure dynamic domain name resolution and the domain name suffix `com` on the device that serves as a DNS client so that the device can use domain name `host` to access the host with the domain name `host.com` and the IPv6 address `1::1/64`.

Figure 74 Network diagram

Configuration procedure

Before performing the following configuration, make sure that the device and the host are accessible to each other via available routes, and the IPv6 addresses of the interfaces are configured as shown [Figure 74](#).

This configuration may vary with DNS servers. The following configuration is performed on a PC running Windows Server 2003. Make sure that the DNS server supports the IPv6 DNS function so that the server can process IPv6 DNS packets, and the interfaces of the DNS server can forward IPv6 packets.

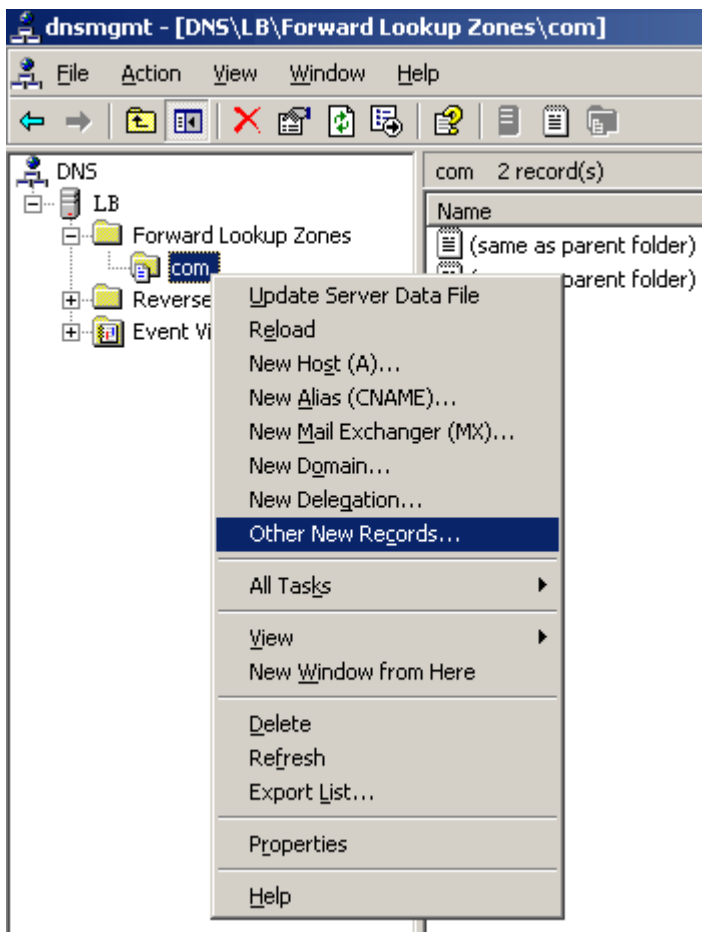

1. Configure the DNS server:
 - a. Select **Start > Programs > Administrative Tools > DNS**.
The DNS server configuration page appears, as shown in [Figure 75](#).
 - b. Right-click **Forward Lookup Zones**, select **New Zone**, and then follow the instructions to create a new zone named **com**.

Figure 75 Creating a zone

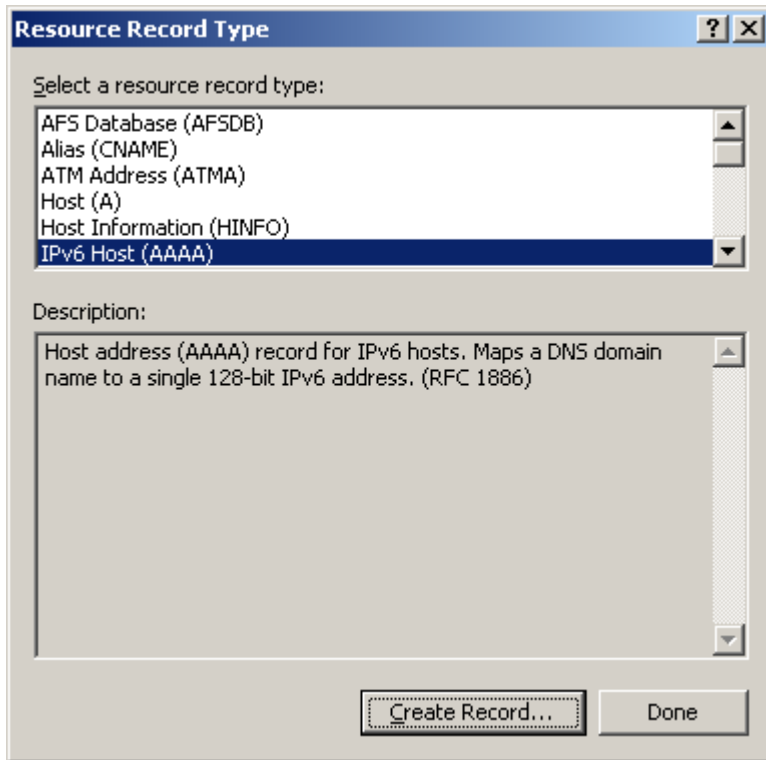

- c. On the DNS server configuration page, right-click zone **com** and select **Other New Records**.

Figure 76 Creating a record

- d. On the page that appears, select **IPv6 Host (AAAA)** as the resource record type, and click **Create Record**.

Figure 77 Selecting the resource record type

- e. On the page that appears, enter host name **host** and IPv6 address **1::1**.
 - f. Click **OK**.
- The mapping between the IP address and host name is created.

Figure 78 Adding a mapping between domain name and IPv6 address

The screenshot shows a window titled "New Resource Record" with a tab labeled "IPv6 Host (AAAA)". Inside the window, there are three text input fields. The first is labeled "Host (uses parent domain if left blank):" and contains the text "host". The second is labeled "Fully qualified domain name (FQDN):" and contains "host.com.". The third is labeled "IP version 6 host address:" and contains "1::1". At the bottom of the window, there are two buttons: "OK" and "Cancel".

2. Configure the DNS client:

Enable dynamic domain name resolution.

```
<Device> system-view
```

```
[Device] dns resolve
```

Specify the DNS server 2::2.

```
[Device] dns server ipv6 2::2
```

Configure com as the DNS suffix.

```
[Device] dns domain com
```

Verifying the configuration

Use the **ping ipv6 host** command on the device to verify that the communication between the device and the host is normal and that the corresponding destination IP address is 1::1.

```
[Device] ping ipv6 host
```

```
Trying DNS resolve, press CTRL_C to break
```

```
Trying DNS server (2::2)
```

```
PING host.com (1::1):
```

```
56 data bytes, press CTRL_C to break
```

```
Reply from 1::1
```

```
bytes=56 Sequence=1 hop limit=126 time = 2 ms
```

```
Reply from 1::1
```

```
bytes=56 Sequence=2 hop limit=126 time = 1 ms
Reply from 1::1
bytes=56 Sequence=3 hop limit=126 time = 1 ms
Reply from 1::1
bytes=56 Sequence=4 hop limit=126 time = 1 ms
Reply from 1::1
bytes=56 Sequence=5 hop limit=126 time = 1 ms
```

```
--- host.com ping statistics ---
```

```
5 packet(s) transmitted
```

```
5 packet(s) received
```

```
0.00% packet loss
```

```
round-trip min/avg/max = 1/1/2 ms
```

Configuring tunneling(only available on the HP 5500 EI)

Overview

Tunneling is an encapsulation technology: one network protocol encapsulates packets of another network protocol and transfers them over a virtual point-to-point connection. The virtual connection is called a tunnel. Packets are encapsulated and de-encapsulated at both ends of a tunnel. Tunneling refers to the whole process from data encapsulation to data transfer to data de-encapsulation.

Tunneling provides the following features:

- Transition techniques, such as IPv6 over IPv4 tunneling, to interconnect IPv4 and IPv6 networks.
- Virtual Private Networks (VPNs) for guaranteeing communication security, such as IPv4 over IPv4 tunneling, IPv4/IPv6 over IPv6 tunneling, Generic Routing Encapsulation (GRE), Dynamic Virtual Private Network (DVPN), and IPsec tunneling.
- Traffic engineering, such as Multiprotocol Label Switching traffic engineering (MPLS TE) to prevent network congestion.

Unless otherwise specified, the term "tunnel" used throughout this chapter refers to an IPv6 over IPv4, IPv4 over IPv4, IPv4 over IPv6, or IPv6 over IPv6 tunnel.

IPv6 over IPv4 tunneling

Implementation

IPv6 over IPv4 tunneling adds an IPv4 header to IPv6 data packets so that IPv6 packets can pass an IPv4 network through a tunnel to realize internetworking between isolated IPv6 networks, as shown in [Figure 79](#). The IPv6 over IPv4 tunnel can be established between two hosts, a host and a device, or two devices. The tunnel destination node can forward IPv6 packets if it is not the destination of the IPv6 packets.

The devices at both ends of an IPv6 over IPv4 tunnel must support the IPv4/IPv6 dual stack.

Figure 79 IPv6 over IPv4 tunnel

The IPv6 over IPv4 tunnel processes packets in the following ways.

1. A host in the IPv6 network sends an IPv6 packet to Device A at the tunnel source.

2. After determining from the routing table that the packet needs to be forwarded through the tunnel, Device A encapsulates the IPv6 packet with an IPv4 header and forwards it through the physical interface of the tunnel.
3. Upon receiving the packet, Device B de-encapsulates the packet.
4. Device B forwards the packet according to the destination address in the de-encapsulated IPv6 packet. If the destination address is the device itself, Device B forwards the IPv6 packet to the upper-layer protocol for processing.

Tunnel types

Depending on how the IPv4 address of the tunnel destination is acquired, IPv6 over IPv4 tunnels are divided into the following types:

- **Manually configured tunnel**—The destination address of the tunnel cannot be automatically acquired through the destination IPv6 address of an IPv6 packet at the tunnel source, and must be manually configured.
- **Automatic tunnel**—The destination address of the tunnel is an IPv6 address with an IPv4 address embedded, and the IPv4 address can be automatically acquired through the destination IPv6 address of an IPv6 packet at the tunnel source.

Table 10 IPv6 over IPv4 tunnel modes and key parameters

Tunnel type	Tunnel mode	Tunnel source/destination address	Tunnel interface address type
Manually configured tunnel	IPv6 manual tunneling	The source/destination IP address is a manually configured IPv4 address.	IPv6 address
	6to4 tunneling	The source IP address is a manually configured IPv4 address. The destination IP address does not need to be configured.	6to4 address, in the format of 2002:IPv4-source-address::/48
Automatic tunnel	Intra-site automatic tunnel addressing protocol (ISATAP) tunneling	The source IP address is a manually configured IPv4 address. The destination IP address does not need to be configured.	ISATAP address, in the format of Prefix:0:5EFE:IPv4-source-address/64

According to the way an IPv6 packet is encapsulated, IPv6 over IPv4 tunnels are divided into the following modes:

- IPv6 manual tunneling

A manually configured tunnel is a point-to-point link. Each link is a separate tunnel. IPv6 manual tunnels are mainly used to provide stable connections for regular secure communication between border routers or between border routers and hosts for access to remote IPv6 networks.
- 6to4 tunneling

An automatic 6to4 tunnel is a point-to-multipoint tunnel mainly constructed between edge routers, and is used to connect multiple isolated IPv6 networks over an IPv4 network to remote IPv6 networks. The embedded IPv4 address in an IPv6 address is used to automatically acquire the destination IPv4 address of the tunnel.

The automatic 6to4 tunnel adopts 6to4 addresses. The address format is 2002:abcd:efgh:subnet number::interface ID/64, where 2002 represents the fixed IPv6 address prefix, and abcd:efgh represents the 32-bit globally unique source IPv4 address of the 6to4 tunnel, in hexadecimal

notation. For example, 1.1.1.1 can be represented by 0101:0101. The part that follows 2002:abcd:efgh uniquely identifies a host in a 6to4 network. The tunnel destination is automatically determined by the embedded IPv4 address, which makes it easy to create a 6to4 tunnel.

The tunnel can forward IPv6 packets because the 16-bit subnet number of the 64-bit address prefix in 6to4 addresses can be customized and the first 48 bits in the address prefix are fixed to a permanent value and the IPv4 address of the tunnel source or destination.

Figure 80 6to4 tunnel

- ISATAP tunneling

An ISATAP tunnel is a point-to-multipoint automatic tunnel. The destination of a tunnel can automatically be acquired from the embedded IPv4 address in the destination address of an IPv6 packet.

When an ISATAP tunnel is used, the destination address of an IPv6 packet and the IPv6 address of a tunnel interface both adopt special ISATAP addresses. The ISATAP address format is prefix(64bit):0:5EFE:abcd:efgh. The 64-bit prefix is the prefix of a valid IPv6 unicast address, but abcd:efgh is a 32-bit source IPv4 address in hexadecimal, which might not be globally unique. Through the embedded IPv4 address, an ISATAP tunnel can be automatically created to transfer IPv6 packets.

The ISATAP tunnel is mainly used for communication between IPv6 routers or between a host and an IPv6 router over an IPv4 network.

Figure 81 Principle of ISATAP tunneling

Protocols and standards

- RFC 1853, *IP in IP Tunneling*
- RFC 2473, *Generic Packet Tunneling in IPv6 Specification*
- RFC 2893, *Transition Mechanisms for IPv6 Hosts and Routers*
- RFC 3056, *Connection of IPv6 Domains via IPv4 Clouds*
- RFC 4214, *Intra-Site Automatic Tunnel Addressing Protocol (ISATAP)*

Tunneling configuration task list

Task	Remarks
Configuring a tunnel interface	Required.
Configuring an IPv6 over IPv4 tunnel	Configuring an IPv6 manual tunnel
	Configuring a 6to4 tunnel
	Configuring an ISATAP tunnel
	Optional. Use one as needed.

Configuring a tunnel interface

Configure a Layer 3 virtual tunnel interface on each device on a tunnel so that devices at both ends can send, identify, and process packets from the tunnel.

Configuration guidelines

Follow these guidelines when you configure a tunnel interface:

- Before configuring a tunnel interface on a switch, you may need create a service loopback group with its service type as Tunnel, and add unused Layer 2 Ethernet interfaces of the switch to the service loopback group.
- On the switch, an encapsulated packet cannot be forwarded a second time at Layer 3 by using the destination address and routing table, but is sent to the loopback interface, which then sends the packet to the forwarding module for Layer 3 forwarding. You must reference a service loopback group on the tunnel interface. Otherwise, the tunnel interface will not be up and packets cannot be transmitted over the tunnel. For creation and configuration of a service loopback group, see *Layer 2—LAN Switching Configuration Guide*.
- The **tunnel bandwidth** command does not change the actual bandwidth of the tunnel interface, but sets a bandwidth value for dynamical routing protocols to calculate the cost of a tunnel path. You can determine the value according to the bandwidth of the output interface.
- The switch fragments IP unicast packets larger than the MTU on the tunnel interface, and sends an ICMP error packet to the source device to inform it to modify its MTU.
- The switch fragments IPv6 unicast packets larger than the MTU on the tunnel interface, and sends an ICMPv6 error packet to the source device to inform it to modify its MTU. The minimum MTU value in the ICMPv6 error packet is 1280 bytes, and you must configure a MTU no smaller than 1280 bytes for the tunnel (such as an IPv6 over IPv4 tunnel or an IPv6 over IPv6 tunnel).
- By default, sending of ICMP destination unreachable packets is disabled. To enable it, use the **ip unreachable enable** command.

Configuration procedure

To configure a tunnel interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a tunnel interface and enter its view.	interface tunnel <i>number</i>	By default, no tunnel interface is created.

Step	Command	Remarks
3. Configure the description for the interface.	description <i>text</i>	Optional. By default, the description of a tunnel interface is Tunnelnumber Interface .
4. Reference a service loopback group.	service-loopback-group <i>number</i>	By default, the tunnel does not reference any service loopback group.
5. Set the MTU of the tunnel interface.	mtu <i>size</i>	Optional. 64000 bytes by default. <ul style="list-style-type: none"> An MTU set on any tunnel interface is effective on all existing tunnel interfaces. You can issue this command multiple times, but only the last configuration takes effect.
6. Set the bandwidth of the tunnel interface.	tunnel bandwidth <i>bandwidth-value</i>	Optional. By default, the bandwidth of the tunnel interface is 64 kbps.
7. Restore the default setting.	default	Optional.
8. Shut down the tunnel interface.	shutdown	Optional. By default, the interface is up.

Configuring an IPv6 manual tunnel

Configuration prerequisites

Configure IP addresses for interfaces (such as the VLAN interface, and loopback interface) on the device to ensure normal communication. One of the interfaces will be used as the source interface of the tunnel.

Configuration guidelines

Follow these guidelines when you configure an IPv6 manual tunnel:

- After a tunnel interface is deleted, all the features configured on the tunnel interface will be deleted.
- To encapsulate and forward IPv6 packets whose destination address does not belong to the subnet where the current tunnel interface resides, you must configure a static route or dynamic routing for forwarding those packets through this tunnel interface. If you configure a static route to that destination IPv6 address, specify this tunnel interface as the outbound interface, or the peer tunnel interface address as the next hop. A similar configuration is required at the other tunnel end. If you configure dynamic routing at both ends, enable the dynamic routing protocol on both tunnel interfaces. For the detailed configuration, see *Layer 3—IP Routing Configuration Guide*.

Configuration procedure

To configure an IPv6 manual tunnel:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6.	ipv6	By default, the IPv6 packet forwarding function is disabled.
3. Enter tunnel interface view.	interface tunnel <i>number</i>	N/A
4. Configure an IPv6 address for the tunnel interface.	<ul style="list-style-type: none"> • Configure a global unicast IPv6 address or a site-local address: <ul style="list-style-type: none"> ○ ipv6 address { <i>ipv6-address prefix-length</i> <i>ipv6-address/prefix-length</i> } ○ ipv6 address <i>ipv6-address/prefix-length eui-64</i> • Configure a link-local IPv6 address: <ul style="list-style-type: none"> ○ ipv6 address auto link-local ○ ipv6 address <i>ipv6-address link-local</i> 	<p>The link-local IPv6 address configuration is optional.</p> <p>By default,</p> <ul style="list-style-type: none"> • No IPv6 global unicast address or site-local address is configured for the tunnel interface. • A link-local address is automatically created when an IPv6 global unicast address or site-local address is configured.
5. Specify the IPv6 manual tunnel mode.	tunnel-protocol ipv6-ipv4	<p>IPv6 manual tunnel by default.</p> <p>The same tunnel mode should be configured at both ends of the tunnel. Otherwise, packet delivery will fail.</p>
6. Configure a source address or interface for the tunnel.	source { <i>ip-address</i> <i>interface-type interface-number</i> }	By default, no source address or interface is configured for the tunnel.
7. Configure a destination address for the tunnel.	destination <i>ip-address</i>	By default, no destination address is configured for the tunnel.
8. Return to system view.	quit	N/A
9. Enable dropping of IPv6 packets using IPv4-compatible IPv6 addresses.	tunnel discard ipv4-compatible-packet	<p>Optional.</p> <p>Disabled by default.</p>

Configuration example

Network requirements

As shown in [Figure 1](#), two IPv6 networks are connected over an IPv4 network. Configure an IPv6 over IPv4 tunnel between Switch A and Switch B to make the two IPv6 networks reachable to each other. If the destination IPv4 address cannot be automatically obtained from the destination IPv6 addresses of packets, configure an IPv6 manual tunnel.

Figure 1 Network diagram

Configuration procedure

Before configuring an IPv6 manual tunnel, make sure that Switch A and Switch B have the corresponding VLAN interfaces created and can reach each other.

- Configure Switch A:

Enable IPv6.

```
<SwitchA> system-view
[SwitchA] ipv6
```

Configure an IPv4 address for VLAN-interface 100.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ip address 192.168.100.1 255.255.255.0
[SwitchA-Vlan-interface100] quit
```

Configure an IPv6 address for VLAN-interface 101.

```
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] ipv6 address 3002::1 64
[SwitchA-Vlan-interface101] quit
```

Create service loopback group 1 to support the tunnel service.

```
[SwitchA] service-loopback group 1 type tunnel
```

Assign GigabitEthernet 1/0/3 to service loopback group 1, and disable STP, NDP, and LLDP on the interface.

```
[SwitchA] interface GigabitEthernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] undo stp enable
[SwitchA-GigabitEthernet1/0/3] undo ndp enable
[SwitchA-GigabitEthernet1/0/3] undo lldp enable
[SwitchA-GigabitEthernet1/0/3] port service-loopback group 1
[SwitchA-GigabitEthernet1/0/3] quit
```

Configure a manual IPv6 tunnel.

```
[SwitchA] interface tunnel 0
[SwitchA-Tunnel0] ipv6 address 3001::1/64
[SwitchA-Tunnel0] source vlan-interface 100
[SwitchA-Tunnel0] destination 192.168.50.1
[SwitchA-Tunnel0] tunnel-protocol ipv6-ipv4
```

Reference service loopback group 1 on the tunnel.

```
[SwitchA-Tunnel0] service-loopback-group 1
[SwitchA-Tunnel0] quit
```

Configure a static route to IPv6 Group 2 through Tunnel 0 on Switch A.

```
[SwitchA] ipv6 route-static 3003:: 64 tunnel 0
```

- **Configure Switch B**
 - # Enable IPv6.

```
<SwitchB> system-view
[SwitchB] ipv6
```
 - # Configure an IPv4 address for VLAN-interface 100.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ip address 192.168.50.1 255.255.255.0
[SwitchB-Vlan-interface100] quit
```
 - # Configure an IPv6 address for VLAN-interface 101.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] ipv6 address 3003::1 64
[SwitchB-Vlan-interface101] quit
```
 - # Create service loopback group 1 to support the tunnel service.

```
[SwitchB] service-loopback group 1 type tunnel
```
 - # Assign GigabitEthernet 1/0/3 to service loopback group 1, and disable STP, NDP, and LLDP.

```
[SwitchB] interface GigabitEthernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] undo stp enable
[SwitchB-GigabitEthernet1/0/3] undo ndp enable
[SwitchB-GigabitEthernet1/0/3] undo lldp enable
[SwitchB-GigabitEthernet1/0/3] port service-loopback group 1
[SwitchB-GigabitEthernet1/0/3] quit
```
 - # Configure an IPv6 manual tunnel.

```
[SwitchB] interface tunnel 0
[SwitchB-Tunnel0] ipv6 address 3001::2/64
[SwitchB-Tunnel0] source vlan-interface 100
[SwitchB-Tunnel0] destination 192.168.100.1
[SwitchB-Tunnel0] tunnel-protocol ipv6-ipv4
```
 - # Reference service loopback group 1 on the tunnel.

```
[SwitchB-Tunnel0] service-loopback-group 1
[SwitchB-Tunnel0] quit
```
 - # Configure a static route to IPv6 Group 1 through Tunnel 0 on Switch B.

```
[SwitchB] ipv6 route-static 3002:: 64 tunnel 0
```

Verifying the configuration

Display the status of the tunnel interfaces on Switch A and Switch B.

```
[SwitchA] display ipv6 interface tunnel 0
Tunnel0 current state :UP
Line protocol current state :UP
IPv6 is enabled, link-local address is FE80::C0A8:6401
Global unicast address(es):
  3001::1, subnet is 3001::/64
Joined group address(es):
  FF02::1:FF00:0
  FF02::1:FF00:1
  FF02::1:FFA8:6401
  FF02::2
  FF02::1
```

```

MTU is 1480 bytes
ND reachable time is 30000 milliseconds
ND retransmit interval is 1000 milliseconds
Hosts use stateless autoconfig for addresses
IPv6 Packet statistics:
  InReceives:                55
...
[SwitchB] display ipv6 interface tunnel 0
Tunnel0 current state :UP
Line protocol current state :UP
IPv6 is enabled, link-local address is FE80::C0A8:3201
Global unicast address(es):
  3001::2, subnet is 3001::/64
Joined group address(es):
  FF02::1:FF00:0
  FF02::1:FF00:1
  FF02::1:FFA8:3201
  FF02::2
  FF02::1
MTU is 1480 bytes
ND reachable time is 30000 milliseconds
ND retransmit interval is 1000 milliseconds
Hosts use stateless autoconfig for addresses
IPv6 Packet statistics:
  InReceives:                55
...

```

Ping the IPv6 address of VLAN-interface 101 at the peer end from Switch A.

```

[SwitchA] ping ipv6 3003::1
PING 3003::1 : 56 data bytes, press CTRL_C to break
  Reply from 3003::1
  bytes=56 Sequence=1 hop limit=64  time = 1 ms
  Reply from 3003::1
  bytes=56 Sequence=2 hop limit=64  time = 1 ms
  Reply from 3003::1
  bytes=56 Sequence=3 hop limit=64  time = 1 ms
  Reply from 3003::1
  bytes=56 Sequence=4 hop limit=64  time = 1 ms
  Reply from 3003::1
  bytes=56 Sequence=5 hop limit=64  time = 1 ms

--- 3003::1 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 1/1/1 ms

```

Configuring a 6to4 tunnel

Configuration prerequisites

Configure IP addresses for interfaces (such as the VLAN interface, and loopback interface) on the device to ensure normal communication. One of the interfaces will be used as the source interface of the tunnel.

Configuration guidelines

Follow these guidelines when you configure a 6to4 tunnel:

- No destination address needs to be configured for a 6to4 tunnel because the destination address can automatically be obtained from the IPv4 address embedded in the 6to4 IPv6 address.
- To encapsulate and forward IPv6 packets whose destination address does not belong to the subnet where the receiving tunnel interface resides, configure a static route to reach the destination IPv6 address through this tunnel interface on the device. Because automatic tunnels do not support dynamic routing, you can configure a static route to that destination IPv6 address with this tunnel interface as the outbound interface or the peer tunnel interface address as the next hop. A similar configuration is required at the other tunnel end. For the detailed configuration, see *Layer 3—IP Routing Configuration Guide*.
- Automatic tunnel interfaces using the same encapsulation protocol cannot share the same source IP address.

Configuration procedure

To configure a 6to4 tunnel:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6.	ipv6	By default, the IPv6 packet forwarding function is disabled.
3. Enter tunnel interface view.	interface tunnel <i>number</i>	N/A
4. Configure an IPv6 address for the tunnel interface.	<ul style="list-style-type: none">• Configure an IPv6 global unicast address or a site-local address:<ul style="list-style-type: none">○ ipv6 address { <i>ipv6-address prefix-length</i> <i>ipv6-address/prefix-length</i> }○ ipv6 address <i>ipv6-address/prefix-length eui-64</i>• Configure an IPv6 link-local address:<ul style="list-style-type: none">○ ipv6 address auto link-local○ ipv6 address <i>ipv6-address link-local</i>	<p>The IPv6 link-local address configuration is optional.</p> <p>By default,</p> <ul style="list-style-type: none">• No IPv6 global unicast address or site-local address is configured for the tunnel interface.• A link-local address will automatically be generated when an IPv6 global unicast address or site-local address is configured.

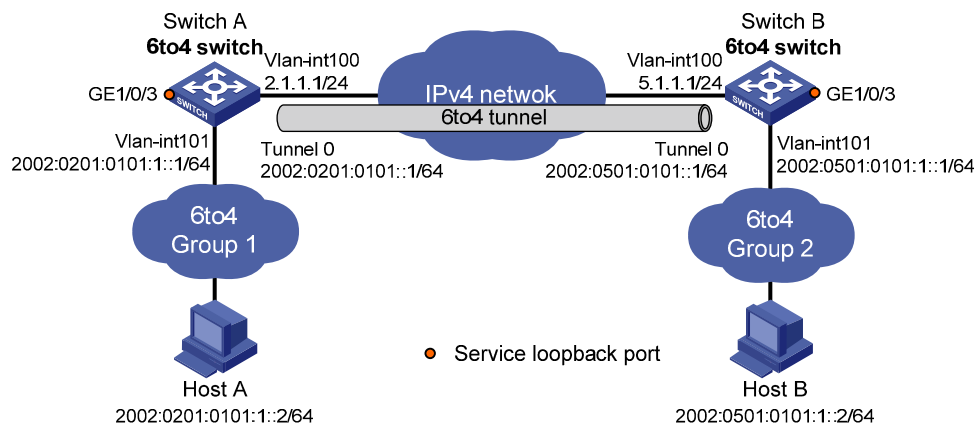

Step	Command	Remarks
5. Specify the 6to4 tunnel mode.	tunnel-protocol ipv6-ipv4 6to4	IPv6 manual tunnel by default. The same tunnel mode should be configured at both ends of the tunnel. Otherwise, packet delivery will fail.
6. Configure a source address or interface for the tunnel.	source { ip-address interface-type interface-number }	By default, no source address or interface is configured for the tunnel.
7. Return to system view.	quit	N/A
8. Enable dropping of IPv6 packets using IPv4-compatible IPv6 addresses.	tunnel discard ipv4-compatible-packet	Optional. Disabled by default.

Configuration example

Network requirements

As shown in Figure 2, two 6to4 networks are connected to an IPv4 network through two 6to4 switches (Switch A and Switch B). Configure a 6to4 tunnel to make Host A and Host B reachable to each other.

Figure 2 Network diagram

Configuration consideration

To enable communication between 6to4 networks, configure 6to4 addresses for 6to4 switches and hosts in the 6to4 networks.

- The IPv4 address of VLAN-interface 100 on Switch A is 2.1.1.1/24, and the corresponding 6to4 prefix is 2002:0201:0101::/48 after it is translated to an IPv6 address. Assign interface Tunnel 0 to subnet 2002:0201:0101::/64 and VLAN-interface 101 to subnet 2002:0201:0101:1::/64.
- The IPv4 address of VLAN-interface 100 on Switch B is 5.1.1.1/24, and the corresponding 6to4 prefix is 2002:0501:0101::/48 after it is translated to an IPv6 address. Assign interface Tunnel 0 to subnet 2002:0501:0101::/64 and VLAN-interface 101 to subnet 2002:0501:0101:1::/64.

Configuration procedure

Before configuring a 6to4 tunnel, make sure that Switch A and Switch B have the corresponding VLAN interfaces created and are reachable to each other.

- **Configure Switch A:**
 - # Enable IPv6.**

```
<SwitchA> system-view
[SwitchA] ipv6
```
 - # Configure an IPv4 address for VLAN-interface 100.**

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ip address 2.1.1.1 24
[SwitchA-Vlan-interface100] quit
```
 - # Configure an IPv6 address for VLAN-interface 101.**

```
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] ipv6 address 2002:0201:0101:1::1/64
[SwitchA-Vlan-interface101] quit
```
 - # Create service loopback group 1 to support the tunnel service.**

```
[SwitchA] service-loopback group 1 type tunnel
```
 - # Assign GigabitEthernet 1/0/3 to service loopback group 1, and disable STP, NDP, and LLDP on the interface.**

```
[SwitchA] interface GigabitEthernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] undo stp enable
[SwitchA-GigabitEthernet1/0/3] undo ndp enable
[SwitchA-GigabitEthernet1/0/3] undo lldp enable
[SwitchA-GigabitEthernet1/0/3] port service-loopback group 1
[SwitchA-GigabitEthernet1/0/3] quit
```
 - # Configure a 6to4 tunnel.**

```
[SwitchA] interface tunnel 0
[SwitchA-Tunnel0] ipv6 address 2002:201:101::1/64
[SwitchA-Tunnel0] source vlan-interface 100
[SwitchA-Tunnel0] tunnel-protocol ipv6-ipv4 6to4
```
 - # Reference service loopback group 1 on the tunnel.**

```
[SwitchA-Tunnel0] service-loopback-group 1
[SwitchA-Tunnel0] quit
```
 - # Configure a static route whose destination address is 2002::/16 and next-hop is the tunnel interface.**

```
[SwitchA] ipv6 route-static 2002:: 16 tunnel 0
```
- **Configure Switch B:**
 - # Enable IPv6.**

```
<SwitchB> system-view
[SwitchB] ipv6
```
 - # Configure an IPv4 address for VLAN-interface 100.**

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ip address 5.1.1.1 24
[SwitchB-Vlan-interface100] quit
```
 - # Configure an IPv6 address for VLAN-interface 101.**

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] ipv6 address 2002:0501:0101:1::1/64
[SwitchB-Vlan-interface101] quit
```
 - # Create service loopback group 1 to support the tunnel service.**

```

[SwitchB] service-loopback group 1 type tunnel
# Assign GigabitEthernet 1/0/3 to service loopback group 1, and disable STP, NDP, and LLDP on
the interface.
[SwitchB] interface GigabitEthernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] undo stp enable
[SwitchB-GigabitEthernet1/0/3] undo ndp enable
[SwitchB-GigabitEthernet1/0/3] undo lldp enable
[SwitchB-GigabitEthernet1/0/3] port service-loopback group 1
[SwitchB-GigabitEthernet1/0/3] quit
# Configure the 6to4 tunnel.
[SwitchB] interface tunnel 0

    Approximate round trip times in milli-seconds:
        Minimum = 0ms, Maximum = 13ms, Average = 3ms

```

Configuring an ISATAP tunnel

Configuration prerequisites

Configure IP addresses for interfaces (such as the VLAN interface, and loopback interface) on the device to ensure normal communication. One of the interfaces will be used as the source interface of the tunnel.

Configuration guidelines

Follow these guidelines when you configure an ISATAP tunnel:

- No destination address needs to be configured for an ISATAP tunnel. The destination address of the tunnel can be automatically obtained through the IPv4 address embedded in the ISATAP address.
- To encapsulate and forward IPv6 packets whose destination address does not belong to the subnet where the receiving tunnel interface resides, configure a static route to reach the destination IPv6 address through this tunnel interface on the device. Because automatic tunnels do not support dynamic routing, you can configure a static route to that destination IPv6 address with this tunnel interface as the outbound interface or the peer tunnel interface address as the next hop. A similar configuration is required at the other tunnel end. For the detailed configuration, see *Layer 3—IP Routing Configuration Guide*.
- The automatic tunnel interfaces using the same encapsulation protocol cannot share the same source IP address.

Configuration procedure

To configure an ISATAP tunnel:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6.	ipv6	By default, the IPv6 forwarding function is disabled.
3. Enter tunnel interface view.	interface tunnel number	N/A
4. Configure an IPv6 address for the tunnel interface.	<ul style="list-style-type: none"> • Configure an IPv6 global unicast address or site-local address: <ul style="list-style-type: none"> ◦ ipv6 address { <i>ipv6-address prefix-length</i> <i>ipv6-address/prefix-length</i> } ◦ ipv6 address <i>ipv6-address/prefix-length eui-64</i> • Configure an IPv6 link-local address: <ul style="list-style-type: none"> ◦ ipv6 address auto link-local ◦ ipv6 address <i>ipv6-address link-local</i> 	<p>The IPv6 link-local address configuration is optional.</p> <p>By default,</p> <ul style="list-style-type: none"> • No IPv6 global unicast address is configured for the tunnel interface. • A link-local address will automatically be generated when an IPv6 global unicast address or link-local address is configured.
5. Specify the ISATAP tunnel mode.	tunnel-protocol ipv6-ipv4 isatap	<p>IPv6 manual tunnel by default.</p> <p>The same tunnel mode should be configured at both ends of the tunnel. Otherwise, packet delivery will fail.</p>
6. Configure a source address or interface for the tunnel.	source { <i>ip-address</i> <i>interface-type interface-number</i> }	By default, no source address or interface is configured for the tunnel.
7. Return to system view.	quit	N/A

Step	Command	Remarks	
8.	Enable dropping of IPv6 packets using IPv4-compatible IPv6 addresses.	tunnel discard ipv4-compatible-packet	Optional. Disabled by default.

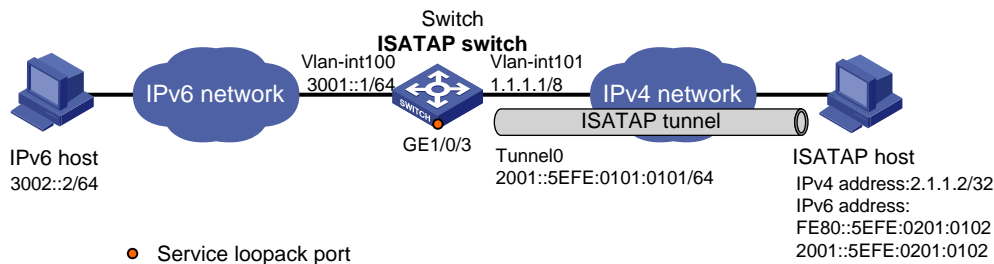

Configuration example

Network requirements

As shown in [Figure 3](#), an IPv6 network is connected to an IPv4 network through an ISATAP switch. IPv6 hosts reside in the IPv4 network.

Configure the IPv6 hosts to access the IPv6 network through the ISATAP tunnel.

Figure 3 Network diagram

Configuration procedure

Before configuring an ISATAP tunnel, make sure that the corresponding VLAN interfaces have been created on the switch, and that VLAN-interface 101 on the ISATAP switch and the ISATAP host can reach each other.

- Configure the switch:

```
# Enable IPv6.
<Switch> system-view
[Switch] ipv6

# Configure addresses for interfaces.
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] ipv6 address 3001::1/64
[Switch-Vlan-interface100] quit
[Switch] interface vlan-interface 101
[Switch-Vlan-interface101] ip address 1.1.1.1 255.0.0.0
[Switch-Vlan-interface101] quit

# Create service loopback group 1 to support the tunnel service.
[Switch] service-loopback group 1 type tunnel

# Assign GigabitEthernet 1/0/3 to service loopback group 1, and disable STP, NDP, and LLDP on the interface.
[Switch] interface GigabitEthernet 1/0/3
[Switch-GigabitEthernet1/0/3] undo stp enable
[Switch-GigabitEthernet1/0/3] undo ndp enable
[Switch-GigabitEthernet1/0/3] undo lldp enable
```

```
[Switch-GigabitEthernet1/0/3] port service-loopback group 1
[Switch-GigabitEthernet1/0/3] quit
```

Configure an ISATAP tunnel.

```
[Switch] interface tunnel 0
[Switch-Tunnel0] ipv6 address 2001::5efe:0101:0101 64
[Switch-Tunnel0] source vlan-interface 101
[Switch-Tunnel0] tunnel-protocol ipv6-ipv4 isatap
```

Disable the RA suppression so that hosts can acquire information such as the address prefix from the RA message released by the ISATAP switch.

```
[Switch-Tunnel0] undo ipv6 nd ra halt
```

Reference service loopback group 1 on the tunnel.

```
[Switch-Tunnel0] service-loopback-group 1
[Switch-Tunnel0] quit
```

Configure a static route to the ISATAP host.

```
[Switch] ipv6 route-static 2001:: 16 tunnel 0
```

- Configure the ISATAP host:

The specific configuration on the ISATAP host is related to its operating system. The following example shows the configuration of the host running the Windows XP.

Install IPv6.

```
C:\>ipv6 install
```

On a Windows XP-based host, the ISATAP interface is usually interface 2. Configure the IPv4 address of the ISATAP router on the interface to complete the configuration on the host. Before doing that, display the ISATAP interface information:

```
C:\>ipv6 if 2
```

```
Interface 2: Automatic Tunneling Pseudo-Interface
  Guid {48FCE3FC-EC30-E50E-F1A7-71172AEEE3AE}
  does not use Neighbor Discovery
  does not use Router Discovery
  routing preference 1
  EUI-64 embedded IPv4 address: 0.0.0.0
  router link-layer address: 0.0.0.0
  preferred link-local fe80::5efe:2.1.1.2, life infinite
  link MTU 1280 (true link MTU 65515)
  current hop limit 128
  reachable time 42500ms (base 30000ms)
  retransmission interval 1000ms
  DAD transmits 0
  default site prefix length 48
```

A link-local address (fe80::5efe:2.1.1.2) in the ISATAP format was automatically generated for the ISATAP interface. Configure the IPv4 address of the ISATAP switch on the ISATAP interface.

```
C:\>ipv6 rlu 2 1.1.1.1
```

Display the information on the ISATAP interface.

```
C:\>ipv6 if 2
```

```
Interface 2: Automatic Tunneling Pseudo-Interface
  Guid {48FCE3FC-EC30-E50E-F1A7-71172AEEE3AE}
  does not use Neighbor Discovery
  uses Router Discovery
```

```

routing preference 1
EUI-64 embedded IPv4 address: 2.1.1.2
router link-layer address: 1.1.1.1
  preferred global 2001::5efe:2.1.1.2, life 29d23h59m46s/6d23h59m46s (public)
  preferred link-local fe80::5efe:2.1.1.2, life infinite
link MTU 1500 (true link MTU 65515)
current hop limit 255
reachable time 42500ms (base 30000ms)
retransmission interval 1000ms
DAD transmits 0
default site prefix length 48

```

By comparison, it is found that the host acquires the address prefix 2001::/64 and automatically generates the address 2001::5efe:2.1.1.2. Meanwhile, "uses Router Discovery" is displayed, indicating that the router discovery function is enabled on the host. At this time, ping the IPv6 address of the tunnel interface of the switch. If the address is successfully pinged, an ISATAP tunnel is established.

```
C:\>ping 2001::5efe:1.1.1.1
```

```
Pinging 2001::5efe:1.1.1.1 with 32 bytes of data:
```

```

Reply from 2001::5efe:1.1.1.1: time=1ms
Reply from 2001::5efe:1.1.1.1: time=1ms
Reply from 2001::5efe:1.1.1.1: time=1ms
Reply from 2001::5efe:1.1.1.1: time=1ms

```

```

Ping statistics for 2001::5efe:1.1.1.1:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 1ms, Maximum = 1ms, Average = 1ms

```

Verifying the configuration

The ISATAP host can access the host in the IPV6 network.

Displaying and maintaining tunneling configuration

Task	Command	Remarks
Display information about tunnel interfaces.	<pre> display interface [tunnel] [brief [down]] [{ begin exclude include } <i>regular-expression</i>] display interface tunnel <i>number</i> [brief] [{ begin exclude include } <i>regular-expression</i>] </pre>	Available in any view
Display IPv6 information on tunnel interfaces.	<pre> display ipv6 interface tunnel [<i>number</i>] [brief] [{ begin exclude include } <i>regular-expression</i>] </pre>	Available in any view
Clear statistics on tunnel interfaces.	<pre> reset counters interface [tunnel [<i>number</i>]] </pre>	Available in user view

Troubleshooting tunneling configuration

Symptom

After the configuration of related parameters such as tunnel source address, tunnel destination address, and tunnel mode, the tunnel interface is still not up.

Solution

1. The common cause is that the physical interface of the tunnel source is not up. Use the **display interface tunnel** or **display ipv6 interface tunnel** commands to view whether the physical interface of the tunnel source is up. If the physical interface is down, check the network connections.
2. Another possible cause is that the tunnel destination is unreachable. Use the **display ipv6 routing-table** or **display ip routing-table** command to view whether the tunnel destination is reachable. If no routing entry is available for tunnel communication in the routing table, configure related routes.

IP routing basics

Hardware compatibility

The HP 5500 SI Switch Series does not support configuring Layer 3 Ethernet interfaces.

The HP 5500 SI Switch Series does not support VPN-related parameters.

The HP 5500 SI Switch Series does not support OSPF, BGP, IS-IS, OSPFv3, IPv6 BGP, or IPv6 IS-IS.

Overview

IP routing directs the forwarding of IP packets on routers based on a routing table. This book focuses on unicast routing protocols. For more information about multicast routing protocols, see *IP Multicast Configuration Guide*.

The term "router" in this chapter refers to both routers and Layer 3 switches.

The types of interfaces that appear in any figures other than the network diagrams for configuration examples are for illustration only. Some of them might be unavailable on your switch.

The term "interface" in the routing features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

Routing table

A router maintains at least two routing tables: one global routing table and one forwarding information base (FIB). The FIB table contains only the optimal routes, and the global routing table contains all routes. The router uses the FIB table to forward packets. For more information about the FIB table, see *Layer 3—IP Services Configuration Guide*.

Routes can be classified by different criteria, as shown in [Table 1](#).

Table 1 Categories of routes

Criterion	Categories
Destination	<ul style="list-style-type: none">• Network route—Destination is a network. The subnet mask is less than 32 bits.• Host route—Destination is a host. The subnet mask is 32 bits.
Whether the destination is directly connected	<ul style="list-style-type: none">• Direct route—Destination is directly connected.• Indirect route—Destination is indirectly connected.
Origin	<ul style="list-style-type: none">• Direct route—A direct route is discovered by the data link protocol on an interface, and is also called an "interface route."• Static route—A static route is manually configured by an administrator.• Dynamic route—A dynamic route is dynamically discovered by a routing protocol.

Static routes are easy to configure and require less system resources. They work well in small and stable networks. In networks where topology changes may occur frequently, using a dynamic routing protocol is better.

To display brief information about a routing table, use the **display ip routing-table** command, as shown in the following example:

```
<Sysname> display ip routing-table
Routing Tables: Public
          Destinations : 7          Routes : 7

Destination/Mask    Proto  Pre  Cost           NextHop         Interface
1.1.1.0/24          Direct  0    0             1.1.1.1         Vlan11
2.2.2.0/24          Static  60   0             12.2.2.2        Vlan12
80.1.1.0/24         OSPF   10   2             80.1.1.1        Vlan13
...
```

A route entry includes the following key items:

- **Destination**—IP address of the destination host or network.
- **Mask**—The network mask specifies, in company with the destination address, the address of the destination network. A logical AND operation between the destination address and the network mask yields the address of the destination network. For example, if the destination address is 129.102.8.10 and the mask 255.255.0.0, the address of the destination network is 129.102.0.0. A network mask is made up of a certain number of consecutive 1s. It can be expressed in dotted decimal format or by the number of the 1s.
- **Pre**—Preference of the route. Among routes to the same destination, the one with the highest preference is optimal.
- **Cost**—When multiple routes to a destination have the same preference, the one with the smallest cost becomes the optimal route.
- **NextHop**—Specifies the IP address of the next hop.
- **Interface**—Specifies the interface through which a matching IP packet is to be forwarded.

Dynamic routing protocols

Dynamic routing protocols dynamically collect and report reachability information to adapt to topology changes. They are suitable for large networks.

Compared with static routing, dynamic routing protocols require more resources, and are complicated to configure.

Dynamic routing protocols can be classified based on different criteria, as shown in [Table 2](#):

Table 2 Dynamic routing protocols

Criterion	Categories
Optional scope	<ul style="list-style-type: none"> • Interior gateway protocols (IGPs)—Work within an autonomous system (AS). Examples include RIP, OSPF, and IS-IS. • Exterior gateway protocols (EGPs)—Work between ASs. The most popular one is BGP.

Criterion	Categories
Routing algorithm	<ul style="list-style-type: none"> • Distance-vector protocols—RIP and BGP. BGP is also considered a path-vector protocol. • Link-state protocols—OSPF and IS-IS.
Destination address type	<ul style="list-style-type: none"> • Unicast routing protocols—RIP, OSPF, BGP, and IS-IS. • Multicast routing protocols—PIM-SM and PIM-DM (For more information, see <i>IP Multicast Configuration Guide</i>).
IP version	<ul style="list-style-type: none"> • IPv4 routing protocols—RIP, OSPF, BGP, and IS-IS. • IPv6 routing protocols—RIPng, OSPFv3, IPv6 BGP, and IPv6 IS-IS.

NOTE:

An AS refers to a group of routers sharing the same routing policy and working under the same administration.

Routing preference

Different routing protocols can find different routes to the same destination. However, not all of those routes are optimal. For route selection, routing protocols, direct routes, and static routes are assigned different preferences. The route with the highest preference is preferred.

The preference of a direct route is always 0 and cannot be changed. You can manually configure preferences for any other route type. Each static route can be configured with a different preference. The following table lists the types of routes and the default preferences. The smaller the preference value, the higher the preference.

Table 3 Route types and their default route preferences

Routing approach	Preference
Direct route	0
OSPF	10
IS-IS	15
Static route	60
RIP	100
OSPF ASE	150
OSPF NSSA	150
IBGP	255
EBGP	255
Unknown (route from an untrusted source)	256

Load sharing

A routing protocol can be configured with multiple equal-cost routes to the same destination. These routes have the same preference and will all be used to accomplish load sharing if there is no route with a higher preference available.

Static routing/IPv6 static routing, RIP/RIPng, OSPF/OSPFv3, BGP/IPv6 BGP, and IS-IS/IPv6 IS-IS supports ECMP load sharing.

The load sharing function is available only on the HP 5500 EI Switch series.

Route backup

Route backup can improve network availability. Among multiple routes to the same destination, the route with the highest preference is the main route and all others are backup routes.

The router forwards matching packets through the main route. When the main route fails, the route with the highest preference among the backup routes is selected to forward packets. When the main route recovers, the router uses it to forward packets.

Route recursion

To use a BGP, static, or RIP route that has an indirectly-connected next hop, a router must perform route recursion to find the outgoing interface to reach the next hop.

Link-state routing protocols, such as OSPF and IS-IS, do not need route recursion, because they obtain directly-connected next hops through route calculation.

Route redistribution

Route redistribution enables routing protocols to learn route information from each other. A dynamic routing protocol can redistribute routes from other protocols including direct routes and static routes. For more information, see the respective chapters on those routing protocols in this configuration guide.

Displaying and maintaining a routing table

Task	Command	Remarks
Display information about the routing table.	display ip routing-table [vpn-instance <i>vpn-instance-name</i>] [verbose] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display information about routes permitted by an IPv4 basic ACL.	display ip routing-table [vpn-instance <i>vpn-instance-name</i>] acl <i>acl-number</i> [verbose] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display information about routes to the specified destination.	display ip routing-table [vpn-instance <i>vpn-instance-name</i>] <i>ip-address</i> [<i>mask</i> <i>mask-length</i>] [longer-match] [verbose] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display information about routes with destination addresses in the specified range.	display ip routing-table [vpn-instance <i>vpn-instance-name</i>] <i>ip-address1</i> { <i>mask</i> <i>mask-length</i> } <i>ip-address2</i> { <i>mask</i> <i>mask-length</i> } [verbose] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view

Task	Command	Remarks
Display routing information permitted by an IPv4 prefix list.	display ip routing-table [vpn-instance <i>vpn-instance-name</i>] ip-prefix <i>ip-prefix-name</i> [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routes of a routing protocol.	display ip routing-table [vpn-instance <i>vpn-instance-name</i>] protocol <i>protocol</i> [inactive verbose] [{ begin exclude include } <i>regular-expression</i>] [{ begin exclude include } <i>regular-expression</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display statistics about the routing table.	display ip routing-table [vpn-instance <i>vpn-instance-name</i>] statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear statistics for the routing table.	reset ip routing-table statistics protocol [vpn-instance <i>vpn-instance-name</i>] { <i>protocol</i> all }	Available in user view
Display IPv6 routing table information.	display ipv6 routing-table [vpn-instance <i>vpn-instance-name</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing information permitted by an IPv6 ACL.	display ipv6 routing-table [vpn-instance <i>vpn-instance-name</i>] acl <i>acl6-number</i> [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing information for a specified destination IPv6 address.	display ipv6 routing-table [vpn-instance <i>vpn-instance-name</i>] <i>ipv6-address</i> <i>prefix-length</i> [longer-match] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 routing information for an IPv6 address range.	display ipv6 routing-table [vpn-instance <i>vpn-instance-name</i>] <i>ipv6-address1</i> <i>prefix-length1</i> <i>ipv6-address2</i> <i>prefix-length2</i> [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing information permitted by an IPv6 prefix list.	display ipv6 routing-table [vpn-instance <i>vpn-instance-name</i>] ipv6-prefix <i>ipv6-prefix-name</i> [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 routing information of a routing protocol.	display ipv6 routing-table [vpn-instance <i>vpn-instance-name</i>] protocol <i>protocol</i> [inactive verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 routing statistics.	display ipv6 routing-table [vpn-instance <i>vpn-instance-name</i>] statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear specified IPv6 routing statistics.	reset ipv6 routing-table statistics protocol [vpn-instance <i>vpn-instance-name</i>] { <i>protocol</i> all }	Available in user view

Configuring static routing

Hardware compatibility

The HP 5500 SI Switch Series does not support VPN and BFD related parameters or FRR.

Introduction

Static route

Static routes are manually configured. If a network's topology is simple, you only need to configure static routes for the network to work properly. The proper configuration and usage of static routes can improve network performance and ensure bandwidth for important network applications.

The disadvantage of using static routes is that they cannot adapt to network topology changes. If a fault or a topological change occurs in the network, the relevant routes will be unreachable and the network breaks. When this happens, the network administrator must modify the static routes manually.

The term "router" in this chapter refers to both routers and Layer 3 switches.

Default route

Without a default route, a packet that does not match any routing entries is discarded.

A default route is used to forward packets that do not match any routing entry. It can be configured in either of the following ways:

- The network administrator can configure a default route with both the destination and mask being 0.0.0.0. The router forwards any packet whose destination address fails to match any entry in the routing table to the next hop of the default static route.
- Some dynamic routing protocols, such as OSPF, RIP, and IS-IS, can also generate a default route. For example, an upstream router running OSPF can generate a default route and advertise it to other routers, which install the default route with the next hop being the upstream router.

Static route configuration items

Before you configure a static route, you must know the following concepts:

- Destination address and mask
In the **ip route-static** command, an IPv4 address is in dotted decimal format. A mask can be either in dotted decimal format or in the form of mask length—the number of consecutive 1s in the mask.
- Output interface and next hop address
When you configure a static route, specify either the output interface, next hop address, or both depending on the specific occasion. The next hop address cannot be a local interface IP address; otherwise, the route configuration will not take effect.

Each route lookup operation has to find the next hop to resolve the destination link layer address.

When you specify the output interface, follow these guidelines:

- If the output interface is a Null 0 interface, no next hop address is required.
- If you specify a broadcast interface (such as an Ethernet interface or VLAN interface) as the output interface, you must specify the corresponding next hop for the output interface.
- Other attributes

You can configure different priorities for different static routes so that route management policies can be more flexible. For example, specifying the same priority for different routes to the same destination enables load sharing, but specifying different priorities for these routes enables route backup.

NOTE:

The load sharing function is available only on the HP 5500 EI Switch series.

Configuring a static route

Before you configure a static route, complete the following tasks:

- Configure the physical parameters for related interfaces.
- Configure the link-layer attributes for related interfaces.
- Configure the IP addresses for related interfaces.

Follow these guidelines when you configure a static route:

- The next hop address cannot be the IP address of a local interface (such as Ethernet interface and VLAN interface). Otherwise, the static route does not take effect.
- If you do not specify the preference when you configure a static route, the default preference will be used. Reconfiguring the default preference applies only to newly created static routes.
- You can flexibly control static routes by configuring tag values and using the tag values in the routing policy.
- If the destination IP address and mask are both configured as 0.0.0.0 with the **ip route-static** command, then the route is the default route.
- For more information about track, see *High Availability Configuration Guide*.

To configure a static route:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Configure a static route.	<ul style="list-style-type: none"> Approach 1: ip route-static <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } { <i>next-hop-address</i> [track <i>track-entry-number</i>] <i>interface-type</i> <i>interface-number</i> [<i>next-hop-address</i>] vpn-instance <i>d-vpn-instance-name</i> <i>next-hop-address</i> [track <i>track-entry-number</i>] } [preference <i>preference-value</i>] [tag <i>tag-value</i>] [permanent] [description <i>description-text</i>] Approach 2: ip route-static vpn-instance <i>s-vpn-instance-name</i>&<1-6> <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } { <i>next-hop-address</i> [public] [track <i>track-entry-number</i>] <i>interface-type</i> <i>interface-number</i> [<i>next-hop-address</i>] vpn-instance <i>d-vpn-instance-name</i> <i>next-hop-address</i> [track <i>track-entry-number</i>] } [preference <i>preference-value</i>] [tag <i>tag-value</i>] [permanent] [description <i>description-text</i>] 	<p>Use either approach.</p> <p>By default, preference for static routes is 60, tag is 0, and no description information is configured.</p> <p>Do not specify the permanent and track keywords simultaneously.</p> <p>If the output interface is down, the permanent static route is still active.</p>
3. Configure the default preference for static routes.	ip route-static default-preference <i>default-preference-value</i>	Optional. 60 by default.

Configuring BFD for static routes

NOTE:

Only the HP 5500 EI Switch Series supports BFD for static routes.

Bidirectional forwarding detection (BFD) provides a general-purpose, standard, medium-, and protocol-independent fast failure detection mechanism. It can uniformly and quickly detect the failures of the bidirectional forwarding paths between two routers for protocols, such as routing protocols. For more information about BFD, see *High Availability Configuration Guide*.

A dynamic routing protocol notifies BFD of its neighbor information. BFD uses such information to establish sessions with neighbors by sending BFD control packets. Static routing has no neighbor discovery mechanism. This section describes how static routing implements BFD.

BFD control packet mode

To use BFD control packets for bidirectional detection between two devices, you must enable BFD control packet mode for each device's static route destined to the peer.

To configure a static route and enable BFD control packet mode for it, specify an outbound interface and a direct next hop—BFD establishes a direct session, or specify an indirect next hop and a specific BFD packet source address—BFD establishes an indirect session—for the static route.

To configure a static route with BFD control packet mode enabled (direct session):

Step	Command	Remarks
4. Enter system view.	system-view	N/A
5. Configure a static route and enable BFD control packet mode for it.	<ul style="list-style-type: none"> Approach 1: ip route-static <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } <i>interface-type interface-number next-hop-address</i> bfd control-packet [preference <i>preference-value</i>] [tag <i>tag-value</i>] [description <i>description-text</i>] Approach 2: ip route-static vpn-instance <i>s-vpn-instance-name</i>&<1-6> <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } <i>interface-type</i> <i>interface-number next-hop-address</i> bfd control-packet [preference <i>preference-value</i>] [tag <i>tag-value</i>] [description <i>description-text</i>] 	Use either approach.

To configure a static route with BFD control packet mode enabled (indirect session):

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a static route and enable BFD control packet mode for it.	<ul style="list-style-type: none"> Approach 1: ip route-static <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } <i>next-hop-address</i> bfd control-packet bfd-source <i>ip-address</i> [preference <i>preference-value</i>] [tag <i>tag-value</i>] [description <i>description-text</i>] Approach 2: ip route-static vpn-instance <i>s-vpn-instance-name</i>&<1-6> <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } <i>next-hop-address</i> bfd control-packet bfd-source <i>ip-address</i> [preference <i>preference-value</i>] [tag <i>tag-value</i>] [description <i>description-text</i>] 	Use either command.

BFD echo packet mode

ⓘ IMPORTANT:

- Enabling BFD for a flapping route could worsen the situation.
- Do not use BFD for a static route with the outbound interface having the spoofing attribute.

With BFD echo packet mode enabled for a static route, the local device sends BFD echo packets to the peer, which loops it back to test the link. For the echo mode, only one end needs to establish the BFD session, and the source address of echo packets must be configured.

To configure BFD echo packet mode for static routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the source address of echo packets.	bfd echo-source-ip <i>ip-address</i>	Not configured by default.

Step	Command	Remarks
3. Enable BFD echo packet mode for static routes.	<ul style="list-style-type: none"> Approach 1: <code>ip route-static dest-address { mask mask-length } interface-type interface-number next-hop-address bfd echo-packet [preference preference-value] [tag tag-value] [description description-text]</code> Approach 2: <code>ip route-static vpn-instance s-vpn-instance-name&<1-6> dest-address { mask mask-length } interface-type interface-number next-hop-address bfd echo-packet [preference preference-value] [tag tag-value] [description description-text]</code> 	Use either approach.

Configuring static route FRR

NOTE:

Only the HP 5500 EI Switch Series supports static route FRR.

When a link or a router fails, the packets on the path may be discarded, or a routing loop occurs. To avoid such problems, you can enable static route fast reroute (FRR).

Figure 1 Network diagram

As shown in Figure 1, upon a link failure, FRR designates a backup next hop by using a routing policy for routes matching the specified criteria. Packets are directed to the backup next hop to avoid traffic interruption.

Configuration prerequisites

Configuring static route FRR needs to reference a routing policy. You can specify a backup next hop in a routing policy by using the **apply fast-reroute backup-interface** command. For more information about the command and routing policy configurations, see "[Configuring routing policies.](#)"

Configuration guidelines

- FRR takes effect only for static routes that have both an outbound interface and next hop.
- Do not use FRR and BFD at the same time.

Configuration procedure

To configure static route FRR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the source address of echo packets.	bfd echo-source-ip <i>ip-address</i>	Not configured by default.
3. Configure static route FRR.	ip route-static [vpn-instance <i>vpn-instance-name</i>] fast-reroute route-policy <i>route-policy-name</i>	Not configured by default.

Displaying and maintaining static routes

Task	Command	Remarks
Display information of static routes.	display ip routing-table protocol static [inactive verbose] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Delete all the static routes.	delete [vpn-instance <i>vpn-instance-name</i>] static-routes all	Available in system view

For more information about the **display ip routing-table protocol static** [**inactive** | **verbose**] [[{ **begin** | **exclude** | **include** } *regular-expression*] command, see *Layer 3—IP Routing Command Reference*.

Static route configuration examples

Basic static route configuration example

Network requirements

Configure static routes in Figure 2 for interconnection between any two hosts.

Figure 2 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure static routes:

Configure a default route on Switch A.

```
<SwitchA> system-view
[SwitchA] ip route-static 0.0.0.0 0.0.0.0 1.1.4.2
```

Configure two static routes on Switch B.

```
<SwitchB> system-view
[SwitchB] ip route-static 1.1.2.0 255.255.255.0 1.1.4.1
[SwitchB] ip route-static 1.1.3.0 255.255.255.0 1.1.5.6
```

Configure a default route on Switch C.

```
<SwitchC> system-view
[SwitchC] ip route-static 0.0.0.0 0.0.0.0 1.1.5.5
```

3. Configure the hosts:

Configure the default gateways of hosts A, B, and C as 1.1.2.3, 1.1.6.1, and 1.1.3.1. (Details not shown.)

4. Display the configuration:

Display the IP routing table on Switch A.

```
[SwitchA] display ip routing-table
```

Routing Tables: Public

Destinations : 7 Routes : 7

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
0.0.0.0/0	Static	60	0	1.1.4.2	Vlan500
1.1.2.0/24	Direct	0	0	1.1.2.3	Vlan300
1.1.2.3/32	Direct	0	0	127.0.0.1	InLoop0
1.1.4.0/30	Direct	0	0	1.1.4.1	Vlan500
1.1.4.1/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0

Display the IP routing table on Switch B.

```
[SwitchB] display ip routing-table
```

Routing Tables: Public

Destinations : 10 Routes : 10

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
1.1.2.0/24	Static	60	0	1.1.4.1	Vlan500
1.1.3.0/24	Static	60	0	1.1.5.6	Vlan600
1.1.4.0/30	Direct	0	0	1.1.4.2	Vlan500
1.1.4.2/32	Direct	0	0	127.0.0.1	InLoop0
1.1.5.4/30	Direct	0	0	1.1.5.5	Vlan600
1.1.5.5/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0
1.1.6.0/24	Direct	0	0	1.1.6.1	Vlan100
1.1.6.1/32	Direct	0	0	127.0.0.1	InLoop0

Use the **ping** command on Host B to test the reachability of Host A (assuming Windows XP runs on the two hosts).

```
C:\Documents and Settings\Administrator>ping 1.1.2.2
```

```
Pinging 1.1.2.2 with 32 bytes of data:
```

```
Reply from 1.1.2.2: bytes=32 time=1ms TTL=255
```

```
Reply from 1.1.2.2: bytes=32 time=1ms TTL=255
```

```
Reply from 1.1.2.2: bytes=32 time=1ms TTL=255
```

```
Reply from 1.1.2.2: bytes=32 time=1ms TTL=255
```

```
Ping statistics for 1.1.2.2:
```

```
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
```

```
Approximate round trip times in milli-seconds:
```

```
    Minimum = 1ms, Maximum = 1ms, Average = 1ms
```

Use the **tracert** command on Host B to test the reachability of Host A.

```
C:\Documents and Settings\Administrator>tracert 1.1.2.2
```

```
Tracing route to 1.1.2.2 over a maximum of 30 hops
```

```
  0  <1 ms    <1 ms    <1 ms    1.1.6.1
  1  <1 ms    <1 ms    <1 ms    1.1.4.1
  2  1 ms     <1 ms    <1 ms    1.1.2.2
```

```
Trace complete.
```

Static route FRR configuration example

Network requirements

Switch S, Switch A, and Switch D are interconnected through static routes, as illustrated in [Figure 3](#). Configure static route FRR so that when the link between Switch S and Switch D fails, traffic can be switched to Link B immediately.

Figure 3 Network diagram

Configuration procedure

1. Configure IP addresses for the interfaces on each switch and configure static routes:

Follow [Figure 3](#) to configure the IP address and subnet mask of each interface on the switches. (Details not shown.)

Configure static routes on Switch S, Switch A, and Switch D so that Switch S can reach Loopback 0 on Switch D and Switch D can reach Loopback 0 on Switch S.

Configure a static route on Switch S.

```
<SwitchS> system-view
[SwitchS] ip route-static 4.4.4.4 32 vlan-interface 200 13.13.13.2
[SwitchS] ip route-static 4.4.4.4 32 vlan-interface 100 12.12.12.2 preference 65
```

Configure a static route on Switch D.

```
<SwitchD> system-view
[SwitchD] ip route-static 1.1.1.1 32 vlan-interface 200 13.13.13.1
[SwitchD] ip route-static 1.1.1.1 32 vlan-interface 101 24.24.24.2 preference 65
```

Configure a static route on Switch A.

```
<SwitchA> system-view
[SwitchA] ip route-static 4.4.4.4 32 vlan-interface 101 24.24.24.4
[SwitchA] ip route-static 1.1.1.1 32 vlan-interface 100 12.12.12.1
```

2. Configure static route FRR:

Configure Switch S.

```
[SwitchS] bfd echo-source-ip 1.1.1.1
[SwitchS] ip ip-prefix abc index 10 permit 4.4.4.4 32
[SwitchS] route-policy frr permit node 10
[SwitchS-route-policy] if-match ip-prefix abc
[SwitchS-route-policy] apply fast-reroute backup-interface vlan-interface 100
backup-nexthop 12.12.12.2
[SwitchS-route-policy] quit
[SwitchS] ip route-static fast-reroute route-policy frr
```

Configure Switch D.

```
[SwitchD] bfd echo-source-ip 4.4.4.4
[SwitchD] ip ip-prefix abc index 10 permit 1.1.1.1 32
[SwitchD] route-policy frr permit node 10
[SwitchD-route-policy] if-match ip-prefix abc
[SwitchD-route-policy] apply fast-reroute backup-interface vlan-interface 101
backup-nexthop 24.24.24.2
[SwitchD-route-policy] quit
[SwitchD] ip route-static fast-reroute route-policy frr
```

3. Verify the configuration:

Display route 4.4.4.4/32 on Switch S to view the backup next hop information.

```
[SwitchS] display ip routing-table 4.4.4.4 verbose
```

```
Routing Table : Public
```

```
Summary Count : 1
```

```

Destination: 4.4.4.4/32
  Protocol: Static          Process ID: 0
  Preference: 60           Cost: 0
  IpPrecedence:           QoSLeId:

```

BFD for static routes configuration example (direct session)

Network requirements

As shown in [Figure 4](#), configure static routes to subnet 120.1.1.0/24 on Switch A, static routes to subnet 121.1.1.0/24 on Switch B, and static routes to subnets 120.1.1.0/24 and 121.1.1.0/24 on Switch C.

Enable BFD so that when the link between Switch A and Switch B through the Layer 2 switch fails, BFD can detect the failure immediately and Switch A and Switch B can communicate through Switch C.

Figure 4 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int10	12.1.1.1/24	Switch B	Vlan-int10	12.1.1.2/24
	Vlan-int11	10.1.1.102/24		Vlan-int13	13.1.1.1/24
Switch C	Vlan-int11	10.1.1.100/24			
	Vlan-int13	13.1.1.2/24			

Configuration procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure BFD:

```

# Configure static routes on Switch A and enable BFD control packet mode for the static route
through the Layer 2 switch.

```

```

<SwitchA> system-view
[SwitchA] interface vlan-interface10
[SwitchA-vlan-interface10] bfd min-transmit-interval 500
[SwitchA-vlan-interface10] bfd min-receive-interval 500
[SwitchA-vlan-interface10] bfd detect-multiplier 9
[SwitchA-vlan-interface10] quit
[SwitchA] ip route-static 120.1.1.0 24 vlan-interface 10 12.1.1.2 bfd control-packet
[SwitchA] ip route-static 120.1.1.0 24 vlan-interface 11 10.1.1.100 preference 65
[SwitchA] quit

```

Configure static routes on Switch B and enable BFD control packet mode for the static route through the Layer 2 switch.

```

<SwitchB> system-view
[SwitchB] interface vlan-interface10
[SwitchB-vlan-interface10] bfd min-transmit-interval 500
[SwitchB-vlan-interface10] bfd min-receive-interval 500
[SwitchB-vlan-interface10] bfd detect-multiplier 9
[SwitchB-vlan-interface10]] quit
[SwitchB] ip route-static 121.1.1.0 24 vlan-interface 10 12.1.1.1 bfd control-packet
[SwitchB] ip route-static 121.1.1.0 24 vlan-interface 13 13.1.1.2 preference 65
[SwitchB] quit

```

Configure static routes on Switch C.

```

<SwitchC> system-view
[SwitchC] ip route-static 120.1.1.0 24 vlan-interface 13 13.1.1.1
[SwitchC] ip route-static 121.1.1.0 24 vlan-interface 11 10.1.1.102

```

3. Verify the configuration:

The following operations are performed on Switch A. The operations on Switch B are similar.

Display BFD sessions on Router A.

```

<SwitchA> display bfd session

```

```

Total Session Num: 1          Init Mode: Active

```

```

Session Working Under Ctrl Mode:

```

LD/RD	SourceAddr	DestAddr	State	Holdtime	Interface
4/7	12.1.1.1	12.1.1.2	Up	2000ms	Vlan10

Display static routes on Switch A.

```

<SwitchA> display ip routing-table protocol static

```

```

Public Routing Table : Static

```

```

Summary Count : 2

```

```

Static Routing table Status : < Active>

```

```

Summary Count : 1

```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
120.1.1.0/24	Static	60	0	12.1.1.2	Vlan10

```

Direct Routing table Status : <Inactive>

```

```

Summary Count : 1

```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
120.1.1.0/24	Static	65	0	10.1.1.100	Vlan11

Enable BFD debugging on Switch A. When the link between Switch A and Layer 2 switch fails, Switch A can detect the failure.

```
<SwitchA> debugging bfd event
```

```
<SwitchA> debugging bfd scm
```

```
<SwitchA> terminal debugging
```

```
%Jul 27 10:18:18:672 2007 SwitchA BFD/4/LOG:Sess[12.1.1.1/12.1.1.2, Vlan10,Ctrl], Sta: UP->DOWN, Diag: 1
```

```
*Jul 27 10:18:18:672 2007 SwitchA BFD/7/EVENT:Send sess-down Msg, [Src:12.1.1.1,Dst:12.1.1.2, Vlan10,Ctrl], instance:0, protocol:STATIC
```

```
*Jul 27 10:18:19:172 2007 SwitchA BFD/7/EVENT:Receive Delete-sess, [Src:12.1.1.1,Dst:12.1.1.2, Vlan10,Ctrl], Direct, Instance:0x0, Proto:STATIC
```

```
*Jul 27 10:18:19:172 2007 SwitchA BFD/7/EVENT:Notify driver to stop receiving bfd control packet
```

Display the static route information on Switch A again. Switch A communicates with Switch B over the static route passing Switch C now.

```
<SwitchA> display ip routing-table protocol static
```

```
Public Routing Table : Static
```

```
Summary Count : 2
```

```
Static Routing table Status : < Active>
```

```

```

```
Summary Count : 1
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
120.1.1.0/24	Static	60	0	12.1.1.2	Vlan10

BFD for static routes configuration example (indirect session)

Network requirements

As shown in [Figure 5](#), Switch A has a route to interface Loopback1 (2.2.2.9/32) on Switch B, with outbound interface VLAN-interface 10. Switch B has a route to interface Loopback1 (1.1.1.9/32) on Switch A, with outbound interface VLAN-interface 12. Switch D has a route to 1.1.1.9/32, with outbound interface VLAN-interface 10, and a route to 2.2.2.9/32, with outbound interface VLAN-interface 12.

Configure static routes to subnet 120.1.1.0/24 on Switch A, static routes to subnet 121.1.1.0/24 on Switch B, and static routes to subnets 120.1.1.0/24 and 121.1.1.0/24 on both Switch C and Switch D. Enable BFD so that when the link between Switch A and Switch B through Switch D fails, BFD can detect the failure immediately and Switch A and Switch B can communicate through Switch C.

Figure 5 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int10	12.1.1.1/24	Switch B	Vlan-int12	11.1.1.1/24
	Vlan-int11	10.1.1.102/24		Vlan-int13	13.1.1.1/24
	Loop1	1.1.1.9/32		Loop1	2.2.2.9/32
Switch C	Vlan-int11	10.1.1.100/24	Switch D	Vlan-int10	12.1.1.2/24
	Vlan-int13	13.1.1.2/24		Vlan-int12	11.1.1.2/24

Configuration procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure BFD:

Configure static routes on Switch A and enable BFD control packet mode for the static route through Switch D.

```
<SwitchA> system-view
[SwitchA] interface loopback 1
[SwitchA-LoopBack1] bfd min-transmit-interval 500
[SwitchA-LoopBack1] bfd min-receive-interval 500
[SwitchA-LoopBack1] bfd detect-multiplier 9
[SwitchA-LoopBack1] quit
[SwitchA] ip route-static 120.1.1.0 24 2.2.2.9 bfd control-packet bfd-source 1.1.1.9
[SwitchA] ip route-static 120.1.1.0 24 vlan-interface 11 10.1.1.100 preference 65
[SwitchA] quit
```

Configure static routes on Switch B and enable BFD control packet mode for the static route through Switch D.

```
<SwitchB> system-view
[SwitchB] interface loopback 1
[SwitchB-LoopBack1] bfd min-transmit-interval 500
[SwitchB-LoopBack1] bfd min-receive-interval 500
[SwitchB-LoopBack1] bfd detect-multiplier 9
[SwitchB-LoopBack1] quit
[SwitchB] ip route-static 121.1.1.0 24 1.1.1.9 bfd control-packet bfd-source 2.2.2.9
[SwitchB] ip route-static 121.1.1.0 24 vlan-interface 13 13.1.1.2 preference 65
[SwitchB] quit
```

Configure static routes on Switch C.

```
<SwitchC> system-view
[SwitchC] ip route-static 120.1.1.0 24 vlan-interface 13 13.1.1.1
```

```
[SwitchC] ip route-static 121.1.1.0 24 vlan-interface 11 10.1.1.102
```

Configure static routes on Switch D.

```
<SwitchD> system-view
```

```
[SwitchD] ip route-static 120.1.1.0 24 vlan-interface 12 11.1.1.1
```

```
[SwitchD] ip route-static 121.1.1.0 24 vlan-interface 10 12.1.1.1
```

3. Verify the configuration:

The following operations are performed on Switch A. The operations on Switch B are similar and not shown.

Display BFD sessions on Switch A.

```
<SwitchA> display bfd session
```

```

Configuring RIP

Hardware compatibility

The HP 5500 SI Switch Series does not support VPN and BFD related parameters or FRR.

Overview

RIP is a simple interior gateway protocol (IGP), mainly used in small-sized networks, such as academic networks and simple LANs. It is not applicable to complex networks.

RIP has been widely used because it is easy to implement, configure, and maintain.

The term "router" in this chapter refers to both routers and Layer 3 switches.

Understanding RIP

RIP is a distance vector (D-V) routing protocol, using UDP packets for exchanging information through port 520.

RIP uses a hop count to measure the distance to a destination. The hop count from a router to a directly connected network is 0. The hop count from a router to a directly connected router is 1. To limit convergence time, the RIP metric value is in the range of 0 to 15. A metric value of 16 (or greater) is considered infinite, which means the destination network is unreachable. Because of this, RIP is not suitable for large-sized networks.

RIP prevents routing loops by implementing the split horizon and poison reverse functions.

RIP routing table

A RIP router has a routing table containing routing entries of all reachable destinations, and each routing entry contains the following elements:

- **Destination address**—IP address of a host or a network.
- **Next hop**—IP address of the adjacent router's interface to reach the destination.
- **Egress interface**—Packet outgoing interface.
- **Metric**—Cost from the local router to the destination.
- **Route time**—Time elapsed since the last routing entry update. The time is reset to 0 every time the routing entry is updated.
- **Route tag**—Identifies a route. Route tags are used in a routing policy to flexibly control routes. For more information about routing policy, see "[Configuring routing policies](#)."

RIP timers

RIP employs the following timers:

- **Update timer**—Defines the interval between routing updates.
- **Timeout timer**—Defines the route aging time. If no update for a route is received within the aging time, the metric of the route is set to 16 in the routing table.

- **Suppress timer**—Defines how long a RIP route stays in suppressed state. When the metric of a route is 16, the route enters the suppressed state. In suppressed state, only routes coming from the same neighbor and whose metric is less than 16 will be received by the router to replace unreachable routes.
- **Garbage-collect timer**—Defines the interval from when the metric of a route becomes 16 to when it is deleted from the routing table. During the garbage-collect timer length, RIP advertises the route with the routing metric set to 16. If no update is announced for that route after the garbage-collect timer expires, then the route is deleted from the routing table.

Routing loops prevention

RIP is a distance vector routing protocol. Because a RIP router advertises its own routing table to neighbors, routing loops may occur.

RIP uses the following mechanisms to prevent routing loops:

- **Counting to infinity**—The metric value of 16 is defined as unreachable. When a routing loop occurs, the metric value of the route will increment to 16.
- **Split horizon**—A router does not send routing information back to the neighboring router the information came from, preventing routing loops and saving bandwidth.
- **Poison reverse**—A router sets the metric of routes received from a neighbor to 16 and sends back these routes to the neighbor to help delete such information from the neighbor's routing table.
- **Triggered updates**—A router advertises updates once the metric of a route is changed instead of after the update period expires to speed up network convergence.

RIP operation

The following procedure describes how RIP works:

1. After RIP is enabled, the router sends request messages to neighboring routers. Neighboring routers return response messages, including information about their routing tables.
2. After receiving this information, the router updates its local routing table, and sends triggered update messages to its neighbors. All routers on the network do this to keep the latest routing information.
3. By default, a RIP router sends its routing table to neighbors every 30 seconds.
4. RIP ages out routes by adopting an aging mechanism to keep only valid routes.

RIP versions

RIP has RIPv1 and RIPv2.

RIPv1, a classful routing protocol, supports message advertisement through broadcast only. RIPv1 protocol messages do not carry mask information, so it can only recognize routing information of natural networks such as Class A, B, and C. For this reason, RIPv1 does not support discontinuous subnets.

RIPv2 is a classless routing protocol and has the following advantages over RIPv1.

- Supports route tags, which are used in routing policies to flexibly control routes.
- Supports masks, route summarization, and Classless Inter-Domain Routing (CIDR).
- Supports designated next hops to select the best ones on broadcast networks.
- Supports multicasting routing updates to reduce resource consumption. Only RIPv2 routers can receive these update messages.

- Supports simple authentication and MD5 authentication to enhance security.

NOTE:

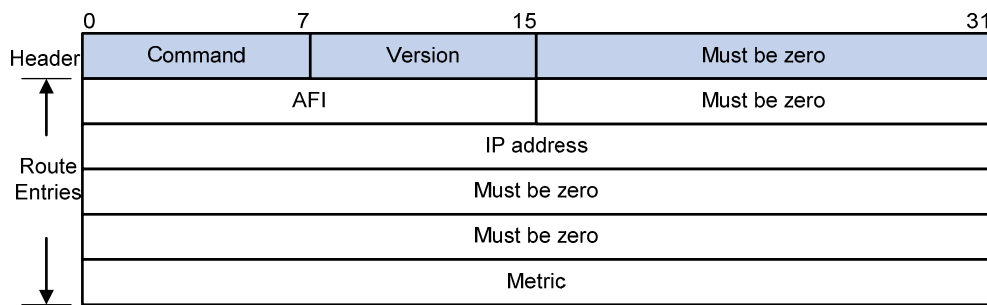

RIPv2 has two types of message transmission: broadcast and multicast. Multicast is the default type using 224.0.0.9 as the multicast address. The interface operating in the RIPv2 broadcast mode can also receive RIPv1 messages.

RIP message format

A RIP message consists of a header and up to 25 route entries. (A RIPv2 authentication message uses the first route entry as the authentication entry, leaving 24 available.)

RIPv1 message format

Figure 6 RIPv1 message format

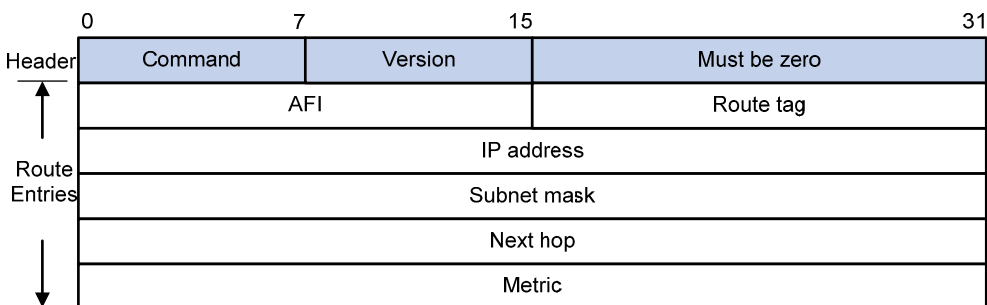

- **Command**—Type of message. 1 indicates request, which is used to request all or part of the routing information from the neighbor; 2 indicates response, which contains all or part of the routing information. A response message consists of up to 25 route entries.
- **Version**—Version of RIP, 0x01 for RIPv1.
- **Must be zero**—This field must be zero
- **AFI**—Address Family Identifier, 2 for IP.
- **IP address**—Destination IP address of the route that can be a natural network, subnet, or a host address.
- **Metric**—Cost of the route.

RIPv2 message format

The format of RIPv2 message is similar to RIPv1.

Figure 7 RIPv2 Message Format

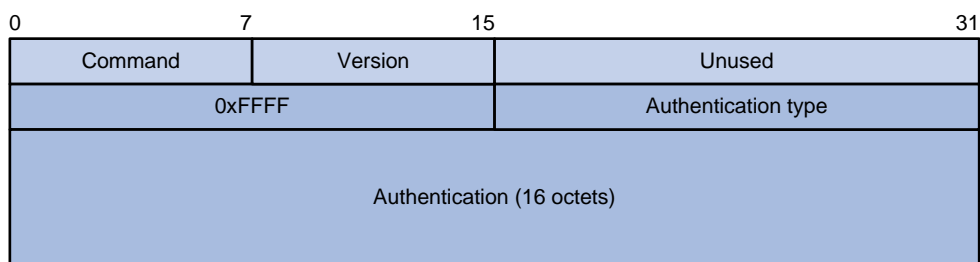

The differences between RIPv1 and RIPv2 messages are stated as follows:

- **Version**—Version of RIP. For RIPv2 the value is 0x02.
- Route tag.
- **IP address**—Destination IP address. It can be a natural network address, subnet address, or host address.
- **Subnet mask**—Mask of the destination address. Unlike RIPv1, RIPv2 can carry subnet information.
- **Next hop**—If set to 0.0.0.0, it indicates that the originator of the route is the best next hop. Otherwise, it indicates a next hop better than the originator of the route.

RIPv2 authentication message format

RIPv2 sets the AFI field of the first route entry to 0xFFFF to identify authentication information.

Figure 8 RIPv2 authentication message

- **Authentication Type**—A value of 2 represents simple authentication. A value of 3 represents MD5. RFC 1723 only defines simple authentication. For more information about MD5 authentication, see RFC 2453, *RIP Version 2*.
- **Authentication**—Authentication data, including password information when simple authentication is adopted or including key ID, MD5 authentication data length and sequence number when MD5 authentication is adopted.

NOTE:

Even though with RIPv1, you can configure the authentication mode in interface view, the configuration will not take effect because RIPv1 does not support authentication.

Supported RIP features

The current implementation supports the following RIP features:

- RIPv1 and RIPv2
- RIP support for multi-VPN-instance
- RIP FRR
- BFD

RIP periodically sends route update requests to neighbors. If no route update response for a route is received within the specified interval, RIP considers the route unreachable. This mechanism cannot detect link faults quickly. After BFD is configured for RIP, and BFD detects a broken link, RIP can quickly age out the unreachable route, thus avoiding interference to other services.

Protocols and standards

- RFC 1058, *Routing Information Protocol*
- RFC 1723, *RIP Version 2 - Carrying Additional Information*
- RFC 1721, *RIP Version 2 Protocol Analysis*
- RFC 1722, *RIP Version 2 Protocol Applicability Statement*
- RFC 1724, *RIP Version 2 MIB Extension*
- RFC 2082, *RIPv2 MD5 Authentication*
- RFC 2453, *RIP Version 2*

RIP configuration task list

Task	Remarks	
Configuring RIP basic functions	Required	
Configuring RIP route control	Configuring an additional routing metric	Optional
	Configuring RIPv2 route summarization	Optional
	Disabling host route reception	Optional
	Advertising a default route	Optional
	Configuring inbound or outbound route filtering	Optional
	Configuring a priority for RIP	Optional
	Configuring RIP route redistribution	Optional
Tuning and optimizing RIP networks	Configuring RIP timers	Optional
	Configuring split horizon and poison reverse	Optional
	Configuring the maximum number of ECMP routes	Optional
	Enabling zero field check on incoming RIPv1 messages	Optional
	Enabling source IP address check on incoming RIP updates	Optional
	Configuring RIPv2 message authentication	Optional
	Specifying a RIP neighbor	Optional
	Configuring RIP-to-MIB binding	Optional
Configuring the RIP packet sending rate	Optional	
Configuring RIP FRR	Optional	
Configuring BFD for RIP	Single-hop detection in BFD echo packet mode	Optional
	Bidirectional detection in BFD control packet mode	Optional

Configuring RIP basic functions

Configuration prerequisites

Before you configure RIP basic functions, complete the following tasks:

- Configure the link layer protocol.
- Configure IP addresses for interfaces, and make sure that all neighboring routers can reach each other.

Enabling RIP and a RIP interface

Follow these guidelines when you enable RIP:

- RIP configurations made in interface view before enabling RIP take effect after RIP is enabled.
- RIP runs only on the interfaces residing on the specified networks. Specify the network after enabling RIP to validate RIP on a specific interface.
- You can enable RIP on all interfaces using the command **network** 0.0.0.0.
- If a physical interface is attached to multiple networks, you cannot advertise these networks in different RIP processes.

To enable RIP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable a RIP process and enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	Disabled by default.
3. Enable RIP on the interface attached to the specified network.	network <i>network-address</i>	Disabled by default.

Configuring the interface behavior

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Disable an or all interfaces from sending routing updates (the interfaces can still receive updates).	silent-interface { <i>interface-type</i> <i>interface-number</i> all }	Optional. By default, all interfaces can send routing updates.
4. Return to system view.	quit	N/A
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Enable the interface to receive RIP messages.	rip input	Optional. Enabled by default.

Step	Command	Remarks
7. Enable the interface to send RIP messages.	rip output	Optional. Enabled by default.

Configuring a RIP version

You can configure a RIP version in RIP view or interface view under the following conditions.

- If neither global nor interface RIP version is configured, the interface sends RIPv1 broadcasts and can receive the following packets: RIPv1 broadcast, RIPv1 unicast, RIPv2 broadcast, RIPv2 multicast, and RIPv2 unicast.
- If an interface has no RIP version configured, it uses the global RIP version; otherwise it uses the RIP version configured on it.
- With RIPv1 configured, an interface sends RIPv1 broadcasts, and can receive RIPv1 broadcasts and RIPv1 unicasts.
- With RIPv2 configured, a multicast interface sends RIPv2 multicasts and can receive RIPv2 unicasts, broadcasts, and multicasts.
- With RIPv2 configured, a broadcast interface sends RIPv2 broadcasts and can receive RIPv1 unicasts and broadcasts, and RIPv2 broadcasts, multicasts, and unicasts.

To configure a RIP version:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify a global RIP version.	version { 1 2 }	Optional. By default, if an interface has a RIP version specified, the version takes precedence over the global one. If no RIP version is specified for an interface, the interface can send RIPv1 broadcasts, and receive RIPv1 broadcasts and unicasts, and RIPv2 broadcasts, multicasts, and unicasts.
4. Return to system view.	quit	N/A
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Specify a RIP version for the interface.	rip version { 1 2 [broadcast multicast] }	Optional. By default, if an interface has no RIP version specified, the global version takes effect. If no global RIP version is specified, the interface can send RIPv1 broadcasts, and receive RIPv1 broadcasts and unicasts, and RIPv2 broadcasts, multicasts, and unicasts.

Setting the DSCP value for RIP packets

An IPv4 packet header contains an 8-bit Type of Service (ToS) field. As defined in RFC 2474, the first six bits set the Differentiated Services Code Point (DSCP) value, and the last two bits are reserved. Network devices use the DSCP value as a reference to determine the packet priority for transmission.

You can set the DSCP value for RIP packets.

To set the DSCP value for RIP packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a RIP process and enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	By default, no RIP process is created.
3. Set the DSCP value for RIP packets.	dscp <i>dscp-value</i>	Optional. By default, the DSCP value in RIP packets is 48.

Configuring RIP route control

In complex networks, you must configure advanced RIP features.

Before you configure RIP routing feature, complete the following tasks:

- Configure IP addresses for interfaces, and make sure that all neighboring routers can reach each other.
- Configure RIP basic functions.

Configuring an additional routing metric

An additional routing metric (hop count) can be added to the metric of an inbound or outbound RIP route.

The outbound additional metric is added to the metric of a sent route, and the route's metric in the routing table is not changed.

The inbound additional metric is added to the metric of a received route before the route is added into the routing table, and the route's metric is changed. If the sum of the additional metric and the original metric is greater than 16, the metric of the route will be 16.

To configure additional routing metrics:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Define an inbound additional routing metric.	rip metricin [route-policy <i>route-policy-name</i>] <i>value</i>	Optional. 0 by default.
4. Define an outbound additional routing metric.	rip metricout [route-policy <i>route-policy-name</i>] <i>value</i>	Optional. 1 by default.

Configuring RIPv2 route summarization

Route summarization means that subnets in a natural network are summarized into a natural network that is sent to other networks. This feature can reduce the size of routing tables.

After route summarization, the smallest metric among all the summarized routes is used as the metric of the summary route.

Enabling RIPv2 route automatic summarization

You can disable RIPv2 route automatic summarization if you want to advertise all subnet routes.

To enable RIPv2 route automatic summarization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable RIPv2 automatic route summarization.	summary	Optional. Enabled by default. If the subnet routes in the routing table are not consecutive, disable automatic route summarization to avoid black hole routing.

Advertising a summary route

Disable RIPv2 route automatic summarization before advertising a summary route on an interface.

To configure RIPv2 to advertise a summary route on the specified interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Disable RIPv2 automatic route summarization.	undo summary	Enabled by default.
4. Return to system view.	quit	N/A
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Advertise a summary route.	rip summary-address <i>ip-address</i> { <i>mask</i> <i>mask-length</i> }	N/A

Disabling host route reception

Perform this task to disable RIPv2 from receiving host routes from the same network and save network resources. This feature does not apply to RIPv1.

To disable RIP from receiving host routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Disable RIP from receiving host routes.	undo host-route	Enabled by default.

Advertising a default route

Under the following conditions, you can configure RIP to advertise a default route with a specified metric to RIP neighbors:

- In RIP view, you can configure all the interfaces of the RIP process to advertise a default route; in interface view, you can configure a RIP interface of the RIP process to advertise a default route. The interface view takes precedence over on the interface.
- If a RIP process is enabled to advertise a default route, to disable an interface of the RIP process from default route advertisement, you can use the **rip default-route no-originate** command on the interface.

To configure RIP to advertise a default route:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable RIP to advertise a default route.	default-route { only originate } [cost <i>cost</i>]	Optional. Not enabled by default.
4. Return to system view.	quit	N/A
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Configure the RIP interface to advertise a default route.	rip default-route { { only originate } [cost <i>cost</i>] no-originate }	Optional. By default, a RIP interface can advertise a default route if the RIP process is configured with default route advertisement.

NOTE:

The router enabled to advertise a default route does not receive default routes from RIP neighbors.

Configuring inbound or outbound route filtering

The device supports route filtering. You can filter routes by configuring the inbound and outbound route filtering policies by referencing an ACL or IP prefix list. You can also configure the router to receive only routes from a specified neighbor.

To configure route filtering:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the filtering of incoming routes.	filter-policy { <i>acl-number</i> gateway <i>ip-prefix-name</i> ip-prefix <i>ip-prefix-name</i> [gateway <i>ip-prefix-name</i>] } import [<i>interface-type interface-number</i>]	Not configured by default. The filter-policy import command filters incoming routes. Routes not passing the filtering will be neither installed into the routing table nor advertised to neighbors.
4. Configure the filtering of outgoing routes.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } export [<i>protocol</i> [<i>process-id</i>] <i>interface-type interface-number</i>]	Not configured by default. The filter-policy export command filters outgoing routes, including routes redistributed with the import-route command.

Configuring a priority for RIP

Multiple IGP protocols can run in a router. If you want RIP routes to have a higher priority than those learned by other routing protocols, then assign RIP a smaller priority value to influence optimal route selection.

To configure a priority for RIP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure a priority for RIP.	preference [route-policy <i>route-policy-name</i>] <i>value</i>	Optional. 100 by default.

Configuring RIP route redistribution

If a router runs RIP and other routing protocols, you can configure RIP to redistribute OSPF, IS-IS, BGP, static, or direct routes.

Only active routes can be redistributed. To display route state information, use the **display ip routing-table protocol** command.

To configure RIP route redistribution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A

Step	Command	Remarks
3. Configure a default metric for redistributed routes.	default cost <i>value</i>	Optional. The default metric of a redistributed route is 0.
4. Redistribute routes from another protocol.	import-route <i>protocol</i> [<i>process-id</i> all-processes allow-ibgp] [cost <i>cost</i> route-policy <i>route-policy-name</i> tag <i>tag</i>] *	By default, no redistribution is configured.

Tuning and optimizing RIP networks

Before you tune and optimize RIP networks, complete the following tasks:

- Configure IP addresses for interfaces, and make sure that all neighboring nodes can reach each other.
- Configure RIP basic functions.

Configuring RIP timers

You can change the RIP network convergence speed by adjusting RIP timers. Based on network performance, make RIP timers of RIP routers identical to each other to avoid unnecessary traffic or route oscillation.

To configure RIP timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure values for RIP timers.	timers { garbage-collect <i>garbage-collect-value</i> suppress <i>suppress-value</i> timeout <i>timeout-value</i> update <i>update-value</i> } *	Optional. The default update timer, timeout timer, suppress timer, and garbage-collect timer are 30s, 180s, 120s and 120s respectively.

Configuring split horizon and poison reverse

The split horizon and poison reverse functions can avoid routing loops. If both split horizon and poison reverse are configured, only the poison reverse function takes effect.

Enabling split horizon

The split horizon function disables an interface from sending routes received from the interface to prevent routing loops between adjacent routers.

To enable split horizon:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable split horizon.	rip split-horizon	Optional. Enabled by default.

Enabling poison reverse

The poison reverse function allows an interface to advertise the routes received from it, but the metric of these routes is set to 16, making them unreachable. This can avoid routing loops between neighbors.

To enable poison reverse:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable poison reverse.	rip poison-reverse	Disabled by default.

Configuring the maximum number of ECMP routes

Perform this task to implement load sharing over ECMP routes.

To configure the maximum number of ECMP routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the maximum number of ECMP routes.	maximum load-balancing <i>number</i>	Optional. 8 by default.

Enabling zero field check on incoming RIPv1 messages

Some fields in the RIPv1 message must be zero. These fields are called "zero fields." You can enable zero field check on received RIPv1 messages. If such a field contains a non-zero value, the RIPv1 message will not be processed. If you are certain that all messages are trustworthy, then disable zero field check to save CPU resources.

This feature does not apply to RIPv2 packets, because they have no zero fields.

To enable zero field check on incoming RIPv1 messages:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable zero field check on received RIPv1 messages.	checkzero	Optional. Enabled by default.

Enabling source IP address check on incoming RIP updates

You can enable source IP address check on incoming RIP updates.

For a message received on an Ethernet interface, RIP compares the source IP address of the message with the IP address of the interface. If they are not in the same network segment, RIP discards the message.

ⓘ IMPORTANT:

Disable the source IP address check feature if the RIP neighbor is not directly connected.

To enable source IP address check on incoming RIP updates:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable source IP address check on incoming RIP messages.	validate-source-address	Optional. Enabled by default.

Configuring RIPv2 message authentication

In a network requiring high security, configure this task to implement RIPv2 message validity check and authentication. This feature does not apply to RIPv1 because RIPv1 does not support authentication. Although you can specify an authentication mode for RIPv1 in interface view, the configuration does not take effect.

RIPv2 supports simple authentication and MD5 authentication.

To configure RIPv2 message authentication:

Step	Command
1. Enter system view.	system-view
2. Enter interface view.	interface <i>interface-type interface-number</i>
3. Configure authentication.	RIPv2 rip authentication-mode { md5 { rfc2082 [cipher] <i>key-string key-id</i> rfc2453 [cipher] <i>key-string</i> } simple [cipher] <i>password</i> }

Specifying a RIP neighbor

Usually, RIP sends messages to broadcast or multicast addresses. On non-broadcast or multicast links, you must manually specify RIP neighbors.

Follow these guidelines when you specify a RIP neighbor:

- Do not use the **peer ip-address** command when the neighbor is directly connected because the neighbor may receive both the unicast and multicast (or broadcast) of the same routing information.
- If a specified neighbor is not directly connected, then disable the source address check on incoming updates.

To specify a RIP neighbor:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify a RIP neighbor.	peer ip-address	N/A
4. Disable source address check on incoming RIP updates.	undo validate-source-address	Not disabled by default.

Configuring RIP-to-MIB binding

This task allows you to enable a specific RIP process to receive SNMP requests.

To bind RIP to MIB:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Bind RIP to MIB.	rip mib-binding <i>process-id</i>	Optional. By default, MIB is bound to RIP process 1.

Configuring the RIP packet sending rate

RIP periodically sends routing information in RIP packets to RIP neighbors.

Sending large numbers of RIP packets at the same time may affect device performance and consume large network bandwidth. To solve this problem, specify the maximum number of RIP packets that can be sent at the specified interval.

To configure the RIP packet sending rate:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable a RIP process and enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the maximum number of RIP packets that can be sent at the specified interval.	output-delay <i>time count</i> <i>count</i>	Optional. By default, an interface sends up to three RIP packets every 20 milliseconds.

Configuring RIP FRR

When a link in a RIP network fails, the traffic is interrupted until RIP completes routing convergence based on the new network topology.

You can enable RIP fast reroute (FRR) to reduce traffic recovery time.

Figure 9 Network diagram for RIP FRR

In [Figure 9](#), after you enable FRR on Router B, RIP designates a backup next hop using a routing policy when a network failure is detected. Packets are directed to the backup next hop to reduce traffic recovery time. At the same time, RIP calculates the shortest path based on the new network topology, and forwards packets over the path after network convergence.

Configuration prerequisites

You need to specify a next hop by using the **apply fast-reroute backup-interface** command in a routing policy and reference the routing policy with RIP FRR. For more information about routing policy configuration, see "[Configuring routing policies.](#)"

Configuration guidelines

- RIP FRR is only effective for non-recursive RIP routes (that are learned from directly connected neighbors).
- Do not use RIP FRR and BFD (for RIP) at the same time; otherwise, RIP FRR may fail to take effect.

Configuration procedure

To configure RIP FRR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the source address of echo packets.	bfd echo-source-ip ip-address	Not configured by default.
3. Enter RIP view.	rip [process-id] [vpn-instance vpn-instance-name]	N/A
4. Enable RIP FRR and reference a routing policy to designate a backup next hop.	fast-reroute route-policy route-policy-name	Disabled by default.

Configuring BFD for RIP

BFD for RIP provides the following link detection modes:

- Single-hop detection in BFD echo packet mode for a directly connected neighbor. In this mode, a BFD session is established only when the neighbor has route information to send.
- Bidirectional detection in BFD control packet mode for an indirectly connected neighbor. In this mode, a BFD session is established only when both ends have routes to send and BFD is enabled on the receiving interface.

For more information about BFD, see *High Availability Configuration Guide*.

Single-hop detection in BFD echo packet mode

To configure BFD for RIP (single-hop detection in BFD echo packet mode):

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the source IP address of BFD echo packets.	bfd echo-source-ip <i>ip-address</i>	By default, no source IP address is configured for BFD echo packets.
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable BFD on the RIP interface.	rip bfd enable	Disabled by default.

Bidirectional detection in BFD control packet mode

This feature only works for RIP neighbors that are directly connected (one hop away from each other).

To configure BFD for RIP (bidirectional detection in BFD control packet mode):

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a RIP process and enter RIP view.	rip [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	By default, RIP is disabled.
3. Specify a RIP neighbor.	peer <i>ip-address</i>	By default, RIP does not unicast updates to any peer.
4. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
5. Enable BFD on the RIP interface.	rip bfd enable	Disabled by default.

NOTE:

Because the **undo peer** command does not remove the neighbor relationship at once, executing the command cannot bring down the BFD session at once.

Displaying and maintaining RIP

Task	Command	Remarks
Display RIP current status and configuration information.	display rip [<i>process-id</i> vpn-instance <i>vpn-instance-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display all active routes in RIP database.	display rip <i>process-id</i> database [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display RIP interface information.	display rip <i>process-id</i> interface [<i>interface-type</i> <i>interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing information about a specified RIP process.	display rip <i>process-id</i> route [<i>ip-address</i> { <i>mask</i> <i>mask-length</i> } peer <i>ip-address</i> statistics] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Reset a RIP process.	reset rip <i>process-id</i> process	Available in user view
Clear the statistics of a RIP process.	reset rip <i>process-id</i> statistics	Available in user view

RIP configuration examples

Configuring RIP version

Network requirements

As shown in [Figure 10](#), enable RIPv2 on all interfaces on Switch A and Switch B.

Figure 10 Network diagram

Configuration procedure

1. Configure an IP address for each interface. (Details not shown.)
2. Configure basic RIP functions:

Configure Switch A.

```
[SwitchA] rip
[SwitchA-rip-1] network 192.168.1.0
[SwitchA-rip-1] network 172.16.0.0
[SwitchA-rip-1] network 172.17.0.0
```

Configure Switch B.

```
[SwitchB] rip
[SwitchB-rip-1] network 192.168.1.0
```

```
[SwitchB-rip-1] network 10.0.0.0
# Display the RIP routing table of Switch A.
[SwitchA] display rip 1 route
Route Flags: R - RIP, T - TRIP
              P - Permanent, A - Aging, S - Suppressed, G - Garbage-collect
-----
Peer 192.168.1.2 on Vlan-interface100
  Destination/Mask      Nexthop      Cost      Tag      Flags      Sec
  10.0.0.0/8           192.168.1.2    1         0        RA         11
```

The output shows that RIPv1 uses a natural mask.

3. Configure RIP version:

Configure RIPv2 on Switch A.

```
[SwitchA] rip
[SwitchA-rip-1] version 2
[SwitchA-rip-1] undo summary
```

Configure RIPv2 on Switch B.

```
[SwitchB] rip
[SwitchB-rip-1] version 2
[SwitchB-rip-1] undo summary
```

Display the RIP routing table on Switch A.

```
[SwitchA] display rip 1 route
Route Flags: R - RIP, T - TRIP
              P - Permanent, A - Aging, S - Suppressed, G - Garbage-collect
-----
Peer 192.168.1.2 on Vlan-interface100
  Destination/Mask      Nexthop      Cost      Tag      Flags      Sec
  10.0.0.0/8           192.168.1.2    1         0        RA         50
  10.2.1.0/24          192.168.1.2    1         0        RA         16
  10.1.1.0/24          192.168.1.2    1         0        RA         16
```

The output shows that RIPv2 uses classless subnet mask.

NOTE:

RIPv1 routing information has a long aging time, so it will exist until it ages out after RIPv2 is configured.

Configuring RIP route redistribution

Network requirements

In the following figure, two RIP processes are running on Switch B, which communicates with Switch A through RIP 100 and with Switch C through RIP 200.

Configure route redistribution on Switch B to make RIP 200 redistribute direct routes and routes from RIP 100. Switch C can then learn routes destined for 10.2.1.0/24 and 11.1.1.0/24, and Switch A cannot learn routes destined for 12.3.1.0/24 and 16.4.1.0/24.

Configure a filtering policy on Switch B to filter out the route 10.2.1.1/24 from RIP 100, making the route not advertised to Switch C.

Figure 11 Network diagram

Configuration procedure

1. Configure an IP address for each interface. (Details not shown.)
2. Configure basic RIP functions:

Enable RIP 100 and specify RIP version 2 on Switch A.

```
<SwitchA> system-view
[SwitchA] rip 100
[SwitchA-rip-100] network 10.0.0.0
[SwitchA-rip-100] network 11.0.0.0
[SwitchA-rip-100] version 2
[SwitchA-rip-100] undo summary
[SwitchA-rip-100] quit
```

Enable RIP 100 and RIP 200 and specify RIP version 2 on Switch B.

```
<SwitchB> system-view
[SwitchB] rip 100
[SwitchB-rip-100] network 11.0.0.0
[SwitchB-rip-100] version 2
[SwitchB-rip-100] undo summary
[SwitchB-rip-100] quit
[SwitchB] rip 200
[SwitchB-rip-200] network 12.0.0.0
[SwitchB-rip-200] version 2
[SwitchB-rip-200] undo summary
[SwitchB-rip-200] quit
```

Enable RIP 200 and specify RIP version 2 on Switch C.

```
<SwitchC> system-view
[SwitchC] rip 200
[SwitchC-rip-200] network 12.0.0.0
[SwitchC-rip-200] network 16.0.0.0
[SwitchC-rip-200] version 2
[SwitchC-rip-200] undo summary
```

Display the routing table of Switch C.

```
[SwitchC] display ip routing-table
```

Routing Tables: Public

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
12.3.1.0/24	Direct	0	0	12.3.1.2	Vlan200
12.3.1.2/32	Direct	0	0	127.0.0.1	InLoop0
16.4.1.0/24	Direct	0	0	16.4.1.1	Vlan400

```

16.4.1.1/32          Direct 0    0          127.0.0.1      InLoop0
127.0.0.0/8         Direct 0    0          127.0.0.1      InLoop0
127.0.0.1/32        Direct 0    0          127.0.0.1      InLoop0

```

3. Configure route redistribution:

On Switch B, configure RIP 200 to redistribute direct routes and routes from RIP 100.

```

[SwitchB] rip 200
[SwitchB-rip-200] import-route rip 100
[SwitchB-rip-200] import-route direct
[SwitchB-rip-200] quit

```

Display the routing table of Switch C.

```

[SwitchC] display ip routing-table
Routing Tables: Public
          Destinations : 8          Routes : 8
Destination/Mask    Proto  Pre  Cost           NextHop         Interface
10.2.1.0/24         RIP    100  1             12.3.1.1        Vlan200
11.1.1.0/24         RIP    100  1             12.3.1.1        Vlan200
12.3.1.0/24         Direct 0    0             12.3.1.2        Vlan200
12.3.1.2/32         Direct 0    0             127.0.0.1       InLoop0
16.4.1.0/24         Direct 0    0             16.4.1.1        Vlan400
16.4.1.1/32         Direct 0    0             127.0.0.1       InLoop0
127.0.0.0/8         Direct 0    0             127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0             127.0.0.1       InLoop0

```

4. Configure an filtering policy to filter redistributed routes:

Define ACL 2000 and reference it to a filtering policy to filter routes redistributed from RIP 100 on Switch B, making the route not advertised to Switch C.

```

[SwitchB] acl number 2000
[SwitchB-acl-basic-2000] rule deny source 10.2.1.1 0.0.0.255
[SwitchB-acl-basic-2000] rule permit
[SwitchB-acl-basic-2000] quit
[SwitchB] rip 200
[SwitchB-rip-200] filter-policy 2000 export rip 100

```

Display the routing table of Switch C.

```

[SwitchC] display ip routing-table
Routing Tables: Public
          Destinations : 7          Routes : 7
Destination/Mask    Proto  Pre  Cost           NextHop         Interface
11.1.1.0/24         RIP    100  1             12.3.1.1        Vlan200
12.3.1.0/24         Direct 0    0             12.3.1.2        Vlan200
12.3.1.2/32         Direct 0    0             127.0.0.1       InLoop0
16.4.1.0/24         Direct 0    0             16.4.1.1        Vlan400
16.4.1.1/32         Direct 0    0             127.0.0.1       InLoop0
127.0.0.0/8         Direct 0    0             127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0             127.0.0.1       InLoop0

```

Configuring an additional metric for a RIP interface

Network requirements

In the following figure, RIP is enabled on all the interfaces of Switch A, Switch B, Switch C, Switch D, and Switch E. The switches are interconnected through RIPv2.

Switch A has two links to Switch D. The link from Switch B to Switch D is more stable than that from Switch C to Switch D. Configure an additional metric for RIP routes received through VLAN-interface 200 on Switch A so that Switch A prefers the 1.1.5.0/24 network learned from Switch B.

Figure 12 Network diagram

Configuration procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure RIP basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] rip 1
[SwitchA-rip-1] network 1.0.0.0
[SwitchA-rip-1] version 2
[SwitchA-rip-1] undo summary
[SwitchA-rip-1] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] rip 1
[SwitchB-rip-1] network 1.0.0.0
[SwitchB-rip-1] version 2
[SwitchB-rip-1] undo summary
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] rip 1
[SwitchC-rip-1] network 1.0.0.0
[SwitchC-rip-1] version 2
[SwitchC-rip-1] undo summary
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] rip 1
[SwitchD-rip-1] network 1.0.0.0
[SwitchD-rip-1] version 2
```

```

[SwitchD-rip-1] undo summary
# Configure Switch E.
<SwitchE> system-view
[SwitchE] rip 1
[SwitchE-rip-1] network 1.0.0.0
[SwitchE-rip-1] version 2
[SwitchE-rip-1] undo summary
# Display the IP routing table of Switch A.
[SwitchA] display rip 1 database
  1.0.0.0/8, cost 0, ClassfulSumm
    1.1.1.0/24, cost 0, nexthop 1.1.1.1, Rip-interface
    1.1.2.0/24, cost 0, nexthop 1.1.2.1, Rip-interface
    1.1.3.0/24, cost 1, nexthop 1.1.1.2
    1.1.4.0/24, cost 1, nexthop 1.1.2.2
    1.1.5.0/24, cost 2, nexthop 1.1.1.2
    1.1.5.0/24, cost 2, nexthop 1.1.2.2

```

The output shows that two RIP routes can reach network 1.1.5.0/24. Their next hops are Switch B (1.1.1.2) and Switch C (1.1.2.2) respectively, with the same cost of 2. Switch C is the next hop router to reach network 1.1.4.0/24, with a cost of 1.

3. Configure an additional metric for the RIP interface:

Configure an additional metric of 3 for VLAN-interface 200 on Switch A.

```

[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] rip metricin 3
[SwitchA-Vlan-interface200] display rip 1 database
  1.0.0.0/8, cost 0, ClassfulSumm
    1.1.1.0/24, cost 0, nexthop 1.1.1.1, Rip-interface
    1.1.2.0/24, cost 0, nexthop 1.1.2.1, Rip-interface
    1.1.3.0/24, cost 1, nexthop 1.1.1.2
    1.1.4.0/24, cost 2, nexthop 1.1.1.2
    1.1.5.0/24, cost 2, nexthop 1.1.1.2

```

The output shows that only one RIP route reaches network 1.1.5.0/24, with the next hop as Switch B (1.1.1.2) and a cost of 2.

Configuring RIP to advertise a summary route

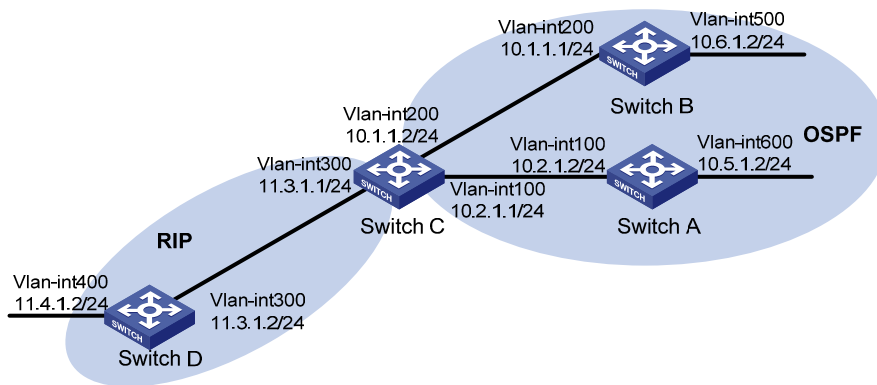

Network requirements

In the following figure, Switch A and Switch B run OSPF, Switch D runs RIP, and Switch C runs OSPF and RIP.

Configure RIP to redistribute OSPF routes on Switch C so that Switch D has routes destined for networks 10.1.1.0/24, 10.2.1.0/24, 10.5.1.0/24, and 10.6.1.0/24.

Configure route summarization on Switch C and advertise only the summary route 10.0.0.0/8, reducing the routing table size of Switch D.

Figure 13 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 10.5.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] network 10.6.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
```

3. Configure RIP basic functions:

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] rip 1
[SwitchC-rip-1] network 11.3.1.0
[SwitchC-rip-1] version 2
[SwitchC-rip-1] undo summary
```

Configure Switch D.

```
<SwitchD> system-view
```

```
[SwitchD] rip 1
[SwitchD-rip-1] network 11.0.0.0
[SwitchD-rip-1] version 2
[SwitchD-rip-1] undo summary
[SwitchD-rip-1] quit
```

Configure RIP to redistribute the routes from OSPF process 1 and direct routes on Switch C.

```
[SwitchC-rip-1] import-route direct
[SwitchC-rip-1] import-route ospf 1
```

Display the routing table information of Switch D.

```
[SwitchD] display ip routing-table
Routing Tables: Public
                Destinations : 10          Routes : 10
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
10.1.1.0/24	RIP	100	1	11.3.1.1	Vlan300
10.2.1.0/24	RIP	100	1	11.3.1.1	Vlan300
10.5.1.0/24	RIP	100	1	11.3.1.1	Vlan300
10.6.1.0/24	RIP	100	1	11.3.1.1	Vlan300
11.3.1.0/24	Direct	0	0	11.3.1.2	Vlan300
11.3.1.2/32	Direct	0	0	127.0.0.1	InLoop0
11.4.1.0/24	Direct	0	0	11.4.1.2	Vlan400
11.4.1.2/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0

4. Configure route summarization on Switch C and advertise only the summary route 10.0.0.0/8:

```
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] rip summary-address 10.0.0.0 8
```

Display the routing table information of Switch D.

```
[SwitchD] display ip routing-table
Routing Tables: Public
                Destinations : 7          Routes : 7
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
10.0.0.0/8	RIP	100	1	11.3.1.1	Vlan300
11.3.1.0/24	Direct	0	0	11.3.1.2	Vlan300
11.3.1.2/32	Direct	0	0	127.0.0.1	InLoop0
11.4.1.0/24	Direct	0	0	11.4.1.2	Vlan400
11.4.1.2/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0

RIP FRR configuration example

Network requirements

Switch S, Switch A, and Switch D are interconnected through RIPv2, as illustrated in Figure 14. Configure RIP FRR so that when Link A between Switch S and Switch D fails, services can be switched to Link B immediately.

Figure 14 Network diagram

Configuration procedure

1. Configure IP addresses for the interfaces on each switch and configure RIPv2:
Follow Figure 14 to configure the IP address and subnet mask of each interface on the switches. (Details not shown.)
Configure RIPv2 on the switches, ensuring that Switch A, Switch D, and Switch S can communicate with each other at Layer 3. (Details not shown.)

2. Configure RIP FRR:

Configure Switch S.

```
<SwitchS> system-view
[SwitchS] bfd echo-source-ip 1.1.1.1
[SwitchS] ip ip-prefix abc index 10 permit 4.4.4.4 32
[SwitchS] route-policy frr permit node 10
[SwitchS-route-policy] if-match ip-prefix abc
[SwitchS-route-policy] apply fast-reroute backup-interface vlan-interface 100
backup-nexthop 12.12.12.2
[SwitchS-route-policy] quit
[SwitchS] rip 1
[SwitchS-rip-1] fast-reroute route-policy frr
[SwitchS-rip-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bfd echo-source-ip 4.4.4.4
[SwitchD] ip ip-prefix abc index 10 permit 1.1.1.1 32
[SwitchD] route-policy frr permit node 10
[SwitchD-route-policy] if-match ip-prefix abc
[SwitchD-route-policy] apply fast-reroute backup-interface vlan-interface 101
backup-nexthop 24.24.24.2
[SwitchD-route-policy] quit
[SwitchD] rip 1
[SwitchD-rip-1] fast-reroute route-policy frr
```

```
[SwitchD-rip-1] quit47
```

3. Verify the configuration:

Display route 4.4.4.4/32 on Switch S and you can view the backup next hop information.

```
[SwitchS] display ip routing-table 4.4.4.4 verbose
```

```
Routing Table : Public
```

```
Summary Count : 1
```

```
Destination: 4.4.4.4/32

Configuring BFD for RIP (single-hop detection in BFD echo packet mode)

Network requirements

In the following figure, Switch A and Switch C are interconnected through a Layer 2 switch. VLAN-interface 100 of the two switches runs RIP process 1, BFD is enabled on VLAN-interface 100 of Switch A.

Switch A is connected to Switch C through Switch B. VLAN-interface 200 on Switch A runs RIP process 2; VLAN-interface 300 on Switch C, and VLAN-interface 200 and VLAN-interface 300 on Switch B run RIP process 1.

Configure a static route and enable static route redistribution into RIP on Switch C. Switch A learns the static route sent by Switch C, the outbound interface of the route is the interface connected to the Layer 2 switch.

Configure BFD so that when the link between Switch C and the Layer 2 switch fails, BFD can quickly detect the link failure and notify it to RIP, and the BFD session goes down. In response, RIP deletes the neighbor relationship with Switch C and the route information received from Switch C. Then, Switch A learns the static route sent by Switch C with the outbound interface being the interface connected to Switch B.

Figure 15 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure RIP basic functions:

Configure Switch A.

```
[SwitchA] rip 1
[SwitchA-rip-1] network 192.168.1.0
[SwitchA-rip-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] rip bfd enable
[SwitchA-Vlan-interface100] quit
[SwitchA] rip 2
[SwitchA-rip-2] network 192.168.2.0
```

Configure Switch B.

```
[SwitchB] rip 1
[SwitchB-rip-1] network 192.168.2.0
[SwitchB-rip-1] network 192.168.3.0
[SwitchB-rip-1] quit
```

Configure Switch C.

```
[SwitchC] rip 1
[SwitchC-rip-1] network 192.168.1.0
[SwitchC-rip-1] network 192.168.3.0
[SwitchC-rip-1] import-route static
[SwitchC-rip-1] quit
```

3. Configure BFD parameters:

Configure Switch A.

```
[SwitchA] bfd session init-mode active
[SwitchA] bfd echo-source-ip 11.11.11.11
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] bfd min-transmit-interval 500
[SwitchA-Vlan-interface100] bfd min-receive-interval 500
[SwitchA-Vlan-interface100] bfd detect-multiplier 7
[SwitchA-Vlan-interface100] quit
[SwitchA] quit
```

4. Configure a static route on Switch C:

```
[SwitchC] ip route-static 100.1.1.1 24 null 0
```

5. Verify the configuration:

Display the BFD session information of Switch A.

```
<SwitchA> display bfd session
Total Session Num: 1          Init Mode: Active
Session Working Under Echo Mode:
LD          SourceAddr      DestAddr      State   Holdtime   Interface
5           192.168.1.1      192.168.1.2  Up      2000ms     Vlan100
```

Display the RIP route 100.1.1.0/24 learned by Switch A.

```
<SwitchA> display ip routing-table 100.1.1.0 24 verbose
Routing Table : Public
Summary Count : 2
  Destination: 100.1.1.0/24
    Protocol: RIP          Process ID: 1

Configuring BFD for RIP (bidirectional detection in BFD control packet mode)

Network requirements

In the following figure, Switch A is connected to Switch C through Switch B. VLAN-interface 100 on Switch A, VLAN-interface 200 on Switch C, and VLAN-interface 200 and VLAN-interface 100 on Switch B run RIP process 1.

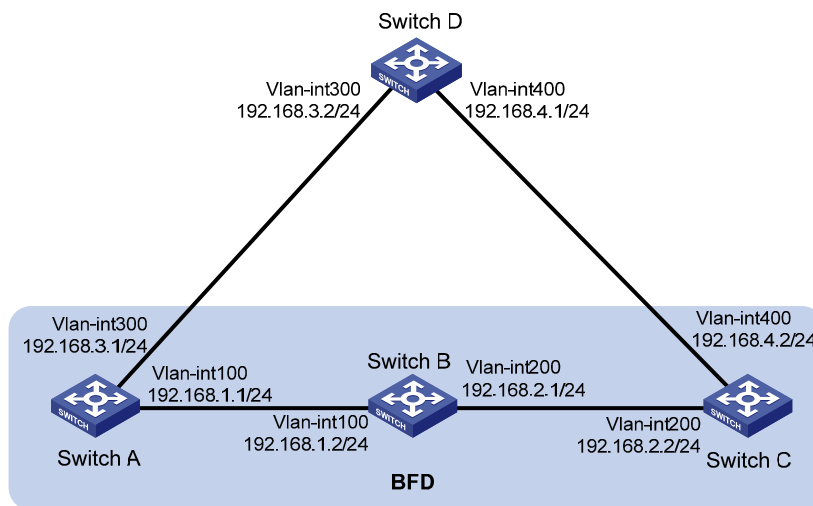

Configure a static route to Switch C on Switch A, and configure a static route to Switch A on Switch C. Enable BFD on VLAN-interface 100 of Switch A and VLAN-interface 200 of Switch C.

Switch A is connected to Switch C through Switch D. VLAN-interface 300 on Switch A runs RIP process 2; VLAN-interface 400 on Switch C, and VLAN-interface 300 and VLAN-interface 400 on Switch D run RIP process 1.

Enable static route redistribution into RIP on Switch A and Switch C so that Switch A and Switch C have routes to send to each other. Switch A learns the static route sent by Switch C, the outbound interface is the interface connected to Switch B.

Configure BFD so that when the link between Switch B and Switch C fails, BFD can quickly detect the link failure and notify it to RIP, and the BFD session goes down. In response, RIP deletes the neighbor relationship with Switch C and the route information received from Switch C. Then, Switch A learns the static route sent by Switch C, the outbound interface of the route is the interface connected to Switch D.

Figure 16 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure RIP basic functions and enable static route redistribution so that Switch A and Switch C have routes to send to each other:

Configure Switch A.

```
[SwitchA] rip 1
[SwitchA-rip-1] network 192.168.1.0
[SwitchA-rip-1] peer 192.168.2.2
[SwitchA-rip-1] undo validate-source-address
[SwitchA-rip-1] import-route static
[SwitchA-rip-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] rip bfd enable
[SwitchA-Vlan-interface100] quit
[SwitchA] rip 2
[SwitchA-rip-2] network 192.168.3.0
[SwitchA-rip-2] quit
```

Configure Switch C.

```
[SwitchC] rip 1
[SwitchC-rip-1] network 192.168.2.0
[SwitchC-rip-1] network 192.168.4.0
[SwitchC-rip-1] peer 192.168.1.1
[SwitchC-rip-1] undo validate-source-address
[SwitchC-rip-1] import-route static
```

```
[SwitchC-rip-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] rip bfd enable
[SwitchC-Vlan-interface200] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] rip 1
[SwitchD-rip-1] network 192.168.3.0
[SwitchD-rip-1] network 192.168.4.0
```

3. Configure BFD parameters:

Configure Switch A.

```
[SwitchA] bfd session init-mode active
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] bfd min-transmit-interval 500
[SwitchA-Vlan-interface100] bfd min-receive-interval 500
[SwitchA-Vlan-interface100] bfd detect-multiplier 7
[SwitchA-Vlan-interface100] quit
```

Configure Switch C.

```
[SwitchC] bfd session init-mode active
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] bfd min-transmit-interval 500
[SwitchC-Vlan-interface200] bfd min-receive-interval 500
[SwitchC-Vlan-interface200] bfd detect-multiplier 7
[SwitchC-Vlan-interface200] quit
```

4. Configure static routes.

Configure a static route to Switch C on Switch A.

```
[SwitchA] ip route-static 192.168.2.0 24 vlan-interface 100 192.168.1.2
[SwitchA] ip route-static 101.1.1.0 24 null 0
[SwitchA] quit
```

Configure a static route to Switch A on Switch C.

```
[SwitchC] ip route-static 192.168.1.0 24 vlan-interface 200 192.168.2.1
[SwitchC] ip route-static 100.1.1.0 24 null 0
```

! IMPORTANT:

If you specify null 0 interface as the output interface for a static route, do not specify the IP address of a directly connected network as the destination IP address.

5. Verify the configuration:

Display the BFD session information of Switch A.

```
<SwitchA> display bfd session
Total Session Num: 1          Init Mode: Active
Session Working Under Ctrl Mode:
LD/RD      SourceAddr      DestAddr      State Holdtime Interface
6/3        192.168.1.1     192.168.2.2   Up    1700ms   vlan100
```

Display the RIP route 100.1.1.0/24 learned on Switch A.

```
<SwitchA> display ip routing-table 100.1.1.0 24 verbose
Routing Table : Public
```

```

Summary Count : 2
  Destination: 100.1.1.0/24

Troubleshooting RIP

No RIP updates received

Symptom

No RIP updates are received when the links function.

Analysis

After enabling RIP, you must use the **network** command to enable corresponding interfaces. Ensure no interfaces are disabled from handling RIP messages.

If the peer is configured to send multicast messages, the same must be configured on the local end.

Solution

1. Use the **display current-configuration** command to check RIP configuration.
2. Use the **display rip** command to check whether an interface is disabled.

Route oscillation occurred

Symptom

When all links function, route oscillation occurs on the RIP network. After displaying the routing table, you may find some routes intermittently appear and disappear in the routing table.

Analysis

In the RIP network, make sure that all the same timers within the entire network are identical and have logical relationships between them. For example, the timeout timer value must be greater than the update timer value.

Solution

1. Use the **display rip** command to check the configuration of RIP timers.
2. Use the **timers** command to adjust timers properly.

Configuring OSPF

Hardware compatibility

The HP 5500 SI Switch Series does not support OSPF.

Introduction to OSPF

Open Shortest Path First (OSPF) is a link state interior gateway protocol developed by the OSPF working group of the IETF. Now, OSPF version 2 (RFC 2328) is used. Unless otherwise noted, OSPF refers to OSPFv2 throughout this chapter. The term "router" in this chapter refers to both routers and Layer 3 switches.

OSPF has the following features:

- **Wide scope**—Supports various network sizes and up to several hundred routers in an OSPF routing domain.
- **Fast convergence**—Transmits routing updates instantly upon network topology changes.
- **Loop-free**—Computes routes with the shortest path first (SPF) algorithm to avoid routing loops.
- **Area-based network partition**—Splits an AS into different areas to facilitate management. In addition, routing information transmitted between areas is summarized to reduce traffic and routing table sizes.
- **Equal-cost multi-path (ECMP) routing**—Supports multiple equal-cost routes to a destination.
- **Routing hierarchy**—Supports a four-level routing hierarchy that prioritizes routes into intra-area, inter-area, external Type-1, and external Type-2 routes.
- **Authentication**—Supports interface-based packet authentication to ensure the security of packet exchange.
- **Support for multicast**—Multicasts protocol packets on some types of links.

Basic concepts

Autonomous System

An Autonomous System (AS) comprises a group of routers that run the same routing protocol.

OSPF route computation

OSPF computes routes in an area as follows:

- Based on the network topology around itself, each router generates Link State Advertisements (LSAs) and sends them to other routers in update packets.
- Each OSPF router collects LSAs from other routers to compose a link state database (LSDB). An LSA describes the network topology around a router, and the LSDB describes the entire network topology of the AS.
- Each router transforms the LSDB in the area to a weighted directed graph, which is the topology of the entire network. All the routers of the area have the same graph.

- Each router uses the SPF algorithm to compute a shortest path tree showing the routes to the nodes in the AS. The router itself is the root of the tree.

Router ID

An OSPF process running on a router must have its own router ID. This ID is a 32-bit unsigned integer that uniquely identifies the router in the AS.

OSPF packets

OSPF uses the following types of packets:

- **Hello**—Periodically sent to find and maintain neighbors, containing the values of some timers, information about the DR, BDR, and known neighbors.
- **Database description (DD)**—Describes the digest of each LSA in the LSDB, exchanged between two routers for data synchronization.
- **Link state request (LSR)**—Requests needed LSAs from the neighbor. After exchanging the DD packets, the two routers know which LSAs of the neighbor are missing from their LSDBs. They then send an LSR packet to each other, requesting the missing LSAs. The LSA packet contains the digest of the missing LSAs.
- **Link state update (LSU)**—Transmits the requested LSAs to the neighbor.
- **Link state acknowledgment (LSAck)**—Acknowledges received LSU packets. It contains the headers of received LSAs (an LSAck packet can acknowledge multiple LSAs).

LSA types

OSPF sends routing information in LSAs, which—as defined in RFC 2328—have the following types:

- **Router LSA**—Type-1 LSA, originated by all routers, flooded throughout a single area only. This LSA describes the collected states of the router's interfaces to an area.
- **Network LSA**—Type-2 LSA, originated for broadcast and NBMA networks by the designated router, flooded throughout a single area only. This LSA contains the list of routers connected to the network.
- **Network Summary LSA**—Type-3 LSA, originated by ABRs (Area Border Routers), and flooded throughout the LSA's associated area. Each summary-LSA describes a route to a destination outside the area, yet still inside the AS (an inter-area route).
- **ASBR Summary LSA**—Type-4 LSA, originated by ABRs and flooded throughout the LSA's associated area. Type 4 summary-LSAs describe routes to ASBR (Autonomous System Boundary Router).
- **AS External LSA**—Type-5 LSA, originated by ASBRs, and flooded throughout the AS (except stub and NSSA areas). Each AS-external-LSA describes a route to another AS.
- **NSSA LSA**—Type-7 LSA, as defined in RFC 1587, originated by ASBRs in NSSAs (Not-So-Stubby Areas) and flooded throughout a single NSSA. NSSA LSAs describe routes to other ASs.
- **Opaque LSA**—A proposed type of LSA, the format consisting of a standard LSA header and application specific information. Opaque LSAs are used by the OSPF protocol or by some application to distribute information into the OSPF routing domain. The opaque LSA includes Type 9, Type 10, and Type 11. The Type 9 opaque LSA is flooded into the local subnet, the Type 10 is flooded into the local area, and the Type 11 is flooded throughout the AS.

Neighbor and Adjacency

In OSPF, "neighbor" and "adjacency" are different concepts.

- **Neighbor**—After startup, OSPF sends a hello packet on each OSPF interface. A router that receives the hello packet checks parameters in the packet. If the parameters match its own, the router considers the sending router an OSPF neighbor.
- **Adjacency**—Two OSPF neighbors establish an adjacency relationship to synchronize their LSDBs. Therefore, any two neighbors without exchanging route information do not establish an adjacency.

Area based OSPF network partition

Network partition

In a large OSPF routing domain, the LSDB becomes very huge and SPF computation consumes many storage and CPU resources.

In addition, because topology changes can easily occur, OSPF packets generated for route information synchronization are enormous, occupying excessive bandwidth.

To solve these problems, OSPF splits an AS into multiple areas, each of which is identified by an area ID. The boundaries between areas are routers rather than links. A network segment (or a link) can only reside in one area. An OSPF interface must be specified to belong to its attached area, as shown in Figure 17.

Figure 17 Area based OSPF network partition

After network partition, ABRs perform route summarization to reduce the number of LSAs advertised to other areas and minimize the effect of topology changes.

Backbone area and virtual links

Each AS has a backbone area that distributes routing information between non-backbone areas. Routing information between non-backbone areas must be forwarded by the backbone area. OSPF requires the following:

- All non-backbone areas must maintain connectivity to the backbone area.
- The backbone area itself must maintain connectivity.

In practice, the requirements may not be satisfied due to lack of physical links. OSPF virtual links can solve this problem.

A virtual link is established between two ABRs through a non-backbone area and is configured on both ABRs to take effect. The non-backbone area is called a transit area.

In the following figure, Area 2 has no direct physical link to the backbone area 0. You can configure a virtual link between the two ABRs to connect Area 2 to the backbone area.

Figure 18 Virtual link application 1

Virtual links can also be used to provide redundant links. If the backbone area cannot maintain internal connectivity due to the failure of a physical link, you can configure a virtual link to replace the failed physical link, as shown in Figure 19.

Figure 19 Virtual link application 2

The virtual link between the two ABRs acts as a point-to-point connection. You can configure interface parameters such as hello interval on the virtual link as they are configured on a physical interface.

The two ABRs on the virtual link unicast OSPF packets to each other, and the OSPF routers in between convey these OSPF packets as normal IP packets.

Stub area

A stub area does not distribute Type-5 LSAs, so the routing table size and amount of routing information in this area are reduced significantly. The ABR generates a default route into the area.

You can configure the stub area as a totally stub area, where the ABR advertises neither inter-area routes nor external routes.

Stub area configuration is optional, and not every area is eligible to be a stub area. In general, a stub area resides on the border of the AS.

When you configure a totally stub area, follow these guidelines:

- The backbone area cannot be a totally stub area.
- To configure an area as a stub area, the **stub** command must be configured on routers in the area.

- To configure an area as a totally stub area, the **stub** command must be configured on routers in the area, and the ABR of the area must be configured with the **stub [no-summary]** command.
- A totally stub area cannot have an ASBR because AS external routes cannot be distributed into the stub area.
- Virtual links cannot transit totally stub areas.

NSSA area

Similar to a stub area, an NSSA area does not import AS external LSAs (Type-5 LSAs), but can import Type-7 LSAs generated by the NSSA ASBR. The NSSA ABR translates Type-7 LSAs into Type-5 LSAs and advertises the Type-5 LSAs to other areas.

In the following figure, the OSPF AS contains Area 1, Area 2, and Area 0. The other two ASs run RIP. Area 1 is an NSSA area. The ASBR redistributes RIP routes in Type-7 LSAs into Area 1. Upon receiving these Type-7 LSAs, the NSSA ABR translates them to Type-5 LSAs, and then advertises the Type-5 LSAs to Area 0.

The ASBR of Area 2 redistributes RIP routes in Type-5 LSAs into the OSPF routing domain. However, Area 1 does not receive these Type-5 LSAs because it is an NSSA area.

Virtual links cannot transit NSSA areas.

Figure 20 NSSA area

Comparison between the areas

Figure 21 Comparison between the areas

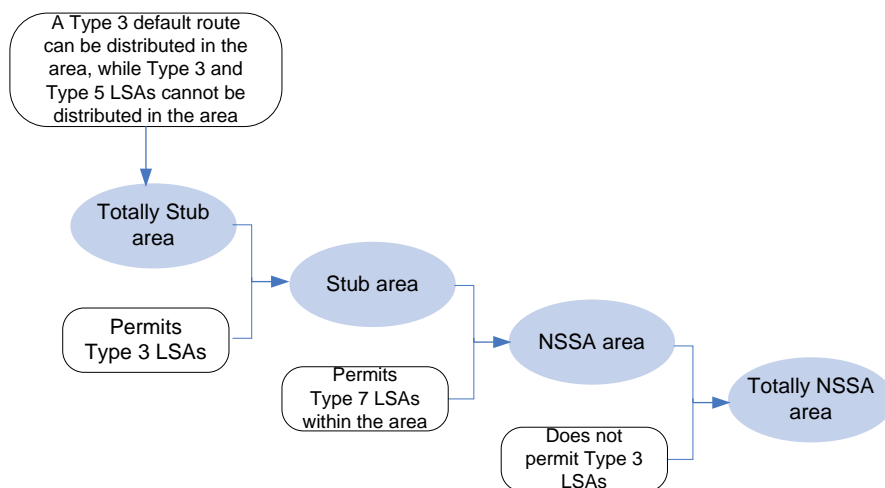

Figure 21 shows the comparison of the areas:

- In a totally stub area, the ABR distributes a Type 3 default route, rather than external routes and inter-area routes.
- A stub area can import inter-area routes, but a stub area cannot.

- An NSSA area can import external routes in Type 7 LSAs through the ASBR, but a stub area cannot.
- A totally NSSA area cannot import inter-area routes but an NSSA area can.

Router types

Router classification

The following are OSPF router types and their positions in the AS:

- **Internal router**—All interfaces on an internal router belong to one OSPF area.
- **Area Border Router (ABR)**—An ABR belongs to more than two areas, one of which must be the backbone area. It connects the backbone area to a non-backbone area. The connection between an ABR and the backbone area can be physical or logical.
- **Backbone router**—At least one interface of a backbone router must reside in the backbone area. All ABRs and internal routers in area 0 are backbone routers.
- **Autonomous System Boundary Router (ASBR)**—A router exchanging routing information with another AS is an ASBR, which may not reside on the border of the AS. It can be an internal router or an ABR.

Figure 22 OSPF router types

Route types

OSPF prioritize routes into the following levels:

- Intra-area route
- Inter-area route
- Type-1 external route
- Type-2 external route

The intra-area and inter-area routes describe the network topology of the AS. The external routes describe routes to external ASs.

OSPF classifies external routes as Type-1 or Type-2. A Type-1 external route has high credibility. The cost from a router to the destination of the Type-1 external route = the cost from the router to the corresponding ASBR + the cost from the ASBR to the destination of the external route.

A Type-2 external route has low credibility, so OSPF considers the cost from the ASBR to the destination of the Type-2 external route is much greater than the cost from the ASBR to an OSPF internal router. The cost from the internal router to the destination of the Type-2 external route = the cost from the ASBR to the destination of the Type-2 external route. If two routes to the same destination have the same cost, OSPF takes the cost from the router to the ASBR into consideration to determine the best route.

OSPF network classification

OSPF network types

OSPF classifies networks into the following types depending on different link layer protocols:

- **Broadcast**—When the link layer protocol is Ethernet or FDDI, OSPF considers the network type as broadcast by default. On a broadcast network, hello, LSU, and LSAck packets are multicast to 224.0.0.5 that identifies all OSPF routers or 224.0.0.6 that identifies the DR, and DD packets and LSR packets are unicast.
- **NBMA (Non-Broadcast Multi-Access)**—When the link layer protocol is Frame Relay, ATM, or X.25, OSPF considers the network type as NBMA by default. OSPF packets are unicast on a NBMA network.
- **P2MP (point-to-multipoint)**—By default, OSPF considers no link layer protocol as P2MP, which is a conversion from other network types such as NBMA. On a P2MP network, OSPF packets are multicast to 224.0.0.5.
- **P2P (point-to-point)**—When the link layer protocol is PPP or HDLC, OSPF considers the network type as P2P. On a P2P network, OSPF packets are multicast to 224.0.0.5.

NBMA network configuration guidelines

Typical NBMA networks include ATM and Frame Relay networks.

Because NBMA interfaces cannot broadcast hello packets, you must specify neighbors manually and configure router priorities for the neighbors.

An NBMA network is fully meshed, which means any two routers in the NBMA network have a direct virtual circuit for communication. If direct connections are not available between some routers, the network type of associated interfaces must be configured as P2MP. If such an interface has only one neighbor, configure its network type as P2P.

The differences between NBMA and P2MP networks are as follows:

- NBMA networks are fully meshed, non-broadcast, and multi access. P2MP networks are not required to be fully meshed.
On an NBMA network, you must elect the DR and BDR, while on a P2MP network, DR and BDR are not available.
- NBMA is the default network type, but P2MP is a conversion from another network type, such as NBMA.
- On a NBMA network, OSPF packets are unicast, and neighbors are manually configured on routers. On a P2MP network, OSPF packets are multicast.

DR and BDR

Introduction

On a broadcast or NBMA network, any two routers need to establish an adjacency to exchange routing information with each other. If n routers are present on the network, $n(n-1)/2$ adjacencies are required. In addition, any topology change on the network results in traffic for route synchronization, which consumes many system and bandwidth resources. The Designated Router (DR) was introduced to solve this problem. On a network, a DR is elected to advertise routing information among other routers.

If the DR fails, routers on the network have to elect another DR and synchronize information with the new DR. It is time-consuming and prone to routing calculation errors. The Backup Designated Router (BDR) can solve this problem.

The BDR is elected along with the DR and establishes adjacencies with all other routers. When the DR fails, the BDR becomes the new DR in a very short time. Meanwhile, other routers elect a new BDR.

Routers other than the DR and BDR are called "DRothers". They do not establish adjacencies with one another. Thus the number of adjacencies is reduced.

In [Figure 23](#), solid lines are Ethernet physical links, and dashed lines represent OSPF adjacencies. In the network with the DR and BDR, only seven adjacencies are needed.

Figure 23 DR and BDR in a network

DR and BDR election

Routers in a network elect the DR and BDR according to their router priorities and router IDs. Routers with a router priority value higher than 0 are candidates for DR/BDR election.

The election votes are hello packets. Each router sends the DR elected by itself in a hello packet to all the other routers. If two routers on the network declare themselves as the DR, the router with the higher router priority wins. If router priorities are the same, the router with the higher router ID wins. In addition, a router with router priority 0 cannot become the DR or BDR.

- DR election is available on broadcast and NBMA interfaces rather than P2P and P2MP interfaces.
- A DR is an interface of a router and belongs to a single network segment. Another interface of the router may be a BDR or DROther.
- If a router with the highest router priority is added after DR/BDR election, the router cannot become the DR immediately.
- The DR may not be the router with the highest priority in a network, and the BDR may not be the router with the second highest priority.

OSPF packet formats

OSPF packets are directly encapsulated into IP packets. OSPF uses the IP protocol number 89. The format of an OSPF LSU packet is shown in [Figure 24](#).

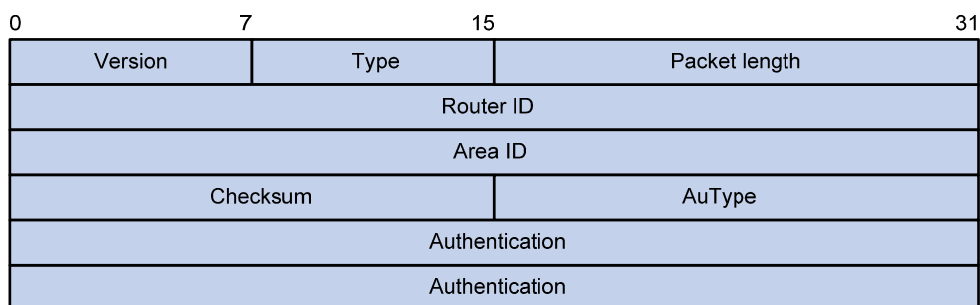

Figure 24 OSPF packet format

OSPF packet header

OSPF packets are classified into five types that have the same packet header.

Figure 25 OSPF packet header

Major fields of the OSPF packet header are as follows:

- **Version**—OSPF version number, which is 2 for OSPFv2.
- **Type**—OSPF packet type from 1 to 5, corresponding to hello, DD, LSR, LSU, and LSAck, respectively.
- **Packet length**—Total length of the OSPF packet in bytes, including the header.
- **Router ID**—ID of the advertising router.
- **Area ID**—ID of the area where the advertising router resides.
- **Checksum**—Checksum of the message.
- **AuType**—Authentication type, ranging from 0 to 2, corresponding to non-authentication, simple (plaintext) authentication, and MD5 authentication, respectively.
- **Authentication**—Information determined by authentication type. It is not defined for authentication type 0. It is defined as password information for authentication type 1, and defined as Key ID, MD5 authentication data length, and sequence number for authentication type 2.

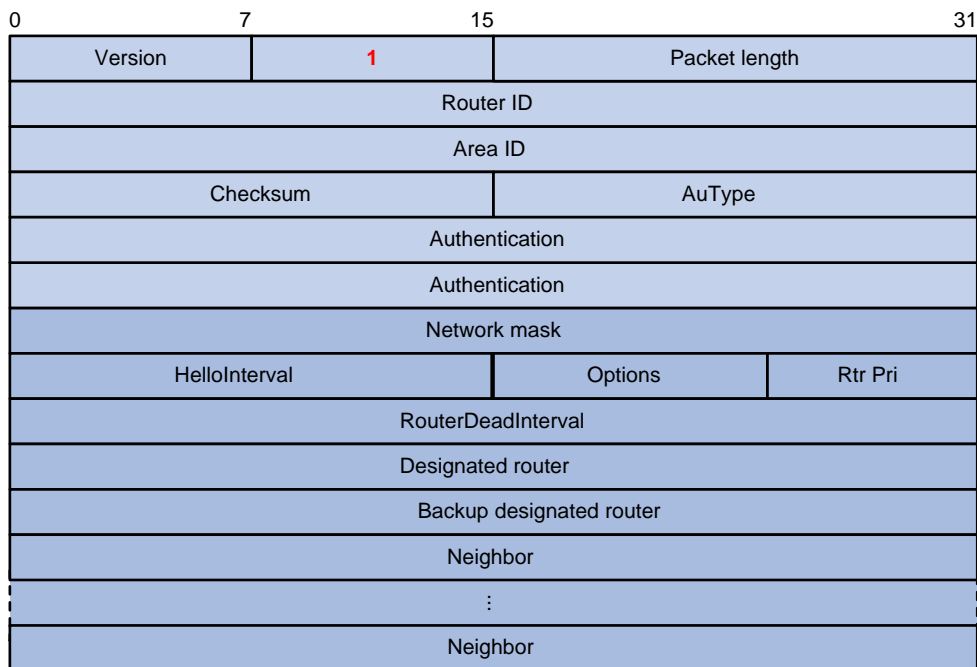

NOTE:

MD5 authentication data is added following an OSPF packet rather than contained in the Authentication field.

Hello packet

A router sends hello packets periodically to find and maintain neighbor relationships, and to elect the DR or BDR, including information about values of timers, DR, BDR, and neighbors that are already known.

Figure 26 Hello packet format

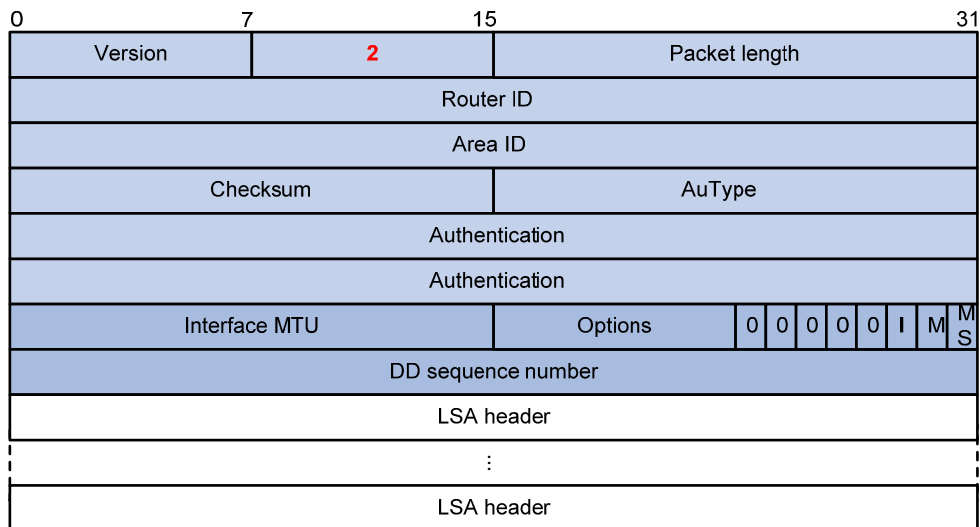

Major fields of the hello packet are as follows:

- **Network mask**—Network mask associated with the router’s sending interface. If two routers have different network masks, they cannot become neighbors.
- **HelloInterval**—Interval for sending hello packets. If two routers have different intervals, they cannot become neighbors.
- **Rtr Pri**—Router priority. A value of 0 means the router cannot become the DR or BDR.
- **RouterDeadInterval**—Time before declaring a silent router down. If two routers have different dead intervals, they cannot become neighbors.
- **Designated router**—IP address of the DR.
- **Backup designated router**—IP address of the BDR.
- **Neighbor**—Router ID of the neighbor router.

DD packet

Two routers exchange database description (DD) packets, describing their LSDBs for database synchronization. A DD packet contains only the headers of LSAs to reduce traffic.

Figure 27 DD packet format

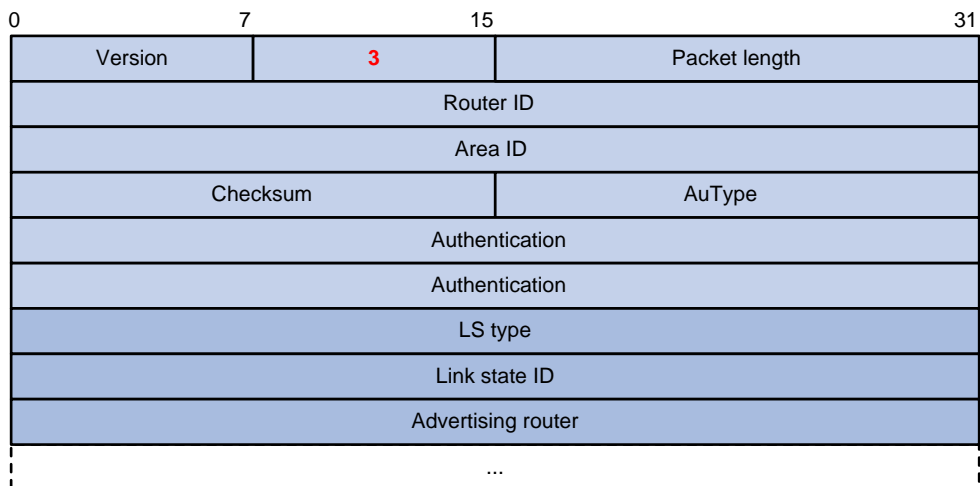

Major fields of the DD packets are as follows:

- **Interface MTU**—Specifies the largest IP datagram in bytes that the interface can send without fragmentation.
- **I (Initial)**—The Init bit, which is set to 1 if the packet is the first DD packet. It is set to 0 if not.
- **M (More)**—The More bit, which is set to 0 if the packet is the last DD packet. It is set to 1 if more DD packets are to follow.
- **MS (Master/Slave)**—The Master/Slave bit. When set to 1, it indicates that the router is the master during the database exchange process; otherwise, the router is the slave router.
- **DD sequence number**—Used to sequence the collection of DD packets. The initial value is set by the master. The DD sequence number then increments until the complete database description has been sent.

LSR packet

After exchanging DD packets, two routers know which LSAs of the peer are missing from the local LSDB. Then, they send (link state request) LSR packets to request the missing LSAs. An LSR packet contains the brief of the missing LSAs.

Figure 28 LSR packet format

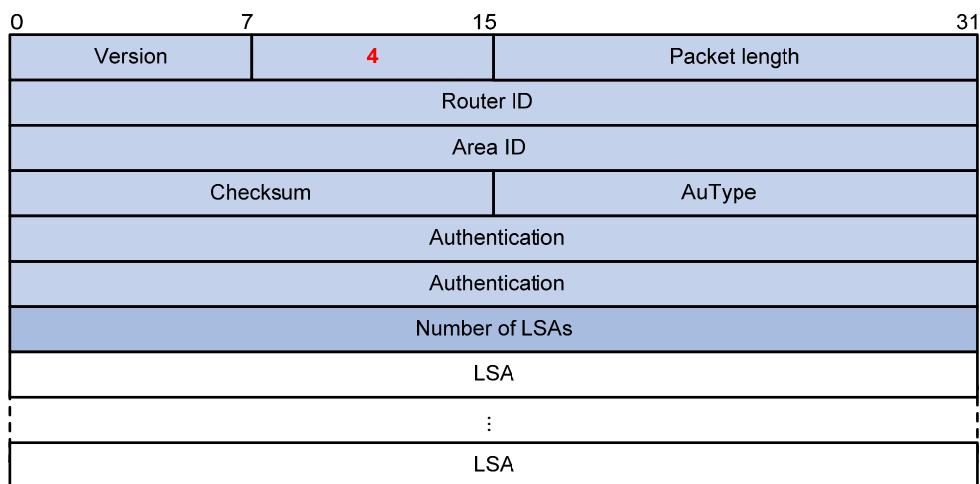

Major fields of the LSR packets are as follows:

- **LS type**—Type of the LSA to be requested. Type 1 for example indicates the Router LSA.
- **Link state ID**—Determined by LSA type.
- **Advertising router**—ID of the router that sent the LSA.

LSU packet

LSU (Link State Update) packets are used to send the requested LSAs to the peer. Each packet carries a collection of LSAs.

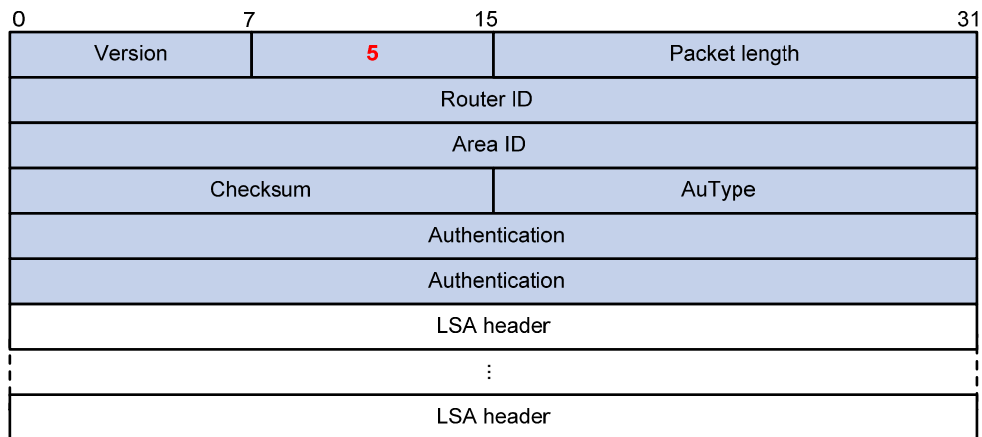

Figure 29 LSU packet format

LSAck packet

Link State Acknowledgment (LSAck) packets are used to acknowledge received LSU packets. An LSAck packet carries the headers of LSAs to be acknowledged.

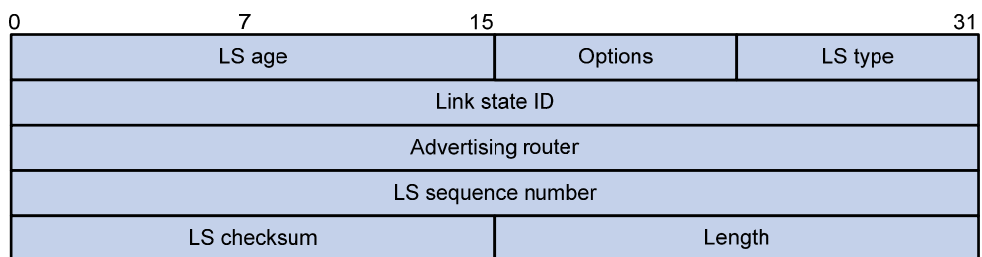

Figure 30 LSAck packet format

LSA header format

All LSAs have the same header.

Figure 31 LSA header format

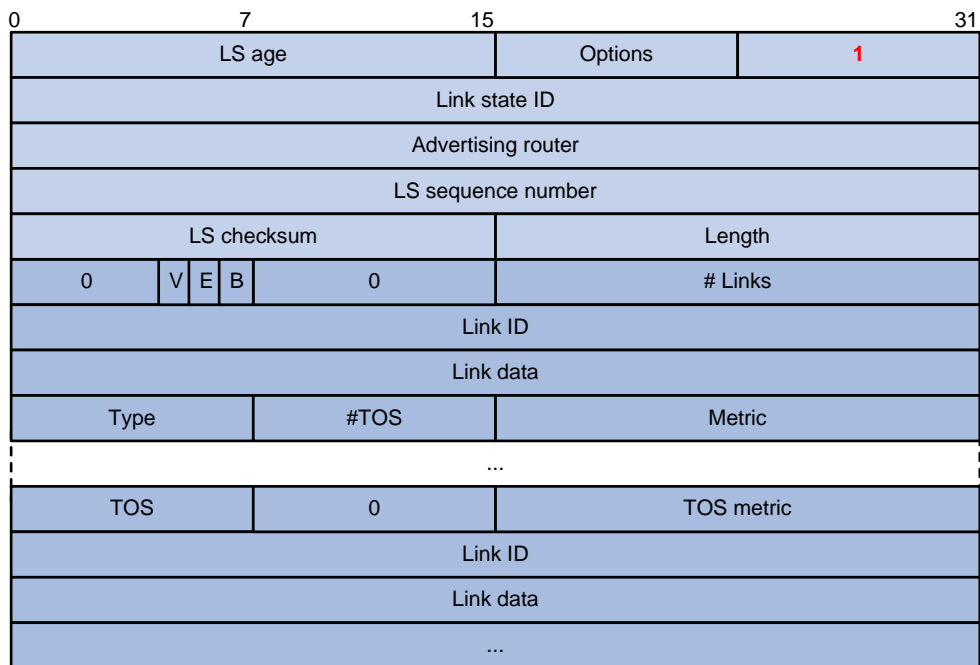

Major fields of the LSA header are as follows:

- **LS age**—Time, in seconds, elapsed since the LSA was originated. An LSA ages in the LSDB (added by 1 per second), but does not age during transmission.
- **LS type**—Type of the LSA.
- **Link state ID**—The contents of this field depend on the LSA's type.
- **LS sequence number**—Used by other routers to judge new and old LSAs.
- **LS checksum**—Checksum of the LSA except the LS age field.
- **Length**—Length in bytes of the LSA, including the LSA header.

LSAs formats

- Router LSA

Figure 32 Router LSA format

Major fields of the Router LSA are as follows:

- **Link state ID**—ID of the router that originated the LSA.
- **V (Virtual Link)**—Set to 1 if the router that originated the LSA is a virtual link endpoint.
- **E (External)**—Set to 1 if the router that originated the LSA is an ASBR.
- **B (Border)**—Set to 1 if the router that originated the LSA is an ABR.
- **# Links**—Number of router links (interfaces) to the area, as described in the LSA.
- **Link ID**—Determined by link type.
- **Link data**—Determined by link type.
- **Type**—Link type. A value of 1 indicates a point-to-point link to a remote router; a value of 2 indicates a link to a transit network; a value of 3 indicates a link to a stub network; and a value of 4 indicates a virtual link.
- **#TOS**—Number of different TOS metrics given for this link. If no TOS metric is given for the link, this field is set to 0. TOS is not supported in RFC 2328. The #TOS field is reserved for early versions of OSPF.
- **Metric**—Cost of using this router link.
- **TOS**—IP Type of Service that this metric refers to.
- **TOS metric**—TOS-specific metric information.
- Network LSA

A Network LSA is originated by the DR on a broadcast or NBMA network. The LSA describes all routers attached to the network.

Figure 33 Network LSA format

0	7	15	31
LS age		Options	2
Link state ID			
Advertising router			
LS sequence number			
LS checksum		Length	
Network mask			
Attached router			
...			

Major fields of the Network LSA are as follows:

- **Link state ID**—The interface address of the DR.
- **Network mask**—The mask of the network (a broadcast or NBMA network).
- **Attached router**—The IDs of the routers, which are adjacent to the DR, including the DR itself.
- Summary LSA

Network summary LSAs (Type-3 LSAs) and ASBR summary LSAs (Type-4 LSAs) are originated by ABRs. Except for the Link state ID field, the formats of Type 3 and 4 summary-LSAs are identical.

Figure 34 Summary LSA format

0	7	15	31
LS age		Options	3or4
Link state ID			
Advertising router			
LS sequence number			
LS checksum		Length	
Network mask			
0	Metric		
TOS	TOS metric		
...			

Major fields of the Summary LSA are as follows:

- **Link state ID**—For a Type-3 LSA, it is an IP address outside the area. For a type 4 LSA, it is the router ID of an ASBR outside the area.
- **Network mask**—The network mask for the type 3 LSA. It is set to 0.0.0.0 for the Type-4 LSA.
- **Metric**—The metric to the destination.

NOTE:

A Type-3 LSA can be used to advertise a default route if the link state ID and network mask are set to 0.0.0.0.

- AS external LSA

An AS external LSA is originated by an ASBR, and describes routing information to a destination outside the AS.

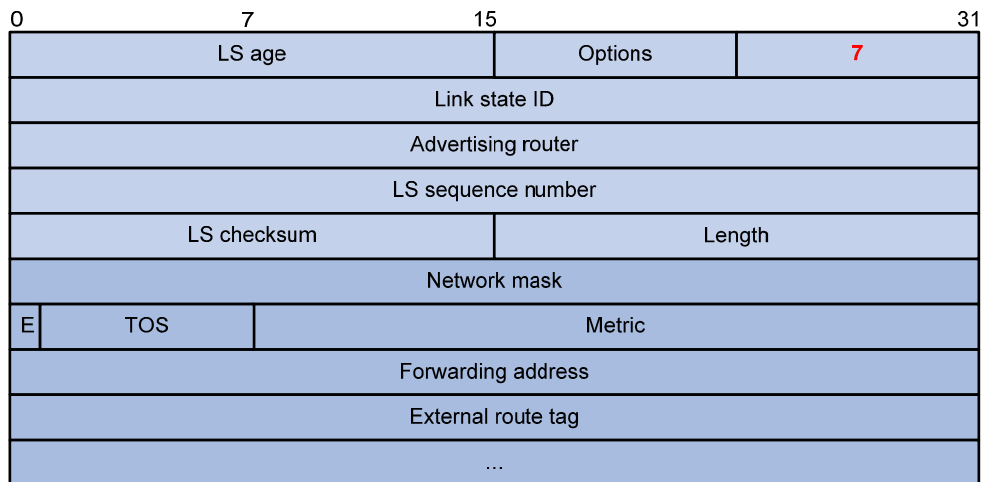

Figure 35 AS external LSA format

0	7	15	31
LS age		Options	5
Link state ID			
Advertising router			
LS sequence number			
LS checksum		Length	
Network mask			
E	0	Metric	
Forwarding address			
External route tag			
E	TOS	TOS metric	
Forwarding address			
External route tag			
...			

Major fields of the AS external LSA are as follows:

- **Link state ID**—The IP address of another AS to be advertised. When describing a default route, the Link state ID is always set to default destination (0.0.0.0) and the network mask is set to 0.0.0.0
- **Network mask**—The IP address mask for the advertised destination
- **E (External Metric)**—The type of the external metric value, which is set to 1 for type 2 external routes, and set to 0 for type 1 external routes. See "[Route types](#)" for a description of external route types.
- **Metric**—The metric to the destination.
- **Forwarding address**—Data traffic for the advertised destination is forwarded to this address.
- **External route tag**—A tag attached to each external route. This is not used by the OSPF protocol. It may be used to manage external routes.
- **NSSA external LSA**
An NSSA external LSA originates from the ASBR in an NSSA, and is flooded in the NSSA area only. It has the same format as the AS external LSA.

Figure 36 NSSA external LSA format

Supported features

Multi-process

This feature allows multiple OSPF processes to run on a router both simultaneously and independently. Routing information interactions between different processes simulate interactions between different routing protocols. Multiple OSPF processes can use the same RID.

An interface of a router can only belong to a single OSPF process.

Authentication

OSPF can authenticate OSPF packets. Only packets that pass the authentication are received. If an incoming hello packet cannot pass authentication, the neighbor relationship cannot be established.

The authentication type for interfaces attached to a single area must be identical. Authentication types include non-authentication, plaintext authentication, and MD5 ciphertext authentication. The authentication password for interfaces that are attached to a network segment must be identical.

OSPF Graceful Restart

Graceful Restart (GR) ensures the continuity of packet forwarding when a routing protocol restarts or an active/standby switchover occurs:

- **GR Restarter**—Graceful restarting router. It must have GR capability.
- **GR Helper**—A neighbor of the GR Restarter. It helps the GR Restarter to complete the GR process.

After an OSPF GR Restarter restarts, it must perform the following tasks.

- Obtain OSPF neighbor information.
- Obtain the LSDB.

Before restart, the GR Restarter negotiates GR capability with GR Helpers. During the restart of the GR Restarter, GR Helpers still advertise their adjacencies with the GR Restarter. After restart, the GR Restarter sends GR Helpers an OSPF GR signal so that the GR Helpers do not reset their neighbor relationships with the GR Restarter. Upon receiving responses from neighbors, the GR Restarter creates the neighbor relationships.

After that, the GR Restarter synchronizes the LSDB with GR-capable neighbors, updates its routing table and forwarding table, and removes stale routes.

BFD

Bidirectional forwarding detection (BFD) provides a single mechanism to quickly detect and monitor the connectivity of links between OSPF neighbors, reducing network convergence time. For more information about BFD, see *High Availability Configuration Guide*.

Protocols and standards

OSPF configuration task list

Make a proper plan before configuring OSPF.

To run OSPF in a routing domain, you must first enable OSPF on the routers. Then use the default settings of parameters such as the hello interval, LSA delay timer, and SPF calculation interval. You can also configure them as needed. OSPF routers should be configured on an area basis. Wrong configurations may cause communication failures, routing information blocks, and routing loops.

Complete the following tasks to configure OSPF:

Task	Remarks
Enabling OSPF	Required
Configuring OSPF areas	Configuring a stub area
	Configuring an NSSA area
	Configuring a virtual link
Configuring OSPF network types	Configuring the OSPF network type for an interface as broadcast
	Configuring the OSPF network type for an interface as NBMA
	Configuring the OSPF network type for an interface as P2MP
	Configuring the OSPF network type for an interface as P2P
Configuring OSPF route control	Configuring OSPF route summarization
	Configuring OSPF inbound route filtering
	Configuring ABR Type-3 LSA filtering
	Configuring an OSPF cost for an interface
	Configuring the maximum number of OSPF routes
	Configuring the maximum number of ECMP routes

Task	Remarks	
Tuning and optimizing OSPF networks	Configuring OSPF preference	Optional
	Configuring OSPF route redistribution	Optional
	Configuring OSPF packet timers	Optional
	Specifying LSA transmission delay	Optional
	Specifying SPF calculation interval	Optional
	Specifying the LSA arrival interval	Optional
	Specifying the LSA generation interval	Optional
	Disabling interfaces from receiving and sending OSPF packets	Optional
	Configuring stub routers	Optional
	Configuring OSPF authentication	Optional
	Adding the interface MTU into DD packets	Optional
	Configuring the maximum number of external LSAs in LSDB	Optional
	Enabling compatibility with RFC 1583	Optional
	Logging neighbor state changes	Optional
	Configuring OSPF network management	Optional
	Enabling message logging	Optional
	Enabling the advertisement and reception of opaque LSAs	Optional
	Configuring OSPF to give priority to receiving and processing hello packets	Optional
	Configuring the LSU transmit rate	Optional
	Setting the DSCP value for OSPF packets	Optional
Enabling OSPF ISPF	Optional	
Configuring OSPF FRR	Optional	
Configuring OSPF Graceful Restart	Configuring the OSPF GR Restarter	Optional
	Configuring the OSPF GR Helper	Optional
	Triggering OSPF Graceful Restart	Optional
Configuring BFD for OSPF	Optional	

Enabling OSPF

You must enable OSPF before performing other OSPF configuration tasks.

Configuration prerequisites

Configure the link layer protocol, and IP addresses for interfaces so that neighboring nodes can reach each other.

Configuration procedure

To enable OSPF on a router, create an OSPF process and specify areas with which the process is associated, and the network segments contained in each area. If an interface's IP address resides on a network segment of an area, the interface belongs to the area and is enabled with OSPF, and OSPF advertises the direct route of the interface.

To run OSPF, a router must have a router ID, which is the unique identifier of the router in the AS. Following is additional information about router IDs:

- You can specify a router ID when creating the OSPF process. Any two routers in an AS must have different router IDs. In practice, the ID of a router is the IP address of one of its interfaces.
- If you specify no router ID when creating the OSPF process, the global router ID is used. HP recommends you to specify a router ID when you create the OSPF process.

OSPF can run multiple processes and supports VPNs as follows:

- When a router runs multiple OSPF processes, specify a router ID for each process, which takes effect locally and has no influence on packet exchange between routers. Two routers having different process IDs can exchange packets.
- OSPF support for VPNs enables an OSPF process to run in a specified VPN.

To enable OSPF:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a global router ID.	router id <i>router-id</i>	Optional. Not configured by default. If no global router ID is configured, the highest loopback interface IP address, if any, is used as the router ID. If no loopback interface IP address is available, the highest physical interface IP address is used, regardless of the interface status.
3. Enable an OSPF process and enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	Not enabled by default.
4. Configure a description for the OSPF process.	description <i>description</i>	Optional. Not configured by default.
5. Configure an OSPF area and enter OSPF area view.	area <i>area-id</i>	Not configured by default.
6. Configure a description for the area.	description <i>description</i>	Optional. Not configured by default.
7. Specify a network to enable OSPF on the interface attached to the network.	network <i>ip-address</i> <i>wildcard-mask</i>	Not configured by default. A network segment can only belong to one area.

Configuring OSPF areas

After splitting an OSPF AS into multiple areas, configure some areas as stub areas or NSSA areas as needed.

If no connection can be achieved between the backbone and a non-backbone area, or within the backbone itself, you can configure virtual links to solve it.

Configuration prerequisites

Before you configure an OSPF area, complete the following tasks:

- Configure IP addresses for interfaces, and make sure that all neighboring nodes can reach each other at the network layer.
- Configure OSPF basic functions.

Configuring a stub area

Configure a non-backbone area at the AS edge as a stub area by configuring the **stub** command on all the routers attached to the area. In this way, Type-5 LSAs will not be flooded within the stub area, reducing the routing table size. The ABR generates a default route into the stub area so all packets destined outside of the AS are sent through the default route.

To further reduce the routing table size and routing information exchanged in the stub area, configure it as a totally stub area by using the **stub [no-summary]** command on the ABR. In this way, neither AS external routes nor inter-area routing information will be distributed into the area. All the packets destined outside of the AS or area will be sent to the ABR for forwarding.

To configure OSPF areas:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enter area view.	area <i>area-id</i>	N/A
4. Configure the area as a stub area.	stub [default-route-advertise-always no-summary] *	Not configured by default. You must use the stub command on routers attached to a stub area. The backbone area cannot be a totally stub area. A (totally) stub area cannot have an ASBR because AS external routes cannot be distributed into the stub area.
5. Specify a cost for the default route advertised to the stub area.	default-cost <i>cost</i>	Optional. 1 by default. The default-cost command takes effect only on the ABR of a stub area.

NOTE:

Virtual links cannot transit totally stub areas.

Configuring an NSSA area

A stub area cannot redistribute routes. Configure the area as an NSSA area to allow for route redistribution by keeping other stub area characteristics.

To configure an NSSA area:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enter area view.	area <i>area-id</i>	N/A
4. Configure the area as an NSSA area.	nssa [default-route-advertise no-import-route no-summary translate-always translator-stability-interval <i>value</i>] *	Not configured by default. You must use the nssa command on all the routers attached to an NSSA area.
5. Specify a cost for the default route advertised to the NSSA area.	default-cost <i>cost</i>	Optional. 1 by default. The default-cost command is available only on the ABR/ASBR of an NSSA area.

Configuring a virtual link

Non-backbone areas exchange routing information via the backbone area. Connectivity between the backbone and non-backbone areas and within the backbone must be maintained.

If the required physical links are not available for this connectivity maintenance, you can configure virtual links to resolve it.

To configure a virtual link:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enter area view.	area <i>area-id</i>	N/A

Step	Command	Remarks
4. Configure a virtual link.	<code>vlink-peer router-id [hello seconds retransmit seconds trans-delay seconds dead seconds simple [plain cipher] password { md5 hmac-md5 } key-id [plain cipher] password] *</code>	You must configure this command on both ends of a virtual link. hello and dead intervals must be identical on both ends of the virtual link.

Configuring OSPF network types

OSPF classifies networks into the following types by the link layer protocol:

- **Broadcast**—When the link layer protocol is Ethernet or FDDI, OSPF considers the network type as broadcast by default.
- **NBMA**—When the link layer protocol is Frame Relay, ATM, or X.25, OSPF considers the network type as NBMA by default.
- **P2P**—When the link layer protocol is PPP, LAPB, or HDLC, OSPF considers the network type as P2P by default.

The following are examples of how you can change the network type of an interface as needed:

- When an NBMA network becomes fully meshed through address mapping—any two routers in the network have a direct virtual circuit in between, you can change the network type to broadcast to avoid manual configuration of neighbors.
- When some routers in the broadcast network do not support multicast, you can change the network type to NBMA.
- An NBMA network must be fully meshed. If it is partially meshed, you can change the network type to P2MP to simplify configuration and save network costs.
- If a router on an NBMA network has only one neighbor, you can change the network type to P2P to save network costs.

If two interfaces on a link are both configured as the broadcast, NBMA, or P2MP network type, they cannot establish a neighbor relationship unless they are on the same network segment.

Configuration prerequisites

Before you configure OSPF network types, complete the following tasks:

- Configure IP addresses for interfaces, making neighboring nodes accessible with each other at network layer.
- Configure OSPF basic functions.

Configuring the OSPF network type for an interface as broadcast

Step	Command	Remarks
1. Enter system view.	<code>system-view</code>	N/A
2. Enter interface view.	<code>interface interface-type interface-number</code>	N/A

Step	Command	Remarks
3.	Configure the OSPF network type for the interface as broadcast. ospf network-type broadcast	By default, the network type of an interface depends on the link layer protocol.
4.	Configure a router priority for the interface. ospf dr-priority priority	Optional. The default router priority is 1.

Configuring the OSPF network type for an interface as NBMA

After configuring the network type of an interface as NBMA, you must make some special configurations.

Because NBMA interfaces cannot find neighbors via broadcasting hello packets, you must specify neighbors and their router priorities. (A router priority of 0 means the router does not have the DR election right. A router priority greater than 0 means the router has the DR election right.)

The router priority configured with the **ospf dr-priority** command is for actual DR election. The priority configured with the **peer** command indicates whether a neighbor has the election right or not. If you configure the router priority for a neighbor as 0, the local router will assume the neighbor has no election right, and thus send no hello packets to this neighbor. However, if the local router is the DR or BDR, it still sends hello packets to the neighbor with priority 0 for neighborhood establishment.

To configure the OSPF network type for an Interface as NBMA:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter interface view. interface interface-type interface-number	N/A
3.	Configure the OSPF network type for the interface as NBMA. ospf network-type nbma	By default, the network type of an interface depends on the link layer protocol.
4.	Configure a router priority for the interface. ospf dr-priority priority	Optional. The default router priority is 1.
5.	Exit to system view. quit	N/A
6.	Enter OSPF view. ospf [process-id router-id router-id vpn-instance vpn-instance-name] *	N/A
7.	Specify a neighbor and its router priority. peer ip-address [cost value dr-priority dr-priority]	N/A

Configuring the OSPF network type for an interface as P2MP

Step	Command	Remarks
1.	Enter system view. system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the OSPF network type for the interface as P2MP.	ospf network-type p2mp [unicast]	By default, the network type of an interface depends on the link layer protocol. After you configure the OSPF network type for an interface as P2MP unicast, all packets are unicast over the interface. The interface cannot broadcast hello packets to discover neighbors. In that case, you need to manually specify the neighbors.
4. Exit to system view.	quit	N/A
5. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
6. Specify a neighbor and its router priority on a P2MP unicast network.	peer <i>ip-address</i> [cost <i>value</i> dr-priority <i>dr-priority</i>]	Required if the interface type is P2MP unicast.

Configuring the OSPF network type for an interface as P2P

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the OSPF network type for the interface as P2P.	ospf network-type p2p	By default, the network type of an interface depends on the link layer protocol.

Configuring OSPF route control

This section describes how to control the advertisement and reception of OSPF routing information, as well as route redistribution from other protocols.

Configuration prerequisites

Before you configure OSPF route control, complete the following tasks:

- Configure IP addresses for interfaces.
- Configure OSPF basic functions.
- Configure filters if routing information filtering is needed.

Configuring OSPF route summarization

Route summarization is when an ABR or ASBR summarizes routes with the same prefix into a single route and distributes it to other areas.

Route summarization reduces the traffic of routing information exchanged between areas and the sizes of routing tables on routers, improving route calculation speed on routers.

For example, there are three internal routes in an area: 19.1.1.0/24, 19.1.2.0/24, and 19.1.3.0/24. By configuring route summarization on the ABR, the three routes are summarized into the route 19.1.0.0/16 that is advertised to other areas.

Configuring route summarization on an ABR

If contiguous network segments are available in the area, you can summarize them into a single network segment. An ABR generates Type-3 LSAs on a per network segment basis for an attached non-backbone area.

The ABR in the area distributes only the summary LSA to reduce the scale of LSDBs on routers in other areas and the influence of topology changes.

To configure route summarization on an ABR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enter OSPF area view.	area <i>area-id</i>	N/A
4. Configure ABR route summarization.	abr-summary <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } [advertise not-advertise] [cost <i>cost</i>]	Not configured by default. The command is available on an ABR only.

Configuring route summarization when redistributing routes into OSPF on an ASBR

Without route summarization, an ASBR advertises each redistributed route in a separate ASE LSA. After a summary route is configured, the ASBR advertises only the summary route in an ASE LSA instead of more specific routes, which reduces the number of LSAs in the LSDB.

The ASBR summarizes redistributed Type-5 LSAs that fall into the specified address range. If the ASBR is in an NSSA area, it also summarizes Type-7 LSAs that fall into the specified address range. If the ASBR is also the ABR, it summarizes Type-5 LSAs translated from Type-7 LSAs.

To configure route summarization when redistributing routes into OSPF on an ASBR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure ASBR route summarization.	asbr-summary <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } [tag <i>tag</i> not-advertise cost <i>cost</i>] *	The command is available on an ASBR only. Not configured by default.

Configuring OSPF inbound route filtering

OSPF calculates routes by using LSAs. The calculated routes can be filtered and only permitted routes are installed into the OSPF routing table.

OSPF provides the following filtering methods:

- Filters routing information by destination address through ACLs and IP address prefixes
- Filters routing information by next hop through the filtering criteria configured with the **gateway** keyword
- Filters routing information by destination address through ACLs and IP address prefixes and by next hop through the filtering criteria configured with the **gateway** keyword
- Filters routing information by routing policy specified by the **route-policy** keyword

For more information about IP prefix list and routing policy, see "[Configuring routing policies.](#)"

To configure inbound route filtering:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure inbound route filtering.	filter-policy { <i>acl-number</i> [gateway <i>ip-prefix-name</i>] gateway <i>ip-prefix-name</i> ip-prefix <i>ip-prefix-name</i> [gateway <i>ip-prefix-name</i>] route-policy <i>route-policy-name</i> } import	Not configured by default.

Configuring ABR Type-3 LSA filtering

You can configure an ABR to filter Type-3 LSAs advertised to an area.

To configure Type-3 LSA filtering on an ABR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enter area view.	area <i>area-id</i>	N/A
4. Configure ABR Type-3 LSA filtering.	filter { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } { import export }	Not configured by default.

Configuring an OSPF cost for an interface

You can configure an OSPF cost for an interface by using either of the following methods:

- Configure the cost value in interface view.
- Configure a bandwidth reference value for the interface. OSPF computes the cost with this formula: Interface OSPF cost = Bandwidth reference value (100 Mbps)/Interface bandwidth (Mbps). If the

calculated cost is greater than 65535, the value of 65535 is used. If the calculated cost is less than 1, the value of 1 is used.

If the cost value is not configured for an interface, OSPF computes the interface cost automatically.

To configure an OSPF cost for an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an OSPF cost for the interface.	ospf cost <i>value</i>	Optional. The default cost depends on the interface type: 1 for a VLAN interface; 0 for a loopback interface; computed according to the bandwidth for other interfaces.

To configure a bandwidth reference value:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure a bandwidth reference value.	bandwidth-reference <i>value</i>	Optional. The value defaults to 100 Mbps.

Configuring the maximum number of OSPF routes

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure the maximum number of OSPF routes.	maximum-routes { external inter intra } <i>number</i>	Optional. The number varies with devices.

Configuring the maximum number of ECMP routes

Perform this task to implement load sharing over ECMP routes.

To configure the maximum number of ECMP routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure the maximum number of ECMP routes.	maximum load-balancing <i>maximum</i>	Optional. 8 by default.

Configuring OSPF preference

A router can run multiple routing protocols, and each protocol is assigned a preference. When the routing protocols find routes to the same destination, the route found by the protocol with the highest preference is selected as the best route.

To configure OSPF preference:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure a preference for OSPF.	preference [ase] [route-policy <i>route-policy-name</i>] <i>value</i>	Optional. By default, the preference of OSPF internal routes is 10, and the preference of OSPF external routes is 150.

Configuring OSPF route redistribution

This section describes configuring OSPF to redistribute manually configured routes or routes discovered by other routing protocols.

Only active routes can be redistributed. Use the **display ip routing-table protocol** command to view route state information.

Configuring route redistribution into OSPF

On a router running OSPF and other routing protocols, you can configure OSPF to redistribute routes from other protocols such as RIP, IS-IS, BGP, static, and direct routes, and advertise them in Type-5 LSAs or Type-7 LSAs.

By filtering redistributed routes, OSPF translates only permitted routes into Type-5 LSAs or Type-7 LSAs for advertisement.

To configure OSPF route redistribution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A

Step	Command	Remarks
3. Configure OSPF to redistribute routes from another protocol.	import-route <i>protocol</i> [<i>process-id</i> all-processes allow-ibgp] [cost <i>cost</i> type <i>type</i> tag <i>tag</i> route-policy <i>route-policy-name</i>] *	Not configured by default
4. Configure OSPF to filter redistributed routes before advertisement.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } export [<i>protocol</i> [<i>process-id</i>]]	Optional Not configured by default

Configuring OSPF to redistribute a default route

Using the **import-route** command cannot redistribute a default external route. To do so, you must use the **default-route-advertise** command.

To configure OSPF to redistribute a default external route:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Redistribute a default route.	default-route-advertise [[[always permit-calculate-other] cost <i>cost</i> route-policy <i>route-policy-name</i> type <i>type</i>] * summary <i>cost</i>]	Not redistributed by default. The default-route-advertise summary cost command is applicable only to VPN, and the default route is redistributed in a Type-3 LSA. The PE router advertises the default route to the CE router.

Configuring the default parameters for redistributed routes

You can configure default parameters, such as the cost, upper limit, tag and type for redistributed routes. Tags indicate information related to protocols. For example, when redistributing BGP routes, OSPF uses tags to identify AS IDs.

To configure the default parameters for redistributed routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A

Step	Command	Remarks
3.	Configure the default parameters for redistributed routes (cost, route number, tag, and type). default { cost <i>cost</i> limit <i>limit</i> tag <i>tag</i> type <i>type</i> } *	Optional. The default cost is 1, the default maximum number of routes redistributed per time is 1000, the default tag is 1, and default type of redistributed routes is Type-2.

Advertising a host route

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter OSPF view. ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3.	Enter area view. area <i>area-id</i>	N/A
4.	Advertise a host route. host-advertise <i>ip-address cost</i>	Optional. Not advertised by default.

Tuning and optimizing OSPF networks

You can optimize your OSPF network in the following ways:

- Change OSPF packet timers to adjust the OSPF network convergence speed and network load. On low-speed links, consider the delay time for sending LSAs.
- Change the SPF calculation interval to reduce resource consumption caused by frequent network changes.
- Configure OSPF authentication to improve security.
- Configure OSPF network management functions, such as binding OSPF MIB with a process, sending trap information, and collecting log information.

Configuration prerequisites

Before you configure OSPF network optimization, complete the following tasks:

- Configure IP addresses for interfaces.
- Configure OSPF basic functions.

Configuring OSPF packet timers

You can configure the following timers on OSPF interfaces as needed.

- **Hello timer**—Interval for sending hello packets. It must be identical on OSPF neighbors. The longer the interval, the lower the convergence speed, and the smaller the network load.

- **Poll timer**—Interval for sending hello packets to a neighbor that is down on the NBMA network. The poll interval is at least four times the hello interval.
- **Dead timer**—Interval within which if the interface receives no hello packet from the neighbor, it declares the neighbor is down. The dead interval must be at least four times the hello interval on an interface.
- **LSA retransmission timer**—Interval within which if the interface receives no acknowledgement packets after sending an LSA to the neighbor, it retransmits the LSA. An interval setting that is too small can cause unnecessary LSA retransmissions. This interval is typically set bigger than the round-trip time of a packet between two neighbors.

To configure timers for OSPF packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify the hello interval.	ospf timer hello <i>seconds</i>	Optional. The hello interval defaults to 10 seconds on P2P and broadcast interfaces, and defaults to 30 seconds on P2MP and NBMA interfaces. The default hello interval is restored when the network type for an interface is changed.
4. Specify the poll interval.	ospf timer poll <i>seconds</i>	Optional. The poll interval defaults to 120 seconds.
5. Specify the dead interval.	ospf timer dead <i>seconds</i>	Optional. The default dead interval is 40 seconds on P2P and broadcast interfaces and 120 seconds on P2MP and NBMA interfaces. The default dead interval is restored when the network type for an interface is changed.
6. Specify the retransmission interval.	ospf timer retransmit <i>interval</i>	Optional. The retransmission interval defaults to 5 seconds.

Specifying LSA transmission delay

Each LSA in the LSDB has an age that is incremented by 1 every second, but the age does not change during transmission. It is necessary to add a transmission delay into the age time especially for low-speed links.

To specify the LSA transmission delay on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
3. Specify the LSA transmission delay.	ospf trans-delay <i>seconds</i>	Optional. 1 second by default.

Specifying SPF calculation interval

LSDB changes lead to SPF calculations. When the topology changes frequently, a large amount of network and router resources are occupied by SPF calculation. Adjust the SPF calculation interval to reduce the impact.

When network changes are not frequent, the *minimum-interval* is adopted. If network changes become frequent, the SPF calculation interval is incremented by *incremental-interval* × 2ⁿ⁻² (n is the number of calculation times) each time a calculation occurs until the *maximum-interval* is reached.

To configure SPF calculation interval:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Specify the SPF calculation interval.	spf-schedule-interval <i>maximum-interval</i> [<i>minimum-interval</i> [<i>incremental-interval</i>]]	Optional. By default, the interval is 5 seconds.

Specifying the LSA arrival interval

After receiving the same LSA as the previously received LSA within the LSA arrival interval, OSPF discards the LSA.

To configure the LSA arrival interval:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure the LSA arrival interval.	lsa-arrival-interval <i>interval</i>	Optional. 1000 milliseconds by default. Make sure this interval is smaller than or equal to the interval set with the lsa-generation-interval command.

Specifying the LSA generation interval

You can adjust the LSA generation interval to protect network resources and routers from being over consumed by frequent network changes.

When network changes are not frequent, LSAs are generated at the *minimum-interval*. If network changes become frequent, the LSA generation interval is incremented by *incremental-interval* × 2ⁿ⁻² (n is the number of generation times) each time a LSA generation occurs until the *maximum-interval* is reached.

To configure the LSA generation interval:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure the LSA generation interval.	lsa-generation-interval <i>maximum-interval</i> [<i>initial-interval</i> [<i>incremental-interval</i>]]	Optional. By default, the maximum interval is 5 seconds, the minimum interval is 0 milliseconds, and the incremental interval is 5000 milliseconds.

Disabling interfaces from receiving and sending OSPF packets

Follow these guidelines when you disable interfaces from receiving and sending OSPF packets:

- Different OSPF processes can disable the same interface from receiving and sending OSPF packets. The **silent-interface** command disables only the interfaces associated with the current process rather than interfaces associated with other processes.
- After an OSPF interface is set to **silent**, other interfaces on the router can advertise direct routes of the interface in Router LSAs, but the interface cannot send any packet. This configuration can enhance OSPF adaptability and reduce resource consumption.

To disable interfaces from receiving and sending routing information:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Disable interfaces from receiving and sending OSPF packets.	silent-interface { <i>interface-type</i> <i>interface-number</i> all }	Optional. Not disabled by default.

Configuring stub routers

A stub router is used for traffic control. It tells other OSPF routers to not use it to forward data.

The Router LSAs from the stub router may contain different link type values. A value of 3 means a link to a stub network, and the cost of the link will not be changed. A value of 1, 2, or 4 means a point-to-point link, a link to a transit network, or a virtual link. On such links, a maximum cost value of 65535 is used. Thus, neighbors find that the links to the stub router have large costs that they will not send packets to the stub router for forwarding as long as another route with a smaller cost exists.

To configure a router as a stub router:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure the router as a stub router.	stub-router	By default, the router is not a stub router in any OSPF process.

Configuring OSPF authentication

You can configure OSPF packet authentication to ensure the security of packet exchanges.

After authentication is configured, OSPF only receives packets that pass authentication. Failed packets cannot establish neighboring relationships.

To configure OSPF authentication, you must configure the same area authentication mode on all the routers in the area. In addition, the authentication mode and password for all interfaces attached to the same area must be identical.

To configure OSPF authentication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enter area view.	area <i>area-id</i>	N/A
4. Configure the authentication mode.	authentication-mode { md5 simple }	Not configured by default.
5. Return to OSPF view.	quit	N/A
6. Return to system view.	quit	N/A
7. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
8. Configure interface authentication mode.	<ul style="list-style-type: none"> Configure the simple authentication mode: ospf authentication-mode simple [cipher plain] <i>password</i> Configure the MD5 authentication mode: ospf authentication-mode { hmac-md5 md5 } <i>key-id</i> [cipher plain] <i>password</i> 	Use either approach. Not configured by default.

Adding the interface MTU into DD packets

By default, an interface adds 0 into the interface MTU field of a DD packet to be sent rather than the interface MTU. You can enable an interface to add its MTU into DD packets.

To add the interface MTU into DD packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the interface to add its MTU into DD packets.	ospf mtu-enable	Optional. Not enabled by default.

Configuring the maximum number of external LSAs in LSDB

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Specify the maximum number of external LSAs in the LSDB.	lsdb-overflow-limit <i>number</i>	Optional. Not specified by default.

Enabling compatibility with RFC 1583

RFC 1583 specifies a different method than RFC 2328 for selecting an external route from multiple LSAs. If RFC 1583 is made compatible with RFC 2328, the routes in the backbone area are preferred; if not, the routes in the non-backbone area are preferred to reduce the burden of the backbone area.

To avoid routing loops, HP recommends configuring all the routers to be either compatible or incompatible with RFC 1583.

To make them compatible:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enable compatibility with RFC 1583.	rfc1583 compatible	Optional. Enabled by default.

Logging neighbor state changes

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enable the logging of neighbor state changes.	log-peer-change	Optional. Enabled by default.

Configuring OSPF network management

With trap generation enabled, OSPF generates traps to report important events. Traps fall into the following levels.

- **Level-3**—Fault traps
- **Level-4**—Alarm traps
- **Level-5**—Normal but important traps
- **Level-6**—Notification traps

The generated traps are sent to the information center of the device. The output rules of the traps such as whether to output the traps and the output direction are determined according to the information center configuration. (For information center configuration, see *Network Management and Monitoring Configuration Guide*.)

To configure OSPF network management:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Bind OSPF MIB to an OSPF process.	ospf mib-binding <i>process-id</i>	Optional. By default, the OSPF process with the smallest <i>process-id</i> is bound with OSPF MIB.
3. Enable OSPF trap generation.	snmp-agent trap enable ospf [<i>process-id</i>] [ifaauthfail ifcfgerror ifrxbadpkt ifstatechange iftxretransmit lsdbapproachoverflow lsdboverflow maxagelsa nbrstatechange originatelsa vifcfgerror virifaauthfail virifrxbadpkt virifstatechange viriftxretransmit virnbrstatechange] *	Optional. Enabled by default.

Enabling message logging

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enable message logging.	enable log [config error state]	Not enabled by default.

Enabling the advertisement and reception of opaque LSAs

With this feature enabled, OSPF can receive and advertise Type 9, Type 10, and Type 11 opaque LSAs.

To enable the advertisement and reception of opaque LSAs:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enable the advertisement and reception of opaque LSAs.	opaque-capability enable	Optional. Disabled by default.

Configuring OSPF to give priority to receiving and processing hello packets

To ensure OSPF runs properly, a router receives and processes hello packets and other protocol packets at the same time. When the router has established neighbor relationships with multiple routers, and the routing table size is big, the router must receive and process large numbers of packets. In this case, you can configure OSPF to give priority to receiving and processing hello packets to ensure stable neighbor relationships.

To configure OSPF to give priority to receiving and processing hello packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure OSPF to give priority to receiving and processing hello packets.	ospf packet-process prioritized-treatment	Not configured by default.

Configuring the LSU transmit rate

Sending large numbers of LSU packets affects router performance and consumes too much network bandwidth. You can configure the router to send LSU packets at a proper interval and limit the maximum number of LSU packets sent out of an OSPF interface each time.

To configure the LSU transmit rate:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Configure the LSU transmit rate.	transmit-pacing interval <i>interval</i> count <i>count</i>	Optional. By default, an OSPF interface sends up to three LSU packets every 20 milliseconds.

Setting the DSCP value for OSPF packets

An IPv4 packet header contains an 8-bit TOS field. As defined in RFC 2474, the first six bits set the Differentiated Services Code Point (DSCP) value and the last two bits are reserved. Network devices use the DSCP value as a reference to determine the packet priority for transmission.

You can set the DSCP value for OSPF packets.

To set the DSCP value for OSPF packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable an OSPF process and enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	By default, OSPF is not enabled.
3. Set the DSCP value for OSPF packets.	dscp <i>dscp-value</i>	Optional. By default, the DSCP value in OSPF packets is 48.

Enabling OSPF ISPF

When a network topology is changed, Incremental Shortest Path First (ISPF) allows the system to recompute only the affected part of the shortest path tree (SPT), instead of the entire SPT.

To enable OSPF ISPF:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enable OSPF ISPF.	ispf enable	Optional. Disabled by default.

Configuring OSPF FRR

When a link fails, the packets on the link are discarded, and a routing loop may occur until OSPF completes routing convergence based on the new network topology.

You can enable OSPF fast reroute (FRR) to solve this problem.

Figure 37 Network diagram for OSPF FRR

In [Figure 37](#), after you enable FRR on Router B, OSPF automatically calculates or designates a backup next hop when a link failure is detected. Packets are directed to the backup next hop. At the same time, OSPF calculates the shortest path based on the new network topology, and forwards packets over the path after routing convergence.

You can either configure OSPF FRR to calculate a backup next hop automatically, or to designate a backup next hop by using a routing policy.

Configuration prerequisites

Before you configure OSPF FRR, complete the following tasks:

- Configure network layer addresses for interfaces.
- Enable OSPF.

Configuration guidelines

- Do not use FRR and BFD at the same time. Otherwise, FRR may fail to take effect.
- Do not use the **fast-reroute auto** command together with the commands **vlink-peer**.

Configuring OSPF FRR to automatically calculate a backup next hop

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the source address of echo packets.	bfd echo-source-ip <i>ip-address</i>	Not configured by default.
3. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
4. Enable OSPF FRR to automatically calculate a backup next hop.	fast-reroute auto [abr-only]	Not configured by default. If abr-only is specified, the route to the ABR is selected as the backup path.

Configuring OSPF FRR to designate a backup next hop with a routing policy

Before configuring this task, you need to use the **apply fast-reroute backup-interface** command to specify a backup next hop in the routing policy to be referenced. For more information about the **apply fast-reroute backup-interface** command and routing policy configuration, see "[Configuring routing policies](#)."

To configure OSPF FRR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the source address of echo packets.	bfd echo-source-ip <i>ip-address</i>	Not configured by default.
3. Enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
4. Enable OSPF FRR to designate a backup next hop by using a routing policy.	fast-reroute route-policy <i>route-policy-name</i>	Not configured by default.

Configuring OSPF Graceful Restart

OSPF GR involves the following:

- **IETF standard GR**—Uses Opaque LSAs to implement GR.
- **Non IETF standard GR**—Uses link local signaling (LLS) to advertise GR capability and uses out of band synchronization to synchronize the LSDB.

A device can act as a GR Restarter and GR Helper at the same time.

Configuring the OSPF GR Restarter

You can configure the IETF standard or non IETF standard OSPF GR Restarter.

Configuring the IETF standard OSPF GR Restarter

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable OSPF and enter its view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enable opaque LSA advertisement capability.	opaque-capability enable	Disabled by default.
4. Enable the IETF standard Graceful Restart capability.	graceful-restart ietf	Disabled by default.
5. Configure the Graceful Restart interval.	graceful-restart interval <i>timer</i>	Optional. 120 seconds by default.

Configuring the non-IETF standard OSPF GR Restarter

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable OSPF and enter its view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enable the link-local signaling capability.	enable link-local-signaling	Disabled by default.
4. Enable the out-of-band re-synchronization capability.	enable out-of-band-resynchronization	Disabled by default.
5. Enable non-IETF standard Graceful Restart capability for OSPF.	graceful-restart [nonstandard]	Disabled by default.
6. Configure Graceful Restart interval for OSPF.	graceful-restart interval <i>timer</i>	Optional. 120 seconds by default.

Configuring the OSPF GR Helper

You can configure the IETF standard or non-IETF standard OSPF GR Helper.

Configuring the IETF standard OSPF GR Helper

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable OSPF and enter its view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enable opaque LSA reception and advertisement.	opaque-capability enable	Not enabled by default.
4. Configure the neighbors for which the router can serve as a GR Helper.	graceful-restart help { <i>acl-number</i> prefix <i>prefix-list</i> }	Optional. The router can serve as a GR Helper for any OSPF neighbor by default.

Configuring the non IETF standard OSPF GR Helper

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable OSPF and enter its view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A
3. Enable the link-local signaling capability.	enable link-local-signaling	Disabled by default.
4. Enable the out-of-band re-synchronization capability.	enable out-of-band-resynchronization	Disabled by default.
5. Configure the neighbors for which the router can serve as a GR Helper.	graceful-restart help { <i>acl-number</i> prefix <i>prefix-list</i> }	Optional. The router can serve as a GR Helper for any OSPF neighbor by default.

Triggering OSPF Graceful Restart

Performing a Master/Slave switchover, or performing the following configuration on an OSPF router, will trigger OSPF Graceful Restart.

To trigger OSPF Graceful Restart:

Task	Command	Remarks
Trigger OSPF Graceful Restart.	reset ospf [<i>process-id</i>] process graceful-restart	Available in user view

Configuring BFD for OSPF

OSPF supports the following BFD detection methods:

- Control packet bidirectional detection, which requires BFD configuration to be made on both OSPF routers on the link.
- Echo packet single-hop detection, which requires BFD configuration to be made on one OSPF router on the link.

Configuring control packet bidirectional detection

Both ends of a BFD session must be on the same network segment and in the same area. One network segment can only belong to one area.

To enable BFD control packet bidirectional detection on an OSPF interface:

Step	Command	Description
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable BFD control packet bidirectional detection on the interface.	ospf bfd enable	Not enabled by default.

Configuring echo packet single-hop detection

Step	Command	Description
1. Enter system view.	system-view	N/A
2. Configure the source address of echo packets.	bfd echo-source-ip <i>ip-address</i>	Not configured by default.
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable BFD echo packet single-hop detection on the interface.	ospf bfd enable echo	Not enabled by default.

Displaying and maintaining OSPF

Task	Command	Remarks
Display OSPF brief information.	display ospf [<i>process-id</i>] brief [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPF statistics.	display ospf [<i>process-id</i>] cumulative [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display Link State Database information.	display ospf [<i>process-id</i>] lsdb [brief [{ ase router network summary asbr nssa opaque-link opaque-area opaque-as } [<i>link-state-id</i>]] [originate-router advertising-router-id self-originate]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPF neighbor information.	display ospf [<i>process-id</i>] peer [verbose] [<i>interface-type interface-number</i>] [<i>neighbor-id</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Reset an OSPF process.	reset ospf [<i>process-id</i>] process [graceful-restart]	Available in user view
Re-enable OSPF route redistribution.	reset ospf [<i>process-id</i>] redistribution	Available in user view

OSPF configuration examples

These examples only cover commands for OSPF configuration.

Configuring OSPF basic functions

Network requirements

As shown in [Figure 38](#), all switches run OSPF. The AS is split into three areas, where Switch A and Switch B act as ABRs to forward routing information between areas.

After configuration, all switches can learn routes to every network segment in the AS.

Figure 38 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] area 1
[SwitchA-ospf-1-area-0.0.0.1] network 10.2.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.1] quit
[SwitchA-ospf-1] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] area 2
[SwitchB-ospf-1-area-0.0.0.2] network 10.3.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.2] quit
[SwitchB-ospf-1] quit
```

Configure Switch C

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] network 10.2.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.1] network 10.4.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.1] quit
[SwitchC-ospf-1] quit
```

Configure Switch D

```
<SwitchD> system-view
[SwitchD] ospf
[SwitchD-ospf-1] area 2
[SwitchD-ospf-1-area-0.0.0.2] network 10.3.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.2] network 10.5.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.2] quit
[SwitchD-ospf-1] quit
```

3. Verify the configuration:

Display information about neighbors on Switch A.

```
[SwitchA] display ospf peer verbose
```

```
OSPF Process 1 with Router ID 10.2.1.1
```

```
Neighbors
```

```
Area 0.0.0.0 interface 10.1.1.1(Vlan-interface100)'s neighbors
```

```

  round-trip min/avg/max = 1/1/2 ms

```

Configuring OSPF route redistribution

Network requirements

As shown in [Figure 39](#), all the switches run OSPF, and the AS is divided into three areas. Switch A and Switch B act as ABRs to forward routes between areas. Switch C is configured as an ASBR to redistribute external routes (static routes). Routing information is propagated properly in the AS.

Figure 39 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF basic functions. (See "[Configuring OSPF basic functions](#)")
3. Configure OSPF to redistribute routes:

```
# On Switch C, configure a static route destined for network 3.1.2.0/24.
```

```
<SwitchC> system-view
[SwitchC] ip route-static 3.1.2.1 24 10.4.1.2
```

```
# On Switch C, configure OSPF to redistribute static routes.
```

```
[SwitchC] ospf 1
```

```
[SwitchC-ospf-1] import-route static
```

4. Verify the configuration:

```
# Display the ABR/ASBR information of Switch D.
```

```
<SwitchD> display ospf abr-asbr
```

```
OSPF Process 1 with Router ID 10.5.1.1

Configuring OSPF to advertise a summary route

Network requirements

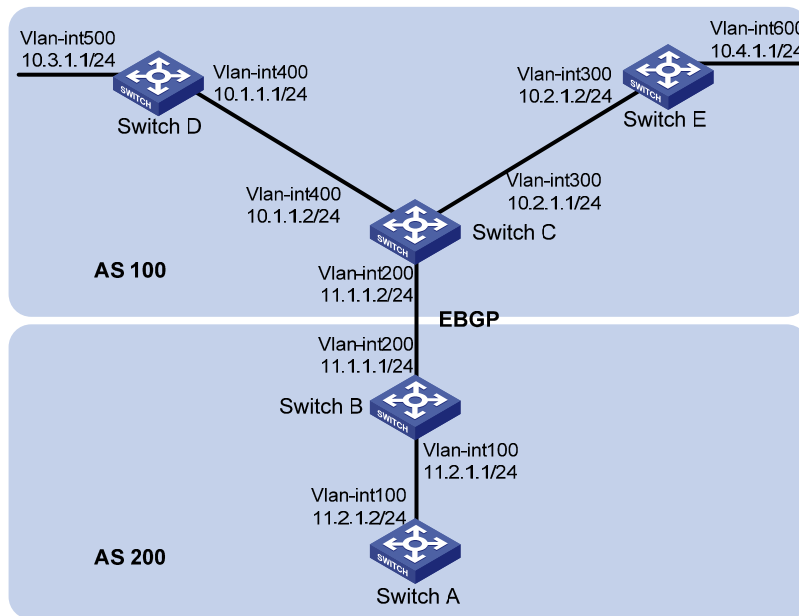

As shown in [Figure 40](#):

- Switch A and Switch B are in AS 200, which runs OSPF.
- Switch C, Switch D, and Switch E are in AS 100, which runs OSPF.

An EBGP connection is established between Switch B and Switch C. Switch B and Switch C are configured to redistribute OSPF routes and direct routes into BGP and BGP routes into OSPF.

Switch B is configured with route summarization and advertises only the summary route 10.0.0.0/8 to reduce Switch A's routing table size.

Figure 40 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF basic functions:
 - # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 11.2.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit
```

 - # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 11.2.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

 - # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

 - # Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ospf
```

```
[SwitchD-ospf-1] area 0
[SwitchD-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] network 10.3.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] quit
```

Configure Switch E.

```
<SwitchE> system-view
[SwitchE] ospf
[SwitchE-ospf-1] area 0
[SwitchE-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
[SwitchE-ospf-1-area-0.0.0.0] network 10.4.1.0 0.0.0.255
[SwitchE-ospf-1-area-0.0.0.0] quit
[SwitchE-ospf-1] quit
```

3. Configure BGP to redistribute OSPF routes and direct routes:

Configure Switch B.

```
[SwitchB] bgp 200
[SwitchB-bgp] peer 11.1.1.2 as 100
[SwitchB-bgp] import-route ospf
[SwitchB-bgp] import-route direct
[SwitchB-bgp] quit
```

Configure Switch C.

```
[SwitchC] bgp 100
[SwitchC-bgp] peer 11.1.1.1 as 200
[SwitchC-bgp] import-route ospf
[SwitchC-bgp] import-route direct
[SwitchC-bgp] quit
```

4. Configure Switch B and Switch C to redistribute BGP routes into OSPF:

Configure OSPF to redistribute routes from BGP on Switch B.

```
[SwitchB] ospf
[SwitchB-ospf-1] import-route bgp
```

Configure OSPF to redistribute routes from BGP on Switch C.

```
[SwitchC] ospf
[SwitchC-ospf-1] import-route bgp
```

Display the OSPF routing table of Switch A.

```
[SwitchA] display ip routing-table
Routing Tables: Public
                Destinations : 8                Routes : 8
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
10.1.1.0/24	O_ASE	150	1	11.2.1.1	Vlan100
10.2.1.0/24	O_ASE	150	1	11.2.1.1	Vlan100
10.3.1.0/24	O_ASE	150	1	11.2.1.1	Vlan100
10.4.1.0/24	O_ASE	150	1	11.2.1.1	Vlan100
11.2.1.0/24	Direct	0	0	11.2.1.2	Vlan100
11.2.1.2/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0

- Configure summary route 10.0.0.0/8 on Switch B and advertise it:

```
[SwitchB-ospf-1] asbr-summary 10.0.0.0 8
```

Display the OSPF routing table of Switch A.

```
[SwitchA] display ip routing-table
```

```
Routing Tables: Public
```

```
Destinations : 5          Routes : 5
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
10.0.0.0/8	O_ASE	150	2	11.2.1.1	Vlan100
11.2.1.0/24	Direct	0	0	11.2.1.2	Vlan100
11.2.1.2/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0

The output shows that routes 10.1.1.0/24, 10.2.1.0/24, 10.3.1.0/24 and 10.4.1.0/24 are summarized into one route 10.0.0.0/8.

Configuring an OSPF stub area

Network requirements

Figure 41 shows an AS is split into three areas, where all switches run OSPF. Switch A and Switch B act as ABRs to forward routing information between areas. Switch D acts as the ASBR to redistribute routes (static routes).

Configure Area 1 as a stub area, reducing LSAs to this area without affecting route reachability.

Figure 41 Network diagram

Configuration procedure

- Configure IP addresses for interfaces. (Details not shown.)
- Configure OSPF basic functions. (See "Configuring OSPF basic functions")
- Configure Switch D to redistribute static routes:

```
<SwitchD> system-view
```

```
[SwitchD] ip route-static 3.1.2.1 24 10.5.1.2
```

```
[SwitchD] ospf
```

```
[SwitchD-ospf-1] import-route static
```

```
[SwitchD-ospf-1] quit
```

Display ABR/ASBR information on Switch C.

```
<SwitchC> display ospf abr-asbr
```

```
OSPF Process 1 with Router ID 10.4.1.1
Routing Table to ABR and ASBR
```

Type	Destination	Area	Cost	NextHop	RtType
Intra	10.2.1.1	0.0.0.1	3	10.2.1.1	ABR
Inter	10.3.1.1	0.0.0.1	5	10.2.1.1	ABR
Inter	10.5.1.1	0.0.0.1	7	10.2.1.1	ASBR

Display OSPF routing table information on Switch C.

```
<SwitchC> display ospf routing
```

```
OSPF Process 1 with Router ID 10.4.1.1
Routing Tables
```

Routing for Network

Destination	Cost	Type	NextHop	AdvRouter	Area
10.2.1.0/24	3	Transit	10.2.1.2	10.2.1.1	0.0.0.1
10.3.1.0/24	7	Inter	10.2.1.1	10.2.1.1	0.0.0.1
10.4.1.0/24	3	Stub	10.4.1.1	10.4.1.1	0.0.0.1
10.5.1.0/24	17	Inter	10.2.1.1	10.2.1.1	0.0.0.1
10.1.1.0/24	5	Inter	10.2.1.1	10.2.1.1	0.0.0.1

Routing for ASEs

Destination	Cost	Type	Tag	NextHop	AdvRouter
3.1.2.0/24	1	Type2	1	10.2.1.1	10.5.1.1

Total Nets: 6

Intra Area: 2 Inter Area: 3 ASE: 1 NSSA: 0

The output shows that because Switch C resides in a normal OSPF area, its routing table contains an external route.

4. Configure Area 1 as a Stub area:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 1
[SwitchA-ospf-1-area-0.0.0.1] stub
[SwitchA-ospf-1-area-0.0.0.1] quit
[SwitchA-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] stub
[SwitchC-ospf-1-area-0.0.0.1] quit
[SwitchC-ospf-1] quit
```

```
# Display OSPF routing information on Switch C
```

```
[SwitchC] display ospf routing
```

```
OSPF Process 1 with Router ID 10.4.1.1
Routing Tables
```

```
Routing for Network
```

Destination	Cost	Type	NextHop	AdvRouter	Area
0.0.0.0/0	4	Inter	10.2.1.1	10.2.1.1	0.0.0.1
10.2.1.0/24	3	Transit	10.2.1.2	10.2.1.1	0.0.0.1
10.3.1.0/24	7	Inter	10.2.1.1	10.2.1.1	0.0.0.1
10.4.1.0/24	3	Stub	10.4.1.1	10.4.1.1	0.0.0.1
10.5.1.0/24	17	Inter	10.2.1.1	10.2.1.1	0.0.0.1
10.1.1.0/24	5	Inter	10.2.1.1	10.2.1.1	0.0.0.1

```
Total Nets: 6
```

```
Intra Area: 2 Inter Area: 4 ASE: 0 NSSA: 0
```

The output shows that when Switch C resides in the stub area, a default route takes the place of the external route.

```
# Filter Type-3 LSAs out the stub area
```

```
[SwitchA] ospf
```

```
[SwitchA-ospf-1] area 1
```

```
[SwitchA-ospf-1-area-0.0.0.1] stub no-summary
```

```
[SwitchA-ospf-1-area-0.0.0.1] quit
```

```
# Display OSPF routing information on Switch C.
```

```
[SwitchC] display ospf routing
```

```
OSPF Process 1 with Router ID 10.4.1.1
Routing Tables
```

```
Routing for Network
```

Destination	Cost	Type	NextHop	AdvRouter	Area
0.0.0.0/0	4	Inter	10.2.1.1	10.2.1.1	0.0.0.1
10.2.1.0/24	3	Transit	10.2.1.2	10.4.1.1	0.0.0.1
10.4.1.0/24	3	Stub	10.4.1.1	10.4.1.1	0.0.0.1

```
Total Nets: 3
```

```
Intra Area: 2 Inter Area: 1 ASE: 0 NSSA: 0
```

After this configuration, routing entries on the stub router are further reduced, containing only one default external route.

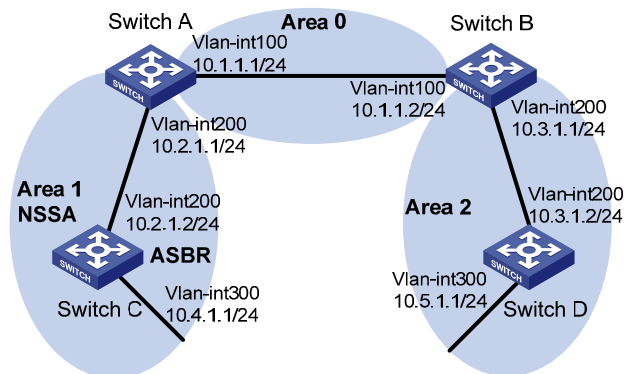

Configuring an OSPF NSSA area

Network requirements

Figure 42 shows an AS is split into three areas, where all switches run OSPF. Switch A and Switch B act as ABRs to forward routing information between areas.

Configure Area 1 as an NSSA area and configure Switch C as the ASBR to redistribute static routes into the AS.

Figure 42 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces.
2. Configure OSPF basic functions. (See "[Configuring OSPF basic functions](#)")
3. Configure Area 1 as an NSSA area:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 1
[SwitchA-ospf-1-area-0.0.0.1] nssa default-route-advertise no-summary
[SwitchA-ospf-1-area-0.0.0.1] quit
[SwitchA-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] nssa
[SwitchC-ospf-1-area-0.0.0.1] quit
[SwitchC-ospf-1] quit
```

NOTE:

- If Switch C in the NSSA area wants to obtain routes to other areas within the AS, you must configure the **nssa** command with the keyword **default-route-advertise** on Switch A (an ABR) so Switch C can obtain a default route.
 - It is recommended to configure the **nssa** command with the keyword **no-summary** on Switch A to reduce the routing table size on NSSA switches. On other NSSA switches, you only need to configure the **nssa** command.
-

Display OSPF routing information on Switch C.

```
[SwitchC] display ospf routing
```

```
OSPF Process 1 with Router ID 10.4.1.1
Routing Tables
```

```

Routing for Network
Destination      Cost      Type      NextHop      AdvRouter      Area
0.0.0.0/0        65536     Inter     10.2.1.1     10.2.1.1       0.0.0.1
10.2.1.0/24      65535     Transit  10.2.1.2     10.4.1.1       0.0.0.1
10.4.1.0/24      3         Stub     10.4.1.1     10.4.1.1       0.0.0.1

```

```
Total Nets: 3
```

```
Intra Area: 2 Inter Area: 1 ASE: 0 NSSA: 0
```

4. Configure Switch C to redistribute static routes:

```
[SwitchC] ip route-static 3.1.3.1 24 10.4.1.2
```

```
[SwitchC] ospf
```

```
[SwitchC-ospf-1] import-route static
```

```
[SwitchC-ospf-1] quit
```

Display OSPF routing information on Switch D.

```
<SwitchD> display ospf routing
```

```
OSPF Process 1 with Router ID 10.5.1.1
```

```
Routing Tables
```

```

Routing for Network
Destination      Cost      Type      NextHop      AdvRouter      Area
10.2.1.0/24      22        Inter     10.3.1.1     10.3.1.1       0.0.0.2
10.3.1.0/24      10        Transit  10.3.1.2     10.3.1.1       0.0.0.2
10.4.1.0/24      25        Inter     10.3.1.1     10.3.1.1       0.0.0.2
10.5.1.0/24      10        Stub     10.5.1.1     10.5.1.1       0.0.0.2
10.1.1.0/24      12        Inter     10.3.1.1     10.3.1.1       0.0.0.2

```

```
Routing for ASEs
```

```

Destination      Cost      Type      Tag      NextHop      AdvRouter
3.1.3.0/24       1         Type2     1         10.3.1.1     10.2.1.1

```

```
Total Nets: 6
```

```
Intra Area: 2 Inter Area: 3 ASE: 1 NSSA: 0
```

The output shows that on Switch D an external route imported from the NSSA area.

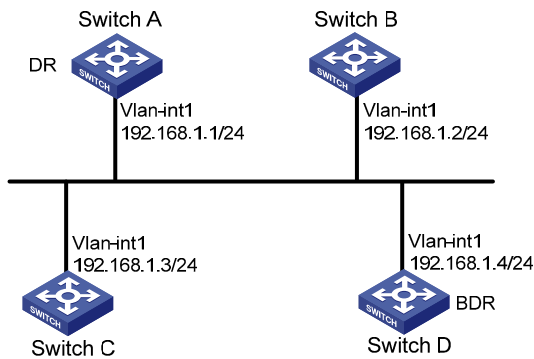

Configuring OSPF DR election

Network requirements

In [Figure 43](#), OSPF Switches A, B, C, and D reside on the same network segment.

Configure Switch A as the DR, and configure Switch C as the BDR.

Figure 43 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] router id 1.1.1.1
[SwitchA] ospf
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] router id 2.2.2.2
[SwitchB] ospf
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] router id 3.3.3.3
[SwitchC] ospf
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] router id 4.4.4.4
[SwitchD] ospf
[SwitchD-ospf-1] area 0
[SwitchD-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] quit
```

```
[SwitchD-ospf-1] return
```

```
# Display OSPF neighbor information on Switch A.
```

```
[SwitchA] display ospf peer verbose
```

```
OSPF Process 1 with Router ID 1.1.1.1  
Neighbors

```

```
Dead timer due in 31 sec
```

```
Neighbor is up for 00:01:28
```

```
Authentication Sequence: [ 0 ]
```

```
Router ID: 4.4.4.4          Address: 192.168.1.4          GR State: Normal
```

```
State: Full Mode: Nbr is Master Priority: 1
```

```
DR: 192.168.1.4 BDR: 192.168.1.3 MTU: 0
```

```
Dead timer due in 31 sec
```

```
Neighbor is up for 00:01:28
```

```
Authentication Sequence: [ 0 ]
```

Switch D becomes the DR, and Switch C is the BDR.

3. Configure router priorities on interfaces:

```
# Configure Switch A.
```

```
[SwitchA] interface vlan-interface 1
```

```
[SwitchA-Vlan-interface1] ospf dr-priority 100
```

```
[SwitchA-Vlan-interface1] quit
```

```
# Configure Switch B.
```

```
[SwitchB] interface vlan-interface 1
```

```
[SwitchB-Vlan-interface1] ospf dr-priority 0
```

```
[SwitchB-Vlan-interface1] quit
```

```
# Configure Switch C.
```

```
[SwitchC] interface vlan-interface 1
```

```
[SwitchC-Vlan-interface1] ospf dr-priority 2
```

```
[SwitchC-Vlan-interface1] quit
```

```
# Display neighbor information on Switch D.
```

```
<SwitchD> display ospf peer verbose
```

```
OSPF Process 1 with Router ID 4.4.4.4  
Neighbors
```

```
Area 0.0.0.0 interface 192.168.1.4(Vlan-interface1)'s neighbors
Router ID: 1.1.1.1      Address: 192.168.1.1      GR State: Normal
State: Full Mode:Nbr is Slave Priority: 100
DR: 192.168.1.4 BDR: 192.168.1.3 MTU: 0
Dead timer due in 31 sec
Neighbor is up for 00:11:17
Authentication Sequence: [ 0 ]
```

```
Router ID: 2.2.2.2      Address: 192.168.1.2      GR State: Normal
State: Full Mode:Nbr is Slave Priority: 0
DR: 192.168.1.4 BDR: 192.168.1.3 MTU: 0
Dead timer due in 35 sec
Neighbor is up for 00:11:19
Authentication Sequence: [ 0 ]
```

```
Router ID: 3.3.3.3      Address: 192.168.1.3      GR State: Normal
State: Full Mode:Nbr is Slave Priority: 2
DR: 192.168.1.4 BDR: 192.168.1.3 MTU: 0
Dead timer due in 33 sec
Neighbor is up for 00:11:15
Authentication Sequence: [ 0 ]
```

The DR and BDR are not changed, because the new router priority settings do not take effect immediately.

4. Restart OSPF process:

Restart the OSPF process of Switch D.

```
<SwitchD> reset ospf 1 process
```

```
Warning : Reset OSPF process? [Y/N]:y
```

Display neighbor information on Switch D.

```
<SwitchD> display ospf peer verbose
```

```
OSPF Process 1 with Router ID 4.4.4.4
Neighbors
```

```
Area 0.0.0.0 interface 192.168.1.4(Vlan-interface1)'s neighbors
Router ID: 1.1.1.1      Address: 192.168.1.1      GR State: Normal
State: Full Mode: Nbr is Slave Priority: 100
DR: 192.168.1.1 BDR: 192.168.1.3 MTU: 0
Dead timer due in 39 sec
Neighbor is up for 00:01:40
Authentication Sequence: [ 0 ]
```

```
Router ID: 2.2.2.2      Address: 192.168.1.2      GR State: Normal
State: 2-Way Mode: None Priority: 0
DR: 192.168.1.1 BDR: 192.168.1.3 MTU: 0
Dead timer due in 35 sec
Neighbor is up for 00:01:44
Authentication Sequence: [ 0 ]
```

```

Router ID: 3.3.3.3          Address: 192.168.1.3      GR State: Normal
State: Full Mode: Nbr is Slave Priority: 2
DR: 192.168.1.1 BDR: 192.168.1.3 MTU: 0
Dead timer due in 39 sec
Neighbor is up for 00:01:41
Authentication Sequence: [ 0 ]

```

Switch A becomes the DR, and Switch C is the BDR.

The *full* neighbor state means an adjacency has been established. The *2-way* neighbor state means the two routers are not the DR or BDR, and they do not exchange LSAs.

Display OSPF interface information.

```
[SwitchA] display ospf interface
```

```

OSPF Process 1 with Router ID 1.1.1.1
Interfaces

```

```
Area: 0.0.0.0
```

IP Address	Type	State	Cost	Pri	DR	BDR
192.168.1.1	Broadcast	DR	1	100	192.168.1.1	192.168.1.3

```
[SwitchB] display ospf interface
```

```

OSPF Process 1 with Router ID 2.2.2.2
Interfaces

```

```
Area: 0.0.0.0
```

IP Address	Type	State	Cost	Pri	DR	BDR
		DROther				

The interface state *DROther* means the interface is not the DR/BDR.

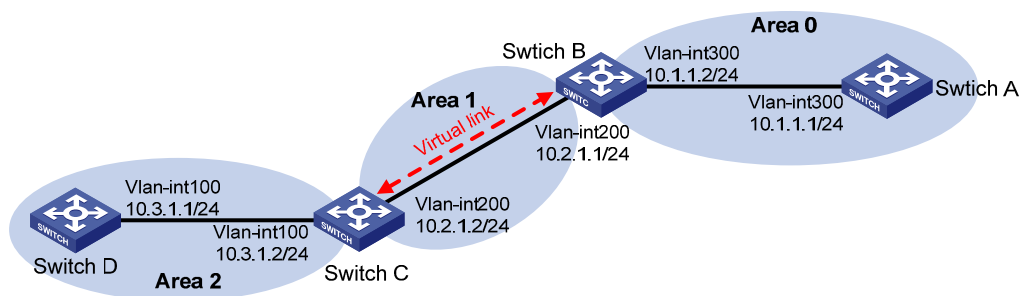

Configuring OSPF virtual links

Network requirements

In [Figure 44](#), Area 2 has no direct connection to Area 0, and Area 1 acts as the Transit Area to connect Area 2 to Area 0 via a configured virtual link between Switch B and Switch C.

After configuration, Switch B can learn routes to Area 2.

Figure 44 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf 1 router-id 1.1.1.1
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf 1 router-id 2.2.2.2
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] area 1
[SwitchB-ospf-1-area-0.0.0.1] network 10.2.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.1] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf 1 router-id 3.3.3.3
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] network 10.2.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.1] quit
[SwitchC-ospf-1] area 2
[SwitchC-ospf-1-area-0.0.0.2] network 10.3.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.2] quit
[SwitchC-ospf-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ospf 1 router-id 4.4.4.4
[SwitchD-ospf-1] area 2
[SwitchD-ospf-1-area-0.0.0.2] network 10.3.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.2] quit
```

Display the OSPF routing table of Switch B.

```
[SwitchB] display ospf routing
```

```
OSPF Process 1 with Router ID 2.2.2.2
```

```
Routing Tables
```

```
Routing for Network
```

Destination	Cost	Type	NextHop	AdvRouter	Area
10.2.1.0/24	2	Transit	10.2.1.1	3.3.3.3	0.0.0.1
10.1.1.0/24	2	Transit	10.1.1.2	2.2.2.2	0.0.0.0

```
Total Nets: 2
```

```
Intra Area: 2 Inter Area: 0 ASE: 0 NSSA: 0
```

Area 0 has no direct connection to Area 2, so the routing table of Switch B has no route to Area 2.

3. Configure a virtual link:

Configure Switch B.

```
[SwitchB] ospf
[SwitchB-ospf-1] area 1
[SwitchB-ospf-1-area-0.0.0.1] vlink-peer 3.3.3.3
[SwitchB-ospf-1-area-0.0.0.1] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
[SwitchC] ospf 1
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] vlink-peer 2.2.2.2
[SwitchC-ospf-1-area-0.0.0.1] quit
```

Display the OSPF routing table of Switch B.

```
[SwitchB] display ospf routing
      OSPF Process 1 with Router ID 2.2.2.2
      Routing Tables

      Routing for Network
      Destination      Cost      Type      NextHop      AdvRouter      Area

```

Switch B has learned the route 10.3.1.0/24 to Area 2.

Configuring OSPF Graceful Restart

Network requirements

As shown in [Figure 45](#), Switch A, Switch B, and Switch C that belong to the same autonomous system and the same OSPF routing domain are GR capable.

Switch A acts as the non-IETF standard GR Restarter, whereas Switch B and Switch C are the GR Helpers and re-synchronize their LSDB with Switch A through OOB communication of GR.

Figure 45 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF basic functions:

Configure Switch A

```
<SwitchA> system-view
[SwitchA] router id 1.1.1.1
[SwitchA] ospf 100
[SwitchA-ospf-100] area 0
[SwitchA-ospf-100-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchA-ospf-100-area-0.0.0.0] quit
```

Configure Switch B

```
<SwitchB> system-view
[SwitchB] router id 2.2.2.2
[SwitchB] ospf 100
[SwitchB-ospf-100] area 0
[SwitchB-ospf-100-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchB-ospf-100-area-0.0.0.0] quit
```

Configure Switch C

```
<SwitchC> system-view
[SwitchC] router id 3.3.3.3
[SwitchC] ospf 100
[SwitchC-ospf-100] area 0
[SwitchC-ospf-100-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchC-ospf-100-area-0.0.0.0] quit
```

3. Configure OSPF GR:

Configure Switch A as the non-IETF standard OSPF GR Restarter: enable the link-local signaling capability, the out-of-band re-synchronization capability, and non IETF standard Graceful Restart capability for OSPF process 100.

```
[SwitchA-ospf-100] enable link-local-signaling
[SwitchA-ospf-100] enable out-of-band-resynchronization
[SwitchA-ospf-100] graceful-restart
[SwitchA-ospf-100] return
```

Configure Switch B as the GR Helper: enable the link-local signaling capability and the out-of-band re-synchronization capability for OSPF process 100.

```
[SwitchB-ospf-100] enable link-local-signaling
[SwitchB-ospf-100] enable out-of-band-resynchronization
# Configure Switch C as the GR Helper: enable the link-local signaling capability and the
out-of-band re-synchronization capability for OSPF process 100.
[SwitchC-ospf-100] enable link-local-signaling
[SwitchC-ospf-100] enable out-of-band-resynchronization
```

4. Verify the configuration:

After the configurations on Switch A, Switch B, and Switch C are completed and the switches are running steadily, enable OSPF Graceful Restart event debugging and then restart the OSPF process using GR on Switch A.

```
<SwitchA> debugging ospf event graceful-restart
<SwitchA> terminal monitor
<SwitchA> terminal debugging
<SwitchA> reset ospf 100 process graceful-restart
Warning : Reset OSPF process? [Y/N]:y
%Dec 12 09:36:12:500 2006 SwitchA RM/3/RMLOG:OSPF-NBRCHANGE: Process 100, Neighbour

OSPF 100 restarted OOB Progress timer for neighbor 192.1.1.2.
%Oct 22 09:36:12:566 2008 SwitchA RM/3/RMLOG:OSPF-NBRCHANGE: Process 100, Neighbour
192.1.1.2(Vlan100) from Loading to Full
OSPF 100 restarted OOB Progress timer for neighbor 192.1.1.2.
OSPF 100 deleted OOB Progress timer for neighbor 192.1.1.2.
OSPF 100 Gr Wait Timeout timer fired.
OSPF 100 deleted GR wait timer.
OSPF 100 deleted GR Interval timer.
OSPF 100 GR Completed for OSPF Router
OSPF 100 notified RM that OSPF process left GR.
RM notified that all protocol left GR.
OSPF 100 started flushing STALE LSA after all protocol left GR.
OSPF 100: Flush Stale Area LSAs
OSPF 100: Start Flush Stale ASE + NSSA LSAs
OSPF 100: End Flush Stale ASE + NSSA LSAs
```

Switch A completes GR with the help of Switch B.

Configuring route filtering

Network requirements

As shown in [Figure 46](#):

- All the switches in the network run OSPF. The AS is divided into three areas.
- Switch A and Switch B work as ABRs.

Configure Switch C as an ASBR to redistribute external routes (static routes), and configure a filter policy on Switch C to filter out redistributed route 3.1.3.0/24.

Configure a routing policy on Switch A to filter route 10.5.1.0/24.

Figure 46 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF basic functions. (See "[Configuring OSPF basic functions](#)")
3. Configure OSPF to redistribute routes:

On Switch C, configure a static route destined for network 3.1.1.0/24.

```
<SwitchC> system-view
[SwitchC] ip route-static 3.1.1.0 24 10.4.1.2
```

On Switch C, configure a static route destined for network 3.1.2.0/24.

```
[SwitchC] ip route-static 3.1.2.0 24 10.4.1.2
```

On Switch C, configure a static route destined for network 3.1.3.0/24.

```
[SwitchC] ip route-static 3.1.3.0 24 10.4.1.2
```

On Switch C, configure OSPF to redistribute static routes.

```
[SwitchC] ospf 1
[SwitchC-ospf-1] import-route static
[SwitchC-ospf-1] quit
```

Display the OSPF routing table of Switch A.

```
<SwitchA> display ip routing-table
```

```
Routing Tables: Public
```

```
Destinations : 12      Routes : 12
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
------------------	-------	-----	------	---------	-----------

3.1.1.0/24	O_ASE	150	1	10.2.1.2	Vlan200
3.1.2.0/24	O_ASE	150	1	10.2.1.2	Vlan200
3.1.3.0/24	O_ASE	150	1	10.2.1.2	Vlan200
10.1.1.0/24	Direct	0	0	10.1.1.1	Vlan200
10.1.1.1/32	Direct	0	0	127.0.0.1	InLoop0
10.2.1.0/24	Direct	0	0	10.2.1.1	Vlan200
10.2.1.1/32	Direct	0	0	127.0.0.1	InLoop0
10.3.1.0/24	OSPF	10	4	10.1.1.2	Vlan100
10.4.1.0/24	OSPF	10	13	10.2.1.2	Vlan200
10.5.1.0/24	OSPF	10	14	10.1.1.2	Vlan100
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0

4. On Switch C, filter out route 3.1.3.0/24:

Configure the IPv4 prefix list.

```
[SwitchC] ip ip-prefix prefix1 index 1 deny 3.1.3.0 24
[SwitchC] ip ip-prefix prefix1 index 2 permit 3.1.1.0 24
[SwitchC] ip ip-prefix prefix1 index 3 permit 3.1.2.0 24
```

Reference the prefix list to filter out route 3.1.3.0/24.

```
[SwitchC] ospf 1
[SwitchC-ospf-1] filter-policy ip-prefix prefix1 export static
```

Display the OSPF routing table of Switch A.

```
<SwitchA> display ip routing-table
```

Routing Tables: Public

Destinations : 11 Routes : 11

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
3.1.1.0/24	O_ASE	150	1	10.2.1.2	Vlan200
3.1.2.0/24	O_ASE	150	1	10.2.1.2	Vlan200
10.1.1.0/24	Direct	0	0	10.1.1.1	Vlan100
10.1.1.1/32	Direct	0	0	127.0.0.1	InLoop0
10.2.1.0/24	Direct	0	0	10.2.1.1	Vlan200
10.2.1.1/32	Direct	0	0	127.0.0.1	InLoop0
10.3.1.0/24	OSPF	10	4	10.1.1.2	Vlan100
10.4.1.0/24	OSPF	10	13	10.2.1.2	Vlan200
10.5.1.0/24	OSPF	10	14	10.1.1.2	Vlan100
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0

The route destined for network 3.1.3.0/24 is filtered out.

5. On Switch A, filter out the route 10.5.1.1/24:

Configure the ACL on Switch A.

```
<SwitchA> system-view
[SwitchA] acl number 2000
[SwitchA-acl-basic-2000] rule 0 deny source 10.5.1.0 0.0.0.255
[SwitchA-acl-basic-2000] rule 1 permit source any
[SwitchA-acl-basic-2000] quit
```

Use the ACL to filter route 10.5.1.0/24.

```
[SwitchA] ospf 1
[SwitchA-ospf-1] filter-policy 2000 import
[SwitchA-ospf-1] quit
# Display the OSPF routing table of Switch A.
[SwitchA] display ip routing-table
Routing Tables: Public
                Destinations : 10          Routes : 10
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
3.1.1.0/24	O_ASE	150	1	10.2.1.2	Vlan200
3.1.2.0/24	O_ASE	150	1	10.2.1.2	Vlan200
10.1.1.0/24	Direct	0	0	10.1.1.1	Vlan100
10.1.1.1/32	Direct	0	0	127.0.0.1	InLoop0
10.2.1.0/24	Direct	0	0	10.2.1.1	Vlan200
10.2.1.1/32	Direct	0	0	127.0.0.1	InLoop0
10.3.1.0/24	OSPF	10	4	10.1.1.2	Vlan100
10.4.1.0/24	OSPF	10	13	10.2.1.2	Vlan200
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0

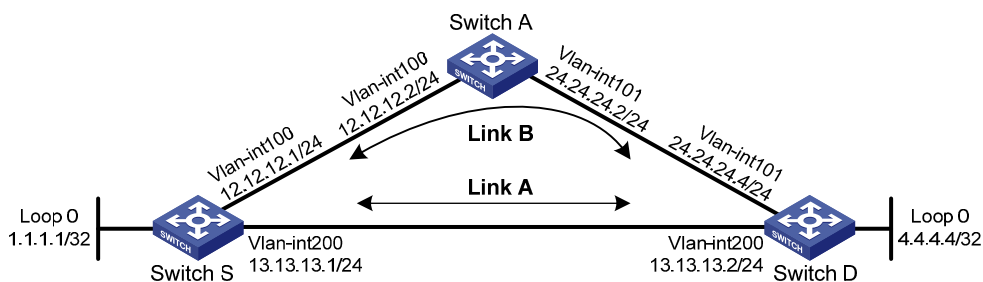

The route destined for 10.5.1.1/24 is filtered out.

Configuring OSPF FRR

Network requirements

Switch S, Switch A, and Switch D belong to the same OSPF domain as illustrated in [Figure 47](#). Configure OSPF FRR so that when the link between Switch S and Switch D fails, traffic can be switched to Link B immediately.

Figure 47 Network diagram

Configuration procedure

1. Configure IP addresses for the interfaces on each switch and configure OSPF.
Follow [Figure 47](#) to configure the IP address and subnet mask of each interface on the switches. (Details not shown.)
Configure OSPF on the switches, ensuring that Switch S, Switch A, and Switch D can communicate with each other at Layer 3. (Details not shown.)
2. Configure OSPF FRR:

You can enable OSPF FRR to either automatically calculate a backup next hop, or to designate a backup next hop by using a routing policy.

Method I: Enable OSPF FRR to automatically calculate the backup next hop.

Configure Switch S.

```
<SwitchS> system-view
[SwitchS] bfd echo-source-ip 1.1.1.1
[SwitchS] ospf 1
[SwitchS-ospf-1] fast-reroute auto
[SwitchS-ospf-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bfd echo-source-ip 4.4.4.4
[SwitchD] ospf 1
[SwitchD-ospf-1] fast-reroute auto
[SwitchD-ospf-1] quit
```

Method II: Enable OSPF FRR to designate a backup next hop by using a routing policy.

Configure Switch S.

```
<SwitchS> system-view
[SwitchS] bfd echo-source-ip 1.1.1.1
[SwitchS] ip ip-prefix abc index 10 permit 4.4.4.4 32
[SwitchS] route-policy frr permit node 10
[SwitchS-route-policy] if-match ip-prefix abc
[SwitchS-route-policy] apply fast-reroute backup-interface vlan-interface 100
backup-nexthop 12.12.12.2
[SwitchS-route-policy] quit
[SwitchS] ospf 1
[SwitchS-ospf-1] fast-reroute route-policy frr
[SwitchS-ospf-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bfd echo-source-ip 4.4.4.4
[SwitchD] ip ip-prefix abc index 10 permit 1.1.1.1 32
[SwitchD] route-policy frr permit node 10
[SwitchD-route-policy] if-match ip-prefix abc
[SwitchD-route-policy] apply fast-reroute backup-interface vlan-interface 101
backup-nexthop 24.24.24.2
[SwitchD-route-policy] quit
[SwitchD] ospf 1
[SwitchD-ospf-1] fast-reroute route-policy frr
[SwitchD-ospf-1] quit
```

3. Verify the configuration:

Display route 4.4.4.4/32 on Switch S and you can view the backup next hop information.

```
[SwitchS] display ip routing-table 4.4.4.4 verbose
Routing Table : Public
Summary Count : 1
```

```
Destination: 4.4.4.4/32
```

```

    Protocol: OSPF                Process ID: 1
    Preference: 10                Cost: 1

    BKTunnel ID: 0x0           BKLabel: NULL
    State: Active Adv          Age: 00h01m27s
    Tag: 0

```

Display route 1.1.1.1/32 on Switch D. You can find the backup next hop information.

```

[SwitchD] display ip routing-table 1.1.1.1 verbose
Routing Table : Public
Summary Count : 1

```

```

    Destination: 1.1.1.1/32
    Protocol: OSPF                Process ID: 1
    Preference: 10                Cost: 1
    IpPrecedence:                QoSLeId:
    NextHop: 13.13.13.1          Interface: Vlan-interface200
    BkNextHop: 24.24.24.2       BkInterface: Vlan-interface101
    RelyNextHop: 0.0.0.0        Neighbor : 0.0.0.0
    Tunnel ID: 0x0              Label: NULL
    BKTunnel ID: 0x0           BKLabel: NULL
    State: Active Adv          Age: 00h01m27s
    Tag: 0

```

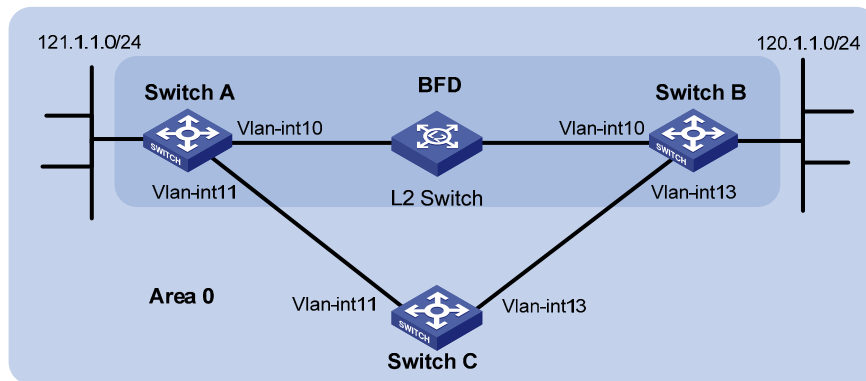

Configuring BFD for OSPF

Network requirements

As shown in [Figure 48](#), OSPF is enabled on Switch A, Switch B and Switch C that are reachable to each other at the network layer.

After the link over which Switch A and Switch B communicate through a Layer 2 switch fails, BFD can quickly detect the failure and notify OSPF of the failure. Switch A and Switch B then communicate through Switch C.

Figure 48 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int10	10.1.0.102/24	Switch B	Vlan-int10	10.1.0.100/24
	Vlan-int11	11.1.1.1/24		Vlan-int13	13.1.1.1/24
Switch C	Vlan-int11	11.1.1.2/24			
	Vlan-int13	13.1.1.2/24			

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 10.1.0.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] network 11.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] network 121.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit
[SwitchA] interface vlan 11
[SwitchA-Vlan-interface11] ospf cost 2
[SwitchA-Vlan-interface11] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 10.1.0.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] network 13.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] network 120.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
[SwitchB] interface vlan-interface 13
[SwitchB-Vlan-interface13] ospf cost 2
[SwitchB-Vlan-interface13] quit
```

Configure Switch C.

```
<SwitchC> system-view
```

```
[SwitchC] ospf
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 11.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] network 13.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

3. Configure BFD:

Enable BFD on Switch A and configure BFD parameters.

```
[SwitchA] bfd session init-mode active
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] ospf bfd enable
[SwitchA-Vlan-interface10] bfd min-transmit-interval 500
[SwitchA-Vlan-interface10] bfd min-receive-interval 500
[SwitchA-Vlan-interface10] bfd detect-multiplier 7
[SwitchA-Vlan-interface10] quit
[SwitchA] quit
```

Enable BFD on Switch B and configure BFD parameters.

```
[SwitchB] bfd session init-mode active
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] ospf bfd enable
[SwitchB-Vlan-interface10] bfd min-transmit-interval 500
[SwitchB-Vlan-interface10] bfd min-receive-interval 500
[SwitchB-Vlan-interface10] bfd detect-multiplier 6
```

4. Verify the configuration:

The following operations are performed on Switch A. The operations on Switch B and Switch C are similar. (Details not shown.)

Display the BFD information of Switch A.

```
<SwitchA> display bfd session
Total Session Num: 1          Init Mode: Active
Session Working Under Ctrl Mode:
LD/RD      SourceAddr      DestAddr      State Holdtime Interface
3/1        10.1.0.102      10.1.0.100   Up    1700ms  vlan10
```

Display routes to 120.1.1.0/24 on Switch A, and you can see that Switch A communicates with Switch B through the Layer 2 switch.

```
<SwitchA> display ip routing-table 120.1.1.0 verbose
Routing Table : Public
Summary Count : 2
  Destination: 120.1.1.0/24
    Protocol: OSPF          Process ID: 0
    Preference: 0          Cost: 2
    IpPrecedence:          QoSLeId:
      NextHop: 192.168.0.100  Interface: Vlan-interface10
      BkNextHop: 0.0.0.0      BkInterface:
      RelyNextHop: 0.0.0.0    Neighbor : 0.0.0.0
      Tunnel ID: 0x0          Label: NULL
      BKTunnel ID: 0x0       BKLabel: NULL
      State: Active Adv      Age: 00h58m10s
```

```

Tag: 0
Destination: 120.1.1.0/24
  Protocol: OSPF          Process ID: 1
  Preference: 10         Cost: 4
IpPrecedence:           QoSLeId:
  NextHop: 10.1.1.100    Interface: Vlan-interface11
  BkNextHop: 0.0.0.0     BkInterface:
  RelyNextHop: 0.0.0.0   Neighbor : 0.0.0.0
  Tunnel ID: 0x0         Label: NULL
  BKTunnel ID: 0x0      BKLabel: NULL
  State: Invalid Adv     Age: 00h58m05s
Tag: 0

```

Enable BFD debugging on Switch A.

```

<SwitchA> debugging bfd scm
<SwitchA> debugging bfd event
<SwitchA> debugging ospf event
<SwitchA> terminal debugging

```

After the link over which Switch A and Switch B communicates through the Layer 2 switch fails, Switch A can quickly detect the changes on Switch B.

```

%Nov 12 18:34:48:823 2005 SwitchA BFD/5/LOG: Sess[10.1.0.102/10.1.0.100, vlan10],

Troubleshooting OSPF configuration

No OSPF neighbor relationship established

Symptom

No OSPF neighbor relationship can be established.

Analysis

If the physical link and lower layer protocols work well, check OSPF parameters configured on interfaces. Two neighbors must have the same parameters, such as the area ID, network segment, and mask (a P2P or virtual link may have different network segments and masks).

Solution

1. Display OSPF neighbor information using the **display ospf peer** command.
2. Display OSPF interface information using the **display ospf interface** command.
3. Ping the neighbor router's IP address to check connectivity.
4. Check OSPF timers. The dead interval on an interface must be at least four times the hello interval.

5. On an NBMA network, using the **peer ip-address** command to specify the neighbor manually is required.
6. On an NBMA or a broadcast network, at least one connected interface must have a router priority higher than 0.

Incorrect routing information

Symptom

OSPF cannot find routes to other areas.

Analysis

The backbone area must maintain connectivity to all other areas. If a router connects to more than one area, at least one area must be connected to the backbone. The backbone cannot be configured as a Stub area.

In a Stub area, all routers cannot receive external routes, and all interfaces connected to the Stub area must belong to the Stub area.

Solution

1. Use the **display ospf peer** command to display neighbors.
2. Use the **display ospf interface** command to display OSPF interface information.
3. Use the **display ospf lsdb** command to display the LSDB to check its integrity.
4. Display information about area configuration using the **display current-configuration configuration ospf** command. If more than two areas are configured, at least one area is connected to the backbone.
5. In a Stub area, all routers attached are configured with the **stub** command. In an NSSA area, all routers attached are configured with the **nssa** command.
6. If a virtual link is configured, use the **display ospf vlink** command to check the state of the virtual link.

Configuring IS-IS

Hardware compatibility

The HP 5500 SI Switch Series does not support IS-IS.

IS-IS overview

Intermediate System-to-Intermediate System (IS-IS) is a dynamic routing protocol designed by the International Organization for Standardization (ISO) to operate on the connectionless network protocol (CLNP).

The IS-IS routing protocol was modified and extended in RFC 1195 by the International Engineer Task Force (IETF) for application in both TCP/IP and OSI reference models, and the new one is named "Integrated IS-IS" or "Dual IS-IS".

IS-IS is an Interior Gateway Protocol (IGP) used within an Autonomous System. It adopts the Shortest Path First (SPF) algorithm for route calculation.

The term "router" in this chapter refers to both routers and Layer 3 switches.

Basic concepts

IS-IS terminology

- **Intermediate system (IS)**—Similar to a router in TCP/IP, it is the basic unit in IS-IS to generate and propagate routing information. In the following text, an IS refers to a router.
- **End system (ES)**—Refers to a host system in TCP/IP. ISO defines the ES-IS protocol for communication between an ES and an IS. An ES does not participate in the IS-IS processing.
- **Routing domain (RD)**—A group of ISs exchanges routing information with each other using the same routing protocol in a routing domain.
- **Area**—A unit in a routing domain. The IS-IS protocol allows a routing domain to be divided into multiple areas.
- **Link State Database (LSDB)**—All link states in the network forms the LSDB. Each IS has at least one LSDB. The IS uses the SPF algorithm and LSDB to generate its own routes.
- **Link State Protocol Data Unit (LSPDU) or Link State Packet (LSP)**—Each IS can generate an LSP, which contains all the link state information of the IS.
- **Network Protocol Data Unit (NPDU)**—A network layer protocol packet in OSI, which is equivalent to an IP packet in TCP/IP.
- **Designated IS**—On a broadcast network, the designated router is also known as the "designated IS".
- **Network service access point (NSAP)**—An NSAP is an OSI network layer address. It identifies an abstract network service access point and describes the network address in the OSI reference model.

IS-IS address format

- NSAP

As shown in [Figure 49](#), an NSAP address consists of the Initial Domain Part (IDP) and the Domain Specific Part (DSP). The IDP is equal to the network ID of an IP address, and the DSP is equal to the subnet and host ID.

The IDP includes the Authority and Format Identifier (AFI) and the Initial Domain Identifier (IDI).

The DSP includes the High Order Part of DSP (HO-DSP), System ID, and SEL, where the HO-DSP identifies the area, the System ID identifies the host, and the SEL identifies the type of service.

The IDP and DSP are variable in length. The length of an NSAP address varies from 8 bytes to 20 bytes.

Figure 49 NSAP address format

- Area address

The area address comprises the IDP and the HO-DSP of the DSP, which identify the area and the routing domain. Different routing domains cannot have the same area address.

Typically, a router only needs one area address, and all nodes in the same routing domain must share the same area address. However, a router can have a maximum of three area addresses to support smooth area merging, partitioning, and switching.

- System ID

A system ID identifies a host or router uniquely. It has a fixed length of 48 bits (6 bytes).

The system ID of a device can be generated from the Router ID. For example, a router uses the IP address 168.10.1.1 of Loopback 0 as the Router ID. The system ID in IS-IS can be obtained in the following ways:

- Extend each decimal number of the IP address to 3 digits by adding 0s from the left, like 168.010.001.001;
- Divide the extended IP address into 3 sections with 4 digits in each section to get the system ID 1680.1000.1001.

If you use other methods for defining a system ID, always make sure that it can uniquely identify a host or router.

- SEL

The NSAP Selector (SEL), or the N-SEL, is similar to the protocol identifier in IP. Different transport layer protocols correspond to different SELs. All SELs in IP are 00.

- Routing method

Because the area information is identified in IS-IS addresses, a Level-1 router can easily identify packets destined to other areas.

- A Level-1 router makes routing decisions based on the system ID. If the destination is not in the area, the packet is forwarded to the nearest Level-1-2 router.
- A Level-2 router routes packets across areas according to the area address.

NET

A network entity title (NET) indicates the network layer information of an IS, and does not include transport layer information. It is a special NSAP address with the SEL being 0. The length of the NET is equal to the NSAP, and is in the range of 8 bytes to 20 bytes.

A NET comprises the following parts:

- **Area ID**—Its length is in the range of 1 to 13 bytes.
- **System ID**—A system ID uniquely identifies a host or router in the area and has a fixed 6-byte length.
- **SEL**—It has a value of 0 and a fixed 1-byte length.

For example, a NET is ab.cdef.1234.5678.9abc.00, where, area ID is ab.cdef, system ID is 1234.5678.9abc, and SEL is 00.

Typically, a router only needs one NET, but it can have a maximum of three NETs for smooth area merging and partitioning. When you configure multiple NETs, ensure their system IDs are the same.

IS-IS area

Two-level hierarchy

IS-IS has a two-level hierarchy to support large scale networks. A large scale routing domain is divided into multiple Areas. Typically, a Level-1 router is deployed within an area, a Level-2 router is deployed between areas, and a Level-1-2 router is deployed between Level-1 and Level-2 routers.

Level-1 and Level-2

- **Level-1 router**—A Level-1 router establishes neighbor relationships with Level-1 and Level-1-2 routers in the same area. The LSDB maintained by the Level-1 router contains the local area routing information. It directs the packets destined for an outside area to the nearest Level-1-2 router.
- **Level-2 router**—A Level-2 router establishes neighbor relationships with the Level-2 and Level-1-2 routers in the same or in different areas. It maintains a Level-2 LSDB containing inter-area routing information. All the Level-2 and Level-1-2 routers must be contiguous to form the backbone of a routing domain.
- **Level-1-2 router**—A router with both Level-1 and Level-2 router functions is a Level-1-2 router. It can establish Level-1 neighbor relationships with the Level-1 and Level-1-2 routers in the same area, or establish Level-2 neighbor relationships with the Level-2 and Level-1-2 routers in different areas. A Level-1 router must be connected to other areas through a Level-1-2 router. The Level-1-2 router maintains two LSDBs, where the Level-1 LSDB is for routing within the area, and the Level-2 LSDB is for routing between areas.

The Level-1 routers in different areas cannot establish neighbor relationships.

The neighbor relationship establishment of Level-2 routers has nothing to do with area.

Figure 50 shows an IS-IS network topology. Area 1 comprises a set of Level-2 routers and is the backbone. The other four areas are non-backbone areas connected to the backbone through Level-1-2 routers.

Figure 50 IS-IS topology 1

Figure 51 is another IS-IS topology. The Level-1-2 routers connect to the Level-1 and Level-2 routers, and form the IS-IS backbone together with the Level-2 routers. No area is defined as the backbone in this topology. The backbone comprises all contiguous Level-2 and Level-1-2 routers, which can reside in different areas.

Figure 51 IS-IS topology 2

NOTE:

The IS-IS backbone does not need to be a specific area.

Both the Level-1 and Level-2 routers use the SPF algorithm to generate the shortest path tree (SPT).

Route leaking

An IS-IS routing domain is comprised of only one Level-2 area and multiple Level-1 areas. A Level-1 area consists of a group of Level-1 routers, and is connected with a Level-2 area rather than other Level-1 areas.

The routing information of a Level-1 area is sent to the Level-2 area through the Level-1-2 router; therefore, the Level-2 router knows the routing information of the entire IS-IS routing domain. But the Level-1-2 router does not share the information of other Level-1 areas and the Level-2 area with the Level-1 area by default.

Because a Level-1 router simply sends packets destined for other areas to the nearest Level-1-2 router, the best paths may not be selected. To resolve this problem, route leaking was introduced. A Level-2 router can advertise Level-2 routing information to a specified Level-1 area. By having the routing information of other areas, a Level-1 router in the area can make a better routing decision for a packet to another area.

IS-IS network type

Network type

IS-IS supports the following network types:

- Broadcast network, such as Ethernet and Token-Ring
- Point-to-point network, such as PPP and HDLC

DIS and pseudonodes

On an IS-IS broadcast network, a router is elected as the Designated Intermediate System (DIS).

The Level-1 and Level-2 DISs are elected. You can assign different priorities to different level DIS elections. The higher a router's priority is, the more likely the router becomes the DIS. If multiple routers with the same highest DIS priority exist, the one with the highest SNPA (Subnetwork Point of Attachment) address (MAC address on a broadcast network) will be elected. A router can be the DIS for different levels.

IS-IS DIS election differs from OSPF DIS election in the following ways:

- A router with priority 0 can also participate in the DIS election.
- When a router is added to the network and becomes the new DIS, an LDP flooding process is triggered.

As shown in [Figure 52](#), the same level routers on a network, including non-DIS routers, establish adjacencies with each other.

Figure 52 DIS in the IS-IS broadcast network

The DIS creates and updates pseudonodes, as well as generates their LSPs, to describe all routers on the network.

A pseudonode represents a virtual node on the broadcast network. It is not a real router. In IS-IS, it is identified by the system ID of the DIS and a one-byte Circuit ID (a non zero value).

Using pseudonodes can reduce the resources consumed by SPF and simplify network topology.

NOTE:

On IS-IS broadcast networks, all routers are adjacent with each other. However, the DIS is responsible for the synchronization of their LSDBs.

IS-IS PDU format

PDU header format

IS-IS packets are encapsulated into link layer frames. The Protocol Data Unit (PDU) consists of two parts, the headers and the variable length fields. The headers comprise the PDU common header and the PDU specific header. All PDUs have the same PDU common header. The specific headers vary by PDU type.

Figure 53 PDU format

Common header format

Figure 54 PDU common header format

				No. of Octets
Intradomain routing protocol discriminator				1
Length indicator				1
Version/Protocol ID extension				1
ID length				1
R	R	R	PDU type	1
Version				1
Reserved				1
Maximum area address				1

Major fields of the PDU common header are as follows:

- **Intradomain routing protocol discriminator**—Set to 0x83.
- **Length indicator**—Length of the PDU header in bytes, including both common and specific headers.
- **Version/Protocol ID extension**—Set to 1(0x01).
- **ID length**—Length of the NSAP address and NET ID.
- **R (Reserved)**—Set to 0.
- **PDU type**—See [Table 4](#).
- **Version**—Set to 1(0x01).
- **Maximum area address**—Maximum number of area addresses supported.

Table 4 PDU type

Type	PDU Type	Acronym
15	Level-1 LAN IS-IS hello PDU	L1 LAN IIH
16	Level-2 LAN IS-IS hello PDU	L2 LAN IIH
17	Point-to-Point IS-IS hello PDU	P2P IIH

Type	PDU Type	Acronym
18	Level-1 Link State PDU	L1 LSP
20	Level-2 Link State PDU	L2 LSP
24	Level-1 Complete Sequence Numbers PDU	L1 CSNP
25	Level-2 Complete Sequence Numbers PDU	L2 CSNP
26	Level-1 Partial Sequence Numbers PDU	L1 PSNP
27	Level-2 Partial Sequence Numbers PDU	L2 PSNP

Hello

Hello packets are used by routers to establish and maintain neighbor relationships. A hello packet is also an IS-to-IS hello PDU (IIH). For broadcast networks, the Level-1 routers use the Level-1 LAN IIHs; and the Level-2 routers use the Level-2 LAN IIHs. The P2P IIHs are used on point-to-point networks.

Figure 55 illustrates the hello packet format in broadcast networks, where the blue fields are the common header.

Figure 55 L1/L2 LAN IIH format

				No. of Octets
Intradomain routing protocol discriminator				1
Length indicator				1
Version/Protocol ID extension				1
ID length				1
R	R	R	PDU type	1
Version				1
Reserved				1
Maximum area address				1
Reserved/Circuit type				1
Source ID				ID length
Holding time				2
PDU length				2
R	Priority			1
LAN ID				ID length+1
Variable length fields				

Major fields of the L1/L2 LAN IIH are as follows:

- **Reserved/Circuit type**—The first six bits are reserved with a value of 0. The last two bits indicate the router type. Here, 00 means reserved, 01 indicates L1, 10 indicates L2, and 11 indicates L1/2.
- **Source ID**—System ID of the router advertising the hello packet.
- **Holding time**—If no hello packets are received from the neighbor within the holding time, the neighbor is considered down.
- **PDU length**—Total length of the PDU in bytes.
- **Priority**—DIS priority.

- **LAN ID**—Includes the system ID and a one-byte pseudonode ID.

Figure 56 shows the hello packet format on the point-to-point networks.

Figure 56 P2P IIH format

				No. of Octets
Intradomain routing protocol discriminator				1
Length indicator				1
Version/Protocol ID extension				1
ID length				1
R	R	R	PDU type	1
Version				1
Reserved				1
Maximum area address				1
Reserved/Circuit type				1
Source ID				ID length
Holding time				2
PDU length				2
Local Circuit ID				1
Variable length fields				

Instead of the priority and LAN ID fields in the LAN IIH, the P2P IIH has a Local Circuit ID field.

LSP packet format

The Link State PDU (LSP) carries link state information. LSP involves two types: Level-1 LSP and Level-2 LSP. The Level-2 LSPs are sent by the Level-2 routers, and the Level-1 LSPs are sent by the Level-1 routers. The Level-1-2 router can send both types of LSPs.

The two types of LSPs have the same format.

Figure 57 L1/L2 LSP format

				No. of Octets
Intradomain routing protocol discriminator				1
Length indicator				1
Version/Protocol ID extension				1
ID length				1
R	R	R	PDU type	1
Version				1
Reserved				1
Maximum area address				1
PDU length				2
Remaining lifetime				2
LSP ID				ID length+2
Sequence number				4
Checksum				2
P	ATT	OL	IS type	1
Variable length fields				

Major fields of the L1/L2 LSP are as follows:

- **PDU length**—Total length of the PDU in bytes.
- **Remaining lifetime**—LSP remaining lifetime in seconds.
- **LSP ID**—Consists of the system ID, the pseudonode ID (one byte) and the LSP fragment number (one byte).
- **Sequence number**—LSP sequence number.
- **Checksum**—LSP checksum.
- **P (Partition Repair)**—Only for L2 LSPs; it indicates whether the router supports partition repair.
- **ATT (Attachment)**—Generated by a L1/L1 router for L1 LSPs only; it indicates that the router generating the LSP is connected to multiple areas.
- **OL (LSDB Overload)**—Indicates that the LSDB is not complete because the router has run out of memory. Other routers will not send packets to the overloaded router, except packets destined to the networks directly connected to the router. For example, in [Figure 58](#), Router A forwards packets to Router C through Router B. Once other routers know the OL field of LSPs from Router B is set to 1, Router A will send packets to Router C via Router D and Router E, but still send to Router B packets destined to the network directly connected to Router B.

Figure 58 LSDB overload

- **IS type**—Type of the router generating the LSP.

SNP format

A sequence number PDU (SNP) acknowledges the latest received LSPs. It is similar to an Acknowledge packet, but more efficient.

SNP involves Complete SNP (CSNP) and Partial SNP (PSNP), which are further divided into Level-1 CSNP, Level-2 CSNP, Level-1 PSNP and Level-2 PSNP.

CSNP covers the summary of all LSPs in the LSDB to synchronize the LSDB between neighboring routers. On broadcast networks, CSNP is sent by the DIS periodically (10s by default). On point-to-point networks, CSNP is only sent during the adjacency establishment.

The CSNP packet format is shown in [Figure 59](#).

Figure 59 L1/L2 CSNP format

				No. of Octets
Intradomain routing protocol discriminator				1
Length indicator				1
Version/Protocol ID extension				1
ID length				1
R	R	R	PDU type	1
Version				1
Reserved				1
Maximum area address				1
PDU length				2
Source ID				ID length+1
Start LSP ID				ID length+2
End LSP ID				ID length+2
Variable length fields				

PSNP only contains the sequence numbers of one or multiple latest received LSPs. It can acknowledge multiple LSPs at one time. When LSDBs are not synchronized, a PSNP is used to request new LSPs from neighbors.

Figure 60 L1/L2 PSNP format

Intradomain routing protocol discriminator				No. of Octets
				1
Length indicator				1
Version/Protocol ID extension				1
ID length				1
R	R	R	PDU type	1
Version				1
Reserved				1
Maximum area address				1
PDU length				2
Source ID				ID length+1
Variable length fields				

CLV

The variable fields of PDU comprise multiple Code-Length-Value (CLV) triplets.

Figure 61 CLV format

Code	No. of Octets
Length	1
Value	Length

Table 5 shows that different PDUs contain different CLVs. Code 1 to 10 of CLV are defined in ISO 10589 (code 3 and 5 are not shown in the table), and others are defined in RFC 1195.

Table 5 CLV name and the corresponding PDU type

CLV Code	Name	PDU Type
1	Area Addresses	IIH, LSP
2	IS Neighbors (LSP)	LSP
4	Partition Designated Level2 IS	L2 LSP
6	IS Neighbors (MAC Address)	LAN IIH
7	IS Neighbors (SNPA Address)	LAN IIH
8	Padding	IIH
9	LSP Entries	SNP
10	Authentication Information	IIH, LSP, SNP
128	IP Internal Reachability Information	LSP
129	Protocols Supported	IIH, LSP
130	IP External Reachability Information	L2 LSP
131	Inter-Domain Routing Protocol Information	L2 LSP

CLV Code	Name	PDU Type
132	IP Interface Address	IIH, LSP

Supported IS-IS features

Multiple instances and processes

IS-IS supports multiple instances and processes. Multiple processes allow an IS-IS process to work in concert with a group of interfaces. A router can run multiple IS-IS processes, and each process corresponds to a unique group of interfaces.

For routers supporting VPN, each IS-IS process is associated with a VPN instance. The VPN instance is also associated with interfaces of the process.

IS-IS Graceful Restart

Graceful Restart (GR) ensures the continuity of packet forwarding when a routing protocol restarts or an active/standby switchover occurs:

- **GR Restarter**—Graceful restarting router. It must be GR capable.
- **GR Helper**—A neighbor of the GR Restarter. It helps the GR Restarter to complete the GR process.

After an IS-IS GR Restarter restarts, it must complete the following tasks to synchronize the LSDB with its neighbors:

- Obtain IS-IS neighbor information without changing adjacencies.
- Obtain the LSDB.

The GR Restarter sends an OSPF GR signal to GR Helpers so that the GR Helpers keep their adjacencies with the GR Restarter, and restores the neighbor table after receiving responses from neighbors. The GR Restarter then synchronizes the LSDB with all GR capable neighbors, calculates routes, updates its routing table and forwarding table, and removes stale routes. The IS-IS routing convergence is then complete.

IS-IS NSR

Nonstop routing (NSR) is a new feature that overcomes the application limit of GR. It backs up IS-IS link state information from the master device to the slave device. When a master/slave switchover occurs, NSR can complete link state recovery and route re-generation without requiring the cooperation of other devices.

Management tag

Management tag simplifies routing information management by carrying the management information of the IP address prefixes (to control route redistribution from other routing protocols) and BGP community and extended community attributes.

LSP fragment extension

IS-IS advertises link state information by flooding LSPs. Because one LSP carries a limited amount of link state information, IS-IS fragments LSPs. Each LSP fragment is uniquely identified by a combination of the System ID, Pseudonode ID (0 for a common LSP or a non-zero value for a Pseudonode LSP), and LSP Number (LSP fragment number) of the node or pseudo node that generated the LSP. The one-byte LSP Number field, allowing a maximum of only 256 fragments to be generated by an IS-IS router, limits the amount of link information the IS-IS router can advertise.

The LSP fragment extension feature allows an IS-IS router to generate more LSP fragments. Up to 50 additional virtual systems can be configured on the router, and each virtual system is capable of generating 256 LSP fragments to enable the IS-IS router to generate up to 13056 LSP fragments.

- Terms
 - **Originating system**—It is the router actually running IS-IS. After LSP fragment extension is enabled, additional virtual systems can be configured for the router. Originating system is the actual IS-IS process that originally runs.
 - **System ID**—System ID of the originating system
 - **Additional system ID**—Additional virtual system IDs are configured for the IS-IS router after LSP fragment extension is enabled. Each additional system ID can generate 256 LSP fragments. Both the additional system ID and the system ID must be unique in the entire routing domain.
 - **Virtual system**—A virtual system is identified by an additional system ID and generates extended LSP fragments.
 - **Original LSP**—The LSP generated by the originating system. The system ID in its LSP ID field is the system ID of the originating system.
 - **Extended LSP**—Extended LSPs are generated by virtual systems. The system ID in its LSP ID field is the virtual system ID.

After additional system IDs are configured, an IS-IS router can advertise more link state information in extended LSP fragments. Each virtual system can be considered a virtual router. An extended LSP fragment is advertised by a virtual system identified by an additional system ID.

- Operation modes:

The LSP fragment extension feature operates in the following modes:

- **Mode-1**—Applicable to a network where some routers do not support LSP fragment extension. In this mode, adjacencies are formed between the originating system and virtual systems, with the link cost from the originating system to each virtual system as 0. Each virtual system acts as a router connected to the originating system in the network, but the virtual systems are reachable through the originating system only. The IS-IS routers not supporting LSP fragment extension can operate properly without modifying the extended LSP fragments received, but some limitation is imposed on the link state information in the extended LSP fragments advertised by the virtual systems.
- **Mode-2**—Applicable to a network where all the routers support LSP fragment extension. In this mode, all the IS-IS routers know which virtual system belongs to which originating system; no limitation is imposed on the link state information of the extended LSP fragments advertised by the virtual systems.

The operation mode of LSP fragment extension is configured based on area and routing level. Mode-1 allows the routers supporting and not supporting LSP fragment extension to interoperate with each other, but it restricts the link state information in the extended fragments. Mode-2 does not restrict the link state information in the extended fragments, and is recommended for an area where all the routers are at the same routing level and support LSP fragment extension.

Dynamic host name mapping mechanism

The dynamic host name mapping mechanism provides the mappings between the host names and the system IDs for the IS-IS routers. The dynamic host name information is announced in the dynamic host name CLV of an LSP.

This mechanism also provides the mapping between a host name and the DIS of a broadcast network, which is announced in the dynamic host name TLV of a pseudonode LSP.

A host name is easier to remember than a system ID. After enabling this feature on the router, you can see the host names instead of system IDs using the **display** command.

BFD

Bidirectional forwarding detection (BFD) provides a single mechanism to quickly detect any link failures between IS-IS neighbors to reduce network convergence time. For more information about BFD, see *High Availability Configuration Guide*.

IS-IS configuration task list

Task	Remarks	
Configuring IS-IS basic functions	Enabling IS-IS	Required
	Configuring the IS level and circuit level	Required
	Configuring the network type of an interface as P2P	Required
	Configuring IS-IS link cost	Optional
	Specifying a priority for IS-IS	Required
Configuring IS-IS routing information control	Configuring the maximum number of ECMP routes	Optional
	Configuring IS-IS route summarization	Optional
	Advertising a default route	Optional
	Configuring IS-IS route redistribution	Optional
	Configuring IS-IS route filtering	Optional
Tuning and	Configuring IS-IS route leaking	Optional
	Specifying intervals for sending IS-IS hello and CSNP packets	Optional

Task		Remarks
optimizing IS-IS networks	Specifying the IS-IS hello multiplier	Optional
	Configuring a DIS priority for an interface	Optional
	Disabling an interface from sending or receiving IS-IS packets	Optional
	Enabling an interface to send small hello packets	Optional
	Configuring LSP parameters	Optional
	Configuring SPF parameters	Optional
	Assigning a high priority to IS-IS routes	Optional
	Setting the LSDB overload bit	Optional
	Configuring system ID to host name mappings	Optional
Enhancing IS-IS network security	Enabling the logging of neighbor state changes	Optional
	Configuring neighbor relationship authentication	Optional
	Configuring area authentication	Optional
	Configuring routing domain authentication	Optional
	Configuring IS-IS GR	Optional
	Configuring IS-IS NSR	Optional
	Configuring IS-IS FRR	Optional
	Enabling IS-IS SNMP trap	Optional
	Binding an IS-IS process with MIBs	Optional
	Configuring BFD for IS-IS	Optional

Configuring IS-IS basic functions

Configuration prerequisites

Before you configure IS-IS basic functions, complete the following tasks:

- Configure the link layer protocol.
- Configure an IP address for each interface, and make sure all neighboring nodes can reach each other at the network layer.

Enabling IS-IS

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the IS-IS routing process and enter its view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	Not enabled by default.
3. Assign a network entity title (NET).	network-entity <i>net</i>	Not assigned by default.
4. Return to system view.	quit	N/A

Step	Command	Remarks
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Enable an IS-IS process on the interface.	isis enable [<i>process-id</i>]	Disabled by default.

Configuring the IS level and circuit level

If only one area is available, HP recommends you to perform the following operations:

- Configure the IS level of all routers as Level-1 or Level-2 rather than different levels because the routers do not need to maintain two identical LSDBs.
- Configure the IS level as Level-2 on all routers in an IP network for scalability.

For an interface of a Level-1 (or Level-2) router, the circuit level can only be Level-1 (or Level-2). For an interface of a Level-1-2 router, the default circuit level is Level-1-2; if the router only needs to form Level-1 (or Level-2) neighbor relationships, then configure the circuit level for its interfaces as Level-1 (or Level-2) to limit neighbor relationship establishment.

To configure the IS level and circuit level:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify the IS level.	is-level { level-1 level-1-2 level-2 }	Optional. The default is Level-1-2.
4. Return to system view.	quit	N/A
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Specify the circuit level.	isis circuit-level [level-1 level-1-2 level-2]	Optional. By default, an interface can establish the Level-1 or Level-2 adjacency.

Configuring the network type of an interface as P2P

Perform this task only for a broadcast network that has up to two attached routers.

Interfaces with different network types operate differently. For example, broadcast interfaces on a network must elect the DIS and flood CSNP packets to synchronize the LSDBs, but P2P interfaces on a network do not need to elect the DIS, and have a different LSDB synchronization mechanism.

If only two routers exist on a broadcast network, configure the network type of attached interfaces as P2P to avoid DIS election and CSNP flooding, saving network bandwidth and speeding up network convergence.

To configure the network type of an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the network type for the interface as P2P.	isis circuit-type p2p	Optional. By default, the network type of an interface depends on the physical media. The network type of a VLAN interface is broadcast.

Configuring IS-IS routing information control

Configuration prerequisites

Before configuring IS-IS routing information control, complete the following tasks:

- Configure network layer addresses for interfaces, and make sure that adjacent nodes can reach each other at the network layer.
- Enable IS-IS.

Configuring IS-IS link cost

The IS-IS cost of an interface is determined in the following order:

1. IS-IS cost specified in interface view.
2. IS-IS cost specified in system view. The cost is applied to the interfaces associated with the IS-IS process.
3. Automatically calculated cost. If the cost style is **wide** or **wide-compatible**, IS-IS automatically calculates the cost using the formula: $\text{interface cost} = (\text{bandwidth reference value} / \text{interface bandwidth}) \times 10$, which is in the range of 1 to 16777214. For other cost styles, [Table 6](#) applies.

Table 6 Automatic cost calculation scheme for cost styles other than wide and wide-compatible

Interface bandwidth	Interface cost
≤ 10 Mbps	60
≤ 100 Mbps	50
≤ 155 Mbps	40
≤ 622 Mbps	30
≤ 2500 Mbps	20
> 2500 Mbps	10

4. If none of the above costs are used, a default cost of 10 applies.

Configuring an IS-IS cost for an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify an IS-IS cost style.	cost-style { narrow wide wide-compatible { compatible narrow-compatible } [relax-spf-limit] }	Optional. narrow by default.
4. Return to system view.	quit	N/A
5. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
6. Specify a cost for the interface.	isis cost <i>value</i> [level-1 level-2]	Optional. No cost is specified for the interface by default.

Configuring a global IS-IS cost

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify an IS-IS cost style.	cost-style { narrow wide wide-compatible { compatible narrow-compatible } [relax-spf-limit] }	Optional. narrow by default.
4. Specify a global IS-IS cost.	circuit-cost <i>value</i> [level-1 level-2]	By default, no global cost is specified.

Enabling automatic IS-IS cost calculation

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify an IS-IS cost style.	cost-style { wide wide-compatible }	narrow by default.
4. Enable automatic IS-IS cost calculation.	auto-cost enable	Disabled by default.
5. Configure a bandwidth reference value for automatic IS-IS cost calculation.	bandwidth-reference <i>value</i>	Optional. 100 Mbps by default.

Specifying a priority for IS-IS

A router can run multiple routing protocols. When routes to the same destination are found by multiple routing protocols, the route learned by the protocol with the highest priority can be adopted. You can reference a routing policy to specify a priority for specific routes. For information about routing policy, see "[Configuring routing policies.](#)"

To configure the priority of IS-IS:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify a priority for IS-IS.	preference { route-policy <i>route-policy-name</i> <i>preference</i> } *	15 by default.

Configuring the maximum number of ECMP routes

Perform this task to implement load sharing over ECMP routes.

To configure the maximum number of ECMP routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify the maximum number of ECMP routes for load balancing.	maximum load-balancing <i>number</i>	8 by default.

Configuring IS-IS route summarization

This task allows you to configure a summary route so routes falling into the network range of the summary route are summarized into one route for advertisement. Doing so can reduce the size of routing tables, as well as the scale of LSP and LSDB. Both IS-IS routes and redistributed routes can be summarized.

The router summarizes only the routes in the locally generated LSPs. The cost of the summary route is the lowest one among the costs of summarized routes.

To configure route summarization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure IS-IS route summarization.	summary <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } [avoid-feedback generate_null0_route tag <i>tag</i> [level-1 level-1-2 level-2]] *	By default, no route summarization is configured.

Advertising a default route

A router running IS-IS cannot redistribute any default routes or advertise a default route to neighbors. Use the following commands to advertise a default route of 0.0.0.0/0 to the same level neighbors.

The default route is only advertised to routers at the same level. You can use a routing policy to generate the default route only when a local routing entry is matched by the policy.

To advertise a default route:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Advertise a default route.	default-route-advertise [route-policy <i>route-policy-name</i> [level-1 level-1-2 level-2]] *	By default, the function is disabled.

Configuring IS-IS route redistribution

Redistributing large numbers of routes on a device may affect the performance of other devices in the network. If this happens, you can configure a limit on the number of redistributed routes in order to limit the number of routes to be advertised.

Only active routes can be redistributed. Use the **display ip routing-table protocol** command to display route state information.

To configure IS-IS route redistribution from other routing protocols:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Redistribute routes from another routing protocol.	import-route <i>protocol</i> [<i>process-id</i> all-processes allow-ibgp] [cost <i>cost</i> cost-type { external internal }] [level-1 level-1-2 level-2] route-policy <i>route-policy-name</i> tag tag] *	By default: <ul style="list-style-type: none"> No route is redistributed. If no level is specified, routes are redistributed into the Level-2 routing table.
4. Configure the maximum number of redistributed Level 1/Level 2 IPv4 routes.	import-route limit <i>number</i>	Optional. The default varies with devices.

Configuring IS-IS route filtering

You can reference a configured ACL, IP prefix list, or routing policy to filter routes calculated from the received LSPs and the routes redistributed from other routing protocols.

Filtering routes calculated from received LSPs

IS-IS saves the LSPs received from neighbors in the LSDB, uses the SPF algorithm to calculate the shortest path tree with itself as the root, and installs the routes into the IS-IS routing table.

By referencing a configured ACL, IP prefix list, or routing policy, you can filter the calculated routes. Only the routes matching the filter can be added into the IS-IS routing table.

To filter routes calculated from received LSPs:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Filter routes calculated from received LSPs.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> route-policy <i>route-policy-name</i> } import	By default, no filtering is configured.

Filtering redistributed routes

IS-IS can redistribute routes from other routing protocols (or other IS-IS processes), add them into the IS-IS routing table, and advertise them in LSPs.

By reference a configured ACL, IP prefix list, or routing policy, you can filter redistributed routes and only the routes matching the filter can be added into the IS-IS routing table and advertised to neighbors.

To configure the filtering of redistributed routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the filtering of routes redistributed from another routing protocol or IS-IS process.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> route-policy <i>route-policy-name</i> } export [<i>protocol</i> [<i>process-id</i>]]	Not configured by default.

Configuring IS-IS route leaking

With IS-IS route leaking enabled, the Level-1-2 router can advertise the routing information of other Level-1 areas and Level-2 area routing information to Level-1 routers.

If a filter policy is specified, only routes passing it can be advertised into Level-1 area.

You can specify a routing policy in the **import-route isis level-2 into level-1** command to filter routes from Level-2 to Level-1. Other routing policies specified for route reception and redistribution does not affect the route leaking.

To configure IS-IS route leaking:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable IS-IS route leaking.	import-route isis level-2 into level-1 [filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> route-policy <i>route-policy-name</i> } tag <i>tag</i>] *	Disabled by default.

Tuning and optimizing IS-IS networks

Configuration prerequisites

Before you tune and optimize IS-IS networks, complete the following tasks:

- Configure IP addresses for interfaces, and make adjacent nodes can reach each other at the network layer.
- Enable IS-IS.

Specifying intervals for sending IS-IS hello and CSNP packets

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify the interval for sending hello packets.	isis timer hello <i>seconds</i> [level-1 level-2]	Optional. 10 seconds by default.
4. Specify the interval for sending CSNP packets on the DIS of a broadcast network.	isis timer csnp <i>seconds</i> [level-1 level-2]	Optional. 10 seconds by default.

NOTE:

The interval between hello packets sent by the DIS is 1/3 the hello interval set with the **isis timer hello** command.

Specifying the IS-IS hello multiplier

If a neighbor receives no hello packets from the router within the advertised hold time, it considers the router down and recalculates the routes. The hold time is the hello multiplier multiplied by the hello interval.

On a broadcast link, Level-1 and Level-2 hello packets are advertised separately; therefore, you need to set a hello multiplier for each level.

On a P2P link, Level-1 and Level-2 hello packets are advertised in P2P hello packets, so you do not need to specify Level-1 or Level-2.

To specify the IS-IS hello multiplier:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify the number of hello packets a neighbor must miss before declaring the router is down.	isis timer holding-multiplier <i>value</i> [level-1 level-2]	Optional. 3 by default.

Configuring a DIS priority for an interface

On an IS-IS broadcast network, you must elect a router as the DIS at a routing level. You can specify a DIS priority at a level for an interface. The greater the interface's priority, the more likely it becomes the DIS. If multiple routers in the broadcast network have the same highest DIS priority, the router with the highest MAC address becomes the DIS.

To specify a DIS priority for an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify a DIS priority for the interface.	isis dis-priority <i>value</i> [level-1 level-2]	Optional. 64 by default.

Disabling an interface from sending or receiving IS-IS packets

After being disabled from sending or receiving hello packets, an interface cannot form a neighbor relationship, but can advertise directly connected networks in LSPs through other interfaces. This can save bandwidth and CPU resources, and ensures other routers know networks directly connected to the interface.

To disable an interface from sending and receiving IS-IS packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Disable the interface from sending and receiving IS-IS packets.	isis silent	Not disabled by default.

Enabling an interface to send small hello packets

IS-IS messages cannot be fragmented at the IP layer because they are directly encapsulated into frames. Any two IS-IS neighboring routers must negotiate a common MTU. To avoid sending big hellos for saving bandwidth, enable the interface to send small hello packets without CLVs.

To enable an interface to send small hello packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the interface to send small hello packets without CLVs.	isis small-hello	Standard hello packets are sent by default.

Configuring LSP parameters

Configuring LSP timers

- Specify the maximum age of LSPs.

Each LSP has an age that decreases in the LSDB. Any LSP with an age of 0 is deleted from the LSDB. You can adjust the age value based on the scale of a network.

To specify the maximum age of LSPs:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify the maximum LSP age.	timer lsp-max-age <i>seconds</i>	Optional. 1200 seconds by default.

- Specify the LSP refresh interval and generation interval.

Each router needs to refresh LSPs generated by itself at a configurable interval and send them to other routers to prevent valid routes from being aged out. A smaller refresh interval speeds up network convergence but consumes more bandwidth.

When the network topology changes, for example, a neighbor is down or up, or the interface metric, system ID, or area ID is changed, the router generates an LSP after a configurable interval. If such a change occurs frequently, excessive LSPs are generated, consuming a large amount of router resources and bandwidth. To solve the problem, you can adjust the LSP generation interval.

To specify the LSP refresh interval and generation interval:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify the LSP refresh interval.	timer lsp-refresh <i>seconds</i>	Optional. 900 seconds by default.
4. Specify the LSP generation interval.	timer lsp-generation <i>maximum-interval</i> [<i>initial-interval</i> [<i>second-wait-interval</i>]] [level-1 level-2]	Optional. 2 seconds by default.

- Specify LSP sending intervals.

If a change occurs in the LSDB, IS-IS advertises the changed LSP to neighbors. You can specify the minimum interval for sending such LSPs.

On a P2P link, IS-IS requires an advertised LSP be acknowledged. If no acknowledgement is received within a configurable interval, IS-IS will retransmit the LSP.

To configure LSP sending intervals:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify the minimum interval for sending LSPs and the maximum LSP number that can be sent at a time.	isis timer lsp <i>time</i> [count <i>count</i>]	Optional. By default, the minimum interval is 33 milliseconds, and the maximum LSP number that can be sent at a time is 5.
4. Specify the LSP retransmission interval on a P2P link.	isis timer retransmit <i>seconds</i>	Optional. 5 seconds by default. Configure a proper LSP retransmission interval to avoid unnecessary retransmissions.

Specifying LSP lengths

IS-IS messages cannot be fragmented at the IP layer because they are directly encapsulated in frames. IS-IS routers in an area must send LSPs smaller than the smallest interface MTU in this area.

If the IS-IS routers have different interface MTUs, HP recommends configuring the maximum size of generated LSP packets to be smaller than the smallest interface MTU in this area. If they are not, the routers must dynamically adjust the LSP packet size to fit the smallest interface MTU, which takes time and affects other services.

To specify LSP lengths:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify the maximum length of generated Level-1 LSPs or Level-2 LSPs.	lsp-length originate <i>size</i> [level-1 level-2]	1497 bytes by default.
4. Specify the maximum length of received LSPs.	lsp-length receive <i>size</i>	1497 bytes by default.

Enabling LSP flash flooding

Changed LSPs may trigger SPF recalculation, so you can enable LSP flash flooding to advertise the changed LSPs before the router recalculates routes. Doing so can speed up network convergence.

To enable LSP flash flooding:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable LSP flash flooding.	flash-flood [flood-count <i>flooding-count</i> max-timer-interval <i>flooding-interval</i> [level-1 level-2]] *	Not enabled by default.

Enabling LSP fragment extension

After LSP fragment extension is enabled for an IS-IS process, the MTUs of all the interfaces running the IS-IS process must not be less than 512; otherwise, LSP fragment extension will not take effect.

At least one virtual system must be configured for the router to generate extended LSP fragments. An IS-IS process allows 50 virtual systems.

To enable LSP fragment extension:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable LSP fragment extension and specify the working mode.	lsp-fragments-extend [[level-1 level-1-2 level-2] [mode-1 mode-2]] *	Not enabled by default.
4. Configure a virtual system ID.	virtual-system <i>virtual-system-id</i>	Not configured by default.

Configuring SPF parameters

When the LSDB changes on a router, a route calculation starts. Frequent route calculations consume a lot of system resources. You can set an appropriate interval for SPF calculations to improve efficiency.

To configure the SPF parameters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the SPF calculation interval.	timer spf <i>maximum-interval</i> [<i>initial-interval</i> [<i>second-wait-interval</i>]]	Optional. The default SPF calculation interval is 10 seconds.

Assigning a high priority to IS-IS routes

An IS-IS topology change causes network convergence. By assigning a high priority to specific IS-IS routes, you can achieve faster network convergence.

To assign a high priority to IS-IS routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A

Step	Command	Remarks
3.	Assign a high priority to IS-IS routes.	Optional. Not assigned by default. If no IS-IS route is assigned a high priority, IS-IS host routes are processed first in network convergence because they have higher priority than other types of IS-IS routes.

Setting the LSDB overload bit

By setting the overload bit in sent LSPs, a router informs other routers of a failure that makes it incapable of routing and forwarding packets.

When an IS-IS router cannot record the complete LSDB due to running out of memory or some other reasons, it will calculate wrong routes. To make troubleshooting easier, you can temporarily isolate the router from the IS-IS network by setting the overload bit.

To set the LSDB overload bit:

Step	Command	Remarks
1.	Enter system view.	N/A
2.	Enter IS-IS view.	N/A
3.	Set the overload bit.	Not set by default.

Configuring system ID to host name mappings

In IS-IS, a system ID identifies a router or host uniquely. A system ID has a fixed length of 6 bytes. When an administrator needs to view IS-IS neighbor information, routing table or LSDB information, using the system IDs in dotted decimal notation is not convenient. To solve it, you can configure the mappings between system IDs and host names, as host names are easier to remember and use.

Such mappings can be configured manually or dynamically. Note the following:

- Using the **display isis lsdb** command on a router configured with dynamic system ID to host name mapping displays router names rather than system IDs.
- If you configure both dynamic and static system ID to host name mappings on a router, the host name for dynamic system ID to host name mapping applies.

Configuring a static system ID to host name mapping

Step	Command	Remarks
1.	Enter system view.	N/A
2.	Enter IS-IS view.	N/A

Step	Command	Remarks
3.	Configure a system ID to host name mapping for a remote IS. is-name map <i>sys-id map-sys-name</i>	A system ID can only correspond to a host name.

Configuring dynamic system ID to host name mapping

Configure a static system ID to host name mapping for any other router in a network. When a new router is added into the network or a mapping must be modified, perform configuration on all routers.

You can configure dynamic system ID to host name mapping. To do so, you must configure a host name for each router in the network. Each router advertises the host name in dynamic host name CLVs to other routers. Then, all routers in the network have all the mappings to generate a mapping table.

In addition, you can configure a name for the DIS in a broadcast network to help check the origin of LSPs in the LSDB.

To configure dynamic system ID to host name mapping:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter IS-IS view. isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3.	Specify a host name for the router. is-name <i>sys-name</i>	Not specified by default.
4.	Return to system view. quit	N/A
5.	Enter interface view. interface <i>interface-type</i> <i>interface-number</i>	N/A
6.	Configure a DIS name. isis dis-name <i>symbolic-name</i>	Optional. Not configured by default. This command takes effect only on a router with dynamic system ID to host name mapping configured. This command is not supported on P2P interfaces.

Enabling the logging of neighbor state changes

Logging of neighbor state changes enables the router to output neighbor state changes to the console terminal.

To enable the logging of neighbor state changes:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter IS-IS view. isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3.	Enable the logging of neighbor state changes. log-peer-change	Enabled by default.

Enhancing IS-IS network security

To enhance the security of an IS-IS network, you can configure IS-IS authentication. IS-IS authentication involves neighbor relationship authentication, area authentication and routing domain authentication.

Configuration prerequisites

Before you enhance IS-IS network security, complete the following tasks:

- Configure IP addresses for interfaces, and make sure that all neighboring nodes can reach each other at the network layer.
- Enable IS-IS.

Configuring neighbor relationship authentication

With neighbor relationship authentication configured, an interface adds the password in the specified mode into hello packets to the peer and checks the password in the received hello packets. If the authentication succeeds, it forms the neighbor relationship with the peer.

Follow these guidelines when you configure neighbor relationship authentication:

- The authentication mode and password at both ends must be identical.
- The **level-1** and **level-2** keywords are configurable on an interface that has IS-IS enabled.
- If you configure an authentication mode and a password without specifying a level, the authentication mode and password apply to both Level-1 and Level-2.
- If neither **ip** nor **osi** is specified, the OSI related fields in LSPs are checked.

To configure neighbor relationship authentication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify the authentication mode and password.	isis authentication-mode { md5 simple } [cipher] <i>password</i> [level-1 level-2] [ip osi]	By default, no authentication is configured.

Configuring area authentication

Area authentication enables a router not to install routing information from untrusted routers into the Level-1 LSDB. The router encapsulates the authentication password in the specified mode into Level-1 packets (LSP, CSNP, and PSNP) and checks the password in received Level-1 packets.

Routers in a common area must have the same authentication mode and password.

To configure area authentication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A

Step	Command	Remarks
3. Specify the area authentication mode and password.	area-authentication-mode { md5 simple } [cipher] <i>password</i> [ip osi]	By default, no area authentication is configured.

Configuring routing domain authentication

Routing domain authentication prevents untrusted routing information from entering into a routing domain. A router with the authentication configured encapsulates the password in the specified mode into Level-2 packets (LSP, CSNP, PSNP) and check the password in received Level-2 packets.

All the routers in the backbone must have the same authentication mode and password.

To configure routing domain authentication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Specify the routing domain authentication mode and password.	domain-authentication-mode { md5 simple } [cipher] <i>password</i> [ip osi]	By default, no routing domain authentication is configured.

Configuring IS-IS GR

Restarting IS-IS on a router causes network disconnections and route reconvergence.

With the Graceful Restart (GR) feature, the restarting router—known as the GR Restarter—can notify the event to its GR capable neighbors. GR capable neighbors—known as the GR Helpers—will keep their adjacencies with the router within a configurable GR interval. After the restart, the router contacts its neighbors to retrieve its routing table.

During this process, the network keeps stable.

The IS-IS GR and IS-IS NSR features are mutually exclusive.

To configure GR on the GR Restarter and GR Helper:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IS-IS, and enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	Disabled by default.
3. Enable the GR capability for IS-IS.	graceful-restart	Disabled by default.
4. Set the Graceful Restart interval.	graceful-restart interval <i>timer</i>	300 seconds by default. The Graceful Restart interval is set as the holding time in the hello PDUs. Within the interval, the neighbors will keep their adjacency with the GR Restarter.

Step	Command	Remarks
5. Suppress the SA bit during restart.	graceful-restart suppress-sa	Optional. By default, the SA bit is not suppressed. By enabling the GR Restarter to suppress the Suppress-Advertisement (SA) bit in the hello PDUs, the neighbors will still advertise their adjacency with the GR Restarter.

Configuring IS-IS NSR

According to the GR feature, after a master/slave switchover, the GR Restarter obtains routing information from its neighbors and the IS-IS process on the new master needs to learn all routes. If the network topology has changed during the switchover period, removed routes cannot be updated to the device, which may cause black hole routes.

NSR is introduced to solve the problem. It backs up IS-IS link state information from the master device to the slave device. After a master/slave switchover, NSR can complete link state recovery and route re-generation without requiring the cooperation of other devices.

The IS-IS NSR and IS-IS GR features are mutually exclusive.

To configure IS-IS NSR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [process-id] [vpn-instance vpn-instance-name]	N/A
3. Enable IS-IS NSR.	non-stop-routing	Disabled by default.
4. Set the NSR interval.	non-stop-routing interval interval-value	0 seconds by default, that is, no NSR interval is configured.

Configuring IS-IS FRR

When a link fails, the packets on the path are discarded, or a routing loop occurs until IS-IS completes the routing convergence based on the new network topology.

You can enable IS-IS fast reroute (FRR) to reduce traffic recovery time.

Figure 62 Network diagram for IS-IS FRR

In [Figure 62](#), after you enable FRR on Router B, IS-IS automatically calculates or designates a backup next hop when a link failure is detected. In this way, packets are directed to the backup next hop to reduce

traffic recovery time. Meanwhile, IS-IS calculates the shortest path based on the new network topology, and forwards packets over the path after network convergence.

You can either enable IS-IS FRR to calculate a backup next hop automatically, or to designate a backup next hop with a routing policy for routes matching specific criteria.

Configuration prerequisites

Before you configure IS-IS FRR, complete the following tasks:

- Configure IP addresses for interfaces, and make sure that all neighboring nodes can reach each other at the network layer.
- Enable IS-IS.

Configuration guidelines

- Do not use FRR and BFD at the same time. Otherwise, FRR may fail to take effect.
- The automatic backup next hop calculation of FRR and that of TE are mutually exclusive.

Configuring IS-IS FRR to automatically calculate a backup next hop

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the source address of echo packets.	bfd echo-source-ip <i>ip-address</i>	Not configured by default
3. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
4. Enable IS-IS FRR to automatically calculate a backup next hop.	fast-reroute auto	Not configured by default

Configuring IS-IS FRR to designate a backup next hop with a routing policy

You can use the **apply fast-reroute backup-interface** command to specify a backup next hop in a routing policy for routes matching specific criteria. For more information about the **apply fast-reroute backup-interface** command and routing policy configurations, see the "[Configuring routing policies.](#)"

To configure IS-IS FRR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the source address of echo packets.	bfd echo-source-ip <i>ip-address</i>	Not configured by default.
3. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
4. Enable IS-IS FRR to designate a backup next hop by using a routing policy.	fast-reroute route-policy <i>route-policy-name</i>	Not configured by default.

Enabling IS-IS SNMP trap

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable SNMP trap.	is-snmp-traps enable	Enabled by default

Binding an IS-IS process with MIBs

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Bind the IS-IS process with MIBs.	isis mib-binding <i>process-id</i>	By default, MIBs are bound with IS-IS process 1.

Configuring BFD for IS-IS

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Enable IS-IS on the interface.	isis enable [<i>process-id</i>]	Disabled by default.
4. Enable BFD on the IS-IS interface.	isis bfd enable	Not enabled by default.

Displaying and maintaining IS-IS

Task	Command	Remarks
Display brief IS-IS configuration information.	display isis brief [<i>process-id</i> vpn-instance <i>vpn-instance-name</i>] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the status of IS-IS debug switches.	display isis debug-switches { <i>process-id</i> vpn-instance <i>vpn-instance-name</i> } [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the IS-IS Graceful Restart state.	display isis graceful-restart status [level-1 level-2] [<i>process-id</i> vpn-instance <i>vpn-instance-name</i>] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks

IS-IS configuration examples

IS-IS basic configuration

Network requirements

As shown in [Figure 63](#), Switch A, B, C, and D reside in an IS-IS AS. Switch A and B are Level-1 switches, Switch D is a Level-2 switch, and Switch C is a Level-1-2 switch. Switch A, B, and C are in Area 10, and Switch D is in Area 20.

Figure 63 Network diagram for IS-IS basic configuration

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure IS-IS:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] is-level level-1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] is-level level-1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis enable 1
[SwitchB-Vlan-interface200] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] isis enable 1
[SwitchC-Vlan-interface100] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis enable 1
[SwitchC-Vlan-interface200] quit
```

```
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis enable 1
[SwitchC-Vlan-interface300] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] isis 1
[SwitchD-isis-1] is-level level-2
[SwitchD-isis-1] network-entity 20.0000.0000.0004.00
[SwitchD-isis-1] quit
[SwitchD] interface vlan-interface 100
[SwitchD-Vlan-interface100] isis enable 1
[SwitchD-Vlan-interface100] quit
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] isis enable 1
[SwitchD-Vlan-interface300] quit
```

3. Verify the configuration:

Display the IS-IS LSDB of each switch to check the LSP integrity.

```
[SwitchA] display isis lsdb
```

```
Database information for ISIS(1)
```

DIS election configuration

Network requirements

As shown in [Figure 64](#), Switch A, B, C, and D reside in IS-IS area 10 on a broadcast network (Ethernet). Switch A and Switch B are Level-1-2 switches, Switch C is a Level-1 switch, and Switch D is a Level-2 switch. Change the DIS priority of Switch A to make it elected as the Level-1-2 DIS router.

Figure 64 Network diagram for DIS selection

Configuration procedure

1. Configure an IP address for each interface. (Details not shown.)
2. Enable IS-IS:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
```

```

Display information about IS-IS interfaces of Switch D.

```
[SwitchD] display isis interface
```

```

Interface information for ISIS(1)
-----

```

```
Interface: Vlan-interface100
```

```

Id      IPV4.State    IPV6.State    MTU    Type    DIS
001     Up           Down         1497   L1/L2   No/Yes

```

By using the default DIS priority, Switch C is the Level-1 DIS, and Switch D is the Level-2 DIS. The pseudonodes of Level-1 and Level-2 are 0000.0000.0003.01 and 0000.0000.0004.01.

3. Configure the DIS priority of Switch A:

```
[SwitchA] interface vlan-interface 100
```

```
[SwitchA-Vlan-interface100] isis dis-priority 100
```

```
[SwitchA-Vlan-interface100] quit
```

Display IS-IS neighbors of Switch A.

```

Configuring IS-IS route redistribution

Network requirements

As shown in [Figure 65](#), Switch A, Switch B, Switch C, and Switch D reside in the same AS. They use IS-IS to interconnect. Switch A and Switch B are Level-1 routers, Switch D is a Level-2 router, and Switch C is a Level-1-2 router.

Redistribute RIP routes into IS-IS on Switch D.

Figure 65 Network diagram for IS-IS route redistribution

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure IS-IS basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] is-level level-1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] is-level level-1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis enable 1
[SwitchB-Vlan-interface200] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis enable 1
[SwitchC-Vlan-interface200] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] isis enable 1
[SwitchC-Vlan-interface100] quit
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis enable 1
[SwitchC-Vlan-interface300] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] isis 1
[SwitchD-isis-1] is-level level-2
[SwitchD-isis-1] network-entity 20.0000.0000.0004.00
[SwitchD-isis-1] quit
[SwitchD] interface interface vlan-interface 300
[SwitchD-Vlan-interface300] isis enable 1
[SwitchD-Vlan-interface300] quit
```

Display IS-IS routing information on each switch.

```
[SwitchA] display isis route
```

Route information for ISIS(1)

ISIS(1) IPv4 Level-1 Forwarding Table

IPv4 Destination	IntCost	ExtCost	ExitInterface	NextHop	Flags
10.1.1.0/24	10	NULL	VLAN100	Direct	D/L/-
10.1.2.0/24	20	NULL	VLAN100	10.1.1.1	R/-/-
192.168.0.0/24	20	NULL	VLAN100	10.1.1.1	R/-/-
0.0.0.0/0	10	NULL	VLAN100	10.1.1.1	R/-/-

Flags: D-Direct, R-Added to RM, L-Advertised in LSPs, U-Up/Down Bit Set

```
[SwitchC] display isis route
```

Route information for ISIS(1)

ISIS(1) IPv4 Level-1 Forwarding Table

IPv4 Destination	IntCost	ExtCost	ExitInterface	NextHop	Flags
10.1.1.0/24	10	NULL	VLAN100	Direct	D/L/-
10.1.2.0/24	10	NULL	VLAN200	Direct	D/L/-
192.168.0.0/24	10	NULL	VLAN300	Direct	D/L/-

Flags: D-Direct, R-Added to RM, L-Advertised in LSPs, U-Up/Down Bit Set

ISIS(1) IPv4 Level-2 Forwarding Table

IPv4 Destination	IntCost	ExtCost	ExitInterface	NextHop	Flags
10.1.1.0/24	10	NULL	VLAN100	Direct	D/L/-
10.1.2.0/24	10	NULL	VLAN200	Direct	D/L/-
192.168.0.0/24	10	NULL	VLAN300	Direct	D/L/-

Flags: D-Direct, R-Added to RM, L-Advertised in LSPs, U-Up/Down Bit Set

[SwitchD] display isis route

Route information for ISIS(1)

ISIS(1) IPv4 Level-2 Forwarding Table

IPv4 Destination	IntCost	ExtCost	ExitInterface	NextHop	Flags
192.168.0.0/24	10	NULL	VLAN300	Direct	D/L/-
10.1.1.0/24	20	NULL	VLAN300	192.168.0.1	R/-/-
10.1.2.0/24	20	NULL	VLAN300	192.168.0.1	R/-/-

Flags: D-Direct, R-Added to RM, L-Advertised in LSPs, U-Up/Down Bit Set

3. Configure RIPv2 on Switch D and Switch E, and configure route redistribution from RIP to IS-IS on Switch D:

Configure RIPv2 on Switch D.

```
[SwitchD] rip 1
[SwitchD-rip-1] network 10.0.0.0
[SwitchD-rip-1] version 2
[SwitchD-rip-1] undo summary
```

Configure RIPv2 on Switch E.

```
[SwitchE] rip 1
[SwitchE-rip-1] network 10.0.0.0
[SwitchE-rip-1] version 2
[SwitchE-rip-1] undo summary
```

```
# Configure route redistribution from RIP to IS-IS on Switch D.
```

```
[SwitchD-rip-1] quit
[SwitchD] isis 1
[SwitchD-isis-1] import-route rip level-2
```

```
# Display IS-IS routing information on Switch C.
```

```
[SwitchC] display isis route
```

```
Route information for ISIS(1)
```

```
-----

10.1.5.0/24	20	NULL	VLAN300	192.168.0.2	R/L/-
10.1.6.0/24	20	NULL	VLAN300	192.168.0.2	R/L/-

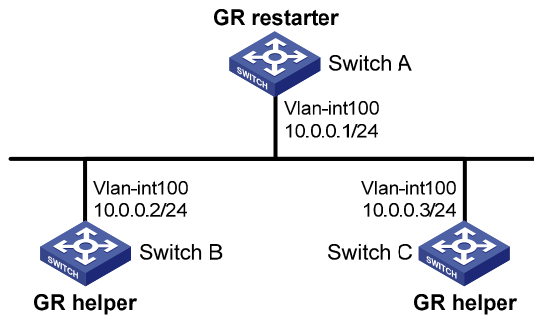

```
Flags: D-Direct, R-Added to RM, L-Advertised in LSPs, U-Up/Down Bit Set
```

IS-IS Graceful Restart configuration example

Network requirements

Switch A, Switch B, and Switch C belong to the same IS-IS routing domain, as illustrated in [Figure 66](#).

Figure 66 Network diagram for IS-IS GR configuration

Configuration procedure

1. Configure IP addresses of the interfaces on each switch and configure IS-IS:
Follow Figure 66 to configure the IP address and subnet mask of each interface. (Details not shown.)
Configure IS-IS on the switches, ensuring that Switch A, Switch B and Switch C can communicate with each other at layer 3 and dynamic route update can be implemented among them with IS-IS. (Details not shown.)

2. Configure IS-IS Graceful Restart:

Enable IS-IS Graceful Restart on Switch A and configure the Graceful Restart Interval.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] graceful-restart
[SwitchA-isis-1] graceful-restart interval 150
[SwitchA-isis-1] return
```

Configurations for Switch B and Switch C are similar; therefore, details are not shown.

3. Verify the configuration:

After Router A establishes adjacencies with Router B and Router C, they begin to exchange routing information. Restart IS-IS on Router A, which enters the restart state and sends connection requests to its neighbors through the Graceful Restart mechanism to synchronize the LSDB. Using the **display isis graceful-restart status** command can display the IS-IS GR status on Router A.

Restart the IS-IS process on Switch A.

```
<SwitchA> reset isis all 1
Warning : Reset ISIS process? [Y/N]:y
```

Check the Graceful Restart status of IS-IS on Switch A.

```
<SwitchA> display isis graceful-restart status
Restart information for IS-IS(1)
```

IS-IS(1) Level-1 Restart Status

Restart Interval: 150

SA Bit Supported

Total Number of Interfaces = 1

Restart Status: RESTARTING

Number of LSPs Awaited: 3

T3 Timer Status:

Remaining Time: 140

```

T2 Timer Status:
    Remaining Time: 59

IS-IS(1) Level-2 Restart Status
Restart Interval: 150
SA Bit Supported
    Total Number of Interfaces = 1
Restart Status: RESTARTING
Number of LSPs Awaited: 3
T3 Timer Status:
    Remaining Time: 140
T2 Timer Status:
    Remaining Time: 59

```

IS-IS NSR configuration example

Network requirements

Switch S, Switch A, and Switch B belong to the same IS-IS routing domain as illustrated in [Figure 67](#). Switch S is an IRF fabric, which is connected to Switch A and Switch B over aggregated links. Enable IS-IS NSR on Switch S to ensure correct routing when a master/slave switchover occurs on Switch S.

Figure 67 Network diagram for IS-IS NSR configuration

Configuration procedure

- Configure IP addresses for the interfaces on each switch and configure IS-IS:
Follow [Figure 67](#) to configure the IP address and subnet mask of each interface on the switches. (Details not shown.)
Configure IS-IS on the switches, ensuring that Switch S, Switch A, and Switch B can communicate with each other at Layer 3 and dynamic route update can be implemented among them with IS-IS. (Details not shown.)
- Configure IS-IS NSR:
Enable IS-IS NSR on Switch S.

```

<SwitchS> system-view
[SwitchS] isis 1
[SwitchS-isis-1] non-stop-routing
[SwitchS-isis-1] non-stop-routing interval 30
[SwitchS-isis-1] return

```
- Verify the configuration:
After Switch S establishes neighbor relationships with Switch A and Switch B, they start to exchange routing information. After network convergence, perform a master/slave switchover on Switch S. During the switchover period, use the **display isis peer** command to check the neighbor relationship between Switch A and Switch S and between Switch B and Switch S; use the **display**

isis route command to check if routes from Switch A to the loopback interface on Switch B and from Switch B to the loopback interface on Switch A exist.

When a master/slave switchover occurs on Switch S, display IS-IS neighbors and routes on Switch A.

```
<SwitchA> display isis peer
```

```

12.12.12.0/32         10         NULL
22.22.22.22/32        10         NULL

Flags: D-Direct, R-Added to RM, L-Advertised in LSPs, U-Up/Down Bit Set

```

The output shows that the neighbor relationships and routing information on Switch A and Switch B have not changed. The neighbors cannot sense the switchover on Switch S.

IS-IS FRR configuration example

Network requirements

Switch S, Switch A, and Switch D belong to the same IS-IS routing domain as illustrated in [Figure 68](#). Configure IS-IS FRR so that when the link between Switch S and Switch D fails, traffic can be switched to Link B immediately.

Figure 68 Network diagram for IS-IS FRR configuration

Configuration procedure

1. Configure IP addresses for the interfaces on each switch and configure IS-IS:

Follow [Figure 68](#) to configure the IP address and subnet mask of each interface on the switches. (Details not shown.)

Configure IS-IS on the switches, ensuring that Switch A, Switch D, and Switch S can communicate with each other at Layer 3. (Details not shown.)

2. Configure IS-IS FRR:

You can enable IS-IS FRR to either automatically calculate a backup next hop, or to designate a backup next hop by using a referenced routing policy.

Method I: Enable IS-IS FRR to automatically calculate a backup next hop.

Configure Switch S.

```
<SwitchS> system-view
[SwitchS] bfd echo-source-ip 1.1.1.1
[SwitchS] isis 1
[SwitchS-isis-1] fast-reroute auto
[SwitchS-isis-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bfd echo-source-ip 4.4.4.4
[SwitchD] isis 1
[SwitchD-isis-1] fast-reroute auto
[SwitchD-isis-1] quit
```

Method II: Enable IS-IS FRR to designate a backup next hop by using a referenced routing policy.

Configure Switch S.

```
<SwitchS> system-view
[SwitchS] bfd echo-source-ip 1.1.1.1
[SwitchS] ip ip-prefix abc index 10 permit 4.4.4.4 32
[SwitchS] route-policy frr permit node 10
[SwitchS-route-policy] if-match ip-prefix abc
[SwitchS-route-policy] apply fast-reroute backup-interface vlan-interface 100
backup-nexthop 12.12.12.2
[SwitchS-route-policy] quit
[SwitchS] isis 1
[SwitchS-isis-1] fast-reroute route-policy frr
[SwitchS-isis-1] quit
```

Configure Switch D.

```

<SwitchD> system-view
[SwitchD] bfd echo-source-ip 4.4.4.4
[SwitchD] ip ip-prefix abc index 10 permit 1.1.1.1 32
[SwitchD] route-policy frr permit node 10
[SwitchD-route-policy] if-match ip-prefix abc
[SwitchD-route-policy] apply fast-reroute backup-interface vlan-interface 101
backup-nexthop 24.24.24.2
[SwitchD-route-policy] quit
[SwitchD] isis 1
[SwitchD-isis-1] fast-reroute route-policy frr
[SwitchD-isis-1] quit

```

3. Verify the configuration:

Display route 4.4.4.4/32 on Switch S and you can view the backup next hop information.

```

[SwitchS] display ip routing-table 4.4.4.4 verbose
Routing Table : Public
Summary Count : 1

```

```

Destination: 4.4.4.4/32
  Protocol: ISIS                Process ID: 1
  Preference: 10                Cost: 10
  IpPrecedence:                QoSLeId:
  NextHop: 13.13.13.2          Interface: Vlan-interface200
  BkNextHop: 12.12.12.2       BkInterface: Vlan-interface100
  RelyNextHop: 0.0.0.0        Neighbor : 0.0.0.0
  Tunnel ID: 0x0              Label: NULL
  BKTunnel ID: 0x0           BKLabel: NULL
  State: Active Adv          Age: 00h01m27s
  Tag: 0

```

Display route 1.1.1.1/32 on Switch D. You can find the backup next hop information.

```

[SwitchD] display ip routing-table 1.1.1.1 verbose
Routing Table : Public
Summary Count : 1

```

```

IS-IS authentication configuration example

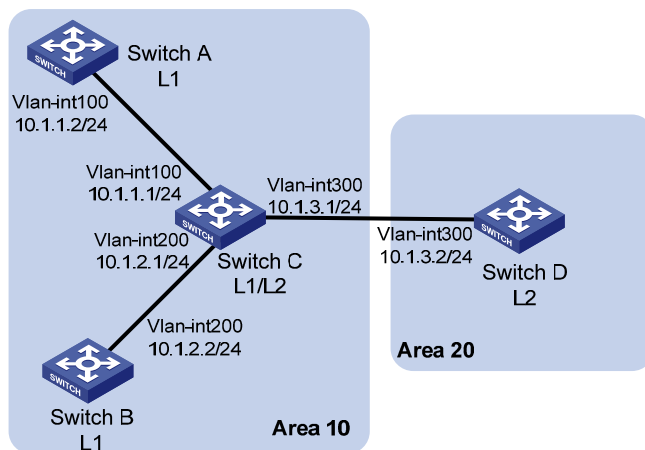

Network requirements

As shown in Figure 69, Switch A, Switch B, Switch C and Switch D reside in the same IS-IS routing domain.

Switch A, Switch B, and Switch C belong to Area 10, and Switch D belongs to Area 20.

Configure relationship authentication between neighbors. Configure area authentication in Area 10 to prevent untrusted routes from entering into the area. Configure routing domain authentication on Switch C and Switch D to prevent untrusted routes from entering the routing domain.

Figure 69 Network diagram for IS-IS authentication configuration

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure IS-IS basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis enable 1
[RouterB--Vlan-interface200] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
```

```
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis enable 1
[SwitchC-Vlan-interface200] quit
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis enable 1
[SwitchC-Vlan-interface300] quit
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis enable 1
[SwitchC-Vlan-interface300] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] isis 1
[SwitchD-isis-1] network-entity 20.0000.0000.0001.00
[SwitchD-isis-1] quit
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] isis enable 1
[SwitchD-Vlan-interface300] quit
```

3. Configure neighbor relationship authentication between neighbors:

Specify the MD5 authentication mode and password **eRq** on VLAN-interface 100 of Switch A and on VLAN-interface 100 of Switch C.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis authentication-mode md5 eRg
[SwitchA-Vlan-interface100] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] isis authentication-mode md5 eRg
[SwitchC-Vlan-interface100] quit
```

Specify the MD5 authentication mode and password **t5Hr** on VLAN-interface 200 of Switch B and on VLAN-interface 200 of Switch C.

```
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis authentication-mode md5 t5Hr
[SwitchB-Vlan-interface200] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis authentication-mode md5 t5Hr
[SwitchC-Vlan-interface200] quit
```

Specify the MD5 authentication mode and password **hSec** on VLAN-interface 300 of Switch D and on VLAN-interface 300 of Switch C.

```
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis authentication-mode md5 hSec
[SwitchC-Vlan-interface300] quit
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] isis authentication-mode md5 hSec
[SwitchD-Vlan-interface300] quit
```

4. Configure area authentication. Specify the MD5 authentication mode and password **10Sec** on Switch A, Switch B, and Switch C:

```
[SwitchA] isis 1
```

```

[SwitchA-isis-1] area-authentication-mode md5 10Sec
[SwitchA-isis-1] quit
[SwitchB] isis 1
[SwitchB-isis-1] area-authentication-mode md5 10Sec
[SwitchB-isis-1] quit
[SwitchC] isis 1
[SwitchC-isis-1] area-authentication-mode md5 10Sec
[SwitchC-isis-1] quit

```

5. Configure routing domain authentication. Specify the MD5 authentication mode and password **1020Sec** on Switch C and Switch D:

```

[SwitchC] isis 1
[SwitchC-isis-1] domain-authentication-mode md5 1020Sec
[SwitchC-isis-1] quit
[SwitchD] isis 1
[SwitchD-isis-1] domain-authentication-mode md5 1020Sec

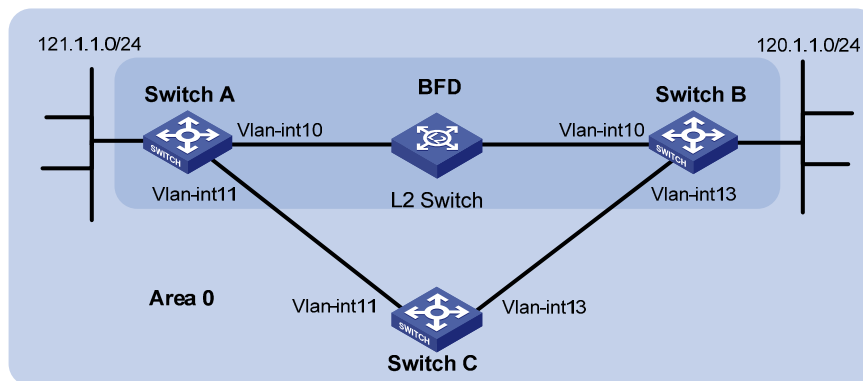

```

Configuring BFD for IS-IS

Network requirements

- As shown in [Figure 70](#), IS-IS is enabled on Switch A, Switch B and Switch C that are reachable to each other at the network layer.
- After the link over which Switch A and Switch B communicate through the Layer-2 switch fails, BFD can quickly detect the failure and notify IS-IS of the failure. Switch A and Switch B then communicate through Switch C.

Figure 70 Network diagram for BFD configuration on an IS-IS link

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int10	10.1.0.102/24	Switch B	Vlan-int10	10.1.0.100/24
	Vlan-int11	11.1.1.1/24		Vlan-int13	13.1.1.1/24
Switch C	Vlan-int11	11.1.1.2/24			
	Vlan-int13	13.1.1.2/24			

Configuration procedure

1. Configure IP addresses for interfaces (Details not shown.).
2. Configure IS-IS basic functions.
Configure Switch A.

```

<SwitchA> system-view
[SwitchA] isis
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis enable
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 11
[SwitchA-Vlan-interface11] isis enable
[SwitchA-Vlan-interface11] quit

```

Configure Switch B.

```

<SwitchB> system-view
[SwitchB] isis
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis enable
[SwitchB-Vlan-interface10] quit
[SwitchB] interface vlan-interface 13
[SwitchB-Vlan-interface13] isis enable
[SwitchB-Vlan-interface13] quit

```

Configure Switch C.

```

<SwitchC> system-view
[SwitchC] isis
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 11
[SwitchC-Vlan-interface11] isis enable
[SwitchC-Vlan-interface11] quit
[SwitchC] interface vlan-interface 13
[SwitchC-Vlan-interface13] isis enable
[SwitchC-Vlan-interface13] quit

```

3. Configure BFD parameters:

Enable BFD on Switch A and configure BFD parameters.

```

[SwitchA] bfd session init-mode active
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis bfd enable
[SwitchA-Vlan-interface10] bfd min-receive-interval 500
[SwitchA-Vlan-interface10] bfd min-transmit-interval 500
[SwitchA-Vlan-interface10] bfd detect-multiplier 7

```

Enable BFD on Switch B and configure BFD parameters.

```

[SwitchB] bfd session init-mode active
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis bfd enable
[SwitchB-Vlan-interface10] bfd min-receive-interval 500
[SwitchB-Vlan-interface10] bfd min-transmit-interval 500
[SwitchB-Vlan-interface10] bfd detect-multiplier 8

```

```
[SwitchB-Vlan-interface10] return
```

4. Verify the configuration:

The following configurations are made on Switch A. Configurations for Switch B are similar. (Details not shown.)

Display the BFD information of Switch A.

```
<SwitchA> display bfd session
Total Session Num: 1          Init Mode: Active
Session Working Under Ctrl Mode:
LD/RD      SourceAddr      DestAddr      State Holdtime Interface
3/1        10.1.0.102      10.1.0.100   Up    1700ms  vlan10
```

Display route 120.1.1.0/24 on Switch A, and you can see that Switch A and Switch B communicate through the Layer-2 switch.

```
<SwitchA> display ip routing-table 120.1.1.0 verbose
Routing Table : Public
Summary Count : 2
  Destination: 120.1.1.0/24

      State: Invalid Adv     Age: 00h58m05s
      Tag: 0
```

Enable debugging on Switch A.

```
<SwitchA> debugging isis bfd-event
<SwitchA> terminal debugging
```

When the link between Switch B and the Layer-2 switch fails, BFD can quickly detect the failure.

```

Configuring BGP

Hardware compatibility

The HP 5500 SI Switch Series does not support BGP.

BGP overview

The Border Gateway Protocol (BGP) is a dynamic inter-AS Exterior Gateway Protocol. The three early BGP versions are BGP-1 (RFC 1105), BGP-2 (RFC 1163) and BGP-3 (RFC 1267). The current version is BGP-4 (RFC 4271), and is the Internet exterior gateway protocol. The term "router" in this chapter refers to both routers and Layer 3 switches, and BGP refers to BGP-4 in this chapter.

BGP has the following characteristics:

- Focuses on the control of route propagation and the selection of optimal routes rather than the route discovery and calculation, which makes BGP, an exterior gateway protocol different from interior gateway protocols such as OSPF and RIP.
- Uses TCP to enhance reliability.
- Supports CIDR.
- Reduces bandwidth consumption by advertising only incremental updates and is applicable to advertising a great amount of routing information on the Internet.
- Eliminates routing loops completely by adding AS path information to BGP route advertisements.
- Provides abundant policies to implement flexible route filtering and selection.
- Provides good scalability.

A router advertising BGP messages is called a "BGP speaker". It establishes peer relationships with other BGP speakers to exchange routing information. When a BGP speaker receives a new route or a route better than the current one from another AS, it will advertise the route to all the other BGP peers in the local AS.

To simplify configuration, multiple peers using an identical policy can be organized as a peer group.

BGP runs on a router in either of the following modes:

- IBGP (internal BGP)
- EBGP (external BGP)

BGP is called "IBGP" when it runs within an AS, and is called "EBGP" when it runs between ASs.

BGP messages formats

Header

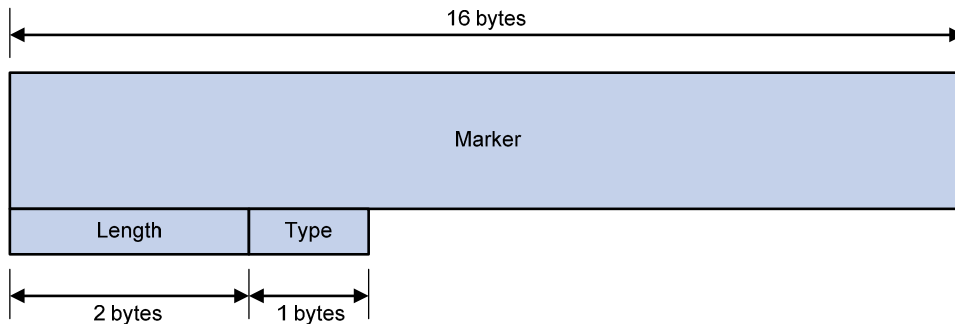

BGP has the following types of messages:

- Open
- Update
- Notification

- Keepalive
- Route-refresh

They have the same header.

Figure 71 BGP message header

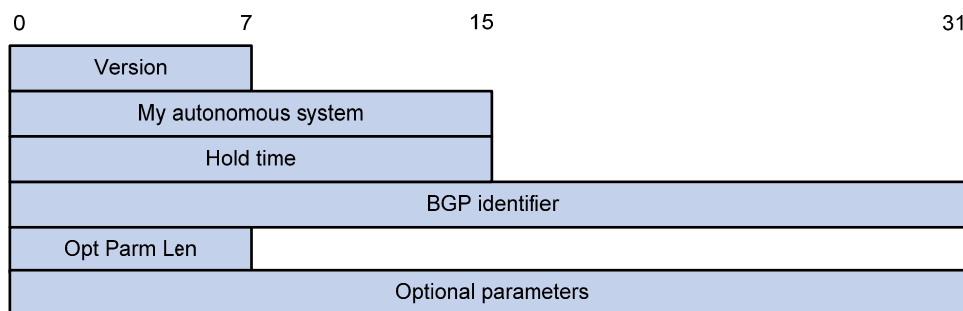

- **Marker**—The 16-byte field is used to delimit BGP messages. The Marker must be all ones.
- **Length**—The two-byte unsigned integer indicates the total length of the message.
- **Type**—This one-byte unsigned integer indicates the type code of the message. The following type codes are defined: 1–Open, 2–Update, 3–Notification, 4–Keepalive, and 5–Route-refresh. The former four listed codes are defined in RFC 1771, and the last listed code is defined in RFC 2918.

Open

After a TCP connection is established, the first message sent by each side is an open message for peer relationship establishment.

Figure 72 BGP open message format

Major fields of the BGP open message are as follows:

- **Version**—This one-byte unsigned integer indicates the protocol version number. The current BGP version is 4.
- **My autonomous system**—This two-byte unsigned integer indicates the autonomous system number of the sender.
- **Hold time**—When establishing a peer relationship, two parties negotiate an identical hold time. If no Keepalive or Update is received from a peer within the hold time, the BGP connection is considered down.
- **BGP identifier**—An IP address that identifies the BGP router.
- **Opt Parm Len (Optional Parameters Length)**—Length of optional parameters, which is set to 0 if no optional parameter is available.

- **Optional parameters**—Used for multiprotocol extensions and other functions.

Update

The update messages are used to exchange routing information between peers. It can advertise feasible routes or remove multiple unfeasible routes.

Figure 73 BGP update message format

Unfeasible routes length	2 Octets
Withdrawn routes	N Octets
Total path attribute length	2 Octets
Path attributes	N Octets
NLRI	N Octets

Each update message can advertise a group of feasible routes with identical attributes, and the routes are contained in the network layer reachability information (NLRI) field. The path attributes field carries the attributes of these routes. Each update message can also carry multiple withdrawn routes in the withdrawn routes field.

Major fields of the BGP update message are as follows:

- **Unfeasible routes length**—The total length of the withdrawn routes field in bytes. A value of 0 indicates no route is withdrawn from service, nor is the withdrawn routes field present in this update message.
- **Withdrawn routes**—This is a variable length field that contains a list of withdrawn IP prefixes.
- **Total path attribute length**—Total length of the path attributes field in bytes. A value of 0 indicates that no NLRI field is present in this update message.
- **Path attributes**—List of path attributes related to NLRI. Each path attribute is a triple <attribute type, attribute length, attribute value> of variable length. BGP uses these attributes to avoid routing loops, and perform routing and protocol extensions.
- **NLRI**— Each feasible route is represented as <length, prefix>.

Notification

A notification message is sent when an error is detected. The BGP connection is closed immediately after sending it.

Figure 74 BGP notification message format

Major fields of the BGP notification message are as follows:

- **Error code**—Type of notification.
- **Error subcode**—Specific information about the nature of the reported error.
- **Data**—Used to diagnose the reason for the notification. The contents of the data field depend on the error code and error subcode. Erroneous data can be recorded in the data field. The data field length is variable.

Keepalive

Keepalive messages are sent between peers to maintain connectivity. Its format contains only the message header.

Route-refresh

A route-refresh message is sent to a peer to request the specified address family routing information.

Figure 75 BGP route-refresh message format

- **AFI**—Address family identifier.
- **Res**—Reserved; set to 0.
- **SAFI**—Subsequent address family identifier.

BGP path attributes

Path attributes classification

BGP path attributes are a group of parameters encapsulated in the path attributes field of update messages. They give detailed route attributes information that can be used for route filtering and selection.

Path attributes fall into the following categories:

- **Well-known mandatory**—Must be recognized by all BGP routers and be included in every Update message. Routing information errors occur without this attribute.
- **Well-known discretionary**—Can be recognized by all BGP routers and optionally included in every Update message as needed.
- **Optional transitive**—Transitive attribute between ASs. A BGP router not supporting this attribute can still receive routes with this attribute and advertise them to other peers.
- **Optional non-transitive**—If a BGP router does not support this attribute, it will not advertise routes with this attribute.

The usage of each BGP path attribute is described in the following table.

Table 7 Usage of BGP path attributes

Name	Category
ORIGIN	Well-known mandatory
AS_PATH	Well-known mandatory
NEXT_HOP	Well-known mandatory
LOCAL_PREF	Well-known discretionary
ATOMIC_AGGREGATE	Well-known discretionary
AGGREGATOR	Optional transitive
COMMUNITY	Optional transitive
MULTI_EXIT_DISC (MED)	Optional non-transitive
ORIGINATOR_ID	Optional non-transitive

Name	Category
CLUSTER_LIST	Optional non-transitive

Usage of BGP path attributes

- **ORIGIN**
 ORIGIN is a well-known mandatory attribute that defines the origin of routing information (how a route became a BGP route). This attribute has the following types:
 - **IGP**—Has the highest priority. Routes added to the BGP routing table using the **network** command have the IGP attribute.
 - **EGP**—Has the second highest priority. Routes obtained via EGP have the EGP attribute.
 - **INCOMPLETE**—Has the lowest priority. The source of routes with this attribute is unknown, which does not mean such routes are unreachable. The routes redistributed from other routing protocols have the INCOMPLETE attribute.
- **AS_PATH**
 AS_PATH is a well-known mandatory attribute. This attribute identifies the autonomous systems through which routing information carried in this Update message has passed. When a route is advertised from the local AS to another AS, each passed AS number is added into the AS_PATH attribute, so the receiver can determine ASs to route the message back. The number of the AS closest to the receiver's AS is leftmost, as shown in [Figure 76](#):

Figure 76 AS_PATH attribute

Generally, a BGP router does not receive routes containing the local AS number to avoid routing loops.

NOTE:

The current implementation supports using the **peer allow-as-loop** command to receive routes containing the local AS number in order to meet special requirements.

Use the AS_PATH attribute for route selection and filtering. BGP gives priority to the route with the shortest AS_PATH length, if other factors are the same. As shown in [Figure 76](#), the BGP router in AS50 gives priority to the route passing AS40 for sending data to the destination 8.0.0.0.

In some applications, you can apply a routing policy to control BGP route selection by modifying the AS_PATH length.

By configuring an AS path filtering list, you can filter routes based on AS numbers contained in the AS_PATH attribute.

- NEXT_HOP

Different from IGP, the NEXT_HOP attribute may not be the IP address of a directly connected router. It involves the following types of values, as shown in [Figure 77](#).

- When advertising a self-originated route to an EBGP peer, a BGP speaker sets the NEXT_HOP for the route to the address of its sending interface.
- When sending a received route to an EBGP peer, a BGP speaker sets the NEXT_HOP for the route to the address of the sending interface.
- When sending a route received from an EBGP peer to an IBGP peer, a BGP speaker does not modify the NEXT_HOP attribute. If load-balancing is configured, the NEXT_HOP attribute of the equal-cost routes is modified. For load-balancing information, see "[BGP route selection.](#)"

Figure 77 NEXT_HOP attribute

- MED (MULTI_EXIT_DISC)

The MED attribute is exchanged between two neighboring ASs, each of which does not advertise the attribute to any other AS.

Similar to metrics used by IGP, MED is used to determine the best route for traffic going into an AS. When a BGP router obtains multiple routes to the same destination, but with different next hops, it considers the route with the smallest MED value the best route given that other conditions are the same. As shown in [Figure 78](#), traffic from AS10 to AS20 travels through Router B that is selected according to MED.

Figure 78 MED attribute

In general, BGP compares MEDs of routes received from the same AS only.

NOTE:

The current implementation supports using the **compare-different-as-med** command to force BGP to compare MED values of routes received from different ASs.

- LOCAL_PREF

The LOCAL_PREF attribute is exchanged between IBGP peers only; therefore, it is not advertised to any other AS. It indicates the priority of a BGP router.

LOCAL_PREF is used to determine the best route for traffic leaving the local AS. When a BGP router obtains from several IBGP peers multiple routes to the same destination, but with different next hops, it considers the route with the highest LOCAL_PREF value as the best route. As shown in Figure 79, traffic from AS20 to AS10 travels through Router C that is selected according to LOCAL_PREF.

Figure 79 LOCAL_PREF attribute

- COMMUNITY

The COMMUNITY attribute is a group of specific data. A route can carry one or more COMMUNITY attribute values (each of which is represented by a four-byte integer). The receiving router processes the route (for example, determining whether to advertise the route and the scope for advertising the route) based on the COMMUNITY attribute values. This simplifies routing policy

usage and facilitates management and maintenance. Well-known community attributes are as follows:

- **Internet**—By default, all routes belong to the Internet community. Routes with this attribute can be advertised to all BGP peers.
- **No_Export**—After received, routes with this attribute cannot be advertised out the local AS or out the local confederation, but can be advertised to other sub-ASs in the confederation. For confederation information, see "[Settlements for problems in large scale BGP networks.](#)"
- **No_Advertise**—After received, routes with this attribute cannot be advertised to other BGP peers.
- **No_Export_Subconfed**—After received, routes with this attribute cannot be advertised out the local AS or other ASs in the local confederation.

BGP route selection

Route selection rules

BGP discards routes with unreachable NEXT_HOPs. If multiple routes to the same destination are available, BGP selects the best route in the following sequence:

1. The route with the highest Preferred_value
2. The route with the highest LOCAL_PREF
3. The route originated by the local router
4. The route with the shortest AS-PATH
5. The IGP, EGP, or INCOMPLETE route in turn
6. The route with the lowest MED value
7. The route learned from EBGP, confederation, or IBGP in turn
8. The route with the smallest next hop metric
9. The route with the shortest CLUSTER_LIST
10. The route with the smallest ORIGINATOR_ID
11. The route advertised by the router with the smallest router ID
12. The route advertised by the peer with the lowest IP address

CLUSTER_IDs of route reflectors form a CLUSTER_LIST. If a route reflector receives a route that contains its own CLUSTER ID in the CLUSTER_LIST, the router discards the route to avoid routing loops.

If load balancing is configured, the system selects available routes to implement load balancing.

Route selection with BGP load balancing

The next hop of a BGP route may not be directly connected. One of the reasons is next hops in routing information exchanged between IBGPs are not modified. The BGP router needs to find the directly connected next hop via IGP. The matching route with the direct next hop is called the "recursive route". The process of finding a recursive route is route recursion.

The system supports BGP load balancing based on route recursion. If multiple recursive routes to the same destination are load balanced (suppose three direct next hop addresses), BGP generates the same number of next hops to forward packets. BGP load balancing based on route recursion is always enabled by the system rather than configured using commands.

BGP differs from IGP in the implementation of load balancing in the following ways:

- IGP routing protocols such as RIP and OSPF compute metrics of routes, and then implement load balancing over routes with the same metric and to the same destination. The route selection criterion is metric.
- BGP has no route computation algorithm, so it cannot implement load balancing according to metrics of routes. However, BGP has abundant route selection rules, through which, it selects available routes for load balancing and adds load balancing to route selection rules.

BGP implements load balancing only on routes that have the same AS_PATH, ORIGIN, LOCAL_PREF, and MED.

BGP load balancing is applicable between EBGP peers, between IBGP peers, and between confederations.

If multiple routes to the same destination are available, BGP selects a configurable number of routes for load balancing.

Figure 80 Network diagram for BGP load balancing

In the above figure, Router D and Router E are IBGP peers of Router C. Router A and Router B both advertise a route destined for the same destination to Router C. If load balancing is configured and the two routes have the same AS_PATH attribute, ORIGIN attribute, LOCAL_PREF and MED, Router C installs both the two routes to its route table for load balancing. After that, Router C forwards to Router D and Router E the route that has AS_PATH unchanged but has NEXT_HOP changed to Router C; other BGP transitive attributes are those of the best route.

BGP route advertisement rules

The current BGP implementation supports the following route advertisement rules:

- When multiple feasible routes to a destination exist, the BGP speaker advertises only the best route to its peers.
- A BGP speaker only advertises routes that it uses.
- A BGP speaker advertises routes learned through EBGP to all BGP peers, including both EBGP and IBGP peers.
- A BGP speaker does not advertise routes from an IBGP peer to other IBGP peers.
- A BGP speaker advertises routes learned through IBGP to EBGP peers. If BGP and IGP synchronization is disabled, those routes are advertised to EBGP peers directly. If the feature is enabled, only after IGP advertises those routes, can BGP advertise the routes to EBGP peers.

- A BGP speaker advertises all routes to a newly connected peer.

IBGP and IGP synchronization

Routing information synchronization between IBGP and IGP avoids giving wrong directions to routers outside of the local AS.

If a non-BGP router works in an AS, it can discard a packet because a destination is unreachable. As shown in Figure 81, Router E has learned a route of 8.0.0.0/8 from Router D via BGP. Router E then sends a packet to 8.0.0.0/8 through Router D, which finds from its routing table that Router B is the next hop (configured using the **peer next-hop-local** command). Because Router D has learned the route to Router B via IGP, it forwards the packet to Router C through route recursion. Router C is unaware of the route 8.0.0.0/8, so it discards the packet.

Figure 81 IBGP and IGP synchronization

For this example, if synchronization is enabled, and the route 8.0.0.0/24 received from Router B is available in its IGP routing table, Router D adds the route into its BGP routing table and advertises the route to the EBGP peer.

You can disable the synchronization feature in the following situations:

- The local AS is not a transitive AS (AS20 is a transitive AS in the above figure).
- Routers in the local AS are IBGP fully meshed.

Settlements for problems in large scale BGP networks

Route summarization

Route summarization can reduce the routing table size on a large network, and allow BGP routers to advertise only summary routes.

The system supports both manual and automatic route summarization. Manual route summarization allows you to determine the attribute of a summary route and whether to advertise the route.

Route dampening

BGP route dampening solves the issue of route instability such as route flaps—a route comes up and disappears in the routing table frequently.

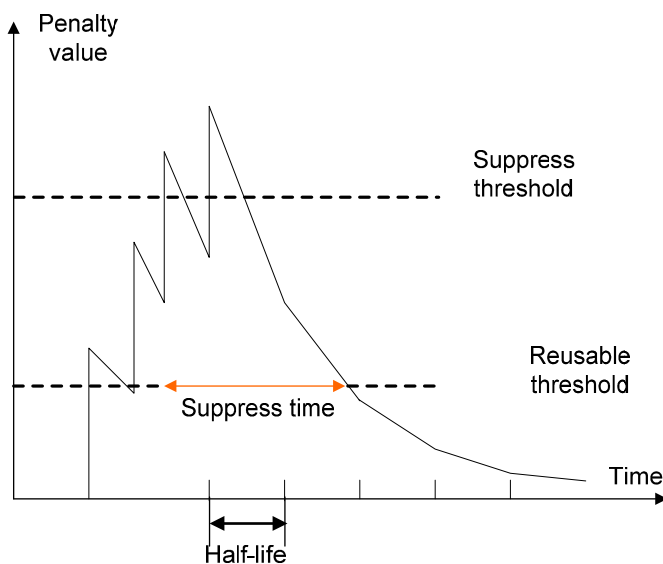

When a route flap occurs, the routing protocol sends an update to its neighbor, and then the neighbor must recalculate routes and modify the routing table. Frequent route flaps consume large bandwidth and CPU resources, which could affect network operation.

In most cases, BGP is used in complex networks, where route changes are more frequent. To solve the problem caused by route flaps, BGP route dampening is used to suppress unstable routes.

BGP route dampening, as shown in Figure 82, uses a penalty value to judge the stability of a route. The bigger the value, the less stable the route. Each time a route flap occurs, BGP adds a penalty value (1000, which is a fixed number and cannot be changed) to the route. When the penalty value of the route exceeds the suppress value, the route is suppressed from being added into the routing table or being advertised to other BGP peers.

The penalty value of the suppressed route will decrease to half of the suppress value after a period of time. This period is called "Half-life". When the value decreases to the reusable threshold value, the route is added into the routing table and advertised to other BGP peers.

Figure 82 BGP route dampening

Peer group

You can organize BGP peers with the same attributes into a group to simplify their configurations.

When a peer joins the peer group, the peer obtains the same configuration as the peer group. If the configuration of the peer group is changed, the configuration of group members is changed.

When a peer is added into a peer group, the peer has the same route update policy as the peer group to improve route distribution efficiency.

If an option is configured for both a peer and its peer group, the last configuration takes effect.

Community

A peer group provides each peer with the same policy. A community provides a group of BGP routers in several ASs with the same policy. Community is a path attribute advertised between BGP peers without being limited by AS.

A BGP router can modify the community attribute for a route before sending it to other peers.

Besides using well-known community attributes, you can define extended community attributes by using a community list to define a routing policy.

Route reflector

IBGP peers must be fully meshed to maintain connectivity. If n routers exist in an AS, the number of IBGP connections is $n(n-1)/2$, and large amounts of network and CPU resources are consumed.

Using route reflectors can resolve this issue. In an AS, a router acts as a route reflector, and other routers act as clients connecting to the route reflector. The route reflector forwards routing information between clients, so BGP sessions between clients need not be established.

A router that is neither a route reflector nor a client is a non-client, which, as shown in [Figure 83](#), must establish BGP sessions to the route reflector and other non-clients.

Figure 83 Network diagram for a route reflector

The route reflector and clients form a cluster. In some cases, you can configure more than one route reflector in a cluster to improve network reliability and prevent a single point of failure, as shown in the following figure. The configured route reflectors must have the same Cluster_ID in order to avoid routing loops.

Figure 84 Network diagram for route reflectors

When the BGP routers in an AS are fully meshed, route reflection is unnecessary because it consumes more bandwidth resources. You can use related commands to disable route reflection.

NOTE:

After route reflection is disabled between clients, routes can still be reflected between a client and a non-client.

Confederation

Confederation is another method to manage growing IBGP connections in ASs. This method splits an AS into multiple sub-ASs. In each sub-AS, IBGP peers are fully meshed, and, as shown in [Figure 85](#), intra-confederation EBGP connections are established between sub-ASs.

Figure 85 Confederation network diagram

A non-confederation BGP speaker is not required to know sub-ASs in the confederation. The ID of the confederation is the number of the AS. In the above figure, AS 200 is the confederation ID.

The deficiency of confederation is as follows:

- When changing an AS into a confederation, you must reconfigure your routers.
- The topology is changed.

In large-scale BGP networks, both route reflector and confederation can be used.

BGP GR

Graceful Restart (GR) ensures the continuity of packet forwarding when BGP restarts or an active/standby switchover occurs:

- **GR Restarter**—Graceful restarting router. It must be GR capable.
- **GR Helper**—A neighbor of the GR Restarter. It helps the GR Restarter to complete the GR process.

The following describes the BGP routing convergence process:

1. To establish a BGP session with a peer, a BGP GR Restarter sends an Open message with GR capability to the peer.
2. Upon receipt of this message, the peer is aware that the sending router is capable of Graceful Restart, and sends an Open message with GR Capability to the GR Restarter to establish a GR

session. If neither party has the GR capability, the session established between them will not be GR capable.

3. When an active/standby switchover occurs on the GR Restarter, sessions on it will go down. Then, GR-capable peers will mark all routes associated with the GR Restarter as stale. However, during the configured GR Time, they still use these routes for packet forwarding.
4. After the restart is completed, the GR Restarter will reestablish GR sessions with its peers and send a new GR message, notifying the completion of restart. Routing information is exchanged between them for the GR Restarter to create a new routing table and forwarding table and have stale routing information removed. Then the BGP routing convergence is complete.

MP-BGP

Overview

BGP-4 supports IPv4 unicasts, but does not support other network layer protocols, such as IPv6.

To support more network layer protocols, IETF extended BGP-4 by introducing Multiprotocol Extensions for BGP-4 (MP-BGP) in RFC 4760.

Routers supporting MP-BGP can communicate with routers not supporting MP-BGP.

MP-BGP extended attributes

In BGP-4, the attributes for IPv4 address format are NLRI, NEXT_HOP and AGGREGATOR (AGGREGATOR contains the IP address of the speaker generating the summary route). They are all carried in updates.

To support multiple network layer protocols, BGP-4 puts information about network layer into NLRI and NEXT_HOP. MP-BGP introduces the following path attributes:

- **MP_REACH_NLRI**—Multiprotocol Reachable NLRI, for advertising feasible routes and next hops
- **MP_UNREACH_NLRI**—Multiprotocol Unreachable NLRI, for withdrawing unfeasible routes

These path attributes are both optional non-transitive, so BGP speakers not supporting multiprotocol ignore these attributes and do not forward them to its peers.

Address family

MP-BGP uses address families to differentiate network layer protocols. For address family values, see RFC 1700, *Assigned Numbers*. The system supports multiple MP-BGP extensions, including VPN extension, and IPv6 extension. Different extensions are configured in respective address family view.

NOTE:

This chapter provides no detailed commands related to any specific extension application in MP-BGP address family view.

BGP configuration task list

Task	Remarks	
Configuring BGP basic functions	Creating a BGP connection	Required.
	Specifying the source interface for TCP connections	Optional.
	Allowing establishment of EBGP connection to an indirectly connected peer or peer group	Optional.
Controlling route generation	Injecting a local network	Required.
	Configuring BGP route redistribution	Use at least one approach.
	Enabling default route redistribution into BGP	Optional.
Controlling route distribution and reception	Configuring BGP route summarization	Optional.
	Advertising a default route to a peer or peer group	
	Configuring BGP route distribution/reception filtering policies	
	Enabling BGP and IGP route synchronization	
	Limiting prefixes received from a peer or peer group	
	Configuring BGP route dampening	
Configuring BGP route attributes	Configuring a shortcut route	Optional.
	Specifying a preferred value for routes received	
	Configuring preferences for BGP routes	
	Configuring the default local preference	
	Configuring the MED attribute	
	Configuring the next hop attribute	
Tuning and optimizing BGP networks	Configuring the AS-PATH attribute	Optional.
	Configuring the BGP keepalive interval and holdtime	Optional.

Task	Remarks	
Configuring the interval for sending the same update	Optional.	
Configuring BGP soft-reset	Optional.	
Enabling the BGP ORF capability	Optional.	
Enabling 4-byte AS number suppression	Optional.	
Setting the DSCP value for BGP packets	Optional.	
Enabling quick EBGP session reestablishment	Optional.	
Enabling MD5 authentication for TCP connections	Optional.	
Configuring BGP load balancing	Optional.	
Forbidding session establishment with a peer or peer group	Optional.	
Configuring a large scale BGP network	Configuring BGP peer groups	Optional.
	Configuring BGP community	Optional.
	Configuring a BGP route reflector	Optional.
	Configuring a BGP confederation	Optional.
Configuring BGP GR	Optional.	
Enabling trap	Optional.	
Enabling logging of peer state changes	Optional.	
Configuring BFD for BGP	Optional.	

Configuring BGP basic functions

This section does not differentiate between BGP and MP-BGP.

Configuration prerequisites

The neighboring nodes are accessible to each other at the network layer.

Creating a BGP connection

A router ID is the unique identifier of a BGP router in an AS.

- To ensure the uniqueness of a router ID and enhance network reliability, you can specify in BGP view the IP address of a local loopback interface as the router ID.
- If no router ID is specified in BGP view, the global router ID is used.
- If the global router ID is used and then it is removed, the system will select a new router ID.
- If the router ID is specified in BGP view, using the **undo router-id** command can make the system select a new router ID.

To create a BGP connection:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a global router ID.	router id <i>router-id</i>	Optional. Not configured by default. If no global router ID is configured, the highest loopback interface IP address—if any—is used as the router ID. If no loopback interface IP address is available, the highest physical interface IP address is used, regardless of the interface status.
3. Enable BGP and enter BGP view.	bgp <i>as-number</i>	Not enabled by default.
4. Specify a router ID.	router-id <i>router-id</i>	Optional. By default, the global router ID is used.
5. Specify a peer or a peer group and its AS number.	peer { <i>group-name</i> <i>ip-address</i> } as-number <i>as-number</i>	Not specified by default.
6. Enable the default use of IPv4 unicast address family for the peers that are established using the peer as-number command.	default ipv4-unicast	Optional. Enabled by default.
7. Enable a peer.	peer <i>ip-address</i> enable	Optional. Enabled by default. A router can reside in only one AS, so the router can run only one BGP process.
8. Configure a description for a peer/peer group.	peer { <i>group-name</i> <i>ip-address</i> } description <i>description-text</i>	Not configured by default. You must create a peer group before configuring it.

Specifying the source interface for TCP connections

BGP uses TCP as the transport layer protocol. By default, BGP uses the output interface of the optimal route to a peer/peer group as the source interface for establishing TCP connections to the peer or peer group.

If a BGP router has multiple links to a peer, and the source interface fails, BGP must reestablish TCP connections, causing network oscillation. To enhance stability of BGP connections, HP recommends using a loopback interface as the source interface.

To establish multiple BGP connections between two routers, you must specify the source interface for establishing TCP connections to each peer on the local router; otherwise, the local BGP router may fail to establish TCP connections to a peer when using the outbound interface of the best route to the peer as the source interface.

To specify the source interface for TCP connections:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Specify the source interface for establishing TCP connections to a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } connect-interface <i>interface-type</i> <i>interface-number</i>	By default, BGP uses the outbound interface of the best route to the BGP peer or peer group as the source interface for establishing a TCP connection to the peer or peer group.

Allowing establishment of EBGP connection to an indirectly connected peer or peer group

Direct physical links must be available between EBGP peers. If they are not, use the **peer ebgp-max-hop** command to establish a TCP connection over multiple hops between two peers.

Do not configure the **peer ebgp-max-hop** command if the two EBGP peers are directly connected.

To allow establishment of EBGP connection to an indirectly connected peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Allow the establishment of EBGP connection to an indirectly connected peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } ebgp-max-hop [<i>hop-count</i>]	Optional. Not allowed by default.

Controlling route generation

Different from IGP, BGP focuses on route generation and advertisement control and optimal route selection.

Generating BGP routes can be done in the following ways:

- Configure BGP to advertise local networks.
- Configure BGP to redistribute routes from other routing protocols, including the default route.

Configuration prerequisites

BGP connections must be created.

Injecting a local network

In BGP view, you can inject a local network to allow BGP to advertise to BGP peers. The origin attribute of routes advertised in this way is IGP. You can also reference a routing policy to flexibly control route advertisement. The network to be injected must be available in the local IP routing table.

To inject a local network:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Inject a network to the BGP routing table.	network <i>ip-address</i> [<i>mask</i> <i>mask-length</i>] route-policy <i>route-policy-name</i>	Optional. Not injected by default.

Configuring BGP route redistribution

BGP does not find routes by itself. Rather, it redistributes routing information in the local AS from other routing protocols. During route redistribution, you can configure BGP to filter routing information from specific routing protocols.

The origin attribute of routes redistributed using the **import-route** command is INCOMPLETE.

Only active routes can be redistributed. You can use the **display ip routing-table protocol** command to display route state information.

To configure BGP route redistribution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable route redistribution from a routing protocol into BGP.	import-route <i>protocol</i> [{ <i>process-id</i> all-processes } [allow-direct med <i>med-value</i> route-policy <i>route-policy-name</i>] *]	Not enabled by default. The allow-direct keyword is available only when the specified routing protocol is OSPF.

Enabling default route redistribution into BGP

Using the **import-route** command cannot redistribute a default route.

To enable default route redistribution into BGP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable route redistribution from a routing protocol into BGP.	import-route <i>protocol</i> [{ <i>process-id</i> all-processes } [allow-direct med <i>med-value</i> route-policy <i>route-policy-name</i>] *]	Not redistributed by default. The allow-direct keyword is available only when the specified routing protocol is OSPF.
4. Enable default route redistribution into BGP.	default-route imported	Optional. Not enabled by default.

Controlling route distribution and reception

Configuration prerequisites

BGP connections must be created.

Configuring BGP route summarization

To reduce the routing table size on medium and large BGP networks, you need to configure route summarization on BGP routers. BGP supports automatic and manual summarization modes. Manual summary routes have a higher priority than automatic ones.

Configuring automatic route summarization

After automatic route summarization is configured, BGP summarizes redistributed IGP subnets to advertise only natural networks. Routes injected with the **network** command cannot be summarized.

To configure automatic route summarization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure automatic route summarization.	summary automatic	Not configured by default.

Configuring manual route summarization

By configuring manual route summarization, you can summarize both redistributed routes and routes injected using the **network** command and determine the mask length for a summary route as needed.

To configure BGP manual route summarization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure manual route summarization.	aggregate <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } [as-set attribute-policy <i>route-policy-name</i> detail-suppressed origin-policy <i>route-policy-name</i> suppress-policy <i>route-policy-name</i>]*	Not configured by default.

Advertising a default route to a peer or peer group

After this task is configured, the BGP router sends a default route with the next hop being itself to the specified peer or peer group. This action is taken regardless of whether the default route is available in the routing table.

To advertise a default route to a peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Advertise a default route to a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } default-route-advertise [route-policy <i>route-policy-name</i>]	Not advertised by default.

Configuring BGP route distribution/reception filtering policies

Configuration prerequisites

Configure following filters as needed:

- ACL
- IP prefix list
- Routing policy
- AS-path ACL

For how to configure an ACL, see *ACL and QoS Configuration Guide*.

For how to configure an IP prefix list, routing policy, and AS-path ACL, see "[Configuring routing policies](#)."

Configuring BGP route distribution filtering policies

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A

Step	Command	Remarks
3. Configure BGP route distribution filtering policies.	<ul style="list-style-type: none"> Configure the filtering of redistributed routes: filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } export [direct isis <i>process-id</i> ospf <i>process-id</i> rip <i>process-id</i> static] Reference a routing policy to filter advertisements to a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } route-policy <i>route-policy-name</i> export Reference an ACL to filter advertisements to a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } filter-policy <i>acl-number</i> export Reference an AS path ACL to filter routing information sent to a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } as-path-acl <i>as-path-acl-number</i> export Reference an IP prefix list to filter routing information sent to a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } ip-prefix <i>ip-prefix-name</i> export 	<p>Configure at least one command. Not configured by default. You can configure a filtering policy as needed.</p> <p>If several filtering policies are configured, they are applied in the following sequence:</p> <ol style="list-style-type: none"> filter-policy export peer filter-policy export peer as-path-acl export peer ip-prefix export peer route-policy export <p>Only routes passing the first policy can go to the next, and only routes passing all the configured policies can be advertised.</p>

Configuring BGP route reception filtering policies

Only routes permitted by the configured filtering policies can be installed into the local BGP routing table. The members of a peer group can have different route reception filtering policies from the peer group.

To configure BGP route reception filtering policies:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A

Step	Command	Remarks
3. Configure BGP route reception filtering policies.	<ul style="list-style-type: none"> Filter incoming routes with an ACL or IP prefix list: filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } import 	Configure at least one command. No route reception filtering is configured by default. If several filtering policies are configured, they are applied in the following sequence: 4. filter-policy import 5. peer filter-policy import 6. peer as-path-acl import 7. peer ip-prefix import 8. peer route-policy import Only routes passing all the configured policies can be received.
	<ul style="list-style-type: none"> Reference a routing policy to filter routes from a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } route-policy <i>route-policy-name</i> import 	
	<ul style="list-style-type: none"> Reference an ACL to filter routing information from a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } filter-policy <i>acl-number</i> import 	
	<ul style="list-style-type: none"> Reference an AS path ACL to filter routing information from a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } as-path-acl <i>as-path-acl-number</i> import 	
	<ul style="list-style-type: none"> Reference an IP prefix list to filter routing information from a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } ip-prefix <i>ip-prefix-name</i> import 	

Enabling BGP and IGP route synchronization

By default, upon receiving an IBGP route, a BGP router checks the route's next hop. If the next hop is reachable, the BGP router advertises the route to EBGP peers. If the synchronization feature is configured, in addition to the reachability check of the next hop, the BGP router must find an active IGP route with the same destination network segment before it can advertise the IBGP route (use the **display ip routing-table protocol** command to check the IGP route state).

To enable BGP and IGP synchronization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable synchronization between BGP and IGP.	synchronization	Not enabled by default.

Limiting prefixes received from a peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A

Step	Command	Remarks
3. Configure the maximum number of prefixes allowed to be received from a peer or peer group.	<ul style="list-style-type: none"> Specify the maximum number of prefixes that can be received from a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } route-limit <i>prefix-number</i> [<i>percentage-value</i>] Specify the maximum number of prefixes that can be received from a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } route-limit <i>prefix-number</i> alert-only [<i>percentage-value</i>] Specify the maximum number of prefixes that can be received from a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } route-limit <i>prefix-number</i> reconnect <i>reconnect-time</i> [<i>percentage-value</i>] 	<p>Use one of the commands.</p> <p>No limit is configured by default.</p> <p>If the specified maximum number is reached:</p> <ul style="list-style-type: none"> For approach 1, the router breaks down the BGP connection to the peer. For approach 2, the router outputs alert information but does not break down the BGP connection to the peer. For approach 3, the router breaks down the BGP connection to the peer and then reestablishes a BGP connection to the peer.

Configuring BGP route dampening

By configuring BGP route dampening, you can suppress unstable routes from being added to the local routing table or being advertised to BGP peers.

To configure BGP route dampening:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure BGP route dampening.	dampening [<i>half-life-reachable</i> <i>half-life-unreachable</i> <i>reuse</i> <i>suppress ceiling</i> route-policy <i>route-policy-name</i>] *	Not configured by default.

Configuring a shortcut route

An EBGp route received has a priority of 255, which is lower than a local route. This task allows you to configure an EBGp route as a shortcut route. It has the same priority as a local route and is more likely to become the optimal route.

To configure a shortcut route:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A

Step	Command	Remarks
3. Configure a shortcut route.	network <i>ip-address</i> [<i>mask</i> <i>mask-length</i>] short-cut	Optional. By default, an EBGP route received has a priority of 255.

Configuring BGP route attributes

Configuration prerequisites

BGP connections must be created.

Specifying a preferred value for routes received

By default, routes received from a peer have a preferred value of 0. Among multiple routes that have the same destination and mask and are learned from different peers, the one with the greatest preferred value is selected as the route to the destination.

To specify a preferred value for routes from a peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Specify a preferred value for routes received from a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } preferred-value <i>value</i>	Optional. By default, the preferred value is 0.

Configuring preferences for BGP routes

A router can run multiple routing protocols with each having a preference. If they find the same route, the route found by the routing protocol with the highest preference is selected.

This task allows you to configure preferences for external, internal, and local BGP routes, and reference a routing policy to set preferences for matching routes as needed.

To configure preferences for BGP routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure preferences for external, internal, and local BGP routes.	preference { <i>external-preference</i> <i>internal-preference</i> <i>local-preference</i> route-policy <i>route-policy-name</i> }	Optional. The default preferences of external, internal, and local BGP routes are 255, 255, and 130.

Configuring the default local preference

The local preference is used to determine the best route for traffic leaving the local AS. When a BGP router obtains from several IBGP peers multiple routes to the same destination but with different next hops, it considers the route with the highest local preference as the best route.

This task allows you to specify the default local preference for routes sent to IBGP peers.

To specify the default local preference:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure the default local preference.	default local-preference <i>value</i>	Optional. 100 by default.

Configuring the MED attribute

MED is used to determine the best route for traffic going into an AS. When a BGP router obtains from EBGP peers multiple routes to the same destination but with different next hops, it considers the route with the smallest MED value as the best route if other conditions are the same.

Configuring the default MED value

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure the default MED value.	default med <i>med-value</i>	Optional. 0 by default.

Enabling the comparison of MED of routes from different ASs

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable the comparison of MED of routes from different ASs.	compare-different-as-med	Not enabled by default.

Enabling the comparison of MED of routes from each AS

Route learning sequence may affect optimal route selection.

Figure 86 Route selection based on MED

As shown in Figure 86, Router D learns network 10.0.0.0 from both Router A and Router B. Because Router B has a smaller router ID, the route learned from it is optimal.

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>i 10.0.0.0	2.2.2.2	50		0	300e
* i	3.3.3.3	50		0	200e

When Router D learns network 10.0.0.0 from Router C, it compares the route with the optimal route in its routing table. Because Router C and Router B reside in different ASs, BGP will not compare the MEDs of the two routes. Router C has a smaller router ID than Router B, the route from Router C becomes optimal.

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>i 10.0.0.0	1.1.1.1	60		0	200e
* i 10.0.0.0	2.2.2.2	50		0	300e
* i	3.3.3.3	50		0	200e

However, Router C and Router A reside in the same AS, and Router C has a greater MED, so network 10.0.0.0 learned from Router C cannot be optimal.

You can configure the **bestroute compare-med** command on Router D. After that, Router D puts routes received from the same AS into a group. Router D then selects the route with the lowest MED from the same group, and compares routes from different groups. This mechanism avoids the above-mentioned problem. The following output is the BGP routing table on Router D after the comparison of MED of routes from each AS is enabled. Network 10.0.0.0 learned from Router B is the optimal route.

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>i 10.0.0.0	2.2.2.2	50		0	300e
* i 10.0.0.0	3.3.3.3	50		0	200e
* i	1.1.1.1	60		0	200e

BGP load balancing cannot be implemented because load balanced routes must have the same AS-path attribute.

To enable the comparison of MED of routes from each AS:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enable the comparison of MED of routes from each AS.	bestroute compare-med	Optional. Not enabled by default.

Enabling the comparison of MED of routes from confederation peers

The MED attributes of routes from confederation peers are not compared if their AS-path attributes contain AS numbers that do not belong to the confederation, such as these three routes: AS-path attributes of them are 65006 65009, 65007 65009, and 65008 65009; and MED values of them are 2, 3, and 1. Because the third route contains an AS number that does not belong to the confederation, the first route becomes the optimal route.

To enable the comparison of MED of routes from confederation peers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enable the comparison of MED of routes from confederation peers.	bestroute med-confederation	Optional. Not enabled by default.

Configuring the next hop attribute

By default, when advertising routes to an IBGP peer or peer group, a BGP router does not set itself as the next hop. However, to ensure a BGP peer can find the correct next hop in some cases, you must configure the router as the next hop for routes sent to the peer.

For example, as shown in [Figure 87](#), Router A and Router B establish an EBGP neighbor relationship, and Router B and Router C establish an IBGP neighbor relationship. When Router B advertises a network learned from Router A to Router C, if Router C has no route to IP address 1.1.1.1/24, you must configure Router B to set itself as the next hop (3.1.1.1/24) for the route to be sent to Router C.

Figure 87 Next hop attribute configuration 1

If a BGP router has two peers on a common broadcast network, it does not set itself as the next hop for routes sent to an EBGP peer by default. As shown in [Figure 88](#), Router A and Router B establish an EBGP neighbor relationship, and Router B and Router C establish an IBGP neighbor relationship. They are on the same broadcast network 1.1.1.0/24. When Router B sends EBGP routes to Router A, it does not set itself as the next hop by default. However, you can configure Router B to set it as the next hop (1.1.1.2/24) for routes sent to Router A by using the **peer next-hop-local** command as needed.

Figure 88 Next hop attribute configuration 2

If you have configured BGP load balancing on a BGP router, the router will set it as the next hop for routes sent to an IBGP peer or peer group. This is done regardless of whether the **peer next-hop-local** command is configured.

To configure the next hop attribute:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Specify the router as the next hop of routes sent to a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } next-hop-local	Optional. By default, the router sets it as the next hop for routes sent to an EBGP peer or peer group, but does not set it as the next hop for routes sent to an IBGP peer or peer group.

Configuring the AS-PATH attribute

Permitting local AS number to appear in routes from a peer or peer group

BGP checks whether the AS_PATH attribute of a route from a peer contains the local AS number. If so, it discards the route to avoid routing loops.

To permit local AS number to appear in routes from a peer or peer group and specify the appearance times.

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Permit local AS number to appear in routes from a peer or peer group and specify the appearance times.	peer { <i>group-name</i> <i>ip-address</i> } allow-as-loop [<i>number</i>]	Optional. By default, the local AS number is not allowed.

Disabling BGP from considering AS_PATH during best route selection

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Disable BGP from considering AS_PATH during best route selection.	bestroute as-path-neglect	Optional. By default, BGP considers AS_PATH during best route selection.

Specifying a fake AS number for a peer or peer group

When Router A in AS 2 is moved to AS 3, you can configure Router A to specify a fake AS number of 2 for created connections to EBGP peers or peer groups. In this way, these EBGP peers still think Router A is in AS 2 and need not change their configurations. This feature ensures uninterrupted BGP services.

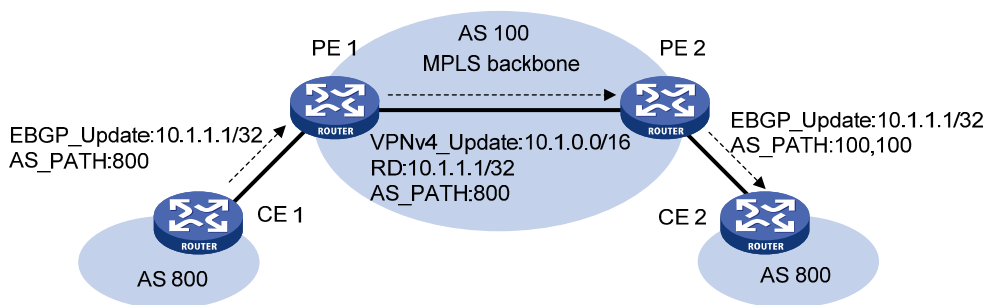

To specify a fake AS number for a peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Specify a fake AS number for a peer or peer group.	peer { group-name ip-address } fake-as as-number	Optional. Not specified by default. This command is only applicable to an EBGP peer or peer group.

Configuring AS number substitution

In L3VPN, if EBGP is used between PE and CE, sites in different geographical areas must have different AS numbers assigned to ensure correct route advertisement. If different CEs use the same AS number, you must configure the relevant PE to replace the AS number of the CE as its own AS number. This feature is used for route advertisement only.

Figure 89 AS number substitution configuration

As shown in the above figure, CE 1 and CE 2 use the same AS number of 800. If AS number substitution for CE 2 is configured on PE 2, and PE 2 receives a BGP update sent from CE 1, PE 2 replaces AS number 800 as its own AS number 100. Similar configuration must also be made on PE 1.

To configure AS number substitution for a peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Replace the AS number of a peer or peer group in the AS_PATH attribute as the local AS number.	peer { group-name ip-address } substitute-as	Not configured by default. Improper AS number substitution configuration may cause route loops; use this command with caution.

Removing private AS numbers from updates to a peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure BGP to remove private AS numbers from the AS_PATH attribute of updates to a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } public-as-only	By default, BGP updates carry private AS numbers.

Ignoring the first AS number of EBGP route updates

Typically, BGP checks the AS_PATH attribute of a route update received from a peer. If the first AS number is not that of the BGP peer, the BGP router discards the route update.

To ignore the first AS number of EBGP route updates:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure BGP to ignore the first AS number of EBGP route updates.	ignore-first-as	By default, BGP checks the first AS number of EBGP route updates.

Tuning and optimizing BGP networks

Configuration prerequisites

BGP connections must be created.

Configuring the BGP keepalive interval and holdtime

After establishing a BGP connection, two routers send keepalive messages periodically to each other to keep the connection. If a router receives no keepalive or update message from the peer within the holdtime, it tears down the connection.

You can configure the keepalive interval and holdtime globally or for a specific peer or peer group. The actual keepalive interval and holdtime depend on the following cases:

- If the holdtime settings on the local and peer routers are different, the smaller one is used. The holdtime is no less than three seconds unless it is set to 0.
- If the keepalive interval is 0 and the negotiated holdtime is not 0, the actual keepalive interval equals one-third of the holdtime. The maximum keepalive interval must be one third of the holdtime and no less than one second.
- If the keepalive interval is not 0, the actual keepalive interval is the smaller one between one third of the holdtime and the keepalive interval.

Follow these guidelines when you configure BGP keepalive interval and holdtime:

- The intervals set with the **peer timer** command are preferred to those set with the **timer** command.

- If the router has established a neighbor relationship with a peer, you must reset the BGP connection to validate the new set timers.
- The **timer** command takes effect for only new connections.
- After **peer timer** command is executed, the peer connection is closed at once, and a new connection to the peer is negotiated using the configured hold time.

To configure BGP keepalive interval and holdtime:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure BGP keepalive interval and holdtime.	<ul style="list-style-type: none"> • Configure the global keepalive interval and holdtime: timer keepalive <i>keepalive</i> hold <i>holdtime</i> • Configure the keepalive interval and holdtime for a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } timer keepalive <i>keepalive</i> hold <i>holdtime</i> 	<p>Optional.</p> <p>By default, the keepalive interval is 60 seconds, and holdtime is 180 seconds.</p>

Configuring the interval for sending the same update

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure the interval for sending the same update to a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } route-update-interval <i>interval</i>	<p>Optional.</p> <p>The intervals for sending the same update to an IBGP peer and an EBGP peer default to 15 seconds and 30 seconds.</p>

Configuring BGP soft-reset

After modifying the route selection policy, reset BGP connections to make the new one take effect.

The current BGP implementation supports the route-refresh feature that enables dynamic route refresh without tearing down BGP connections.

However, if a peer not supporting route-refresh exists in the network, you must configure the **peer keep-all-routes** command to save all routes from the peer, which are used during applying the new route selection policy.

Configuring automatic soft-reset

After route refresh is enabled for peers and a policy is modified, the router advertises a route-refresh message to the peers, which then resend their routing information to the router. After receiving the routing information, the router performs dynamic route update by using the new policy.

To enable BGP route refresh for a peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable BGP route refresh for a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } capability-advertise route-refresh	Optional. Enabled by default.

Configuring manual soft-reset

If a BGP peer does not support route-refresh, you must save updates from the peer on the local router by using the **peer keep-all-routes** command, and use the **refresh bgp** command to refresh the BGP routing table.

If the BGP peer does not support route-refresh and the **peer keep-all-routes** command is not configured for it, you need to decide whether to manually disconnect the peer to learn routes again according to the impact of the new policy.

Following these steps to save all route updates from a peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Disable BGP route-refresh and multi-protocol extension capability for a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } capability-advertise conventional	Enabled by default.
4. Save all routes from a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } keep-all-routes	Not saved by default.
5. Return to user view.	return	N/A
6. Perform manual soft reset on BGP connections.	refresh bgp { all <i>ip-address</i> group <i>group-name</i> external internal } { export import }	N/A

Enabling the BGP ORF capability

The BGP Outbound Route Filtering (ORF) feature allows a BGP speaker to send its BGP peer a set of ORFs through route-refresh messages. The peer then applies the ORFs, in addition to its local routing policies (if any), to filter updates to the BGP speaker, reducing the number of exchanged Update messages and saving network resources.

After you enable the BGP ORF capability, the local BGP router negotiates the ORF capability with the BGP peer through Open messages (determines whether to carry ORF information in messages, and if yes,

whether to carry non-standard ORF information in the packets). After completing the negotiation process and establishing the neighboring relationship, the BGP router and its BGP peer can exchange ORF information through specific route-refresh messages.

For the parameters configured on both sides for ORF capability negotiation, see [Table 8](#).

To enable the BGP ORF capability:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enable BGP route refresh for a peer or peer group.	peer { group-name ip-address } capability-advertise route-refresh	Enabled by default.
4. Enable the non-standard ORF capability for a BGP peer or peer group.	peer { group-name ip-address } capability-advertise orf non-standard	Optional. By default, standard BGP ORF capability defined in RFC 5291 and RFC 5292 is supported. If the peer supports only non-standard ORF, you need to configure this command.
5. Enable the ORF capability for a BGP peer or peer group.	peer { group-name ip-address } capability-advertise orf ip-prefix { both receive send }	Disabled by default.

Table 8 Description of the both, send, and receive parameters and the negotiation result

Local parameter	Peer parameter	Negotiation result
send	<ul style="list-style-type: none"> • receive • both 	The ORF sending capability is enabled locally and the ORF receiving capability is enabled on the peer.
receive	<ul style="list-style-type: none"> • send • both 	The ORF receiving capability is enabled locally and the ORF sending capability is enabled on the peer.
both	both	Both the ORF sending and receiving capabilities are enabled locally and on the peer.

Enabling 4-byte AS number suppression

When a switch that supports 4-byte AS numbers sends an Open message for peer relationship establishment, the Optional parameters field of the message indicates that the AS number occupies four bytes—in the range of 1 to 4294967295. If the peer device does not support 4-byte AS numbers (for examples, it supports only 2-byte AS numbers), the peer relationship cannot be established.

After you enable the 4-byte AS number suppression function, the peer device can then process the Open message even though it does not support 4-byte AS numbers, and the BGP peer relationship can be established.

If the peer device supports 4-byte AS numbers, do not enable the 4-byte AS number suppression function; otherwise, the BGP peer relationship cannot be established.

To enable 4-byte AS number suppression:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable 4-byte AS number suppression.	peer { <i>group-name</i> <i>ip-address</i> } capability-advertise suppress-4-byte-as	Disabled by default.

Setting the DSCP value for BGP packets

An IPv4 packet header contains an 8-bit Type of Service (TOS) field. As defined in RFC 2474, the first six bits set the Differentiated Services Code Point (DSCP) value and the last two bits are reserved. Network devices use the DSCP value as a reference to determine the packet priority for transmission.

You can set the DSCP value for BGP packets.

To configure the DSCP value for packets sent to a BGP peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view or BGP-VPN view.	<ul style="list-style-type: none"> • Enter BGP view: bgp <i>as-number</i> • Enter BGP-VPN instance view: <ul style="list-style-type: none"> a. bgp <i>as-number</i> b. ipv4-family vpn-instance <i>vpn-instance-name</i> 	Use either approach.
3. Set the DSCP value for the BGP packets sent to the specified BGP peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } dscp <i>dscp-value</i>	Optional. By default, the DSCP value in BGP packets is 48.

Enabling quick EBGP session reestablishment

If the router receives no keepalive messages from a BGP peer within the holdtime, it disconnects from the peer.

With quick EBGP connection reestablishment enabled, the router will reestablish a session to the EBGP peer immediately when the link to a directly connected EBGP peer is down.

To enable quick EBGP session reestablishment:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable quick EBGP session reestablishment.	ebgp-interface-sensitive	Optional. Not enabled by default.

Enabling MD5 authentication for TCP connections

BGP employs TCP as the transport protocol. To increase security, configure BGP to perform MD5 authentication when establishing a TCP connection. The two parties must have the same password configured to establish TCP connections.

BGP MD5 authentication is not for BGP packets, but for TCP connections. If the authentication fails, no TCP connection can be established.

To enable MD5 authentication for TCP connections:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable MD5 authentication when establishing a TCP connection to the peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } password { cipher simple } <i>password</i>	Optional. Not enabled by default.

Configuring BGP load balancing

If multiple paths to a destination exist, you can configure load balancing over such paths to improve link utilization.

To configure BGP load balancing:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure the maximum number of BGP routes for load balancing.	balance <i>number</i>	Optional. By default, Load balancing is not enabled.

Forbidding session establishment with a peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Forbid session establishment with a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } ignore	Optional. Not forbidden by default.

Configuring a large scale BGP network

In a large-scale BGP network, configuration and maintenance become difficult because of the large numbers of BGP peers. To facilitate configuration, you can configure peer group, community, route reflector, or confederation as needed.

Configuration prerequisites

Peering nodes are accessible to each other at the network layer.

Configuring BGP peer groups

A peer group is a group of peers with the same route selection policy.

In a large-scale network, many peers may use the same route selection policy. You can configure a peer group and add these peers into this group. In this way, peers can share the same policy as the peer group. When the policy of the group is modified, the modification also applies to peers in it, simplifying configuration.

A peer group is an IBGP peer group if peers in it belong to the same AS, and is an EBGP peer group if peers in it belong to different ASs.

If a peer group has peers added, you cannot remove its AS number using the **undo** form of the command or change its AS number.

Configuring an IBGP peer group

After you create an IBGP peer group and then add a peer into it, the system creates the peer in BGP view and specifies the local AS number for the peer.

To configure an IBGP peer group:

Step	Command
1. Enter system view.	system-view
2. Enter BGP view.	bgp <i>as-number</i>
3. Create an IBGP peer group.	group <i>group-name</i> [internal]
4. Add a peer into the IBGP peer group.	peer <i>ip-address</i> group <i>group-name</i>

Configuring an EBGP peer group

If peers in an EBGP group belong to the same external AS, the EBGP peer group is a pure EBGP peer group; if not, it is a mixed EBGP peer group.

Use one of the following approaches to configure an EBGP peer group:

- Create the EBGP peer group, specify its AS number, and add peers into it. All the added peers share the same AS number.
- Create the EBGP peer group, specify an AS number for a peer, and add the peer into the peer group.
- Create the EBGP peer group and add a peer into it with an AS number specified.

To configure an EBGP peer group using Approach 1:

Step	Command
1. Enter system view.	system-view
2. Enter BGP view.	bgp <i>as-number</i>
3. Create an EBGP peer group.	group <i>group-name</i> external
4. Specify the AS number for the group.	peer <i>group-name</i> as-number <i>as-number</i>
5. Add the peer into the group.	peer <i>ip-address</i> group <i>group-name</i>

NOTE:

- Do not specify any AS number for a peer before adding it into the peer group.
- All of the added peers have the same AS number as that of the peer group.

To configure an EBGP peer group using Approach 2:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Create an EBGP peer group.	group <i>group-name</i> external	N/A
4. Specify an AS number for a peer.	peer <i>ip-address</i> as-number <i>as-number</i>	N/A
5. Add the peer into the group.	peer <i>ip-address</i> group <i>group-name</i> [as-number <i>as-number</i>]	The AS number can be either specified or not specified in the command. If specified, the AS number must be the same as that specified for the peer with the peer <i>ip-address</i> as-number <i>as-number</i> command.

NOTE:

Peers added in the group can have different AS numbers.

To configure an EBGP peer group using Approach 3:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Create an EBGP peer group.	group <i>group-name</i> external	N/A
4. Add a peer into the group and specify its AS number.	peer <i>ip-address</i> group <i>group-name</i> as-number <i>as-number</i>	N/A

NOTE:

- Do not specify any AS number for a peer before adding it into the peer group.
 - Peers added in the group can have different AS numbers.
-

Configuring BGP community

A BGP community is a group of destinations with the same characteristics. It has no geographical boundaries and is independent of ASs.

You can configure a routing policy to define which destinations belong to a BGP community and then advertise the community attribute to a peer or peer group.

You can apply a routing policy to filter routes advertised to or received from a peer or peer group according to the community attribute, which helps simplify policy configuration and management.

For how to configure a routing policy, see "[Configuring routing policies.](#)"

To configure BGP community:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Advertise the community attribute to a peer or peer group.	<ul style="list-style-type: none">• Advertise the community attribute to a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } advertise-community• Advertise the extended community attribute to a peer or peer group: peer { <i>group-name</i> <i>ip-address</i> } advertise-ext-community	Not configured by default.
4. Apply a routing policy to routes advertised to a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } route-policy <i>route-policy-name</i> export	Not configured by default.

Configuring a BGP route reflector

If an AS has many BGP routers, you can configure them as a cluster by configuring one of them as a route reflector and others as clients to reduce IBGP connections.

To enhance network reliability and prevent single point of failure, specify multiple route reflectors for a cluster. The route reflectors in the cluster must have the same cluster ID to avoid routing loops.

It is not required to make clients of a route reflector fully meshed. The route reflector forwards routing information between clients. If clients are fully meshed, disable route reflection between clients to reduce routing costs.

Generally, a cluster has only one route reflector, and the router ID is used to identify the cluster. You can configure multiple route reflectors to improve network stability. To avoid routing loops, specify the same cluster ID for these route reflectors by using the **reflector cluster-id** command.

To configure a BGP route reflector:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure the router as a route reflector and specify a peer or peer group as its client.	peer { <i>group-name</i> <i>ip-address</i> } reflect-client	Not configured by default.
4. Enable route reflection between clients.	reflect between-clients	Optional. Enabled by default.
5. Configure the cluster ID of the route reflector.	reflector cluster-id <i>cluster-id</i>	Optional. By default, a route reflector uses its router ID as the cluster ID.

Configuring a BGP confederation

Configuring a BGP confederation is another way for reducing IBGP connections in an AS.

A confederation contains sub ASs. In each sub AS, IBGP peers are fully meshed. Between sub ASs, EBGP connections are established.

If routers not compliant with RFC 3065 exist in the confederation, use the **confederation nonstandard** command to make the local router compatible with these routers.

Configuring a BGP confederation

After you split an AS into multiple sub ASs, you can configure a router in a sub AS as follows:

1. Enable BGP and specify the AS number of the router.
2. Specify the confederation ID. From an outsider's perspective, the sub ASs of the confederation is a single AS, which is identified by the confederation ID.
3. If the router must establish EBGP connections to other sub ASs, you must specify the peering sub ASs in the confederation.

A confederation contains a maximum of 32 sub ASs. The AS number of a sub AS is effective only in the confederation.

To configure a BGP confederation:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure a confederation ID.	confederation id <i>as-number</i>	Not configured by default.
4. Specify peering sub ASs in the confederation.	confederation peer-as <i>as-number-list</i>	Not configured by default.

Configuring confederation compatibility

If some other routers in the confederation do not comply with RFC 3065, enable confederation compatibility to allow the router to work with those routers.

To configure confederation compatibility:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enable compatibility with routers not compliant with RFC 3065 in the confederation.	confederation nonstandard	Optional. Not enabled by default.

Configuring BGP GR

Perform the following configuration on the GR Restarter and GR Helper.

Follow these guidelines when you configure BGP GR:

- A device can act as a GR Restarter and GR Helper at the same time.
- The maximum time allowed for the peer (the GR restarter) to reestablish a BGP session must be less than the Holdtime carried in the Open message.
- The End-Of-RIB (End of Routing-Information-Base) indicates the end of route updates.

To configure BGP GR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable BGP and enter its view.	bgp as-number	N/A
3. Enable GR Capability for BGP.	graceful-restart	Disabled by default.
4. Configure the maximum time allowed for the peer to reestablish a BGP session.	graceful-restart timer restart timer	Optional. 150 seconds by default.
5. Configure the maximum time to wait for the End-of-RIB marker.	graceful-restart timer wait-for-rib timer	Optional. 180 seconds by default.

Enabling trap

After trap is enabled for BGP, BGP generates Level-4 traps to report important events. The generated traps are sent to the information center of the device. The trap output rules (whether to output the traps and the output direction) are determined according to the information center configuration. (For information center configuration, see *Network Management and Monitoring Configuration Guide*.)

To enable trap:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable trap for BGP.	snmp-agent trap enable bgp	Optional. Enabled by default.

Enabling logging of peer state changes

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable the logging of peer state changes globally.	log-peer-change	Optional. Enabled by default.
4. Enable the logging of peer state changes for a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } log-change	Optional. Enabled by default.

Configuring BFD for BGP

BGP maintains neighbor relationships based on the keepalive timer and holdtime timer, which are set in seconds. BGP defines that the holdtime interval must be at least three times the keepalive interval. This slows down link failure detection; once a failure occurs on a high-speed link, a large quantity of packets will be dropped. BFD is introduced to solve this problem. It detects links between neighbors quickly to reduce convergence time upon link failures.

After a link failure occurs, BFD may detect the failure before the system performs GR. As a result, GR will fail. If GR capability is enabled for BGP, use BFD with caution. If GR and BFD are both enabled, do not disable BFD during a GR process; otherwise, GR may fail. For BFD configuration, see *High Availability Configuration Guide*.

⚠ IMPORTANT:

Before configuring BFD for BGP, you must enable BGP.

To enable BFD for a BGP peer:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable BFD for the specified BGP peer.	peer <i>ip-address</i> bfd	Not enabled for any BGP peer by default.

Displaying and maintaining BGP

Displaying BGP

Task	Command	Remarks
Display peer group information.	display bgp group [<i>group-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display advertised BGP routing information.	display bgp network [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display AS path information.	display bgp paths [<i>as-regular-expression</i> { begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP peer or peer group information.	display bgp peer [<i>ip-address</i> { log-info verbose } <i>group-name</i> log-info verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the prefix information in the ORF packet from the specified BGP peer.	display bgp peer <i>ip-address</i> received ip-prefix [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP routing information.	display bgp routing-table [<i>ip-address</i> [{ <i>mask</i> <i>mask-length</i> } [longer-prefixes]]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing information matching the AS path ACL.	display bgp routing-table as-path-acl <i>as-path-acl-number</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP CIDR routing information.	display bgp routing-table cidr [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP routing information matching the specified BGP community.	display bgp routing-table community [<i>aa:nn</i> <1-13>] [no-advertise no-export no-export-subconfed] * [whole-match] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing information matching a BGP community list.	display bgp routing-table community-list { { <i>basic-community-list-number</i> <i>comm-list-name</i> } [whole-match] <i>adv-community-list-number</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP dampened routing information.	display bgp routing-table dampened [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP dampening parameter information.	display bgp routing-table dampening parameter [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP routing information originating from different ASs.	display bgp routing-table different-origin-as [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP routing flap statistics.	display bgp routing-table flap-info [<i>regular-expression as-regular-expression</i> [as-path-acl <i>as-path-acl-number</i> <i>ip-address</i> [{ <i>mask</i> <i>mask-length</i> } [longer-match]]]] [{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display labeled BGP routing information.	display bgp routing-table label [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing information to or from a peer.	display bgp routing-table peer <i>ip-address</i> { advertised-routes received-routes } [<i>network-address</i> [<i>mask</i> <i>mask-length</i>]] statistic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing information matching a regular expression.	display bgp routing-table regular-expression <i>as-regular-expression</i>	Available in any view

Task	Command	Remarks
Display BGP routing statistics.	display bgp routing-table statistic [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the global router ID.	display router id [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Resetting BGP connections

Task	Command	Remarks
Reset all BGP connections.	reset bgp all	Available in user view
Reset the BGP connections to an AS.	reset bgp as-number	Available in user view
Reset the BGP connection to a peer.	reset bgp ip-address [flap-info]	Available in user view
Reset all EBGP connections.	reset bgp external	Available in user view
Reset the BGP connections to a peer group.	reset bgp group <i>group-name</i>	Available in user view
Reset all IBGP connections.	reset bgp internal	Available in user view
Reset all IPv4 unicast BGP connections.	reset bgp ipv4 all	Available in user view

Clearing BGP information

Task	Command	Remarks
Clear dampened BGP routing information and release suppressed routes.	reset bgp dampening [<i>ip-address</i> [<i>mask</i> <i>mask-length</i>]]	Available in user view
Clear route flap information.	reset bgp flap-info [<i>ip-address</i> [<i>mask-length</i> <i>mask</i>] as-path-acl <i>as-path-acl-number</i> regex <i>as-path-regular-expression</i>]	Available in user view

BGP configuration examples

BGP basic configuration

Network requirements

In [Figure 90](#), run EBGP between Switch A and Switch B and IBGP between Switch B and Switch C so that Switch C can access the network 8.1.1.0/24 connected to Router A.

Figure 90 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure IBGP:
 - To prevent route flapping caused by port state changes, this example uses loopback interfaces to establish IBGP connections.
 - Because loopback interfaces are virtual interfaces, you need to use the **peer connect-interface** command to specify the loopback interface as the source interface for establishing BGP connections.
 - Enable OSPF in AS 65009 to make sure that Switch B can communicate with Switch C through loopback interfaces.

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 65009
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] peer 3.3.3.3 as-number 65009
[SwitchB-bgp] peer 3.3.3.3 connect-interface loopback 0
[SwitchB-bgp] quit
[SwitchB] ospf 1
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 2.2.2.2 0.0.0.0
[SwitchB-ospf-1-area-0.0.0.0] network 9.1.1.1 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 65009
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] peer 2.2.2.2 as-number 65009
[SwitchC-bgp] peer 2.2.2.2 connect-interface loopback 0
[SwitchC-bgp] quit
[SwitchC] ospf 1
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 3.3.3.3 0.0.0.0
[SwitchC-ospf-1-area-0.0.0.0] network 9.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
[SwitchC] display bgp peer
```

```

BGP local router ID : 3.3.3.3
Local AS number : 65009
Total number of peers : 1                Peers in established state : 1

Peer                AS  MsgRcvd  MsgSent  OutQ  PrefRcv  Up/Down  State
2.2.2.2            65009    2        2    0      0 00:00:13 Established

```

The output shows that Switch C has established an IBGP peer relationship with Switch B.

3. Configure EBGP:

- The EBGP peers, Switch A and Switch B (usually belong to different carriers), are located in different ASs. Typically, their loopback interfaces are not reachable to each other, so directly connected interfaces are used for establishing BGP sessions.
- To enable Switch C to access the network 8.1.1.0/24 connected directly to Switch A, inject network 8.1.1.0/24 to the BGP routing table of Switch A.

Configure Switch A.

```

<SwitchA> system-view
[SwitchA] bgp 65008
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] peer 3.1.1.1 as-number 65009
[SwitchA-bgp] network 8.1.1.1 24
[SwitchA-bgp] quit

```

Configure Switch B.

```

[SwitchB] bgp 65009
[SwitchB-bgp] peer 3.1.1.2 as-number 65008
[SwitchB-bgp] quit

```

Display BGP peer information on Switch B.

```

[SwitchB] display bgp peer

```

```

BGP local router ID : 2.2.2.2
Local AS number : 65009
Total number of peers : 2                Peers in established state : 2

Peer                AS  MsgRcvd  MsgSent  OutQ  PrefRcv  Up/Down  State
3.3.3.3            65009    4        4    0      0 00:02:49 Established
3.1.1.2            65008    2        2    0      0 00:00:05 Established

```

The output shows that Switch B has established an IBGP peer relationship with Switch C and an EBGP peer relationship with Switch A.

Display the BGP routing table on Switch A.

```

[SwitchA] display bgp routing-table

```

```

Total Number of Routes: 1

```

```

BGP Local router ID is 1.1.1.1

```

```

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
              h - history, i - internal, s - suppressed, S - Stale

```

Origin : i - IGP, e - EGP, ? - incomplete

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*> 8.1.1.0/24	0.0.0.0	0		0	i

Display the BGP routing table on Switch B.

[SwitchB] display bgp routing-table

Total Number of Routes: 1

BGP Local router ID is 2.2.2.2

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
h - history, i - internal, s - suppressed, S - Stale
Origin : i - IGP, e - EGP, ? - incomplete

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*> 8.1.1.0/24	3.1.1.2	0		0	65008i

Display the BGP routing table on Switch C.

[SwitchC] display bgp routing-table

Total Number of Routes: 1

BGP Local router ID is 3.3.3.3

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
h - history, i - internal, s - suppressed, S - Stale
Origin : i - IGP, e - EGP, ? - incomplete

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
i 8.1.1.0/24	3.1.1.2	0	100	0	65008i

The outputs show that Switch A has learned no route to AS65009, and Switch C has learned network 8.1.1.0 but the next hop 3.1.1.2 is unreachable, so the route is invalid.

4. Redistribute direct routes:

Configure BGP to redistribute direct routes on Switch B, so that Switch A can obtain the route to 9.1.1.0/24 and Switch C can obtain the route to 3.1.1.0/24.

Configure Switch B.

[SwitchB] bgp 65009

[SwitchB-bgp] import-route direct

Display the BGP routing table on Switch A.

[SwitchA] display bgp routing-table

Total Number of Routes: 4

BGP Local router ID is 1.1.1.1

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
h - history, i - internal, s - suppressed, S - Stale

Origin : i - IGP, e - EGP, ? - incomplete

	Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>	2.2.2.2/32	3.1.1.1	0		0	65009?
*	3.1.1.0/24	3.1.1.1	0		0	65009?
*>	8.1.1.0/24	0.0.0.0	0		0	i
*>	9.1.1.0/24	3.1.1.1	0		0	65009?

Two routes 2.2.2.2/32 and 9.1.1.0/24 have been added in Switch A's routing table.

Display the BGP routing table on Switch C.

```
[SwitchC] display bgp routing-table
```

Total Number of Routes: 4

BGP Local router ID is 3.3.3.3

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
h - history, i - internal, s - suppressed, S - Stale
Origin : i - IGP, e - EGP, ? - incomplete

	Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
i	2.2.2.2/32	2.2.2.2	0	100	0	?
*>i	3.1.1.0/24	2.2.2.2	0	100	0	?
*>i	8.1.1.0/24	3.1.1.2	0	100	0	65008i
* i	9.1.1.0/24	2.2.2.2	0	100	0	?

The output shows that the route 8.1.1.0 becomes valid with the next hop as Switch A.

5. Verify the configuration:

Ping 8.1.1.1 on Switch C.

```
[SwitchC] ping 8.1.1.1
```

```
PING 8.1.1.1: 56 data bytes, press CTRL_C to break
Reply from 8.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
Reply from 8.1.1.1: bytes=56 Sequence=2 ttl=254 time=2 ms
Reply from 8.1.1.1: bytes=56 Sequence=3 ttl=254 time=2 ms
Reply from 8.1.1.1: bytes=56 Sequence=4 ttl=254 time=2 ms
Reply from 8.1.1.1: bytes=56 Sequence=5 ttl=254 time=2 ms
--- 8.1.1.1 ping statistics ---
5 packet(s) transmitted
5 packet(s) received
0.00% packet loss
round-trip min/avg/max = 2/2/2 ms
```

BGP and IGP synchronization configuration

Network requirements

As shown in [Figure 91](#), all devices of company A belong to AS 65008, and all devices of company B belong to AS 65009. AS 65008 and AS 65009 are connected through Switch A and Switch B. Switch

A must be able to access network 9.1.2.0/24 in AS 65009, and Switch C must access network 8.1.1.0/24 in AS 65008.

Figure 91 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF:

Enable OSPF in AS 65009, so that Switch B can obtain the route to 9.1.2.0/24.

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf 1
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 2.2.2.2 0.0.0.0
[SwitchB-ospf-1-area-0.0.0.0] network 9.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf 1
[SwitchC-ospf-1] import-route direct
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 9.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

3. Configure the EBGp connection:

Configure the EBGp connection and inject network 8.1.1.0/24 to the BGP routing table of Switch A, so that Switch B can obtain the route to 8.1.1.0/24.

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 65008
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] peer 3.1.1.1 as-number 65009
[SwitchA-bgp] network 8.1.1.0 24
[SwitchA-bgp] quit
```

Configure Switch B.

```
[SwitchB] bgp 65009
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] peer 3.1.1.2 as-number 65008
```

4. Configure BGP and IGP synchronization:

- Configure BGP to redistribute routes from OSPF on Switch B, so that Switch A can obtain the route to 9.1.2.0/24.
- Configure OSPF to redistribute routes from BGP on Switch B, so that Switch C can obtain the route to 8.1.1.0/24.

Configure BGP to redistribute routes from OSPF on Switch B.

```
[SwitchB-bgp] import-route ospf 1
[SwitchB-bgp] quit
[SwitchB] ospf 1
[SwitchB-ospf-1] import-route bgp
[SwitchB-ospf-1] quit
```

Display the BGP routing table on Switch A.

```
[SwitchA] display bgp routing-table
```

Total Number of Routes: 3

BGP Local router ID is 1.1.1.1

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,

h - history, i - internal, s - suppressed, S - Stale

Origin : i - IGP, e - EGP, ? - incomplete

	Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>	3.3.3.3/32	3.1.1.1	1		0	65009?

Reply from 8.1.1.1: bytes=56 Sequence=5 ttl=254 time=2 ms

--- 8.1.1.1 ping statistics ---
 5 packet(s) transmitted
 5 packet(s) received
 0.00% packet loss
 round-trip min/avg/max = 2/2/2 ms

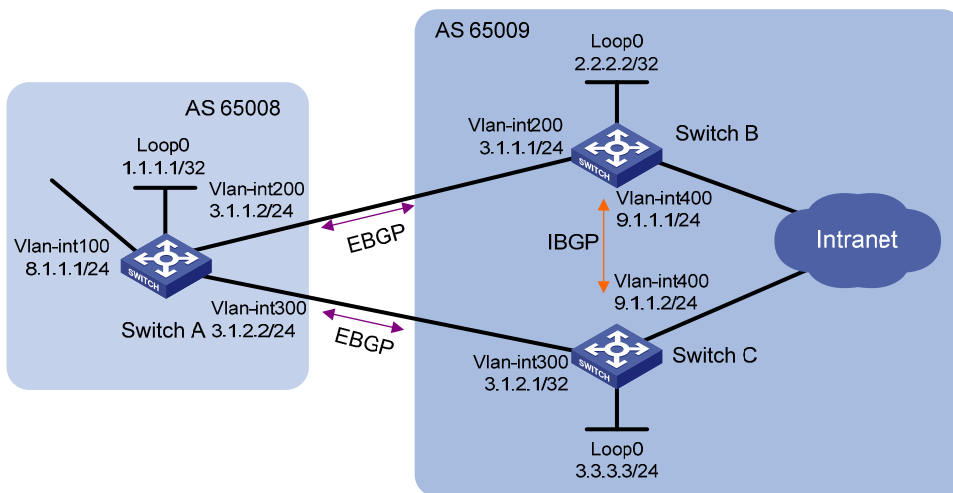

```

BGP load balancing configuration

Network requirements

As shown in [Figure 92](#), all the switches run BGP. Switch A resides in AS 65008, Switch B and Switch C in AS 65009. Between Switch A and Switch B, Switch A and Switch C are EBGP connections, and between Switch B and Switch C is an IBGP connection. Two routes are configured on Switch A for load balancing.

Figure 92 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP connections:
 - On Switch A, establish EBGP connections with Switch B and Switch C; configure BGP to advertise network 8.1.1.0/24 to Switch B and Switch C, so that Switch B and Switch C can access the internal network connected to Switch A.
 - On Switch B, establish an EBGP connection with Switch A and an IBGP connection with Switch C; configure BGP to advertise network 9.1.1.0/24 to Switch A, so that Switch A can access the intranet through Switch B; configure a static route to interface loopback 0 on Switch C (or use a routing protocol like OSPF) to establish the IBGP connection.
 - On Switch C, establish an EBGP connection with Switch A and an IBGP connection with Switch B; configure BGP to advertise network 9.1.1.0/24 to Switch A, so that Switch A can access the intranet through Switch C; configure a static route to interface loopback 0 on Switch B (or use another protocol like OSPF) to establish the IBGP connection.

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 65008
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] peer 3.1.1.1 as-number 65009
[SwitchA-bgp] peer 3.1.2.1 as-number 65009
[SwitchA-bgp] network 8.1.1.1 24
[SwitchA-bgp] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 65009
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] peer 3.1.1.2 as-number 65008
[SwitchB-bgp] peer 3.3.3.3 as-number 65009
[SwitchB-bgp] peer 3.3.3.3 connect-interface loopback 0
[SwitchB-bgp] network 9.1.1.0 255.255.255.0
[SwitchB-bgp] quit
[SwitchB] ip route-static 3.3.3.3 32 9.1.1.2
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 65009
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] peer 3.1.2.2 as-number 65008
[SwitchC-bgp] peer 2.2.2.2 as-number 65009
[SwitchC-bgp] peer 2.2.2.2 connect-interface loopback 0
[SwitchC-bgp] network 9.1.1.0 255.255.255.0
[SwitchC-bgp] quit
[SwitchC] ip route-static 2.2.2.2 32 9.1.1.1
```

Display the BGP routing table on Switch A.

```
[SwitchA] display bgp routing-table
```

```
Total Number of Routes: 3
```

BGP Local router ID is 1.1.1.1

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
h - history, i - internal, s - suppressed, S - Stale
Origin : i - IGP, e - EGP, ? - incomplete

	Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>	8.1.1.0/24	0.0.0.0	0		0	i
*>	9.1.1.0/24	3.1.1.1	0		0	65009i
*		3.1.2.1	0		0	65009i

- The output shows two valid routes to destination 9.1.1.0/24: the route with next hop 3.1.1.1 is marked with a greater-than sign (>), indicating it is the best route (because the ID of Switch B is smaller); the route with next hop 3.1.2.1 is marked with only an asterisk (*), indicating it is a valid route, but not the best.
- By using the **display ip routing-table** command, you can find only one route to 9.1.1.0/24 with next hop 3.1.1.1 and outbound interface VLAN-interface 200.

3. Configure loading balancing:

Since Switch A has two routes to reach AS 65009, configuring load balancing over the two BGP routes on Switch A can improve link utilization.

Configure Switch A.

```
[SwitchA] bgp 65008
[SwitchA-bgp] balance 2
[SwitchA-bgp] quit
```

4. Verify the configuration:

Display the BGP routing table on Switch A.

```
[SwitchA] display bgp routing-table
```

Total Number of Routes: 3

BGP Local router ID is 1.1.1.1

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
h - history, i - internal, s - suppressed, S - Stale
Origin : i - IGP, e - EGP, ? - incomplete

	Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>	8.1.1.0/24	0.0.0.0	0		0	i
*>	9.1.1.0/24	3.1.1.1	0		0	65009i
*>		3.1.2.1	0		0	65009i

- The route 9.1.1.0/24 has two next hops 3.1.1.1 and 3.1.2.1, both of which are marked with a greater-than sign (>), indicating they are the best routes.
- By using the **display ip routing-table** command, you can find two routes to 9.1.1.0/24: one with next hop 3.1.1.1 and outbound interface VLAN-interface 200, the other with next hop 3.1.2.1 and outbound interface VLAN-interface 300.

BGP community configuration

Network requirements

As shown in Figure 93, Switch B establishes EBGP connections with Switch A and C. Configure No_Export community attribute on Switch A to make routes from AS 10 not advertised by AS 20 to any other AS.

Figure 93 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure EBGP:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 10
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] peer 200.1.2.2 as-number 20
[SwitchA-bgp] network 9.1.1.0 255.255.255.0
[SwitchA-bgp] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 20
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] peer 200.1.2.1 as-number 10
[SwitchB-bgp] peer 200.1.3.2 as-number 30
[SwitchB-bgp] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 30
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] peer 200.1.3.1 as-number 20
[SwitchC-bgp] quit
```

Display the BGP routing table on Switch B.

```
[SwitchB] display bgp routing-table 9.1.1.0
```

```
BGP local router ID : 2.2.2.2
```

```
Local AS number : 20
Paths: 1 available, 1 best
```

BGP routing table entry information of 9.1.1.0/24:

```
From : 200.1.2.1 (1.1.1.1)
Original nexthop: 200.1.2.1
AS-path : 10
Origin : igp
Attribute value : MED 0, pref-val 0, pre 255
State : valid, external, best,
Advertised to such 1 peers:
    200.1.3.2
```

Switch B advertised routes to Switch C in AS30.

Display the routing table on Switch C.

```
[SwitchC] display bgp routing-table
```

```
Total Number of Routes: 1
```

```
BGP Local router ID is 3.3.3.3
```

```
Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
              h - history, i - internal, s - suppressed, S - Stale
              Origin : i - IGP, e - EGP, ? - incomplete
```

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*> 9.1.1.0/24	200.1.3.1	0		0	20 10i

Switch C has learned route 9.1.1.0/24 from Switch B.

3. Configure BGP community:

Configure a routing policy.

```
[SwitchA] route-policy comm_policy permit node 0
[SwitchA-route-policy] apply community no-export
[SwitchA-route-policy] quit
```

Apply the routing policy.

```
[SwitchA] bgp 10
[SwitchA-bgp] peer 200.1.2.2 route-policy comm_policy export
[SwitchA-bgp] peer 200.1.2.2 advertise-community
```

Display the routing table on Switch B.

```
[SwitchB] display bgp routing-table 9.1.1.0
BGP local router ID : 2.2.2.2
Local AS number : 20
Paths: 1 available, 1 best
```

BGP routing table entry information of 9.1.1.0/24:

```
From : 200.1.2.1 (1.1.1.1)
Original nexthop: 200.1.2.1
Community : No-Export
AS-path : 10
Origin : igp
```

Attribute value : MED 0, pref-val 0, pre 255
State : valid, external, best,
Not advertised to any peers yet

The route 9.1.1.0/24 is not available in the routing table of Switch C.

BGP route reflector configuration

Network requirements

In Figure 94, all switches run BGP.

- Between Switch A and Switch B is an EBGP connection; between Switch C and Switch B, and between Switch C and Switch D are IBGP connections.
- Switch C is a route reflector with clients Switch B and D.
- Switch D can learn route 1.0.0.0/8 from Switch C.

Figure 94 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP connections:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] peer 192.1.1.2 as-number 200
```

Inject network 1.0.0.0/8 to the BGP routing table.

```
[SwitchA-bgp] network 1.0.0.0
[SwitchA-bgp] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] peer 192.1.1.1 as-number 100
[SwitchB-bgp] peer 193.1.1.1 as-number 200
[SwitchB-bgp] peer 193.1.1.1 next-hop-local
[SwitchB-bgp] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] peer 193.1.1.2 as-number 200
[SwitchC-bgp] peer 194.1.1.2 as-number 200
[SwitchC-bgp] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bgp 200
[SwitchD-bgp] router-id 4.4.4.4
[SwitchD-bgp] peer 194.1.1.1 as-number 200
[SwitchD-bgp] quit
```

3. Configure the route reflector:

Configure Switch C.

```
[SwitchC] bgp 200
[SwitchC-bgp] peer 193.1.1.2 reflect-client
[SwitchC-bgp] peer 194.1.1.2 reflect-client
[SwitchC-bgp] quit
```

4. Verify the configuration:

Display the BGP routing table on Switch B.

```
[SwitchB] display bgp routing-table
```

Total Number of Routes: 1

BGP Local router ID is 200.1.2.2

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
h - history, i - internal, s - suppressed, S - Stale
Origin : i - IGP, e - EGP, ? - incomplete

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*> 1.0.0.0	192.1.1.1	0		0	100i

Display the BGP routing table on Switch D.

```
[SwitchD] display bgp routing-table
```

Total Number of Routes: 1

BGP Local router ID is 200.1.2.1

Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
h - history, i - internal, s - suppressed, S - Stale
Origin : i - IGP, e - EGP, ? - incomplete

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
i 1.0.0.0	193.1.1.2	0	100	0	100i

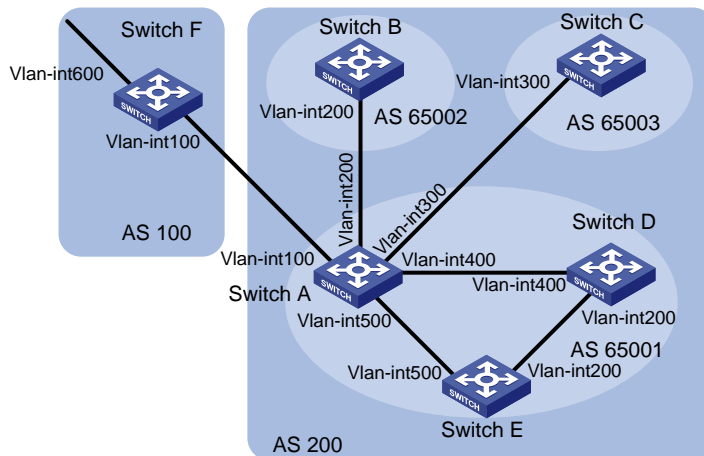

Switch D has learned route 1.0.0.0/8 from Switch C.

BGP confederation configuration

Network requirements

In Figure 95, to reduce IBGP connections in AS 200, split it into three sub-ASs: AS65001, AS65002, and AS65003. Switches in AS65001 are fully meshed.

Figure 95 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	200.1.1.1/24	Switch D	Vlan-int200	10.1.5.1/24
	Vlan-int200	10.1.1.1/24		Vlan-int400	10.1.3.2/24
	Vlan-int300	10.1.2.1/24	Switch E	Vlan-int200	10.1.5.2/24
	Vlan-int400	10.1.3.1/24		Vlan-int500	10.1.4.2/24
	Vlan-int500	10.1.4.1/24		Switch F	Vlan-int100
Switch B	Vlan-int200	10.1.1.2/24	Vlan-int600		9.1.1.1/24
Switch C	Vlan-int300	10.1.2.2/24			

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP confederation:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 65001
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] confederation id 200
[SwitchA-bgp] confederation peer-as 65002 65003
[SwitchA-bgp] peer 10.1.1.2 as-number 65002
[SwitchA-bgp] peer 10.1.1.2 next-hop-local
[SwitchA-bgp] peer 10.1.2.2 as-number 65003
[SwitchA-bgp] peer 10.1.2.2 next-hop-local
[SwitchA-bgp] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 65002
[SwitchB-bgp] router-id 2.2.2.2
```

```
[SwitchB-bgp] confederation id 200
[SwitchB-bgp] confederation peer-as 65001 65003
[SwitchB-bgp] peer 10.1.1.1 as-number 65001
[SwitchB-bgp] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 65003
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] confederation id 200
[SwitchC-bgp] confederation peer-as 65001 65002
[SwitchC-bgp] peer 10.1.2.1 as-number 65001
[SwitchC-bgp] quit
```

3. Configure IBGP connections in AS65001:

Configure Switch A.

```
[SwitchA] bgp 65001
[SwitchA-bgp] peer 10.1.3.2 as-number 65001
[SwitchA-bgp] peer 10.1.3.2 next-hop-local
[SwitchA-bgp] peer 10.1.4.2 as-number 65001
[SwitchA-bgp] peer 10.1.4.2 next-hop-local
[SwitchA-bgp] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bgp 65001
[SwitchD-bgp] router-id 4.4.4.4
[SwitchD-bgp] confederation id 200
[SwitchD-bgp] peer 10.1.3.1 as-number 65001
[SwitchD-bgp] peer 10.1.5.2 as-number 65001
[SwitchD-bgp] quit
```

Configure Switch E.

```
<SwitchE> system-view
[SwitchE] bgp 65001
[SwitchE-bgp] router-id 5.5.5.5
[SwitchE-bgp] confederation id 200
[SwitchE-bgp] peer 10.1.4.1 as-number 65001
[SwitchE-bgp] peer 10.1.5.1 as-number 65001
[SwitchE-bgp] quit
```

4. Configure the EBGP connection between AS100 and AS200:

Configure Switch A.

```
[SwitchA] bgp 65001
[SwitchA-bgp] peer 200.1.1.2 as-number 100
[SwitchA-bgp] quit
```

Configure Switch F.

```
<SwitchF> system-view
[SwitchF] bgp 100
[SwitchF-bgp] router-id 6.6.6.6
[SwitchF-bgp] peer 200.1.1.1 as-number 200
[SwitchF-bgp] network 9.1.1.0 255.255.255.0
```

```
[SwitchF-bgp] quit
```

5. Verify the configuration:

```
# Display the routing table on Switch B.
```

```
[SwitchB] display bgp routing-table
```

```
Total Number of Routes: 1
```

```
BGP Local router ID is 2.2.2.2
```

```
Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,  
              h - history, i - internal, s - suppressed, S - Stale  
              Origin : i - IGP, e - EGP, ? - incomplete
```

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>i 9.1.1.0/24	10.1.1.1	0	100	0	(65001) 100i

```
[SwitchB] display bgp routing-table 9.1.1.0
```

```
BGP local router ID : 2.2.2.2
```

```
Local AS number : 65002
```

```
Paths: 1 available, 1 best
```

```
BGP routing table entry information of 9.1.1.0/24:
```

```
From : 10.1.1.1 (1.1.1.1)  
Relay Nexthop : 0.0.0.0  
Original nexthop: 10.1.1.1  
AS-path : (65001) 100  
Origin : igp  
Attribute value : MED 0, localpref 100, pref-val 0, pre 255  
State : valid, external-confed, best,  
Not advertised to any peers yet
```

```
# Display the BGP routing table on Switch D.
```

```
[SwitchD] display bgp routing-table
```

```
Total Number of Routes: 1
```

```
BGP Local router ID is 4.4.4.4
```

```
Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,  
              h - history, i - internal, s - suppressed, S - Stale  
              Origin : i - IGP, e - EGP, ? - incomplete
```

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>i 9.1.1.0/24	10.1.3.1	0	100	0	100i

```
[SwitchD] display bgp routing-table 9.1.1.0
```

```
BGP local router ID : 4.4.4.4
```

```
Local AS number : 65001
```

```
Paths: 1 available, 1 best
```

```
BGP routing table entry information of 9.1.1.0/24:
```

```

From          : 10.1.3.1 (1.1.1.1)
Relay Nexthop : 0.0.0.0
Original nexthop: 10.1.3.1
AS-path       : 100
Origin        : igp
Attribute value : MED 0, localpref 100, pref-val 0, pre 255
State         : valid, internal, best,
Not advertised to any peers yet

```

The output shows the following:

- Switch F can send route information to Switch B and Switch C through the confederation by establishing only an EBGP connection with Switch A.
- Switch B and Switch D are in the same confederation, but belong to different sub ASs. They obtain external route information from Switch A and generate the same BGP route entries; it seems like they reside in the same AS although they have no direct connection in between.

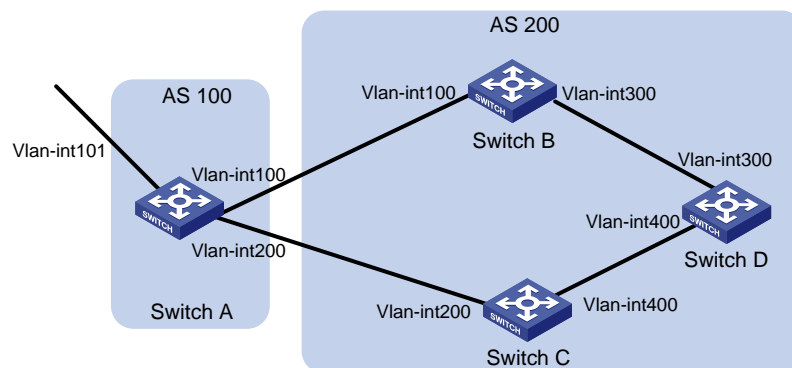

BGP path selection configuration

Network requirements

In [Figure 96](#), all switches run BGP. Between Switch A and Switch B, and between Switch A and Switch C are EBGP connections. Between Switch B and Switch D, and between Switch D and Switch C are IBGP connections. OSPF is the IGP protocol in AS 200.

Configure routing policies, making Switch D use the route 1.0.0.0/8 from Switch C as the optimal.

Figure 96 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int101	1.0.0.0/8	Switch D	Vlan-int400	195.1.1.1/24
	Vlan-int100	192.1.1.1/24		Vlan-int300	194.1.1.1/24
	Vlan-int200	193.1.1.1/24	Switch C	Vlan-int400	195.1.1.2/24
Switch B	Vlan-int100	192.1.1.2/24		Vlan-int200	193.1.1.2/24
	Vlan-int300	194.1.1.2/24			

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF on Switch B, C, and D:

Configure Switch B.

```
<SwitchB> system-view
```

```
[SwitchB] ospf
[SwitchB-ospf] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] network 194.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 193.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] network 195.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ospf
[SwitchD-ospf] area 0
[SwitchD-ospf-1-area-0.0.0.0] network 194.1.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] network 195.1.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] quit
[SwitchD-ospf-1] quit
```

3. Configure BGP connections:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp] peer 192.1.1.2 as-number 200
[SwitchA-bgp] peer 193.1.1.2 as-number 200
```

Inject network 1.0.0.0/8 to the BGP routing table on Switch A.

```
[SwitchA-bgp] network 1.0.0.0 8
[SwitchA-bgp] quit
```

Configure Switch B.

```
[SwitchB] bgp 200
[SwitchB-bgp] peer 192.1.1.1 as-number 100
[SwitchB-bgp] peer 194.1.1.1 as-number 200
[SwitchB-bgp] quit
```

Configure Switch C.

```
[SwitchC] bgp 200
[SwitchC-bgp] peer 193.1.1.1 as-number 100
[SwitchC-bgp] peer 195.1.1.1 as-number 200
[SwitchC-bgp] quit
```

Configure Switch D.

```
[SwitchD] bgp 200
[SwitchD-bgp] peer 194.1.1.2 as-number 200
[SwitchD-bgp] peer 195.1.1.2 as-number 200
[SwitchD-bgp] quit
```

4. Configure attributes for route 1.0.0.0/8, making Switch D give priority to the route learned from Switch C:

o Method I

Configure a higher MED value for the route 1.0.0.0/8 advertised from Switch A to peer 192.1.1.2.

Define an ACL numbered 2000 to permit route 1.0.0.0/8.

```
[SwitchA] acl number 2000
[SwitchA-acl-basic-2000] rule permit source 1.0.0.0 0.255.255.255
[SwitchA-acl-basic-2000] quit
```

Define two routing policies, **apply_med_50**, which sets the MED for route 1.0.0.0/8 to 50, and **apply_med_100**, which sets the MED for route 1.0.0.0/8 to 100.

```
[SwitchA] route-policy apply_med_50 permit node 10
[SwitchA-route-policy] if-match acl 2000
[SwitchA-route-policy] apply cost 50
[SwitchA-route-policy] quit
[SwitchA] route-policy apply_med_100 permit node 10
[SwitchA-route-policy] if-match acl 2000
[SwitchA-route-policy] apply cost 100
[SwitchA-route-policy] quit
```

Apply routing policy **apply_med_50** to the route advertised to peer 193.1.1.2 (Switch C), and **apply_med_100** to the route advertised to peer 192.1.1.2 (Switch B).

```
[SwitchA] bgp 100
[SwitchA-bgp] peer 193.1.1.2 route-policy apply_med_50 export
[SwitchA-bgp] peer 192.1.1.2 route-policy apply_med_100 export
[SwitchA-bgp] quit
```

Display the BGP routing table on Switch D.

```
[SwitchD] display bgp routing-table
```

```
Total Number of Routes: 2
```

```
BGP Local router ID is 194.1.1.1
```

```
Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
```

```
h - history, i - internal, s - suppressed, S - Stale
```

```
Origin : i - IGP, e - EGP, ? - incomplete
```

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>i 1.0.0.0	193.1.1.1	50	100	0	100i
* i	192.1.1.1	100	100	0	100i

Route 1.0.0.0/8 is the optimal.

o Method II

Configure different local preferences on Switch B and C for route 1.0.0.0/8, making Switch D give priority to the route from Switch C.

Define an ACL numbered 2000 on Router C, permitting route 1.0.0.0/8.

```
[SwitchC] acl number 2000
[SwitchC-acl-basic-2000] rule permit source 1.0.0.0 0.255.255.255
[SwitchC-acl-basic-2000] quit
```

```
# Configure a routing policy named localpref on Switch C, setting the local preference of route 1.0.0.0/8 to 200 (the default is 100).
```

```
[SwitchC] route-policy localpref permit node 10
[SwitchC-route-policy] if-match acl 2000
[SwitchC-route-policy] apply local-preference 200
[SwitchC-route-policy] quit
```

```
# Apply routing policy localpref to routes from peer 193.1.1.1.
```

```
[SwitchC] bgp 200
[SwitchC-bgp] peer 193.1.1.1 route-policy localpref import
[SwitchC-bgp] quit
```

```
# Display the routing table on Switch D.
```

```
[SwitchD] display bgp routing-table
```

```
Total Number of Routes: 2
```

```
BGP Local router ID is 194.1.1.1
```

```
Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
              h - history, i - internal, s - suppressed, S - Stale
              Origin : i - IGP, e - EGP, ? - incomplete
```

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>i 1.0.0.0	193.1.1.1	0	200	0	100i
* i	192.1.1.1	0	100	0	100i

```
Route 1.0.0.0/8 from Switch D to Switch C is the optimal.
```

BGP GR configuration

Network requirements

All switches run BGP in [Figure 97](#). Between Switch A and Switch B is an EBGP connection. Switch B and Switch C are connected over an IBGP connection. Enable GR capability for BGP so that the communication between Switch A and Switch C is not affected when a master/slave switchover occurs on Switch B.

Figure 97 Network diagram

Configuration procedure

1. Configure Switch A:

```
# Configure IP addresses for interfaces. (Details not shown.)
```

```
# Configure the EBGP connection.
```

```
<SwitchA> system-view
```

```
[SwitchA] bgp 65008
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] peer 200.1.1.1 as-number 65009
# Inject network 8.0.0.0/8 to the BGP routing table.
[SwitchA-bgp] network 8.0.0.0
# Enable GR capability for BGP.
[SwitchA-bgp] graceful-restart
```

2. Configure Switch B:

```
# Configure IP addresses for interfaces. (Details not shown.)
# Configure the EBGP connection.
<SwitchB> system-view
[SwitchB] bgp 65009
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] peer 200.1.1.2 as-number 65008
# Configure the IBGP connection.
[SwitchB-bgp] peer 9.1.1.2 as-number 65009
# Inject networks 200.1.1.0/24 and 9.1.1.0/24 to the BGP routing table.
[SwitchB-bgp] network 200.1.1.0 24
[SwitchB-bgp] network 9.1.1.0 24
# Enable GR capability for BGP.
[SwitchB-bgp] graceful-restart
```

3. Configure Switch C:

```
# Configure IP addresses for interfaces. (Details not shown.)
# Configure the IBGP connection.
<SwitchC> system-view
[SwitchC] bgp 65009
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] peer 9.1.1.1 as-number 65009
# Enable GR capability for BGP.
[SwitchC-bgp] graceful-restart
```

4. Verify the configuration:

Ping Switch C on Switch A. Meanwhile, perform a master/slave switchover on Switch B. The ping operation is successful during the whole switchover process.

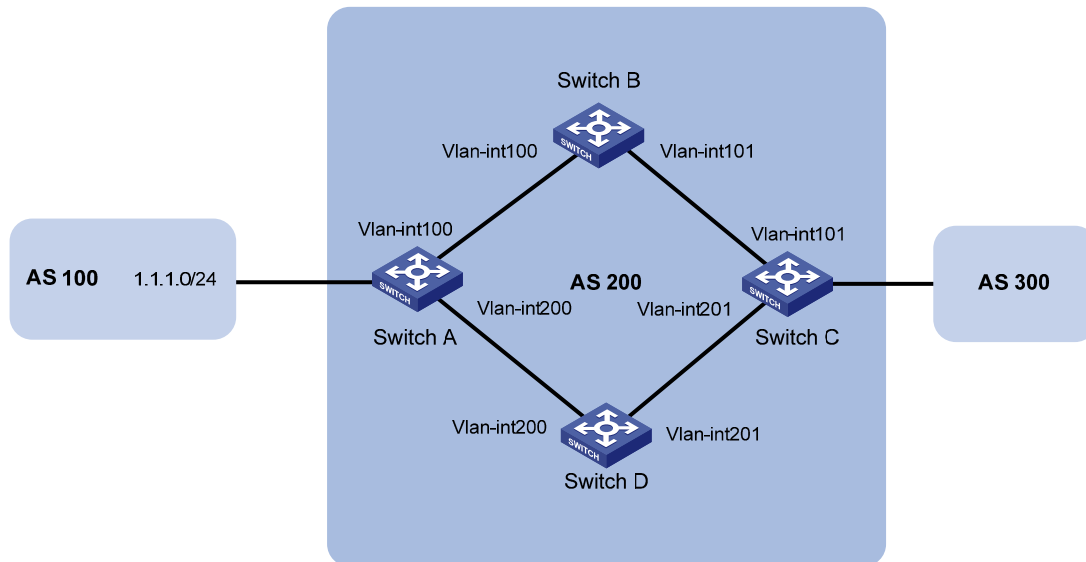

Configuring BFD for BGP

Network requirements

As shown in [Figure 98](#),

- Configure OSPF as the IGP in AS 200.
- Establish two IBGP connections between Switch A and Switch C. When both links are working, Switch C adopts the link Switch A ↔ Switch B ↔ Switch C to exchange packets with network 1.1.1.0/24. Configure BFD over the link. Then if the link fails, BFD can quickly detect the failure and notify it to BGP. Then the link Switch A ↔ Switch D ↔ Switch C takes effect immediately.

Figure 98 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	3.0.1.1/24	Switch C	Vlan-int101	3.0.2.2/24
	Vlan-int200	2.0.1.1/24		Vlan-int201	2.0.2.2/24
Switch B	Vlan-int100	3.0.1.2/24	Switch D	Vlan-int200	2.0.1.2/24
	Vlan-int101	3.0.2.1/24		Vlan-int201	2.0.2.1/24

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF to make sure that Switch A and Switch C are reachable to each other. (Details not shown.)
3. Configure BGP on Switch A:

Establish two IBGP connections between Switch A and Switch C.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp] peer 3.0.2.2 as-number 200
[SwitchA-bgp] peer 2.0.2.2 as-number 200
[SwitchA-bgp] quit
```

When the two links between Switch A and Switch C are both up, Switch C adopts the link Switch A<—>Switch B<—>Switch C to exchange packets with network 1.1.1.0/24. (Set a higher MED value for route 1.1.1.0/24 sent to peer 2.0.2.2 on Switch A.)

- Create ACL 2000 to permit 1.1.1.0/24 to pass.

```
[SwitchA] acl number 2000
[SwitchA-acl-basic-2000] rule permit source 1.1.1.0 24
[SwitchA-acl-basic-2000] quit
```
- Create two route policies, **apply_med_50** and **apply_med_100**. Policy **apply_med_50** sets the MED for route 1.1.1.0/24 to 50. Policy **apply_med_100** sets that to 100.

```
[SwitchA] route-policy apply_med_50 permit node 10
[SwitchA-route-policy] if-match acl 2000
[SwitchA-route-policy] apply cost 50
[SwitchA-route-policy] quit
```

```
[SwitchA] route-policy apply_med_100 permit node 10
[SwitchA-route-policy] if-match acl 2000
[SwitchA-route-policy] apply cost 100
[SwitchA-route-policy] quit
```

- Apply routing policy **apply_med_50** to routes outgoing to peer 3.0.2.2, and apply routing policy **apply_med_100** to routes outgoing to peer 2.0.2.2.

```
[SwitchA] bgp 100
[SwitchA-bgp] peer 3.0.2.2 route-policy apply_med_50 export
[SwitchA-bgp] peer 2.0.2.2 route-policy apply_med_100 export
```

Configure BFD over the link to peer 3.0.2.2 so that when the link Switch A<—>Switch B<—>Switch C fails, BFD can quickly detect the failure and notify it to BGP, and then the link Switch A<—>Switch D<—>Switch C takes effect immediately.

```
[SwitchA-bgp] peer 3.0.2.2 bfd
[SwitchA-bgp] quit
```

4. Configure BGP on Switch C:

```
<SwitchC> system-view
[SwitchC] bgp 100
[SwitchC-bgp] peer 3.0.1.1 as-number 200
[SwitchC-bgp] peer 3.0.1.1 bfd
[SwitchC-bgp] peer 2.0.1.1 as-number 200
[SwitchC-bgp] quit
```

5. Configure BFD parameters (you can use default BFD parameters instead):

Configure Switch A.

```
[SwitchA] bfd session init-mode active
[SwitchA] interface vlan-interface 100
```

- Configure the minimum interval for transmitting BFD control packets as 500 milliseconds.

```
[SwitchA-Vlan-interface100] bfd min-transmit-interval 500
```
- Configure the minimum interval for receiving BFD control packets as 500 milliseconds.

```
[SwitchA-Vlan-interface100] bfd min-receive-interval 500
```
- Configure the detect multiplier as 7.

```
[SwitchA-Vlan-interface100] bfd detect-multiplier 7
```
- Configure the BFD authentication mode as plain-text authentication, and set the authentication key to **ibgpbfd**.

```
[SwitchA-Vlan-interface100] bfd authentication-mode simple 1 ibgpbfd
[SwitchA-Vlan-interface100] quit
```

Configure Switch C.

```
[SwitchC] bfd session init-mode active
[SwitchC] interface vlan-interface 101
[SwitchC-Vlan-interface101] bfd min-transmit-interval 500
[SwitchC-Vlan-interface101] bfd min-receive-interval 500
[SwitchC-Vlan-interface101] bfd detect-multiplier 7
[SwitchC-Vlan-interface101] bfd authentication-mode simple 1 ibgpbfd
[SwitchC-Vlan-interface101] return
```

6. Verify the configuration:

The following operations are made on Switch C. Operations on Switch A are similar. (Details not shown.)

Display detailed BFD session information.

<SwitchC> display bfd session verbose

Total Session Num: 1 Init Mode: Active

IP Session Working Under Ctrl Mode:

```
Local Discr: 17                              Remote Discr: 13
Source IP: 3.0.2.2                          Destination IP: 3.0.1.1
Session State: Up                            Interface: Vlan-interface101
Min Trans Inter: 500ms                      Act Trans Inter: 500ms
Min Recv Inter: 500ms                      Act Detect Inter: 3000ms
Recv Pkt Num: 57                            Send Pkt Num: 53
Hold Time: 2200ms                          Connect Type: Indirect
Running Up for: 00:00:06                    Auth mode: Simple
Protocol: BGP6
Diag Info: No Diagnostic
```

The output shows that a BFD session is established between Switch A's VLAN-interface 100 and Switch C's VLAN-interface 101 and that BFD runs properly.

Display BGP peer information on Switch C, and you can see that Switch C has established two BGP neighborships with Switch A.

<SwitchC> display bgp peer

BGP local router ID : 1.1.1.1

Local AS number : 200

Total number of peers : 2

Peers in established state : 2

Peer	AS	MsgRcvd	MsgSent	OutQ	PrefRcv	Up/Down	State
2.0.1.1	200	7	10	0	0	00:01:05	Established
3.0.1.1	200	7	10	0	0	00:01:34	Established

Display route 1.1.1.0/24 on Switch C, and you can see that Switch A and Switch C communicate through Switch B.

<SwitchC> display ip routing-table 1.1.1.0 24 verbose

Routing Table : Public

Summary Count : 2

```
Destination: 1.1.1.0/24
Protocol: BGP                              Process ID: 0
Preference: 0                              Cost: 50
NextHop: 3.0.1.1                          Interface: Vlan-interface101
BkNextHop: 0.0.0.0                        BkInterface:
RelyNextHop: 3.0.2.1                      Neighbor : 3.0.1.1
Tunnel ID: 0x0                            Label: NULL
State: Active Adv                        Age: 00h08m54s
Tag: 0
```

Destination: 1.1.1.0/24

```

    Protocol: BGP                Process ID: 0
Preference: 0                    Cost: 100
    NextHop: 2.0.1.1            Interface: Vlan-interface201
    BkNextHop: 0.0.0.0          BkInterface:
    RelyNextHop: 2.0.2.1        Neighbor : 2.0.1.1
    Tunnel ID: 0x0              Label: NULL
    State: Invalid Adv           Age: 00h08m54s
    Tag: 0

```

The output shows that Switch C has two routes to reach network 1.1.1.0/24: Switch C \leftrightarrow Switch B \leftrightarrow Switch A, which is the active route; Switch C \leftrightarrow Switch D \leftrightarrow Switch A, which is the backup route.

Enable BFD debugging on Switch C.

```

<SwitchC> debugging bfd scm
<SwitchC> debugging bfd event
<SwitchC> debugging bgp bfd
<SwitchC> terminal monitor
<SwitchC> terminal debugging

```

The following debugging information shows that: when the link between Switch A and Switch B fails, Switch C can quickly detect the link failure.

```

%Nov 5 11:42:24:172 2009 SwitchC BFD/5/BFD_CHANGE_FSM: Sess[3.0.2.2/3.0.1.1,
13/17,VLAN101,Ctrl], Sta: UP->DOWN, Diag: 1
%Nov 5 11:42:24:172 2009 SwitchC BGP/5/BGP_STATE_CHANGED: 3.0.1.1 state is changed
from ESTABLISHED to IDLE.
*Nov 5 11:42:24:187 2009 SwitchC RM/6/RMDEBUG: BGP_BFD: Recv BFD DOWN msg, Src IP
3.0.2.2, Dst IP 3.0.1.1, Instance ID 0.
*Nov 5 11:42:24:187 2009 SwitchC RM/6/RMDEBUG: BGP_BFD: Reset BGP session 3.0.1.1
for BFD session down.
*Nov 5 11:42:24:187 2009 SwitchC RM/6/RMDEBUG: BGP_BFD: Send DELETE msg to BFD,
Connection type DIRECT, Src IP 3.0.2.2, Dst IP 3.0.1.1, Instance ID 0.

```

Display route 1.1.1.0/24 on Switch C, and you can see that Switch A and Switch C communicate through Switch D.

```

<SwitchC> display ip routing-table 1.1.1.0 24 verbose
Routing Table : Public
Summary Count : 1

```

```

Destination: 1.1.1.0/24
    Protocol: BGP                Process ID: 0
Preference: 0                    Cost: 100
    NextHop: 2.0.1.1            Interface: Vlan-interface201
    BkNextHop: 0.0.0.0          BkInterface:
    RelyNextHop: 2.0.2.1        Neighbor : 2.0.1.1
    Tunnel ID: 0x0              Label: NULL
    State: Active Adv           Age: 00h09m54s
    Tag: 0

```

The output shows that Switch C has one route Switch C \leftrightarrow Switch D \leftrightarrow Switch A to reach network 1.1.1.0/24.

Troubleshooting BGP

BGP peer relationship not established

Symptom

Display BGP peer information by using the **display bgp peer** command. The state of the connection to a peer cannot become established.

Analysis

To become BGP peers, any two routers must establish a TCP session using port 179 and exchange Open messages successfully.

Solution

1. Use the **display current-configuration** command to check that the peer's AS number is correct.
2. Use the **display bgp peer command** to check that the peer's IP address is correct.
3. If a loopback interface is used, check that the loopback interface is specified with the **peer connect-interface** command.
4. If the peer is a non-direct EBGP peer, check that the **peer ebgp-max-hop** command is configured.
5. Check that a valid route to the peer is available.
6. Use the **ping** command to check the connectivity to the peer.
7. Use the **display tcp status** command to check the TCP connection.
8. Check whether an ACL disabling TCP port 179 is configured.

Configuring IPv6 static routing

Hardware compatibility

The HP 5500 SI Switch Series does not support VPN-related parameters.

Overview

Static routes are manually configured. They work well in simple networks. Proper configuration and use can improve network performance and ensure enough bandwidth for important applications.

However, static routes also have limitations. Any topology changes require manual configuration and modification to the relevant static routes.

The term "router" in this chapter refers to both routers and Layer 3 switches.

IPv6 static routes features

Similar to IPv4 static routes, IPv6 static routes work well in simple IPv6 network environments.

Their major difference lies in the destination and next hop addresses. IPv6 static routes use IPv6 addresses, whereas IPv4 static routes use IPv4 addresses.

Default IPv6 route

An IPv6 static route with a destination prefix of `::/0` is a default IPv6 route. The default route is used to forward packets that match no specific routes in the routing table.

Configuring an IPv6 static route

In small IPv6 networks, IPv6 static routes can be used to forward packets. In comparison to dynamic routes, it helps to save network bandwidth.

Before you configure an IPv6 static route, complete the following tasks:

- Configure parameters for the related interfaces.
- Configure link layer attributes for the related interfaces.
- Enable IPv6 packet forwarding.
- Make sure that the neighboring nodes can reach each other.

To configure an IPv6 static route:

Step	Command	Remarks
1.	Enter system view. <code>system-view</code>	N/A

Step	Command	Remarks
2. Configure an IPv6 static route.	<ul style="list-style-type: none"> Approach 1: ipv6 route-static <i>ipv6-address prefix-length</i> { <i>interface-type interface-number</i> [<i>next-hop-address</i>] <i>next-hop-address</i> vpn-instance <i>d-vpn-instance-name</i> <i>nexthop-address</i> } [preference <i>preference-value</i>] Approach 2: ipv6 route-static vpn-instance <i>s-vpn-instance-name</i> <1-6> <i>ipv6-address</i> <i>prefix-length</i> { <i>interface-type</i> <i>interface-number</i> [<i>next-hop-address</i>] <i>nexthop-address</i> [public] vpn-instance <i>d-vpn-instance-name nexthop-address</i> } [preference <i>preference-value</i>] 	Use either approach. The default preference of IPv6 static routes is 60.

NOTE:

If you specify a broadcast interface, such as an Ethernet interface or a VLAN interface, as the output interface for a static route, you must specify the next hop address.

Displaying and maintaining IPv6 static routes

Task	Command	Remarks
Display IPv6 static route information.	display ipv6 routing-table protocol static [inactive verbose] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Remove all IPv6 static routes.	delete ipv6 [vpn-instance <i>vpn-instance-name</i>] static-routes all	Available in system view

To delete a single IPv6 static route, use the **undo ipv6 route-static** command. To delete all IPv6 static routes, including the default route, use the **delete ipv6 static-routes all** command.

For more information about the **display ipv6 routing-table protocol static** [**inactive** | **verbose**] [[{ **begin** | **exclude** | **include** } *regular-expression*] command, see *Layer 3—IP Routing Command Reference*.

IPv6 static routing configuration example

Network requirements

As shown in [Figure 99](#), configure IPv6 static routes so that hosts can reach one another.

Figure 99 Network diagram

Configuration procedure

1. Configure the IPv6 addresses for all VLAN interfaces. (Details not shown.)
2. Configure IPv6 static routes:

Configure a default IPv6 static route on Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] ipv6 route-static :: 0 4::2
```

Configure two IPv6 static routes on Switch B.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] ipv6 route-static 1:: 64 4::1
[SwitchB] ipv6 route-static 3:: 64 5::1
```

Configure a default IPv6 static route on Switch C.

```
<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] ipv6 route-static :: 0 5::2
```

3. Configure the IPv6 addresses and gateways for hosts:

Configure the IPv6 addresses for all the hosts based on the network diagram, configure the default gateway of Host A as 1::1, Host B as 2::1, and Host C as 3::1.

4. Verify the configuration:

Display the IPv6 routing table of Switch A.

```
[SwitchA] display ipv6 routing-table
```

Routing Table :

Destinations : 5 Routes : 5

Destination	: ::	Protocol	: Static
NextHop	: 4::2	Preference	: 60
Interface	: Vlan-interface200	Cost	: 0

Destination	: ::1/128	Protocol	: Direct
NextHop	: ::1	Preference	: 0
Interface	: InLoop0	Cost	: 0

Destination	: 1::/64	Protocol	: Direct
NextHop	: 1::1	Preference	: 0
Interface	: Vlan-interface100	Cost	: 0
Destination	: 1::1/128	Protocol	: Direct
NextHop	: ::1	Preference	: 0
Interface	: InLoop0	Cost	: 0
Destination	: FE80::/10	Protocol	: Direct
NextHop	: ::	Preference	: 0
Interface	: NULL0	Cost	: 0

Verify the connectivity with the **ping** command.

```
[SwitchA] ping ipv6 3::1
PING 3::1 : 56 data bytes, press CTRL_C to break
  Reply from 3::1
    bytes=56 Sequence=1 hop limit=254  time = 63 ms
  Reply from 3::1
    bytes=56 Sequence=2 hop limit=254  time = 62 ms
  Reply from 3::1
    bytes=56 Sequence=3 hop limit=254  time = 62 ms
  Reply from 3::1
    bytes=56 Sequence=4 hop limit=254  time = 63 ms
  Reply from 3::1
    bytes=56 Sequence=5 hop limit=254  time = 63 ms

--- 3::1 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 62/62/63 ms
```

Configuring RIPng

Hardware compatibility

The HP 5500 SI Switch Series does not support VPN-related parameters.

Introduction to RIPng

RIP next generation (RIPng) is an extension of RIP-2 for IPv4. Most RIP concepts are applicable in RIPng. The term "router" in this chapter refers to both routers and Layer 3 switches.

RIPng for IPv6 has the following basic differences from RIP:

- **UDP port number**—RIPng uses UDP port 521 for sending and receiving routing information.
- **Multicast address**—RIPng uses FF02:9 as the link-local-router multicast address.
- **Destination Prefix**—128-bit destination address prefix.
- **Next hop**—128-bit IPv6 address.
- **Source address**—RIPng uses FE80::/10 as the link-local source address.

RIPng working mechanism

RIPng is a routing protocol based on the distance vector (D-V) algorithm. RIPng uses UDP packets to exchange routing information through port 521.

RIPng uses a hop count to measure the distance to a destination. The hop count is the metric or cost. The hop count from a router to a directly connected network is 0. The hop count between two directly connected routers is 1. When the hop count is greater than or equal to 16, the destination network or host is unreachable.

By default, the routing update is sent every 30 seconds. If the router receives no routing updates from a neighbor within 180 seconds, the routes learned from the neighbor are considered unreachable. If no routing update is received within another 240 seconds, the router removes these routes from the routing table.

RIPng supports split horizon and poison reverse to prevent routing loops and route redistribution.

Each RIPng router maintains a routing database, which includes route entries of all reachable destinations. A route entry contains the following information:

- **Destination address**—IPv6 address of a host or a network.
- **Next hop address**—IPv6 address of a neighbor along the path to the destination.
- **Egress interface**—Outbound interface that forwards IPv6 packets.
- **Metric**—Cost from the local router to the destination.
- **Route time**—Time elapsed since a route entry is last changed. Each time a route entry is modified, the routing time is set to 0.
- **Route tag**—Identifies the route used in a routing policy to control routing information. For more information about routing policy, see "[Configuring routing policies](#)."

RIPng packet format

Basic format

A RIPng packet consists of a header and multiple route table entries (RTEs). The maximum number of RTEs in a packet depends on the IPv6 MTU of the sending interface.

Figure 100 RIPng basic packet format

Packet header description:

- **Command**—Type of message. 0x01 indicates Request; 0x02 indicates Response.
- **Version**—Version of RIPng. It can only be 0x01.
- **RTE**—Route table entry. It is 20 bytes for each entry.

RTE format

The following are types of RTEs in RIPng:

- **Next hop RTE**—Defines the IPv6 address of a next hop
- **IPv6 prefix RTE**—Describes the destination IPv6 address, route tag, prefix length and metric in the RIPng routing table.

Figure 101 Next hop RTE format

IPv6 next hop address is the IPv6 address of the next hop.

Figure 102 IPv6 prefix RTE format

IPv6 prefix RTE field description:

- **IPv6 prefix**—Destination IPv6 address prefix.
- **Route tag**—Route tag.
- **Prefix len**—Length of the IPv6 address prefix.
- **Metric**—Cost of a route.

RIPng packet processing procedure

Request packet

When a RIPng router first starts or needs to update entries in its routing table, usually a multicast request packet is sent to ask for needed routes from neighbors.

The receiving RIPng router processes RTEs in the request. If only one RTE exists with the IPv6 prefix and prefix length both being 0, and with a metric value of 16, the RIPng router will respond with the entire routing table information in response messages. If multiple RTEs exist in the request message, the RIPng router will examine each RTE, update its metric, and send the requested routing information to the requesting router in the response packet.

Response packet

The response packet containing the local routing table information is generated as follows:

- A response to a request
- An update periodically
- A triggered update caused by route change

After a router receives a response, it checks the validity of the response before adding the route to its routing table, such as whether the source IPv6 address is the link-local address and whether the port number is correct. The response packet that failed the check is discarded.

Protocols and standards

- RFC 2080, *RIPng for IPv6*
- RFC 2081, *RIPng Protocol Applicability Statement*

RIPng configuration task list

Task	Remarks
Configuring RIPng basic functions	Required
Configuring an additional routing metric	Optional
Configuring RIPng route summarization	Optional
Advertising a default route	Optional
Configuring RIPng route control	Configuring a RIPng route filtering policy
	Configuring a priority for RIPng
	Configuring RIPng route redistribution
	Configuring RIPng timers
Tuning and optimizing the RIPng network	Configuring split horizon and poison reverse
	Configuring zero field check on RIPng packets
	Configuring the maximum number of ECMP routes
Applying IPsec policies for RIPng	Optional

Configuring RIPng basic functions

This section presents the information to configure the basic RIPng features.

You must enable RIPng first before configuring other tasks, but it is not necessary for RIPng-related interface configurations, such as assigning an IPv6 address.

Before you configure RIPng basic functions, complete the following tasks:

- Enable IPv6 packet forwarding.
- Configure an IP address for each interface, and make sure that all neighboring nodes can reach each other.

To configure the basic RIPng functions:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a RIPng process and enter RIPng view.	ripng [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	Not created by default.
3. Return to system view.	quit	N/A
4. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
5. Enable RIPng on the interface.	ripng <i>process-id</i> enable	Disabled by default. If RIPng is not enabled on an interface, the interface will not send or receive a RIPng route.

Configuring RIPng route control

Before you configure RIPng, complete the following tasks:

- Configure an IPv6 address on each interface, and make sure that all neighboring nodes can reach each other.
- Configure RIPng basic functions.
- Define an IPv6 ACL before using it for route filtering. For related information, see *ACL and QoS Configuration Guide*.
- Define an IPv6 address prefix list before using it for route filtering. For related information, see "[Configuring routing policies](#)."

Configuring an additional routing metric

An additional routing metric can be added to the metric of an inbound or outbound RIP route.

The outbound additional metric is added to the metric of a sent route. The route's metric in the routing table is not changed.

The inbound additional metric is added to the metric of a received route before the route is added into the routing table, so the route's metric is changed.

To configure an inbound or outbound additional routing metric:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Specify an inbound routing additional metric.	ripng metricin <i>value</i>	Optional. 0 by default.
4. Specify an outbound routing additional metric.	ripng metricout <i>value</i>	Optional. 1 by default.

Configuring RIPng route summarization

Step	Command
1. Enter system view.	system-view
2. Enter interface view.	interface <i>interface-type interface-number</i>
3. Advertise a summary IPv6 prefix.	ripng summary-address <i>ipv6-address prefix-length</i>

Advertising a default route

With this feature enabled, a default route is advertised through the specified interface regardless of whether the default route is available in the local IPv6 routing table.

To advertise a default route:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Advertise a default route.	ripng default-route { only originate } [cost <i>cost</i>]	Not advertised by default.

Configuring a RIPng route filtering policy

Reference a configured IPv6 ACL or prefix list to filter received or advertised routing information. You can also filter outbound routes redistributed from a routing specific routing protocol.

To configure a RIPng route filtering policy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIPng view.	ripng [<i>process-id</i>]	N/A
3. Configure a filter policy to filter incoming routes.	filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> } import	By default, RIPng does not filter incoming routing information.

Step	Command	Remarks
4. Configure a filter policy to filter outgoing routes.	filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> } export [<i>protocol</i> [<i>process-id</i>]]	By default, RIPng does not filter outgoing routing information.

Configuring a priority for RIPng

Any routing protocol has its own protocol priority used for optimal route selection. You can set a priority for RIPng manually. The smaller the value, the higher the priority.

To configure a RIPng priority:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIPng view.	ripng [<i>process-id</i>]	N/A
3. Configure a RIPng priority.	preference [route-policy <i>route-policy-name</i>] <i>preference</i>	Optional. By default, the RIPng priority is 100.

Configuring RIPng route redistribution

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIPng view.	ripng [<i>process-id</i>]	N/A
3. Configure a default routing metric for redistributed routes.	default cost <i>cost</i>	Optional. The default metric of redistributed routes is 0.
4. Redistribute routes from another routing protocol.	import-route <i>protocol</i> [<i>process-id</i>] [allow-ibgp] [cost <i>cost</i> route-policy <i>route-policy-name</i>] *	By default, no route redistribution is configured.

Tuning and optimizing the RIPng network

This section describes how to tune and optimize the performance of the RIPng network, as well as applications under special network environments. Before tuning and optimizing the RIPng network, complete the following tasks:

- Configure a network layer address for each interface.
- Configure the basic RIPng functions.

Configuring RIPng timers

Adjust RIPng timers to optimize the performance of the RIPng network. When adjusting RIPng timers, consider the network performance, and perform unified configurations on routers running RIPng to avoid unnecessary network traffic increase or route oscillation.

To configure RIPng timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIPng view.	ripng [<i>process-id</i>]	N/A
3. Configure RIPng timers.	timers { garbage-collect <i>garbage-collect-value</i> suppress <i>suppress-value</i> timeout <i>timeout-value</i> update <i>update-value</i> } *	Optional. The RIPng timers have the following defaults: <ul style="list-style-type: none"> • 30 seconds for the update timer • 180 seconds for the timeout timer • 120 seconds for the suppress timer • 120 seconds for the garbage-collect timer

Configuring split horizon and poison reverse

If both split horizon and poison reverse are configured, only the poison reverse function takes effect.

Configuring split horizon

The split horizon function disables a route learned from an interface from being advertised through the same interface to prevent routing loops between neighbors. HP recommends enabling split horizon to prevent routing loops.

To configure split horizon:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the split horizon function.	ripng split-horizon	Optional. Enabled by default.

Configuring the poison reverse function

The poison reverse function enables a route learned from an interface to be advertised through the interface. However, the metric of the route is set to 16 (unreachable).

To configure poison reverse:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the poison reverse function.	ripng poison-reverse	Disabled by default.

Configuring zero field check on RIPng packets

Some fields in the RIPng packet must be zero, which are called "zero fields". With zero field check on RIPng packets enabled, if such a field contains a non-zero value, the entire RIPng packet is discarded. If you are sure that all packets are trustworthy, disable the zero field check to reduce the CPU processing time.

To configure RIPng zero field check:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIPng view.	ripng [<i>process-id</i>]	N/A
3. Enable the zero field check.	checkzero	Optional. Enabled by default.

Configuring the maximum number of ECMP routes

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIPng view.	ripng [<i>process-id</i>]	N/A
3. Configure the maximum number of ECMP routes for load balancing.	maximum load-balancing <i>number</i>	Optional. 8 by default.

Applying IPsec policies for RIPng

To protect routing information and defend attacks, RIPng supports using an IPsec policy to authenticate protocol packets.

Outbound RIPng packets carry the Security Parameter Index (SPI) defined in the relevant IPsec policy. A device uses the SPI carried in a received packet to match against the configured IPsec policy. If they match, the device accepts the packet; otherwise, it discards the packet and will not establish a neighbor relationship with the sending device.

You can configure an IPsec policy for a RIPng process or interface. The IPsec policy configured for a process applies to all packets in the process. The IPsec policy configured on an interface applies to packets on the interface. If an interface and its process each have an IPsec policy configured, the interface uses its own IPsec policy.

Configuration prerequisites

Before you apply an IPsec policy for RIPng, complete following tasks:

- Create an IPsec proposal.
- Create an IPsec policy.

For more information about IPsec policy configuration, see *Security Configuration Guide*.

Configuration guidelines

An IPsec policy used for RIPng can only be in manual mode. For more information, see *Security Configuration Guide*.

Configuration procedure

To apply an IPsec policy in a process:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RIPng view.	ripng [<i>process-id</i>]	N/A
3. Apply an IPsec policy in the process.	enable ipsec-policy <i>policy-name</i>	Not configured by default.

To apply an IPsec policy on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Apply an IPsec policy on the interface.	ripng ipsec-policy <i>policy-name</i>	Not configured by default.

Displaying and maintaining RIPng

Task	Command	Remarks
Display configuration information of a RIPng process.	display ripng [<i>process-id</i> vpn-instance <i>vpn-instance-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routes in the RIPng database.	display ripng process-id database [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the routing information of a specified RIPng process.	display ripng process-id route [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display RIPng interface information.	display ripng process-id interface [<i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Reset a RIPng process.	reset ripng process-id process	Available in user view
Clear statistics of a RIPng process.	reset ripng process-id statistics	Available in user view

RIPng configuration examples

Configuring RIPng basic functions

Network requirements

In Figure 103, all switches run RIPng. Configure Switch B to filter the route (3::/64) learned from Switch C, which means the route will not be added to the routing table of Switch B, and Switch B will not forward it to Switch A.

Figure 103 Network diagram

Configuration procedure

1. Configure the IPv6 address for each interface. (Details not shown.)
2. Configure basic RIPng functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ripng 1
[SwitchA-ripng-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ripng 1 enable
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 400
[SwitchA-Vlan-interface400] ripng 1 enable
[SwitchA-Vlan-interface400] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ripng 1
[SwitchB-ripng-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ripng 1 enable
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ripng 1 enable
[SwitchB-Vlan-interface100] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ripng 1
[SwitchC-ripng-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] ripng 1 enable
[SwitchC-Vlan-interface200] quit
```

```

[SwitchC] interface vlan-interface 500
[SwitchC-Vlan-interface500] ripng 1 enable
[SwitchC-Vlan-interface500] quit
[SwitchC] interface vlan-interface 600
[SwitchC-Vlan-interface600] ripng 1 enable
[SwitchC-Vlan-interface600] quit
# Display the routing table of Switch B.
[SwitchB] display ripng 1 route
    Route Flags: A - Aging, S - Suppressed, G - Garbage-collect
-----

Peer FE80::20F:E2FF:FE23:82F5 on Vlan-interface100
Dest 1::/64,
    via FE80::20F:E2FF:FE23:82F5, cost 1, tag 0, A, 6 Sec
Dest 2::/64,
    via FE80::20F:E2FF:FE23:82F5, cost 1, tag 0, A, 6 Sec

Peer FE80::20F:E2FF:FE00:100 on Vlan-interface200
Dest 3::/64,
    via FE80::20F:E2FF:FE00:100, cost 1, tag 0, A, 11 Sec
Dest 4::/64,

```

Configuring RIPng route redistribution

Network requirements

Two RIPng processes are running on Switch B, which communicates with Switch A through RIPng 100 and with Switch C through RIPng 200.

Configure route redistribution on Switch B, letting the two RIPng processes redistribute routes from each other. Set the default cost of redistributed routes from RIPng 200 to 3.

Figure 104 Network diagram

Configuration procedure

1. Configure IPv6 addresses for the interfaces. (Details not shown.)
2. Configure RIPng basic functions:
 - # Enable RIPng 100 on Switch A.
 - <SwitchA> system-view

```
[SwitchA] ripng 100
[SwitchA-ripng-100] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ripng 100 enable
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] ripng 100 enable
[SwitchA-Vlan-interface200] quit
```

Enable RIP 100 and RIP 200 on Switch B.

```
<SwitchB> system-view
[SwitchB] ripng 100
[SwitchB-ripng-100] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ripng 100 enable
[SwitchB-Vlan-interface100] quit
[SwitchB] ripng 200
[SwitchB-ripng-200] quit
[SwitchB] interface vlan-interface 300
[SwitchB-Vlan-interface300] ripng 200 enable
[SwitchB-Vlan-interface300] quit
```

Enable RIPng 200 on Switch C.

```
<SwitchC> system-view
[SwitchC] ripng 200
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] ripng 200 enable
[SwitchC-Vlan-interface300] quit
[SwitchC] interface vlan-interface 400
[SwitchC-Vlan-interface400] ripng 200 enable
[SwitchC-Vlan-interface400] quit
```

Display the routing table of Switch A.

```
[SwitchA] display ipv6 routing-table
```

Routing Table :

Destinations : 6 Routes : 6

```
Destination: ::1/128                      Protocol : Direct
NextHop      : ::1                        Preference: 0
Interface    : InLoop0                    Cost      : 0
```

```
Destination: 1::/64                      Protocol : Direct
NextHop      : 1::1                        Preference: 0
Interface    : Vlan100                    Cost      : 0
```

```
Destination: 1::1/128                    Protocol : Direct

Configuring RIPng IPsec policies

Network requirements

In the following figure, configure RIPng on the switches, and configure IPsec policies on the switches to authenticate and encrypt protocol packets.

Figure 105 Network diagram

Configuration procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure RIPng basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ripng 1
[SwitchA-ripng-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ripng 1 enable
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ripng 1
[SwitchB-ripng-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ripng 1 enable
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ripng 1 enable
[SwitchB-Vlan-interface100] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ripng 1
[SwitchC-ripng-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] ripng 1 enable
[SwitchC-Vlan-interface200] quit
```

3. Configure RIPng IPsec policies:

On Switch A, create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy001**, specify the manual mode for it,

reference IPsec proposal **tran1**, set the SPIs of the inbound and outbound SAs to 12345, and the keys for the inbound and outbound SAs using ESP to abcdefg.

```
[SwitchA] ipsec proposal tran1
[SwitchA-ipsec-proposal-tran1] encapsulation-mode transport
[SwitchA-ipsec-proposal-tran1] transform esp
[SwitchA-ipsec-proposal-tran1] esp encryption-algorithm des
[SwitchA-ipsec-proposal-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-proposal-tran1] quit
[SwitchA] ipsec policy policy001 10 manual
[SwitchA-ipsec-policy-manual-policy001-10] proposal tran1
[SwitchA-ipsec-policy-manual-policy001-10] sa spi outbound esp 12345
[SwitchA-ipsec-policy-manual-policy001-10] sa spi inbound esp 12345
[SwitchA-ipsec-policy-manual-policy001-10] sa string-key outbound esp abcdefg
[SwitchA-ipsec-policy-manual-policy001-10] sa string-key inbound esp abcdefg
[SwitchA-ipsec-policy-manual-policy001-10] quit
```

On Switch B, create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy001**, specify the manual mode for it, reference IPsec proposal **tran1**, set the SPIs of the inbound and outbound SAs to 12345, and the keys for the inbound and outbound SAs using ESP to abcdefg.

```
[SwitchB] ipsec proposal tran1
[SwitchB-ipsec-proposal-tran1] encapsulation-mode transport
[SwitchB-ipsec-proposal-tran1] transform esp
[SwitchB-ipsec-proposal-tran1] esp encryption-algorithm des
[SwitchB-ipsec-proposal-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-proposal-tran1] quit
[SwitchB] ipsec policy policy001 10 manual
[SwitchB-ipsec-policy-manual-policy001-10] proposal tran1
[SwitchB-ipsec-policy-manual-policy001-10] sa spi outbound esp 12345
[SwitchB-ipsec-policy-manual-policy001-10] sa spi inbound esp 12345
[SwitchB-ipsec-policy-manual-policy001-10] sa string-key outbound esp abcdefg
[SwitchB-ipsec-policy-manual-policy001-10] sa string-key inbound esp abcdefg
[SwitchB-ipsec-policy-manual-policy001-10] quit
```

On Switch C, create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy001**, specify the manual mode for it, reference IPsec proposal **tran1**, set the SPIs of the inbound and outbound SAs to 12345, and the keys for the inbound and outbound SAs using ESP to abcdefg.

```
[SwitchC] ipsec proposal tran1
[SwitchC-ipsec-proposal-tran1] encapsulation-mode transport
[SwitchC-ipsec-proposal-tran1] transform esp
[SwitchC-ipsec-proposal-tran1] esp encryption-algorithm des
[SwitchC-ipsec-proposal-tran1] esp authentication-algorithm sha1
[SwitchC-ipsec-proposal-tran1] quit
[SwitchC] ipsec policy policy001 10 manual
[SwitchC-ipsec-policy-manual-policy001-10] proposal tran1
[SwitchC-ipsec-policy-manual-policy001-10] sa spi outbound esp 12345
[SwitchC-ipsec-policy-manual-policy001-10] sa spi inbound esp 12345
```

```
[SwitchC-ipsec-policy-manual-policy001-10] sa string-key outbound esp abcdefg
[SwitchC-ipsec-policy-manual-policy001-10] sa string-key inbound esp abcdefg
[SwitchC-ipsec-policy-manual-policy001-10] quit
```

4. Apply the IPsec policies in the RIPng process:

Configure Switch A.

```
[SwitchA] ripng 1
[SwitchA-ripng-1] enable ipsec-policy policy001
[SwitchA-ripng-1] quit
```

Configure Switch B.

```
[SwitchB] ripng 1
[SwitchB-ripng-1] enable ipsec-policy policy001
[SwitchB-ripng-1] quit
```

Configure Switch C.

```
[SwitchC] ripng 1
[SwitchC-ripng-1] enable ipsec-policy policy001
[SwitchC-ripng-1] quit
```

5. Verify the configuration:

RIPng traffic between Switches A, B and C is protected by IPsec.

Configuring OSPFv3

Hardware compatibility

The HP 5500 SI Switch Series does not support OSPFv3.

Introduction to OSPFv3

OSPFv3 overview

Open Shortest Path First version 3 (OSPFv3) supports IPv6 and complies with RFC 2740 (OSPF for IPv6). The term "router" in this chapter refers to both routers and Layer 3 switches.

OSPFv3 and OSPFv2 have the following similarities:

- 32-bits router ID and area ID
- Packets, including Hello, DD (Data Description), LSR (Link State Request), LSU (Link State Update), and LSAck (Link State Acknowledgment)
- Mechanism for finding neighbors and establishing adjacencies
- Mechanism for LSA flooding and aging

OSPFv3 and OSPFv2 have the following differences:

- OSPFv3 runs on a per-link basis, and OSPFv2 runs on a per-IP-subnet basis.
- OSPFv3 supports multiple instances per link, but OSPFv2 does not.
- OSPFv3 identifies neighbors by Router ID, and OSPFv2 by IP address.

OSPFv3 packets

OSPFv3 has the following packet types: hello, DD, LSR, LSU, and LSAck. These packets have the same packet header, which is different from the OSPFv2 packet header. The OSPFv3 packet header is only 16 bytes in length, has no authentication field, and is added with an Instance ID field to support VPN per link.

Figure 106 OSPFv3 packet header

0	15	31
Version #	Type	Packet length
Router ID		
Area ID		
Checksum	Instance ID	0

Major fields for OSPFv3 packets are as follows:

- **Version #**—Version of OSPF, which is 3 for OSPFv3.
- **Type**—Type of OSPF packet; types 1 to 5 are hello, DD, LSR, LSU, and LSAck.
- **Packet length**—Packet length in bytes, including header.

- **Instance ID**—Instance ID for a link.
- **0**—Reserved. It must be 0.

OSPFv3 LSA types

OSPFv3 sends routing information in LSAs, which, as defined in RFC 2740, have the following types:

- **Router-LSA**—Originated by all routers. This LSA describes the collected states of the router's interfaces to an area, and is flooded throughout a single area only.
- **Network-LSA**—Originated for broadcast and NBMA networks by the Designated Router. This LSA contains the list of routers connected to the network, and is flooded throughout a single area only.
- **Inter-Area-Prefix-LSA**—Similar to Type 3 LSA of OSPFv2, originated by ABRs (Area Border Routers), and flooded throughout the LSA's associated area. Each Inter-Area-Prefix-LSA describes a route with IPv6 address prefix to a destination outside the area, yet still inside the AS (an inter-area route).
- **Inter-Area-Router-LSA**—Similar to Type 4 LSA of OSPFv2, originated by ABRs and flooded throughout the LSA's associated area. Each Inter-Area-Router-LSA describes a route to ASBR (Autonomous System Boundary Router).
- **AS-external-LSA**—Originated by ASBRs, and flooded throughout the AS (except Stub and NSSA areas). Each AS-external-LSA describes a route to another autonomous system. A default route can be described by an AS-external-LSA.
- **Link-LSA**—A router originates a separate Link-LSA for each attached link. Link-LSAs have link-local flooding scope. Each Link-LSA describes the IPv6 address prefix of the link and Link-local address of the router.
- **Intra-Area-Prefix-LSA**—Each Intra-Area-Prefix-LSA contains IPv6 prefix information on a router, stub area, or transit area information, and has area flooding scope. It was introduced because Router-LSAs and Network-LSAs do not contain address information.

RFC 5187 defines the Type 11 LSA, Grace-LSA. A Grace-LSA is generated by a GR (Graceful Restart) Restarter at reboot and transmitted on the local link. The restarter describes the cause and interval of the reboot in the Grace-LSA to tell its neighbors that it performs a GR operation.

OSPFv3 timers

Timers in OSPFv3 include the following:

- OSPFv3 packet timer
- LSA delay timer
- SPF timer
- GR timer

OSPFv3 packet timer

Hello packets are sent periodically between neighboring routers for finding and maintaining neighbor relationships, or for DR or BDR election. The hello interval must be identical on neighboring interfaces. The smaller the hello interval, the faster the network convergence speed and the bigger the network load.

If a router does not receive a hello packet from a neighbor within a given period—dead interval, it then declares the peer down.

After sending an LSA to its adjacency, a router waits for an acknowledgment from the adjacency. If no response is received after the retransmission interval elapses, the router will send the LSA again. The retransmission interval must be longer than the round-trip time of the LSA.

LSA delay time

Each LSA has an age in the local LSDB (incremented by one per second), but an LSA does not age on transmission. You must add an LSA delay time into the age time before transmission, which is important for low-speed networks.

SPF timer

Whenever the LSDB changes, an SPF calculation occurs. If recalculations become frequent, a large amount of resources will be occupied. You can adjust the SPF calculation interval and delay time to protect networks from being overloaded by frequent changes.

GR timer

If a failure to establish adjacencies occurs during a GR, the device will be in the GR process for a long time. To avoid this, configure the GR timer for the device to exit the GR process when the timer expires.

OSPFv3 features supported

- Basic features defined in RFC 2740
- OSPFv3 stub area
- OSPFv3 multi-process
- VPN instances
- OSPFv3 GR
- BFD

Protocols and standards

- RFC 2740, *OSPF for IPv6*
- RFC 2328, *OSPF Version 2*
- RFC 5187, *OSPFv3 Graceful Restart*

OSPFv3 configuration task list

Task	Remarks
Enabling OSPFv3	Required
Configuring OSPFv3 area parameters	Configuring an OSPFv3 stub area Optional
	Configuring an OSPFv3 virtual link Optional
Configuring OSPFv3 network types	Configuring the OSPFv3 network type for an interface Optional
	Configuring an NBMA or P2MP neighbor Optional
Configuring OSPFv3 routing information control	Configuring OSPFv3 route summarization Optional
	Configuring OSPFv3 inbound route filtering Optional
	Configuring an OSPFv3 cost for an interface Optional
	Configuring the maximum number of OSPFv3 ECMP routes Optional

Task	Remarks	
Tuning and optimizing OSPFv3 networks	Configuring a priority for OSPFv3	Optional
	Configuring OSPFv3 route redistribution	Optional
	Configuring OSPFv3 timers	Optional
	Configuring a DR priority for an interface	Optional
	Ignoring MTU check for DD packets	Optional
	Disabling interfaces from receiving and sending OSPFv3 packets	Optional
	Enabling the logging of neighbor state changes	Optional
Configuring OSPFv3 GR	Configuring GR Restarter	Optional
	Configuring GR Helper	Optional
Configuring BFD for OSPFv3	Optional	
Applying IPsec policies for OSPFv3	Optional	

Enabling OSPFv3

Configuration prerequisites

Before you enable OSPFv3, complete the following tasks:

- Make neighboring nodes accessible with each other at the network layer.
- Enable IPv6 packet forwarding.

Enabling OSPFv3

To enable an OSPFv3 process on a router, you must enable the OSPFv3 process globally, assign the OSPFv3 process a router ID, and enable the OSPFv3 process on related interfaces.

A router ID uniquely identifies a router within an AS. You must specify a unique router ID for each OSPFv3 router within the AS to ensure normal operation. If a router runs multiple OSPFv3 processes, you must specify a unique router ID for each process.

An OSPFv3 process ID has only local significance. Process 1 on a router can exchange packets with process 2 on another router.

To enable OSPFv3:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable an OSPFv3 process and enter its view.	ospfv3 [<i>process-id</i>] [vpn-instance <i>vpn-instance-name</i>]	By default, no OSPFv3 process is enabled.
3. Specify a router ID.	router-id <i>router-id</i>	N/A
4. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
5. Enable an OSPFv3 process on the interface.	ospfv3 <i>process-id</i> area <i>area-id</i> [instance <i>instance-id</i>]	Not enabled by default.

Configuring OSPFv3 area parameters

The stub area and virtual link features of OSPFv3 are the same as OSPFv2.

Splitting an OSPFv3 AS into multiple areas reduces the number of LSAs and extends OSPFv3 applications. For those non-backbone areas residing on the AS boundary, configure them as stub areas to further reduce the size of routing tables and the number of LSAs.

Non-backbone areas exchange routing information through the backbone area. The backbone and non-backbone areas—including the backbone itself—must be contiguous. In practice, necessary physical links may not be available for this connectivity. You can configure virtual links to address the problem.

Configuration prerequisites

Before you configure OSPFv3 area parameters, complete the following tasks:

- Enable IPv6 packet forwarding.
- Configure OSPFv3 basic functions.

Configuring an OSPFv3 stub area

Follow these guidelines when you configure an OSPFv3 stub area:

- You cannot remove an OSPFv3 area directly. The area can be removed only when you remove all configurations in area view and all interfaces attached to the area become down.
- All the routers attached to a stub area must be configured with the **stub** command. The keyword **no-summary** is only available on the ABR of the stub area.
- If you use the **stub** command with the keyword **no-summary** on an ABR, the ABR advertises a default route in an Inter-Area-Prefix-LSA into the stub area. No AS-external-LSA, Inter-Area-Prefix-LSA, or Inter-Area-Router-LSA is advertised in the area. The stub area of this kind is also known as a "totally stub area."

To configure an OSPFv3 stub area:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Enter OSPFv3 area view.	area <i>area-id</i>	N/A
4. Configure the area as a stub area.	stub [no-summary]	Not configured by default.
5. Specify a cost for the default route advertised to the stub area.	default-cost <i>value</i>	Optional. 1 by default.

Configuring an OSPFv3 virtual link

You can configure a virtual link to maintain connectivity between a non-backbone area and the backbone, or in the backbone itself.

ⓘ IMPORTANT:

- Both ends of a virtual link are ABRs that must be configured with the **vlink-peer** command.
- Do not configure virtual links in the areas of a GR-capable process.

To configure a virtual link:

Step	Command
1. Enter system view.	system-view
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]
3. Enter OSPFv3 area view.	area <i>area-id</i>
4. Configure a virtual link.	vlink-peer <i>router-id</i> [hello <i>seconds</i> retransmit <i>seconds</i> trans-delay <i>seconds</i> dead <i>seconds</i> instance <i>instance-id</i>] *

Configuring OSPFv3 network types

OSPFv3 classifies networks into the following types by the link layer protocol.

By default, the default OSPFv3 interface network types vary with the link layer protocols of the interfaces:

- When the link layer protocol is PPP, OSPFv3 considers the network type as P2P by default.
- When the link layer protocol is Ethernet, OSPFv3 considers the network type as broadcast by default.

You can change the network type of an OSPFv3 interface as needed. For example:

- An NBMA network must be fully connected. Any two routers in the network must be directly reachable to each other through a virtual circuit. If no such direct link is available, you must change the network type through a command.
- If direct connections are not available between some routers in an NBMA network, the type of interfaces associated must be configured as P2MP, or as P2P for interfaces with only one neighbor.

Configuration prerequisites

Before you configure OSPFv3 network types, complete the following tasks:

- Configure IPv6 functions.
- Configure OSPFv3 basic functions.

Configuring the OSPFv3 network type for an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure a network type for the OSPFv3 interface.	ospfv3 network-type { broadcast nbma p2mp [non-broadcast] p2p } [instance <i>instance-id</i>]	Optional. The network type of an interface depends on the media type of the interface.

Configuring an NBMA or P2MP neighbor

For NBMA and P2MP interfaces (only when in unicast mode), specify the link-local IP addresses of their neighbors because these interfaces cannot find neighbors through broadcasting hello packets. You can also specify DR priorities for neighbors.

To configure an NBMA or P2MP (unicast) neighbor and its DR priority:

Step	Command
1. Enter system view.	system-view
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>
3. Specify an NBMA or P2MP (unicast) neighbor and its DR priority.	ospfv3 peer <i>ipv6-address</i> [dr-priority <i>dr-priority</i>] [instance <i>instance-id</i>]

Configuring OSPFv3 routing information control

This section describes how to configure the control of OSPF routing information advertisement and reception, and redistribution from other protocols.

Configuration prerequisites

Before you configure OSPFv3 routing information control, complete the following tasks:

- Enable IPv6 packet forwarding.
- Configure OSPFv3 basic functions.

Configuring OSPFv3 route summarization

If contiguous network segments exist in an area, use the **abr-summary** command to summarize them into one network segment on the ABR. The ABR will advertise only the summary route. Any LSA in the specified network segment will not be advertised, reducing the LSDB size in other areas.

To configure route summarization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Enter OSPFv3 area view.	area <i>area-id</i>	N/A

Step	Command	Remarks
4. Configure a summary route.	abr-summary <i>ipv6-address</i> <i>prefix-length</i> [not-advertise]	Not configured by default. The abr-summary command takes effect on ABRs only.

Configuring OSPFv3 inbound route filtering

According to some rules, you can configure OSPFv3 to filter routes that are computed from received LSAs.

To configure OSPFv3 inbound route filtering:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Configure inbound route filtering.	filter-policy { <i>acl-number</i> ipv6-prefix <i>ipv6-prefix-name</i> } import	Not configured by default. The filter-policy import command can only filter routes computed by OSPFv3. Only routes not filtered out can be added into the local routing table.

Configuring an OSPFv3 cost for an interface

You can configure an OSPFv3 cost for an interface with one of the following methods:

- Configure the cost value in interface view.
- Configure a bandwidth reference value for the interface, and OSPFv3 computes the cost automatically based on the bandwidth reference value: Interface OSPFv3 cost = Bandwidth reference value (100 Mbps) ÷ Interface bandwidth (Mbps). If the calculated cost is greater than 65535, the value of 65535 is used; if the calculated cost is smaller than 1, the value of 1 is used.

If the cost value is not configured for an interface, OSPFv3 computes the interface cost value automatically.

To configure an OSPFv3 cost for an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an OSPFv3 cost for the interface.	ospfv3 cost <i>value</i> [instance <i>instance-id</i>]	Optional. The default cost depends on the interface type: 1 for a VLAN interface; 0 for a loopback interface; computed according to the bandwidth for other interfaces.

To configure a bandwidth reference value:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Configure a bandwidth reference value.	bandwidth-reference <i>value</i>	Optional. 100 Mbps by default.

Configuring the maximum number of OSPFv3 ECMP routes

Perform this task to implement load sharing over ECMP routes.

To configure the maximum number of ECMP routes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Specify the maximum number of ECMP routes.	maximum load-balancing <i>maximum</i>	Optional. 8 by default.

Configuring a priority for OSPFv3

A router may run multiple routing protocols. The system assigns a priority to each protocol. When these routing protocols find the same route, the route found by the protocol with the highest priority is selected.

To configure a priority for OSPFv3:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Configure a priority for OSPFv3.	preference [<i>ase</i>] [route-policy <i>route-policy-name</i>] <i>preference</i>	Optional. By default, the priority of OSPFv3 internal routes is 10, and priority of OSPFv3 external routes is 150.

Configuring OSPFv3 route redistribution

Follow these guidelines when you configure OSPFv3 route redistribution:

- Executing the **import-route** or **default-route-advertise** command on a router makes it become an ASBR.
- You can only inject and advertise a default route using the **default-route-advertise** command.
- Because OSPFv3 is a link state routing protocol, it cannot directly filter LSAs to be advertised. You must filter redistributed routes first. Routes that are not filtered out can be advertised in LSAs into the routing domain.

- Using the **filter-policy export** command filters routes redistributed with the **import-route** command. If the **import-route** command is not configured, executing the **filter-policy export** command does not take effect.

To configure OSPFv3 route redistribution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Specify a default cost for redistributed routes.	default cost <i>value</i>	Optional. 1 by default.
4. Redistribute routes from another protocol, or another OSPFv3 process.	import-route <i>protocol</i> [<i>process-id</i> allow-ibgp] [cost <i>value</i> route-policy <i>route-policy-name</i> type <i>type</i>] *	Not configured by default.
5. Inject a default route.	default-route-advertise [always cost <i>value</i> type <i>type</i> route-policy <i>route-policy-name</i>] *	Optional. Not injected by default.
6. Filter redistributed routes.	filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> } export [isisv6 <i>process-id</i> ospfv3 <i>process-id</i> ripng <i>process-id</i> bgp4+ direct static]	Optional. Not configured by default.

Tuning and optimizing OSPFv3 networks

This section describes configurations of OSPFv3 timers, interface DR priority, MTU check ignorance for DD packets, and disabling interfaces from sending OSPFv3 packets.

The following are OSPFv3 timers:

- Packet timer**—Specified to adjust topology convergence speed and network load.
- LSA delay timer**—Specified especially for low-speed links.
- SPF timer**—Specified to protect networks from being overloaded due to frequent network changes.

For a broadcast network, you can configure DR priorities for interfaces to affect DR or BDR election.

After an interface is disabled from sending OSPFv3 packets, other routers cannot obtain any information from the interface.

Configuration prerequisites

Before you tune and optimize OSPFv3 networks, complete the following tasks:

- Enable IPv6 packet forwarding.
- Configure OSPFv3 basic functions.

Configuring OSPFv3 timers

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the hello interval.	ospfv3 timer hello <i>seconds</i> [instance <i>instance-id</i>]	Optional. By default, the hello interval on P2P, broadcast interfaces is 10 seconds.
4. Specify the poll interval.	ospfv3 timer poll <i>seconds</i> [instance <i>instance-id</i>]	Optional. By default, the poll interval is 120 seconds.
5. Configure the dead interval.	ospfv3 timer dead <i>seconds</i> [instance <i>instance-id</i>]	Optional. By default, the dead interval on P2P, broadcast interfaces is 40 seconds. The dead interval set on neighboring interfaces cannot be too short. Otherwise, a neighbor is easily considered down.
6. Configure the LSA retransmission interval.	ospfv3 timer retransmit <i>interval</i> [instance <i>instance-id</i>]	Optional. By default, the LSA retransmission interval is 5 seconds. The LSA retransmission interval cannot be too short; otherwise, unnecessary retransmissions occur.
7. Configure the LSA transmission delay.	ospfv3 trans-delay <i>seconds</i> [instance <i>instance-id</i>]	Optional. By default, the LSA transmission delay is 1 second.
8. Return to system view.	quit	N/A
9. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
10. Configure the SPF timers.	spf timers <i>delay-interval</i> <i>hold-interval</i>	Optional. By default, <i>delay-interval</i> is 5 seconds and <i>hold-interval</i> is 10 seconds. Setting both the <i>delay-interval</i> and <i>hold-interval</i> to 0 triggers an SPF calculation at once, improving the network convergence speed.

Configuring a DR priority for an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
3. Configure a DR priority.	ospfv3 dr-priority <i>priority</i> [instance <i>instance-id</i>]	Optional. By default, the DR priority is 1. The DR priority of an interface determines the interface's qualification in DR election. Interfaces having the priority 0 cannot become a DR or BDR.

Ignoring MTU check for DD packets

When LSAs are few in DD packets, it is unnecessary to check the MTU in DD packets to improve efficiency.

To ignore MTU check for DD packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Ignore MTU check for DD packets.	ospfv3 mtu-ignore [instance <i>instance-id</i>]	Not ignored by default.

Disabling interfaces from receiving and sending OSPFv3 packets

Follow these guidelines when you disable interfaces from receiving and sending OSPF packets:

- Multiple OSPFv3 processes can disable the same interface from receiving and sending OSPFv3 packets. Using the **silent-interface** command disables only the interfaces associated with the current process.
- After an OSPF interface is set to **silent**, direct routes of the interface can still be advertised in Intra-Area-Prefix-LSAs via other interfaces, but other OSPFv3 packets cannot be advertised. No neighboring relationship can be established on the interface. This feature can enhance the adaptability of OSPFv3 networking.

To disable interfaces from receiving and sending OSPFv3 packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Disable interfaces from receiving and sending OSPFv3 packets.	silent-interface { <i>interface-type</i> <i>interface-number</i> all }	Not disabled by default.

Enabling the logging of neighbor state changes

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Enable the logging of neighbor state changes.	log-peer-change	Enabled by default.

Configuring OSPFv3 GR

ⓘ IMPORTANT:

You cannot configure OSPFv3 GR after configuring OSPFv3 virtual links, because they are not supported at the same time.

Graceful Restart ensures the continuity of packet forwarding when a routing protocol restarts or a master/slave switchover occurs:

- **GR Restarter**—Graceful restarting router. It must be Graceful Restart capable.
- **GR Helper**—The neighbor of the GR Restarter. It helps the GR Restarter to complete the GR process.

To prevent service interruption after a master/slave switchover, a GR Restarter running OSPFv3 must complete the following tasks:

- Keep the GR Restarter forwarding entries stable during reboot.
- Establish all adjacencies and obtain complete topology information after reboot.

After the master/slave switchover, the GR Restarter sends a Grace-LSA to tell its neighbors that it performs a GR. Upon receiving the Grace-LSA, the neighbors with the GR Helper capability enter the helper mode (and are then called "GR Helpers"). Then, the GR Restarter retrieves its adjacencies and LSDB with the help of the GR Helpers.

Configuring GR Restarter

You can configure the GR Restarter capability on a GR Restarter.

To configure GR Restarter:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Enable the GR capability.	graceful-restart enable	Disabled by default.
4. Configure the GR interval.	graceful-restart interval <i>interval-value</i>	Optional. 120 seconds by default.

Configuring GR Helper

You can configure the GR Helper capability on a GR Helper.

To configure GR Helper

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Enable the GR Helper capability.	graceful-restart helper enable	Optional. Enabled by default.
4. Enable strict LSA checking.	graceful-restart helper strict-lsa-checking	Optional. Disabled by default.

Configuring BFD for OSPFv3

Bidirectional forwarding detection (BFD) provides a mechanism to quickly detect the connectivity of links between OSPFv3 neighbors, thus to improve the convergence speed of OSPFv3. For more information about BFD, see *High Availability Configuration Guide*.

After discovering neighbors by sending hello packets, OSPFv3 notifies BFD of the neighbor addresses, and BFD uses these addresses to establish sessions. Before a BFD session is established, it is in the down state. In this state, BFD control packets are sent at an interval of no less than one second to reduce BFD control packet traffic. After the BFD session is established, BFD control packets are sent at the negotiated interval, thereby implementing fast fault detection.

To configure BFD for OSPFv3, you need to configure OSPFv3 first.

To configure BFD for OSPFv3:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Specify a router ID.	router-id <i>router-id</i>	N/A
4. Quit the OSPFv3 view.	quit	N/A
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Enable an OSPFv3 process on the interface.	ospfv3 <i>process-id</i> area <i>area-id</i> [instance <i>instance-id</i>]	Not enabled by default.
7. Enable BFD on the interface.	ospfv3 bfd enable [instance <i>instance-id</i>]	Not enabled by default.

Applying IPsec policies for OSPFv3

To protect routing information and defend attacks, OSPFv3 can authenticate protocol packets by using an IPsec policy.

Outbound OSPFv3 packets carry the Security Parameter Index (SPI) defined in the relevant IPsec policy. A device uses the SPI carried in a received packet to match against the configured IPsec policy. If they match, the device accepts the packet; otherwise, it discards the packet and will not establish a neighbor relationship with the sending device.

You can configure an IPsec policy for an area, an interface or a virtual link.

- To implement area-based IPsec protection, you need to configure the same IPsec policy on the routers in the target area.
- To implement interface-based IPsec protection, you need to configure the same IPsec policy on the interfaces between two neighboring routers.
- To implement virtual link-based IPsec protection, you need to configure the same IPsec policy on the two routers connected over the virtual link.

If an interface and its area each have an IPsec policy configured, the interface uses its own IPsec policy. If a virtual link and area 0 each have an IPsec policy configured, the virtual link uses its own IPsec policy.

Configuration prerequisites

Before you apply an IPsec policy for OSPFv3, complete following tasks.

- Create an IPsec proposal.
- Create an IPsec policy.

For more information about IPsec policy configuration, see *Security Configuration Guide*.

Configuration guidelines

An IPsec policy used for OSPFv3 can only be in manual mode. For more information, see *Security Configuration Guide*.

Configuration procedure

To apply an IPsec policy in an area:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Enter OSPF area view.	area <i>area-id</i>	N/A
4. Apply an IPsec policy in the area.	enable ipsec-policy <i>policy-name</i>	Not configured by default.

To apply an IPsec policy on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Apply an IPsec policy on the interface.	ospfv3 ipsec-policy <i>policy-name</i> [instance <i>instance-id</i>]	Not configured by default

To apply an IPsec policy on a virtual link:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter OSPFv3 view.	ospfv3 [<i>process-id</i>]	N/A
3. Enter OSPF area view.	area <i>area-id</i>	N/A

Step	Command	Remarks
4. Apply an IPsec policy on a virtual link.	vlink-peer <i>router-id</i> [hello <i>seconds</i> retransmit <i>seconds</i> trans-delay <i>seconds</i> dead <i>seconds</i> instance <i>instance-id</i> ipsec-policy <i>policy-name</i>] *	Not configured by default.

Displaying and maintaining OSPFv3

Task	Command	Remarks
Display OSPFv3 process brief information.	display ospfv3 [<i>process-id</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 interface information.	display ospfv3 interface [<i>interface-type</i> <i>interface-number</i> statistic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 LSDB information.	display ospfv3 [<i>process-id</i>] lsdb [[external inter-prefix inter-router intra-prefix link network router grace] [<i>link-state-id</i>] [originate-router <i>router-id</i>] total] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 LSDB statistics.	display ospfv3 lsdb statistic [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 neighbor information.	display ospfv3 [<i>process-id</i>] [area <i>area-id</i>] peer [[<i>interface-type</i> <i>interface-number</i>] [verbose] <i>peer-router-id</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 neighbor statistics.	display ospfv3 peer statistic [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 routing table information.	display ospfv3 [<i>process-id</i>] routing [<i>ipv6-address</i> <i>prefix-length</i> <i>ipv6-address/prefix-length</i> abr-routes asbr-routes all statistics] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 area topology information.	display ospfv3 [<i>process-id</i>] topology [area <i>area-id</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 virtual link information.	display ospfv3 [<i>process-id</i>] vlink [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 next hop information.	display ospfv3 [<i>process-id</i>] next-hop [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 link state request list information.	display ospfv3 [<i>process-id</i>] request-list [{ external inter-prefix inter-router intra-prefix link network router grace] [<i>link-state-id</i>] [originate-router <i>ip-address</i>] statistics] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display OSPFv3 link state retransmission list information.	display ospfv3 [<i>process-id</i>] retrans-list [{ external inter-prefix inter-router intra-prefix link network router grace] [<i>link-state-id</i>] [originate-router <i>ip-address</i>] statistics] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display OSPFv3 statistics.	display ospfv3 statistic [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the GR status of the specified OSPFv3 process.	display ospfv3 [<i>process-id</i>] graceful-restart status [{ begin exclude include } <i>regular-expression</i>]	Available in any view

OSPFv3 configuration examples

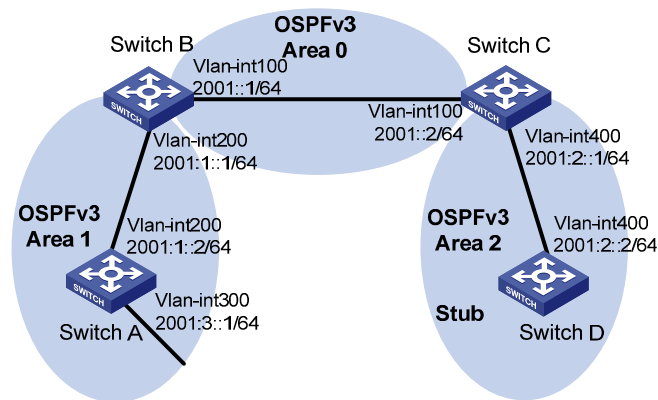

Configuring OSPFv3 areas

Network requirements

In Figure 107, all switches run OSPFv3. The AS is split into three areas, in which, Switch B and Switch C act as ABRs to forward routing information between areas.

Configure Area 2 as a stub area in order to reduce LSAs in the area without affecting route reachability.

Figure 107 Network diagram

Configuration procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure OSPFv3 basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] ospfv3
[SwitchA-ospfv3-1] router-id 1.1.1.1
[SwitchA-ospfv3-1] quit
[SwitchA] interface vlan-interface 300
[SwitchA-Vlan-interface300] ospfv3 1 area 1
[SwitchA-Vlan-interface300] quit
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] ospfv3 1 area 1
[SwitchA-Vlan-interface200] quit
```

Configure Switch B.

```
<SwitchB> system-view
```

```
[SwitchB] ipv6
[SwitchB] ospfv3
[SwitchB-ospf-1] router-id 2.2.2.2
[SwitchB-ospf-1] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ospfv3 1 area 0
[SwitchB-Vlan-interface100] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ospfv3 1 area 1
[SwitchB-Vlan-interface200] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] ospfv3
[SwitchC-ospfv3-1] router-id 3.3.3.3
[SwitchC-ospfv3-1] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] ospfv3 1 area 0
[SwitchC-Vlan-interface100] quit
[SwitchC] interface vlan-interface 400
[SwitchC-Vlan-interface400] ospfv3 1 area 2
[SwitchC-Vlan-interface400] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ipv6
[SwitchD] ospfv3
[SwitchD-ospfv3-1] router-id 4.4.4.4
[SwitchD-ospfv3-1] quit
[SwitchD] interface Vlan-interface 400
[SwitchD-Vlan-interface400] ospfv3 1 area 2
[SwitchD-Vlan-interface400] quit
```

Display OSPFv3 neighbor information on Switch B.

```
[SwitchB] display ospfv3 peer
```

```

                OSPFv3 Area ID 0.0.0.0 (Process 1)
-----
Neighbor ID    Pri   State           Dead Time   Interface   Instance ID
3.3.3.3        1     Full/DR         00:00:39   Vlan100    0
```

```

                OSPFv3 Area ID 0.0.0.1 (Process 1)
-----
Neighbor ID    Pri   State           Dead Time   Interface   Instance ID
1.1.1.1        1     Full/Backup     00:00:38   Vlan200    0
```

Display OSPFv3 neighbor information on Switch C.

```
[SwitchC] display ospfv3 peer
```

```

                OSPFv3 Area ID 0.0.0.0 (Process 1)
-----
Neighbor ID    Pri   State           Dead Time   Interface   Instance ID
```

```
2.2.2.2          1      Full/Backup    00:00:39    Vlan100      0
```

```
OSPFv3 Area ID 0.0.0.2 (Process 1)
```

```
-----  
Neighbor ID      Pri   State           Dead Time   Interface   Instance ID  
4.4.4.4          1     Full/DR         00:00:38   Vlan400     0
```

```
# Display OSPFv3 routing table information on Switch D.
```

```
[SwitchD] display ospfv3 routing
```

```
E1 - Type 1 external route,   IA - Inter area route,   I - Intra area route  
E2 - Type 2 external route,   * - Selected route
```

```
OSPFv3 Router with ID (4.4.4.4) (Process 1)
```

```
-----  
*Destination: 2001::/64  
Type           : IA                               Cost       : 2  
NextHop        : FE80::F40D:0:93D0:1             Interface: Vlan400  
  
*Destination: 2001:1::/64  
Type           : IA                               Cost       : 3  
NextHop        : FE80::F40D:0:93D0:1             Interface: Vlan400  
  
*Destination: 2001:2::/64  
Type           : I                               Cost       : 1  
NextHop        : directly-connected              Interface: Vlan400  
  
*Destination: 2001:3::/64  
Type           : IA                               Cost       : 4  
NextHop        : FE80::F40D:0:93D0:1             Interface: Vlan400
```

3. Configure Area 2 as a stub area:

```
# Configure Switch D
```

```
[SwitchD] ospfv3
```

```
[SwitchD-ospfv3-1] area 2
```

```
[SwitchD-ospfv3-1-area-0.0.0.2] stub
```

```
# Configure Switch C, and specify the cost of the default route sent to the stub area as 10.
```

```
[SwitchC] ospfv3
```

```
[SwitchC-ospfv3-1] area 2
```

```
[SwitchC-ospfv3-1-area-0.0.0.2] stub
```

```
[SwitchC-ospfv3-1-area-0.0.0.2] default-cost 10
```

```
# Display OSPFv3 routing table information on Switch D. A default route is added, and its cost is the cost of a direct route plus the configured cost.
```

```
[SwitchD] display ospfv3 routing
```

```
E1 - Type 1 external route,   IA - Inter area route,   I - Intra area route  
E2 - Type 2 external route,   * - Selected route
```

```
OSPFv3 Router with ID (4.4.4.4) (Process 1)
```

```

*Destination: ::/0
  Type       : IA                               Cost       : 11
  NextHop    : FE80::F40D:0:93D0:1           Interface:  Vlan400

*Destination: 2001::/64
  Type       : IA                               Cost       : 2
  NextHop    : FE80::F40D:0:93D0:1           Interface:  Vlan400

*Destination: 2001:1::/64
  Type       : IA                               Cost       : 3
  NextHop    : FE80::F40D:0:93D0:1           Interface:  Vlan400

*Destination: 2001:2::/64
  Type       : I                                Cost       : 1
  NextHop    : directly-connected            Interface:  Vlan400

*Destination: 2001:3::/64
  Type       : IA                               Cost       : 4
  NextHop    : FE80::F40D:0:93D0:1           Interface:  Vlan400

```

4. Configure Area 2 as a totally stub area:

Configure Area 2 as a totally stub area on Switch C.

```
[SwitchC-ospfv3-1-area-0.0.0.2] stub no-summary
```

Display OSPFv3 routing table information on Switch D. Route entries are reduced. All non-direct routes are removed except the default route.

```
[SwitchD] display ospfv3 routing
```

```

E1 - Type 1 external route,   IA - Inter area route,   I - Intra area route
E2 - Type 2 external route,   * - Selected route

```

```
OSPFv3 Router with ID (4.4.4.4) (Process 1)
```

```

-----
*Destination: ::/0
  Type       : IA                               Cost       : 11
  NextHop    : FE80::F40D:0:93D0:1           Interface:  Vlan400

*Destination: 2001:2::/64
  Type       : I                                Cost       : 1
  NextHop    : directly-connected            Interface:  Vlan400

```

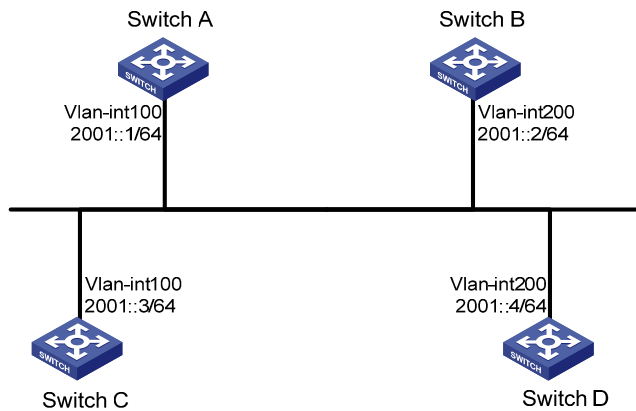

Configuring OSPFv3 DR election

Network requirements

As shown in [Figure 108](#):

- The priority of Switch A is 100, the highest priority on the network, so it will be the DR.
- The priority of Switch C is 2, the second highest priority on the network, so it will be the BDR.
- The priority of Switch B is 0, so it cannot become the DR.
- Router D has the default priority 1.

Figure 108 Network diagram

Configuration procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure OSPFv3 basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] ospfv3
[SwitchA-ospfv3-1] router-id 1.1.1.1
[SwitchA-ospfv3-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ospfv3 1 area 0
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] ospfv3
[SwitchB-ospfv3-1] router-id 2.2.2.2
[SwitchB-ospfv3-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ospfv3 1 area 0
[SwitchB-Vlan-interface200] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] ospfv3
[SwitchC-ospfv3-1] router-id 3.3.3.3
[SwitchC-ospfv3-1] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] ospfv3 1 area 0
[SwitchC-Vlan-interface100] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ipv6
```

```
[SwitchD] ospfv3
[SwitchD-ospfv3-1] router-id 4.4.4.4
[SwitchD-ospfv3-1] quit
[SwitchD] interface vlan-interface 200
[SwitchD-Vlan-interface200] ospfv3 1 area 0
[SwitchD-Vlan-interface200] quit
```

Display neighbor information on Switch A. The switches have the same default DR priority 1. Then, Switch D (the switch with the highest Router ID) is elected as the DR, and Switch C is the BDR.

```
[SwitchA] display ospfv3 peer
      OSPFv3 Area ID 0.0.0.0 (Process 1)
```

```
-----
Neighbor ID      Pri   State           Dead Time   Interface   Instance ID
2.2.2.2          1     2-Way/DROther   00:00:36   Vlan200     0
3.3.3.3          1     Full/Backup     00:00:35   Vlan100     0
4.4.4.4          1     Full/DR         00:00:33   Vlan200     0
```

Display neighbor information on Switch D. The neighbor states are all full.

```
[SwitchD] display ospfv3 peer
      OSPFv3 Area ID 0.0.0.0 (Process 1)
```

```
-----
Neighbor ID      Pri   State           Dead Time   Interface   Instance ID
1.1.1.1          1     Full/DROther    00:00:30   Vlan100     0
2.2.2.2          1     Full/DROther    00:00:37   Vlan200     0
3.3.3.3          1     Full/Backup     00:00:31   Vlan100     0
```

3. Configure DR priorities for interfaces:

Configure the DR priority of VLAN-interface 100 as 100 on Switch A.

```
[SwitchA] interface Vlan-interface 100
[SwitchA-Vlan-interface100] ospfv3 dr-priority 100
[SwitchA-Vlan-interface100] quit
```

Configure the DR priority of VLAN-interface 200 as 0 on Switch B.

```
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ospfv3 dr-priority 0
[SwitchB-Vlan-interface200] quit
```

Configure the DR priority of VLAN-interface 100 of Switch C as 2.

```
[SwitchC] interface Vlan-interface 100
[SwitchC-Vlan-interface100] ospfv3 dr-priority 2
[SwitchC-Vlan-interface100] quit
```

Display neighbor information on Switch A. DR priorities have been updated, but the DR and BDR are not changed.

```
[SwitchA] display ospfv3 peer
      OSPFv3 Area ID 0.0.0.0 (Process 1)
```

```
-----
Neighbor ID      Pri   State           Dead Time   Interface   Instance ID
2.2.2.2          0     2-Way/DROther   00:00:38   Vlan200     0
3.3.3.3          2     Full/Backup     00:00:32   Vlan100     0
4.4.4.4          1     Full/DR         00:00:36   Vlan200     0
```

Display neighbor information on Switch D. Switch D is still the DR.

```
[SwitchD] display ospfv3 peer
```

```

OSPFv3 Area ID 0.0.0.0 (Process 1)
-----
Neighbor ID      Pri   State           Dead Time   Interface   Instance ID
1.1.1.1          100  Full/DROther    00:00:33   Vlan100    0
2.2.2.2          0     Full/DROther    00:00:36   Vlan200    0
3.3.3.3          2     Full/Backup     00:00:40   Vlan100    0

```

4. Restart DR and BDR election:

Use the **shutdown** and **undo shutdown** commands on interfaces to restart DR and BDR election. (Details not shown.)

Display neighbor information on Switch A. Switch C becomes the BDR.

```

[SwitchA] display ospfv3 peer
OSPFv3 Area ID 0.0.0.0 (Process 1)
-----
Neighbor ID      Pri   State           Dead Time   Interface   Instance ID
2.2.2.2          0     Full/DROther    00:00:31   Vlan200    0
3.3.3.3          2     Full/Backup     00:00:39   Vlan100    0
4.4.4.4          1     Full/DROther    00:00:37   Vlan200    0

```

Display neighbor information on Switch D. Switch A becomes the DR.

```

[SwitchD] display ospfv3 peer
OSPFv3 Area ID 0.0.0.0 (Process 1)
-----
Neighbor ID      Pri   State           Dead Time   Interface   Instance ID
1.1.1.1          100  Full/DR         00:00:34   Vlan100    0
2.2.2.2          0     2-Way/DROther  00:00:34   Vlan200    0
3.3.3.3          2     Full/Backup     00:00:32   Vlan100    0

```

Configuring OSPFv3 route redistribution

Network requirements

As shown in [Figure 109](#):

- Switch A, Switch B, and Switch C are in Area 2.
- OSPFv3 process 1 and OSPFv3 process 2 are enabled on Switch B. Switch B communicates with Switch A and Switch C through OSPFv3 process 1 and OSPFv3 process 2.

Configure OSPFv3 process 2 to redistribute direct routes and the routes from OSPFv3 process 1 on Switch B and set the default metric for redistributed routes to 3. Then, Switch C can learn the routes destined for 1::0/64 and 2::0/64, and Switch A cannot learn the routes destined for 3::0/64 or 4::0/64.

Figure 109 Network diagram

Configuration procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure OSPFv3 basic functions:

Enable OSPFv3 process 1 on Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] ospfv3 1
[SwitchA-ospfv3-1] router-id 1.1.1.1
[SwitchA-ospfv3-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ospfv3 1 area 2
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 200

Interface    : NULL0                             Cost       : 0

```

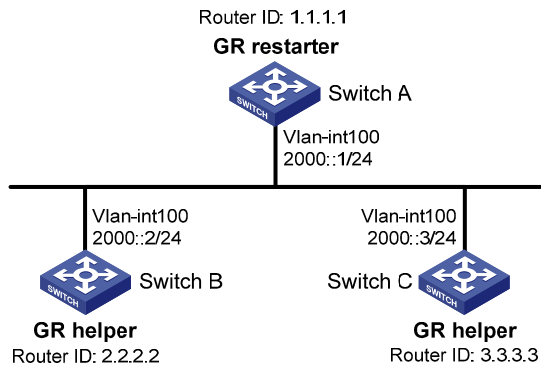

Configuring OSPFv3 GR

Network requirements

As shown in [Figure 110](#), Switch A, Switch B, and Switch C that belong to the same AS and the same OSPFv3 routing domain are GR capable.

Switch A acts as the GR Restarter. Switch B and Switch C are the GR Helpers and synchronize their LSDBs with Switch A through out-of-band (OOB) communication of GR.

Figure 110 Network diagram

Configuration procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure OSPFv3 basic functions:
 - # On Switch A, enable OSPFv3 process 1, enable GR, and set the router ID to 1.1.1.1.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] ospfv3 1
[SwitchA-ospfv3-1] router-id 1.1.1.1
[SwitchA-ospfv3-1] graceful-restart enable
[SwitchA-ospfv3-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ospfv3 1 area 1
[SwitchA-Vlan-interface100] quit
```
 - # Enable OSPFv3 on Switch B and set the router ID to 2.2.2.2. (By default, GR helper is enabled on Switch B).

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] ospfv3 1
[SwitchB-ospfv3-1] router-id 2.2.2.2
[SwitchB-ospfv3-1] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ospfv3 1 area 1
[SwitchB-Vlan-interface100] quit
```
 - # Enable OSPFv3 on Switch C and set the router ID to 3.3.3.3. (By default, GR helper is enabled on Switch C).

```
<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] ospfv3 1
[SwitchC-ospfv3-1] router-id 3.3.3.3
[SwitchC-ospfv3-1] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] ospfv3 1 area 1
[SwitchC-Vlan-interface100] quit
```
3. Verify the configuration:

After all switches function properly, perform a master/slave switchover on Switch A to trigger an OSPFv3 GR operation.

Configuring BFD for OSPFv3

Network requirements

In Figure 111, configure OSPFv3 on Switch A, Switch B and Switch C and configure BFD over the link Switch A ↔ L2 Switch ↔ Switch B.

After the link Switch A ↔ L2 Switch ↔ Switch B fails, BFD can quickly detect the failure and notify OSPFv3 of the failure. Then Switch A and Switch B communicate through Switch C.

Figure 111 Network diagram

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Switch A	Vlan-int10	2001::1/64	Switch B	Vlan-int10	2001::2/64
	Vlan-int11	2001:2::1/64		Vlan-int13	2001:3::2/64
Switch C	Vlan-int11	2001:2::2/64			
	Vlan-int13	2001:3::1/64			

Configuration procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure OSPF basic functions:

```
# Configure Switch A. Enable OSPFv3 and configure the router ID as 1.1.1.1.
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] ospfv3
[SwitchA-ospfv3-1] router-id 1.1.1.1
[SwitchA-ospfv3-1] quit
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] ospfv3 1 area 0
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 11
[SwitchA-Vlan-interface11] ospfv3 1 area 0
[SwitchA-Vlan-interface11] quit

# Configure Switch B. Enable OSPFv3 and configure the router ID as 2.2.2.2.
<SwitchB> system-view
[SwitchB] ipv6
```

```

[SwitchB] ospfv3
[SwitchB-ospf-1] router-id 2.2.2.2
[SwitchB-ospf-1] quit
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] ospfv3 1 area 0
[SwitchB-Vlan-interface10] quit
[SwitchB] interface vlan-interface 13
[SwitchB-Vlan-interface13] ospfv3 1 area 0
[SwitchB-Vlan-interface13] quit

```

Configure Switch C. Enable OSPFv3 and configure the router ID as 3.3.3.3.

```

<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] ospfv3
[SwitchC-ospfv3-1] router-id 3.3.3.3
[SwitchC-ospfv3-1] quit
[SwitchC] interface vlan-interface 11
[SwitchC-Vlan-interface11] ospfv3 1 area 0
[SwitchC-Vlan-interface11] quit
[SwitchC] interface vlan-interface 13
[SwitchC-Vlan-interface13] ospfv3 1 area 0
[SwitchC-Vlan-interface13] quit

```

3. Configure BFD:

Enable BFD on Switch A and configure BFD parameters.

```

[SwitchA] bfd session init-mode active
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] ospfv3 bfd enable
[SwitchA-Vlan-interface10] bfd min-transmit-interval 500
[SwitchA-Vlan-interface10] bfd min-receive-interval 500
[SwitchA-Vlan-interface10] bfd detect-multiplier 7
[SwitchA-Vlan-interface10] return

```

Enable BFD on Switch B and configure BFD parameters.

```

[SwitchB] bfd session init-mode active
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] ospfv3 bfd enable
[SwitchB-Vlan-interface10] bfd min-transmit-interval 500
[SwitchB-Vlan-interface10] bfd min-receive-interval 500
[SwitchB-Vlan-interface10] bfd detect-multiplier 6

```

4. Verify the configuration:

The following operations are performed on Switch A. The operations on Switch B are similar, and are not shown.

Display the BFD information of Switch A.

```

<SwitchA> display bfd session
Total Session Num: 1          Init Mode: Active

IPv6 Session Working Under Ctrl Mode:

Local Discr: 1441          Remote Discr: 1450

```

Source IP: FE80::20F:FF:FE00:1202 (link-local address of VLAN-interface 10 on Switch A)

Destination IP: FE80::20F:FF:FE00:1200 (link-local address of VLAN-interface 10 on Switch B)

Session State: Up Interface: Vlan10
Hold Time: /

Display routes to 2001:4::0/64 on Switch A, and you can see that Switch A communicates with Switch B through the Layer 2 switch.

```
<SwitchA> display ipv6 routing-table 2001:4::0 64 verbose
```

Routing Table :

Summary Count : 2

```
Destination : 2001:4:: PrefixLength : 64
NextHop      : 2001::2 Preference : 10
IpPrecedence : QoS LcId :
RelayNextHop : :: Tag : 0H
Neighbor     : :: ProcessID : 0
Interface    : Vlan-interface10 Protocol : OSPFv3
State        : Active Adv Cost : 1
Tunnel ID    : 0x0 Label : NULL
Age          : 4538sec
```

```
Destination : 2001:4:: PrefixLength : 64
NextHop      : 2001:2::2 Preference : 10
IpPrecedence : QoS LcId :
RelayNextHop : :: Tag : 0H
Neighbor     : :: ProcessID : 0
Interface    : Vlan-interface11 Protocol : OSPFv3
State        : Invalid Adv Cost : 2
Tunnel ID    : 0x0 Label : NULL
Age          : 4515sec
```

Enable BFD debugging on Switch A.

```
<SwitchA> debugging bfd scm
```

```
<SwitchA> debugging bfd event
```

```
<SwitchA> debugging ospfv3 event bfd
```

```
<SwitchA> terminal debugging
```

After the link between Switch B and the Layer 2 switch fails, Switch A quickly detects the change on Switch B.

```
%Nov 5 11:37:43:062 2009 SwitchA BFD/5/BFD_CHANGE_FSM: Sess[FE80::20F:FF:FE00:1202/FE80::20F:FF:FE00:1200,15/15,Vlan10,Ctrl], Sta: UP->DOWN, Diag: 1
```

```
%Nov 5 11:37:43:062 2009 SwitchA OSPFV3/5/OSPFv3_NBR_CHG: OSPFv3 1 Neighbor 2.2.2.2(Vlan-interface10) from Full to Down.
```

```
*Nov 5 11:37:43:062 2009 SwitchA RM/6/RMDEBUG: OSPFv3 OSPFv3-BFD: Message Type rcv BFD down, Connect Type direct-connect, Src IP Address FE80::20F:FF:FE00:1202, Dst IP Address FE80::20F:FF:FE00:1200.
```

```
*Nov 5 11:37:43:062 2009 SwitchA RM/6/RMDEBUG: OSPFv3 OSPFv3-BFD: Message Type delete session, Connect Type direct-connect, Src IP Address FE80::20F:FF:FE00:1202, Dst IP Address FE80::20F:FF:FE00:1200.
```

Display the BFD information of Switch A. You can see that Switch A has removed its neighbor relationship with Switch B and therefore no information is output.

```
<SwitchA> display bfd session
```

Display routes to 2001:4::0/64 on Switch A, and you can see that Switch A communicates with Switch B through Switch C.

```
<SwitchA> display ipv6 routing-table 2001:4::0 64 verbose
```

```
Routing Table :
```

```
Summary Count : 1
```

Destination	: 2001:4::	PrefixLength	: 64

Age	: 4610sec		

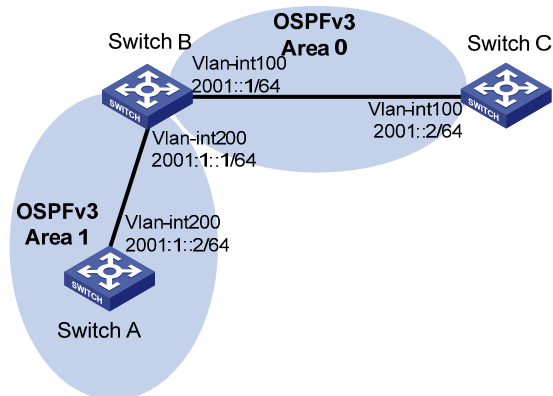

Configuring OSPFv3 IPsec policies

Network requirements

As shown in [Figure 112](#):

- Configure OSPFv3 on the switches. The AS is divided into two areas.
- Configure IPsec policies on the switches to authenticate and encrypt protocol packets.

Figure 112 Network diagram

Configuration procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure OSPFv3 basic functions:

```
# Configure Switch A: enable OSPFv3 and configure the router ID as 1.1.1.1.
```

```
<SwitchA> system-view
```

```
[SwitchA] ipv6
```

```
[SwitchA] ospfv3 1
```

```
[SwitchA-ospfv3-1] router-id 1.1.1.1
```

```
[SwitchA-ospfv3-1] quit
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] ospfv3 1 area 1
[SwitchA-Vlan-interface200] quit
```

Configure Switch B: enable OSPFv3 and configure the router ID as 2.2.2.2.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] ospfv3 1
[SwitchB-ospfv3-1] router-id 2.2.2.2
[SwitchB-ospfv3-1] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ospfv3 1 area 0
[SwitchB-Vlan-interface100] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ospfv3 1 area 1
[SwitchB-Vlan-interface200] quit
```

Configure Switch C: enable OSPFv3 and configure the router ID as 3.3.3.3.

```
<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] ospfv3 1
[SwitchC-ospfv3-1] router-id 3.3.3.3
[SwitchC-ospfv3-1] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] ospfv3 1 area 0
[SwitchC-Vlan-interface100] quit
```

3. Configure OSPFv3 IPsec policies:

On Switch A, create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy001**, specify the manual mode for it, reference IPsec proposal **tran1**, set the SPIs of the inbound and outbound SAs to 12345, and the keys for the inbound and outbound SAs using ESP to abcdefg.

```
[SwitchA] ipsec proposal tran1
[SwitchA-ipsec-proposal-tran1] encapsulation-mode transport
[SwitchA-ipsec-proposal-tran1] transform esp
[SwitchA-ipsec-proposal-tran1] esp encryption-algorithm des
[SwitchA-ipsec-proposal-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-proposal-tran1] quit
[SwitchA] ipsec policy policy001 10 manual
[SwitchA-ipsec-policy-manual-policy001-10] proposal tran1
[SwitchA-ipsec-policy-manual-policy001-10] sa spi outbound esp 12345
[SwitchA-ipsec-policy-manual-policy001-10] sa spi inbound esp 12345
[SwitchA-ipsec-policy-manual-policy001-10] sa string-key outbound esp abcdefg
[SwitchA-ipsec-policy-manual-policy001-10] sa string-key inbound esp abcdefg
[SwitchA-ipsec-policy-manual-policy001-10] quit
```

On Switch B, create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy001**, specify the manual mode for it, reference IPsec proposal **tran1**, set the SPIs of the inbound and outbound SAs to 12345, and the

keys for the inbound and outbound SAs using ESP to abcdefg; create an IPsec proposal named **tran2**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy002**, specify the manual mode for it, reference IPsec proposal **tran2**, set the SPIs of the inbound and outbound SAs to 54321, and the keys for the inbound and outbound SAs using ESP to gfedcba.

```
[SwitchB] ipsec proposal tran1
[SwitchB-ipsec-proposal-tran1] encapsulation-mode transport
[SwitchB-ipsec-proposal-tran1] transform esp
[SwitchB-ipsec-proposal-tran1] esp encryption-algorithm des
[SwitchB-ipsec-proposal-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-proposal-tran1] quit
[SwitchB] ipsec policy policy001 10 manual
[SwitchB-ipsec-policy-manual-policy001-10] proposal tran1
[SwitchB-ipsec-policy-manual-policy001-10] sa spi outbound esp 12345
[SwitchB-ipsec-policy-manual-policy001-10] sa spi inbound esp 12345
[SwitchB-ipsec-policy-manual-policy001-10] sa string-key outbound esp abcdefg
[SwitchB-ipsec-policy-manual-policy001-10] sa string-key inbound esp abcdefg
[SwitchB-ipsec-policy-manual-policy001-10] quit
[SwitchB] ipsec proposal tran2
[SwitchB-ipsec-proposal-tran2] encapsulation-mode transport
[SwitchB-ipsec-proposal-tran2] transform esp
[SwitchB-ipsec-proposal-tran2] esp encryption-algorithm des
[SwitchB-ipsec-proposal-tran2] esp authentication-algorithm sha1
[SwitchB-ipsec-proposal-tran2] quit
[SwitchB] ipsec policy policy002 10 manual
[SwitchB-ipsec-policy-manual-policy002-10] proposal tran2
[SwitchB-ipsec-policy-manual-policy002-10] sa spi outbound esp 54321
[SwitchB-ipsec-policy-manual-policy002-10] sa spi inbound esp 54321
[SwitchB-ipsec-policy-manual-policy002-10] sa string-key outbound esp gfedcba
[SwitchB-ipsec-policy-manual-policy002-10] sa string-key inbound esp gfedcba
[SwitchB-ipsec-policy-manual-policy002-10] quit
```

On Switch C, create an IPsec proposal named **tran2**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy002**, specify the manual mode for it, reference IPsec proposal **tran2**, set the SPIs of the inbound and outbound SAs to 54321, and the keys for the inbound and outbound SAs using ESP to gfedcba.

```
[SwitchC] ipsec proposal tran2
[SwitchC-ipsec-proposal-tran2] encapsulation-mode transport
[SwitchC-ipsec-proposal-tran2] transform esp
[SwitchC-ipsec-proposal-tran2] esp encryption-algorithm des
[SwitchC-ipsec-proposal-tran2] esp authentication-algorithm sha1
[SwitchC-ipsec-proposal-tran2] quit
[SwitchC] ipsec policy policy002 10 manual
[SwitchC-ipsec-policy-manual-policy002-10] proposal tran2
[SwitchC-ipsec-policy-manual-policy002-10] sa spi outbound esp 54321
[SwitchC-ipsec-policy-manual-policy002-10] sa spi inbound esp 54321
[SwitchC-ipsec-policy-manual-policy002-10] sa string-key outbound esp gfedcba
[SwitchC-ipsec-policy-manual-policy002-10] sa string-key inbound esp gfedcba
```

```
[SwitchC-ipsec-policy-manual-policy002-10] quit
```

4. Apply the IPsec policies in areas:

Configure Switch A.

```
[SwitchA] ospfv3 1
[SwitchA-ospfv3-1] area 1
[SwitchA-ospfv3-1-area-0.0.0.1] enable ipsec-policy policy001
[SwitchA-ospfv3-1-area-0.0.0.1] quit
[SwitchA-ospfv3-1] quit
```

Configure Switch B.

```
[SwitchB] ospfv3 1
[SwitchB-ospfv3-1] area 0
[SwitchB-ospfv3-1-area-0.0.0.0] enable ipsec-policy policy002
[SwitchB-ospfv3-1-area-0.0.0.0] quit
[SwitchB-ospfv3-1] area 1
[SwitchB-ospfv3-1-area-0.0.0.1] enable ipsec-policy policy001
[SwitchB-ospfv3-1-area-0.0.0.1] quit
[SwitchB-ospfv3-1] quit
```

Configure Switch C.

```
[SwitchC] ospfv3 1
[SwitchC-ospfv3-1] area 0
[SwitchC-ospfv3-1-area-0.0.0.0] enable ipsec-policy policy002
[SwitchC-ospfv3-1-area-0.0.0.0] quit
[SwitchC-ospfv3-1] quit
```

5. Verify the configuration:

OSPFv3 traffic between Switches A, B, and C is protected by IPsec.

Troubleshooting OSPFv3 configuration

No OSPFv3 neighbor relationship established

Symptom

No OSPF neighbor relationship can be established.

Analysis

If the physical link and lower protocol function properly, check OSPF parameters configured on interfaces. The two neighboring interfaces must have the same parameters, such as the area ID, network segment and mask, and network type. If the network type is broadcast, at least one interface must have a DR priority higher than 0.

Process steps

1. Display neighbor information using the **display ospfv3 peer** command.
2. Display OSPFv3 interface information using the **display ospfv3 interface** command.
3. Ping the neighbor router's IP address to check connectivity.
4. Check OSPF timers. The dead interval on an interface must be at least four times the hello interval.
5. On a broadcast network, at least one interface must have a DR priority higher than 0.

Incorrect routing information

Symptom

OSPFv3 cannot find routes to other areas.

Analysis

The backbone area must maintain connectivity to all other areas. If a router connects to more than one area, at least one area must be connected to the backbone. The backbone cannot be configured as a stub area.

In a stub area, routers cannot receive external routes, and interfaces connected to the stub area must be associated with the stub area.

Solution

1. Use the **display ospfv3 peer** command to display OSPFv3 neighbors.
2. Use the **display ospfv3 interface** command to display OSPFv3 interface information.
3. Use the **display ospfv3 lsdb** command to display LSDB information to check integrity.
4. Display information about area configuration using the **display current-configuration configuration** command. If more than two areas are configured, at least one area is connected to the backbone.
5. In a stub area, all routers are configured with the **stub** command.
6. If a virtual link is configured, use the **display ospf vlink** command to check the neighbor state.

Configuring IPv6 IS-IS

This chapter describes how to configure IPv6 IS-IS, which supports all IPv4 IS-IS features except that it advertises IPv6 routing information instead. For information about IS-IS, see "[Configuring IS-IS](#)."

The term "router" in this chapter refers to both routers and Layer 3 switches.

Hardware compatibility

The HP 5500 SI Switch Series does not support IPv6 IS-IS.

Introduction to IPv6 IS-IS

The IS-IS routing protocol (Intermediate System-to-Intermediate System intra-domain routing information exchange protocol) supports multiple network protocols, including IPv6. The international engineer task force (IETF) defines two type-length-values (TLVs) and a new network layer protocol identifier (NLPID) to enable IS-IS to support IPv6.

TLV is a variable-length field in the link state PDU or link state packet (LSP). The TLVs include the following:

- **IPv6 Reachability**—Defines the prefix, metric of routing information to indicate network reachability, and has a type value of 236 (0xEC).
- **IPv6 Interface Address**—Same as the "IP Interface Address" TLV in IPv4 ISIS, except the 32-bit IPv4 address is translated to the 128-bit IPv6 address.

The NLPID is an eight-bit field that identifies which network layer protocol is supported. For IPv6, the NLPID is 142 (0x8E), which must be carried in hello packets sent by a router that supports IPv6 IS-IS.

Configuring IPv6 IS-IS basic functions

You can implement IPv6 inter-networking through configuring IPv6 IS-IS in IPv6 network environment.

Before the configuration, complete the following tasks:

- Enable IPv6 globally.
- Configure IP addresses for interfaces, and ensure all neighboring nodes are reachable.
- Enable IS-IS.

To configure the basic functions of IPv6 IS-IS:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable an IS-IS process and enter IS-IS view.	isis [process-id]	Not enabled by default.
3. Configure the network entity title for the IS-IS process.	network-entity net	Not configured by default.
4. Enable IPv6 for the IS-IS process.	ipv6 enable	Disabled by default.

Step	Command	Remarks
5. Return to system view.	quit	N/A
6. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
7. Enable IPv6 for an IS-IS process on the interface.	isis ipv6 enable [<i>process-id</i>]	Disabled by default.

Configuring IPv6 IS-IS routing information control

Complete the IPv6 IS-IS basic function configuration before configuring this task.

For information about ACL, see *ACL and QoS Configuration Guide*.

For information about routing policy and IPv6 prefix list, see "[Configuring routing policies](#)."

To configure IPv6 IS-IS routing information control:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IS-IS view.	isis [<i>process-id</i>]	N/A
3. Define the priority for IPv6 IS-IS routes.	ipv6 preference { route-policy <i>route-policy-name</i> <i>preference</i> } *	Optional. 15 by default.
4. Configure an IPv6 IS-IS summary route.	ipv6 summary <i>ipv6-prefix</i> <i>prefix-length</i> [avoid-feedback generate_null0_route [level-1 level-1-2 level-2] tag <i>tag</i>] *	Optional. Not configured by default.
5. Generate an IPv6 IS-IS default route.	ipv6 default-route-advertise [[level-1 level-1-2 level-2] route-policy <i>route-policy-name</i>] *	Optional. By default, no IPv6 default route is defined.
6. Configure IPv6 IS-IS to filter incoming routes.	ipv6 filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> route-policy <i>route-policy-name</i> } import	Optional. By default, no filtering policy is defined.
7. Configure IPv6 IS-IS to redistribute routes from another routing protocol.	ipv6 import-route <i>protocol</i> [<i>process-id</i>] [allow-ibgp] [cost <i>cost</i> [level-1 level-1-2 level-2] route-policy <i>route-policy-name</i> tag <i>tag</i>] *	Optional. Not configured by default.
8. Configure the maximum number of redistributed Level 1/Level 2 IPv6 routes.	ipv6 import-route limit <i>number</i>	Optional. The default varies with devices.
9. Configure the filtering of outgoing redistributed routes.	ipv6 filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> route-policy <i>route-policy-name</i> } export [<i>protocol</i> [<i>process-id</i>]]	Optional. Not configured by default.
10. Enable route leaking.	ipv6 import-route isisv6 level-2 into level-1 [filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> route-policy <i>route-policy-name</i> } tag <i>tag</i>] *	Optional. Not enabled by default.

Step	Command	Remarks
11. Specify the maximum number of equal-cost load balanced routes.	ipv6 maximum load-balancing <i>number</i>	Optional. 8 by default.

NOTE:

The **ipv6 filter-policy export** command is usually combined with the **ipv6 import-route** command. If no *protocol* is specified for the **ipv6 filter-policy export** command, routes redistributed from all routing protocols are filtered before advertisement. If a protocol is specified, only routes redistributed from the routing protocol are filtered for advertisement.

Configuring BFD for IPv6 IS-IS

Bidirectional forwarding detection (BFD) provides a mechanism to quickly detect the connectivity of links between IPv6 IS-IS neighbors, thus to improve the convergence speed of IPv6 IS-IS. For more information about BFD, see *High Availability Configuration Guide*.

To configure BFD for IPv6 IS-IS:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable an IS-IS process and enter IS-IS view.	isis [<i>process-id</i>]	N/A
3. Configure the network entity title for the IS-IS process.	network-entity <i>net</i>	Not configured by default.
4. Enable IPv6 for the IS-IS process.	ipv6 enable	Disabled by default.
5. Return to system view.	quit	N/A
6. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
7. Enable IPv6 for an IS-IS process on the interface.	isis ipv6 enable [<i>process-id</i>]	Disabled by default.
8. Enable BFD on the interface.	isis ipv6 bfd enable	Not enabled by default.

Displaying and maintaining IPv6 IS-IS

Task	Command	Remarks
Display brief IPv6 IS-IS information.	display isis brief [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the status of the debug switches.	display isis debug-switches { <i>process-id</i> vpn-instance <i>vpn-instance-name</i> } [[{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display IS-IS enabled interface information.	display isis interface [statistics [<i>interface-type interface-number</i>] [verbose] [<i>process-id</i> vpn-instance vpn-instance-name] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display LSDB information.	display isis lsdb [[I1 I2 level-1 level-2] [[lsp-id lsp-id lsp-name lspname local] verbose] * [<i>process-id</i> vpn-instance vpn-instance-name] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IS-IS mesh group information.	display isis mesh-group [<i>process-id</i> vpn-instance vpn-instance-name] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the mapping table between the host name and system ID.	display isis name-table [<i>process-id</i> vpn-instance vpn-instance-name] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IS-IS neighbor information.	display isis peer [statistics verbose] [<i>process-id</i> vpn-instance vpn-instance-name] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 IS-IS routing information.	display isis route ipv6 [[level-1 level-2] verbose] * [<i>process-id</i> vpn-instance vpn-instance-name] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display SPF log information.	display isis spf-log [<i>process-id</i> vpn-instance vpn-instance-name] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the statistics of the IS-IS process.	display isis statistics [level-1 level-1-2 level-2] [<i>process-id</i> vpn-instance vpn-instance-name] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear all IS-IS data structure information.	reset isis all [<i>process-id</i> vpn-instance vpn-instance-name]	Available in user view
Clear the IS-IS data information of a neighbor.	reset isis peer system-id [<i>process-id</i> vpn-instance vpn-instance-name]	Available in user view

IPv6 IS-IS configuration examples

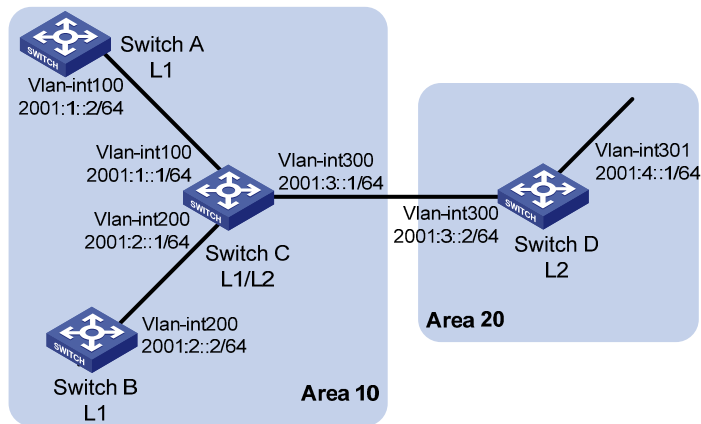

IPv6 IS-IS basic configuration example

Network requirements

As shown in [Figure 113](#), Switch A, Switch B, Switch C, and Switch D reside in the same autonomous system, and all are enabled with IPv6.

Switch A and Switch B are Level-1 switches, Switch D is a Level-2 switch, and Switch C is a Level-1-2 switch. Switch A, Switch B, and Switch C are in area 10, and Switch D is in area 20.

Figure 113 Network diagram

Configuration procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure IPv6 IS-IS:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] isis 1
[SwitchA-isis-1] is-level level-1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] ipv6 enable
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis ipv6 enable 1
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] isis 1
[SwitchB-isis-1] is-level level-1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] ipv6 enable
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis ipv6 enable 1
[SwitchB-Vlan-interface200] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] ipv6 enable
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 100
```

```
[SwitchC-Vlan-interface100] isis ipv6 enable 1
[SwitchC-Vlan-interface100] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis ipv6 enable 1
[SwitchC-Vlan-interface200] quit
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis ipv6 enable 1
[SwitchC-Vlan-interface300] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ipv6
[SwitchD] isis 1
[SwitchD-isis-1] is-level level-2
[SwitchD-isis-1] network-entity 20.0000.0000.0004.00
[SwitchD-isis-1] ipv6 enable
[SwitchD-isis-1] quit
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] isis ipv6 enable 1
[SwitchD-Vlan-interface300] quit
[SwitchD] interface vlan-interface 301
[SwitchD-Vlan-interface301] isis ipv6 enable 1
[SwitchD-Vlan-interface301] quit
```

3. Verify the configuration:

Display the IPv6 IS-IS routing table of Switch A.

```
[SwitchA] display isis route ipv6
```

BFD for IPv6 IS-IS configuration example

Network requirements

As shown in [Figure 114](#), configure IPv6 IS-IS on Switch A, Switch B, and Switch C and configure BFD over the link Switch A \leftrightarrow L2 Switch \leftrightarrow Switch B.

After the link between Switch B and the Layer-2 switch fails, BFD can quickly detect the failure and notify IPv6 IS-IS of the failure. Then Switch A and Switch B communicate through Switch C.

Figure 114 Network diagram

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Switch A	Vlan-int10	2001::1/64	Switch B	Vlan-int10	2001::2/64
	Vlan-int11	2001:2::1/64		Vlan-int13	2001:3::2/64
Switch C	Vlan-int11	2001:2::2/64			
	Vlan-int13	2001:3::1/64			

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)

2. Configure IPv6 IS-IS:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] isis 1
[SwitchA-isis-1] is-level level-1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] ipv6 enable
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis ipv6 enable 1
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 11
[SwitchA-Vlan-interface11] isis ipv6 enable 1
[SwitchA-Vlan-interface11] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] isis 1
```

```

[SwitchB-isis-1] is-level level-1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] ipv6 enable
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis ipv6 enable 1
[SwitchB-Vlan-interface10] quit
[SwitchB] interface vlan-interface 13
[SwitchB-Vlan-interface13] isis ipv6 enable 1
[SwitchB-Vlan-interface13] quit

```

Configure Switch C.

```

<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] ipv6 enable
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 11
[SwitchC-Vlan-interface11] isis ipv6 enable 1
[SwitchC-Vlan-interface11] quit
[SwitchC] interface vlan-interface 13
[SwitchC-Vlan-interface13] isis ipv6 enable 1
[SwitchC-Vlan-interface13] quit

```

3. Configure BFD functions:

Enable BFD on Switch A and configure BFD parameters.

```

[SwitchA] bfd session init-mode active
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis ipv6 bfd enable
[SwitchA-Vlan-interface10] bfd min-transmit-interval 500
[SwitchA-Vlan-interface10] bfd min-receive-interval 500
[SwitchA-Vlan-interface10] bfd detect-multiplier 7
[SwitchA-Vlan-interface10] return

```

Enable BFD on Switch B and configure BFD parameters.

```

[SwitchB] bfd session init-mode active
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis ipv6 bfd enable
[SwitchB-Vlan-interface10] bfd min-transmit-interval 500
[SwitchB-Vlan-interface10] bfd min-receive-interval 500
[SwitchB-Vlan-interface10] bfd detect-multiplier 6

```

4. Verify configuration:

The following operations are made on Switch A. Operations for Switch B are similar and are not shown here.

Display the BFD information of Switch A.

```

<SwitchA> display bfd session
Total Session Num: 1          Init Mode: Active

IPv6 Session Working Under Ctrl Mode:

```

```

Local Discr: 1441 Remote Discr: 1450
Source IP: FE80::20F:FF:FE00:1202 (link-local address of VLAN-interface 10 on
Switch A)
Destination IP: FE80::20F:FF:FE00:1200 (link-local address of VLAN-interface 10 on
Switch B)
Session State: Up Interface: Vlan10
Hold Time: /

```

Display route 2001:4::0/64 on Switch A, and you can see that Switch A and Switch B communicate through the Layer-2 switch.

```
<SwitchA> display ipv6 routing-table 2001:4::0 64 verbose
```

```
Routing Table :
```

```
Summary Count : 2
```

```

Destination : 2001:4::0 PrefixLength : 64
NextHop : 2001::2 Preference : 15

Configuring IPv6 BGP

This chapter describes only configuration for IPv6 BGP. For BGP related information, see "[Configuring BGP](#)." The term "router" in this chapter refers to both routers and Layer 3 switches.

Hardware compatibility

The HP 5500 SI Switch Series does not support IPv6 BGP.

IPv6 BGP overview

BGP-4 was designed to carry only IPv4 routing information, so other network layer protocols such as IPv6 are not supported.

To support multiple network layer protocols, IETF extended BGP-4 by introducing Multiprotocol BGP (MP-BGP), which is defined in RFC 2858 (multiprotocol extensions for BGP-4).

For brevity purposes, MP-BGP for IPv6 is called "IPv6 BGP."

IPv6 BGP puts IPv6 network layer information into the attributes of Network Layer Reachability Information (NLRI) and NEXT_HOP.

The NLRI attribute of IPv6 BGP involves the following:

- **MP_REACH_NLRI**—Multiprotocol Reachable NLRI, for advertising reachable route and next hop information.
- **MP_UNREACH_NLRI**—Multiprotocol Unreachable NLRI, for withdrawal of unreachable routes.

The NEXT_HOP attribute of IPv6 BGP is identified by an IPv6 unicast address or IPv6 local link address.

IPv6 BGP has the same messaging and routing mechanisms as BGP.

IPv6 BGP configuration task list

Task	Remarks
Configuring IPv6 BGP basic Specifying an IPv6 BGP peer	Required

Task	Remarks	
	Injecting a local IPv6 route	Optional
	Configuring a preferred value for routes from a peer or peer group	Optional
	Specifying the source interface for establishing TCP connections	Optional
	Allowing the establishment of an indirect EBGp connection	Optional
	Configuring a description for an IPv6 peer or peer group	Optional
	Disabling session establishment to an IPv6 peer or peer group	Optional
	Logging IPv6 peer or peer group state changes	Optional
Controlling route distribution and reception	Configuring IPv6 BGP route redistribution	Optional
	Configuring IPv6 BGP route summarization	Optional
	Advertising a default route to an IPv6 peer or peer group	Optional
	Configuring outbound route filtering	Optional
	Configuring inbound route filtering	Optional
	Configuring IPv6 BGP and IGP route synchronization	Optional
Configuring IPv6 BGP route attributes	Configuring route dampening	Optional
	Configuring IPv6 BGP preference and default LOCAL_PREF and NEXT_HOP attributes	Optional
	Configuring the MED attribute	Optional
Tuning and optimizing IPv6 BGP networks	Configuring the AS_PATH attribute	Optional
	Configuring IPv6 BGP timers	Optional
	Configuring IPv6 BGP soft reset	Optional
	Enabling the IPv6 BGP ORF capability	Optional
	Enabling 4-byte AS number suppression	Optional
	Setting the DSCP value for IPv6 BGP packets	Optional
	Configuring the maximum number of load-balanced routes	Optional
	Enabling MD5 authentication for TCP connections	Optional
Applying an IPsec policy to an IPv6 BGP peer or peer group	Optional	
Configuring a large-scale IPv6 BGP network	Configuring IPv6 BGP peer group	Optional
	Configuring IPv6 BGP community	Optional
	Configuring an IPv6 BGP route reflector	Optional

Task	Remarks
Configuring BFD for IPv6 BGP	Optional

Configuring IPv6 BGP basic functions

Configuration prerequisites

Before you configure IPv6 BGP basic functions, complete the following tasks:

- Specify IP addresses for interfaces.
- Enable IPv6.

Configuration guidelines

Create a peer group before configuring basic functions for it. For more information, see "[Configuring IPv6 BGP peer group](#)."

Specifying an IPv6 BGP peer

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Specify a router ID.	router-id <i>router-id</i>	Optional. Required if no IP addresses are configured for any interfaces.
4. Enter IPv6 address family view.	ipv6-family	N/A
5. Specify an IPv6 peer.	peer <i>ipv6-address</i> as-number <i>as-number</i>	N/A

Injecting a local IPv6 route

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Inject a local route into the IPv6 BGP routing table.	network <i>ipv6-address prefix-length</i> [short-cut route-policy <i>route-policy-name</i>]	Not added by default.

Configuring a preferred value for routes from a peer or peer group

If you both reference a routing policy and use the command **peer { ipv6-group-name | ipv6-address } preferred-value value** to set a preferred value for routes from a peer, the routing policy sets the specific preferred value for routes matching it. If the preferred value in the routing policy is zero, the routes use the value set with the **peer { ipv6-group-name | ipv6-address } preferred-value value** command. For how to use a routing policy to set a preferred value, see the command **peer { group-name | ipv4-address | ipv6-address } route-policy route-policy-name { import | export }** in this chapter, and the command **apply preferred-value preferred-value** in *Layer 3—IP Routing Command Reference*.

To configure a preferred value for routes from a peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure a preferred value for routes received from an IPv6 peer or peer group.	peer { ipv6-group-name ipv6-address } preferred-value value	By default, the preferred value is 0.

Specifying the source interface for establishing TCP connections

IPv6 BGP uses TCP as the transport layer protocol. By default, IPv6 BGP uses the output interface of the optimal route to a peer or peer group as the source interface for establishing TCP connections to the peer or peer group.

If an IPv6 BGP router has multiple links to a peer, and the source interface fails, IPv6 BGP has to reestablish TCP connections, causing network oscillation. To enhance stability of IPv6 BGP connections, HP recommends using a loopback interface as the source interface.

To establish a BGP connection, specify on the local router the source interface for establishing the TCP connection to the peer on the peering BGP router. Otherwise, the local BGP router may fail to establish TCP connection to the peer when using the outbound interface of the best route as the source interface.

To specify the source interface for establishing TCP connections to a BGP peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A

Step	Command	Remarks
4. Specify the source interface for establishing TCP connections to an IPv6 BGP peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } connect-interface <i>interface-type interface-number</i>	By default, IPv6 BGP uses the outbound interface of the best route to the IPv6 BGP peer or peer group as the source interface for establishing a TCP connection.

Allowing the establishment of an indirect EBGP connection

Direct links must be available between EBGP peers. If not, you can use the **peer ebgp-max-hop** command to establish a multi-hop TCP connection in between. However, do not use this command for direct EBGP connections with loopback interfaces.

To allow the establishment of a non-direct EBGP connection:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Allow the establishment of EBGP connection to an indirectly connected peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } ebgp-max-hop [<i>hop-count</i>]	Not configured by default.

Configuring a description for an IPv6 peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure a description for an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } description <i>description-text</i>	Optional. Not configured by default. The peer group to be configured with a description must have been created.

Disabling session establishment to an IPv6 peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A

Step	Command	Remarks
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Disable session establishment to an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } ignore	Optional. Not disabled by default.

Logging IPv6 peer or peer group state changes

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enable logging of peer changes globally.	log-peer-change	Optional. Enabled by default. For information about the log-peer-change command, see <i>Layer 3—IP Routing Command Reference</i> .
4. Enter IPv6 address family view.	ipv6-family	N/A
5. Enable the state change logging for an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } log-change	Optional. Enabled by default.

Controlling route distribution and reception

This task includes routing information filtering, routing policy application, and route dampening.

Configuration prerequisites

Before you configure route distribution and reception control, complete the following tasks:

- Enable IPv6.
- Configure IPv6 BGP basic functions.

Configuring IPv6 BGP route redistribution

To configure IPv6 BGP route redistribution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A

Step	Command	Remarks
4. Enable default route redistribution into the IPv6 BGP routing table.	default-route imported	Optional. Not enabled by default. If the default-route imported command is not configured, using the import-route command cannot redistribute any IGP default route.
5. Enable route redistribution from another routing protocol.	import-route protocol [<i>process-id</i> [med <i>med-value</i> route-policy <i>route-policy-name</i>] *]	Not enabled by default.

Configuring IPv6 BGP route summarization

To reduce the routing table size on medium and large BGP networks, configure route summarization on BGP routers. BGP supports only manual summarization of IPv6 routes.

To configure IPv6 BGP route summarization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure manual route summarization.	aggregate <i>ipv6-address prefix-length</i> [as-set attribute-policy <i>route-policy-name</i> detail-suppressed origin-policy <i>route-policy-name</i> suppress-policy <i>route-policy-name</i>] *	Not configured by default.

Advertising a default route to an IPv6 peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A

Step	Command	Remarks	
4.	Advertise a default route to an IPv6 peer or peer group.	<pre>peer { ipv6-group-name ipv6-address } default-route-advertise [route-policy route-policy-name]</pre>	<p>Not advertised by default.</p> <p>With the peer default-route-advertise command executed, the local router advertises a default route with itself as the next hop to the specified IPv6 peer or peer group, regardless of whether the default route is available in the routing table.</p>

Configuring outbound route filtering

IPv6 BGP advertises routes passing the specified policy to peers. Using the *protocol* argument can filter only the routes redistributed from the specified protocol. If no *protocol* is specified, IPv6 BGP filters all routes to be advertised, including redistributed routes and routes imported with the **network** command.

To configure outbound route filtering:

Step	Command	Remarks	
1.	Enter system view.	system-view	N/A
2.	Enter BGP view.	bgp as-number	N/A
3.	Enter IPv6 address family view.	ipv6-family	N/A
4.	Configure the filtering of outgoing routes.	<pre>filter-policy { acl6-number ipv6-prefix ipv6-prefix-name } export [protocol process-id]</pre>	Not configured by default.
5.	Apply a routing policy to routes advertised to an IPv6 peer or peer group.	<pre>peer { ipv6-group-name ipv6-address } route-policy route-policy-name export</pre>	Not applied by default.
6.	Specify an IPv6 ACL to filter routes advertised to an IPv6 peer or peer group.	<pre>peer { ipv6-group-name ipv6-address } filter-policy acl6-number export</pre>	Not specified by default.
7.	Specify an AS path ACL to filter routes advertised to an IPv6 peer or peer group.	<pre>peer { ipv6-group-name ipv6-address } as-path-acl as-path-acl-number export</pre>	Not specified by default.
8.	Specify an IPv6 prefix list to filter routes advertised to an IPv6 peer or peer group.	<pre>peer { ipv6-group-name ipv6-address } ipv6-prefix ipv6-prefix-name export</pre>	Not specified by default.

Configuring inbound route filtering

Only routes passing the configured filtering can be added into the local IPv6 BGP routing table.

Members of a peer group can have different inbound route filtering policies.

To configure inbound route filtering:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure inbound route filtering.	filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> } import	Not configured by default.
5. Apply a routing policy to routes from an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } route-policy <i>route-policy-name</i> import	Not applied by default.
6. Specify an ACL to filter routes imported from an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } filter-policy <i>acl6-number</i> import	Not specified by default.
7. Specify an AS path ACL to filter routing information imported from an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } as-path-acl <i>as-path-acl-number</i> import	Not specified by default.
8. Specify an IPv6 prefix list to filter routing information imported from an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } ipv6-prefix <i>ipv6-prefix-name</i> import	Not specified by default.
9. Specify the upper limit of prefixes allowed to receive from an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } route-limit <i>limit</i> [<i>percentage</i>]	Optional. Unlimited by default.

Configuring IPv6 BGP and IGP route synchronization

By default, upon receiving an IBGP route, an IPv6 BGP router checks the route's next hop. If the next hop is reachable, the IPv6 BGP router advertises the route to EBGP peers. If the synchronization feature is configured, in addition to the reachability check of the next hop, the IPv6 BGP router must find an active IGP route with the same destination network segment before it can advertise the IBGP route (use the **display ipv6 routing-table protocol** command to check the IGP route state).

To configure IPv6 BGP and IGP route synchronization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Enable route synchronization between IPv6 BGP and IGP.	synchronization	Not enabled by default.

Configuring route dampening

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure IPv6 BGP route dampening parameters.	dampening [<i>half-life-reachable</i> <i>half-life-unreachable</i> <i>reuse suppress ceiling</i> route-policy <i>route-policy-name</i>]*	Optional. Not configured by default.

Configuring IPv6 BGP route attributes

Use the following IPv6 BGP route attributes to modify BGP routing policy:

- IPv6 BGP protocol preference
- Default LOCAL_PREF attribute
- MED attribute
- NEXT_HOP attribute
- AS_PATH attribute

Configuration prerequisites

Before you configure IPv6 BGP route attributes, complete the following tasks:

- Enable IPv6 function.
- Configure IPv6 BGP basic functions.

Configuring IPv6 BGP preference and default LOCAL_PREF and NEXT_HOP attributes

Follow these guidelines when you configure IPv6 BGP preference and default LOCAL_PREF and NEXT_HOP attributes:

- To ensure an IBGP peer can find the correct next hop, configure routes advertised to the IPv6 IBGP peer or peer group to use the local router as the next hop. If BGP load balancing is configured, the local router specifies itself as the next hop of routes sent to an IPv6 IBGP peer or peer group regardless of whether the **peer next-hop-local** command is configured.
- In a *third party next hop* network where the two IPv6 EBGP peers reside in a common broadcast subnet, the router does not change the next hop for routes sent to the IPv6 EBGP peer or peer group by default, unless the **peer next-hop-local** command is configured.

To configure IPv6 BGP preference and default LOCAL_PREF and NEXT_HOP attributes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure preference values for IPv6 BGP external, internal, and local routes.	preference { <i>external-preference</i> <i>internal-preference</i> <i>local-preference</i> route-policy <i>route-policy-name</i> }	Optional. The default preference values of external, internal, and local routes are 255, 255, and 130.
5. Configure the default local preference.	default local-preference <i>value</i>	Optional. The <i>value</i> defaults to 100.
6. Advertise routes to an IPv6 peer or peer group with the local router as the next hop.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } next-hop-local	By default, IPv6 BGP specifies the local router as the next hop for routes sent to an IPv6 EBGP peer or peer group, but does not change the next hop for routes sent to an IPv6 IBGP peer or peer group.

Configuring the MED attribute

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure a default MED value.	default med <i>med-value</i>	Optional. Defaults to 0.
5. Enable the comparison of MED for routes from different EBGP peers.	compare-different-as-med	Optional. Not enabled by default.
6. Enable the comparison of MED for routes from each AS.	bestroute compare-med	Optional. Disabled by default.
7. Enable the comparison of MED for routes from confederation peers.	bestroute med-confederation	Optional. Disabled by default.

Configuring the AS_PATH attribute

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A

Step	Command	Remarks
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Allow the local AS number to appear in AS_PATH of routes from a peer or peer group and specify the repeat times.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } allow-as-loop [<i>number</i>]	Optional. Not allowed by default.
5. Specify a fake AS number for an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } fake-as <i>as-number</i>	Optional. Not specified by default.
6. Disable IPv6 BGP from considering the AS_PATH during best route selection.	bestroute as-path-neglect	Optional. Enabled by default.
7. Configure to carry only the public AS number in updates sent to a peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } public-as-only	Optional. By default, IPv6 BGP updates carry a private AS number.
8. Substitute the local AS number for the AS number of an IPv6 peer or peer group identified in the AS_PATH attribute.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } substitute-as	Optional. Not substituted by default.

Tuning and optimizing IPv6 BGP networks

This section describes configurations of IPv6 BGP timers, IPv6 BGP connection soft reset, and the maximum number of load balanced routes.

- IPv6 BGP timers

After establishing an IPv6 BGP connection, two routers send keepalive messages periodically to each other to maintain the connection. If a router receives no keepalive message from the peer after the holdtime elapses, it tears down the connection.

When establishing an IPv6 BGP connection, the two parties compare their holdtimes, taking the shorter one as the common holdtime. If the holdtime is 0, neither keepalive message is sent, nor holdtime is checked.

- IPv6 BGP connection soft reset

After modifying a route selection policy, you must reset IPv6 BGP connections to make the new one take effect. The current IPv6 BGP implementation supports the route-refresh feature that enables dynamic route refresh without needing to disconnect IPv6 BGP links.

After this feature is enabled on all IPv6 BGP routers, a router that wants to apply a new route selection policy advertises a route-refresh message to its peers, which then send their routing information to the router. After receiving the routing information, the router can perform dynamic route update by using the new policy without tearing down connections.

If a peer not supporting route-refresh exists in the network, you must configure the **peer keep-all-routes** command to save all routes from the peer. When the routing policy is changed, the system will update the IPv6 BGP routing table and apply the new policy.

Configuration prerequisites

Before you configure IPv6 BGP timers, complete the following tasks:

- Enable IPv6.
- Configure IPv6 BGP basic functions.

Configuring IPv6 BGP timers

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure IPv6 BGP timers.	<ul style="list-style-type: none">• Specify keepalive interval and holdtime: timer keepalive keepalive hold holdtime• Configure keepalive interval and holdtime for an IPv6 peer or peer group: peer { ipv6-group-name .ipv6-address } timer keepalive keepalive hold holdtime	<p>Optional.</p> <p>The keepalive interval defaults to 60 seconds, holdtime defaults to 180 seconds.</p> <p>The holdtime interval must be at least three times the keepalive interval.</p> <p>Timers configured by using the timer command have lower priority than timers configured by using the peer timer command.</p>
5. Configure the interval for sending the same update to an IPv6 peer or peer group.	peer { ipv6-group-name ipv6-address } route-update-interval interval	<p>Optional.</p> <p>The interval for sending the same update to an IBGP peer or an EBGP peer defaults to 15 seconds or 30 seconds.</p>

Configuring IPv6 BGP soft reset

Enabling route refresh

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Enable route refresh.	peer { ipv6-group-name ipv6-address } capability-advertise route-refresh	<p>Optional.</p> <p>Enabled by default.</p>

Performing manual soft-reset

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Save all routes from an IPv6 peer or peer group, not letting them go through the inbound policy.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } keep-all-routes	Optional. Not saved by default. If the peer keep-all-routes command is used, all routes from the peer or peer group are saved regardless of whether the filtering policy is available. These routes will be used to generate IPv6 BGP routes after soft-reset is performed.
5. Return to user view.	return	N/A
6. Soft-reset BGP connections manually.	refresh bgp ipv6 { all <i>ipv6-address</i> group <i>ipv6-group-name</i> external internal } { export import }	N/A

Enabling the IPv6 BGP ORF capability

The BGP Outbound Route Filter (ORF) feature allows a BGP speaker to send its BGP peer a set of ORFs through route-refresh messages. The peer then applies the ORFs, in addition to its local routing policies (if any), to filter updates to the BGP speaker, reducing the number of exchanged update messages and saving network resources.

After you enable the BGP ORF capability, the local BGP router negotiates the ORF capability with the BGP peer through Open messages. The local BGP router determines whether to carry ORF information in messages. If yes, it will further determine whether to carry non-standard ORF information in the packets. After completing the negotiation process and establishing the neighboring relationship, the BGP router and its BGP peer can exchange ORF information through specific route-refresh messages.

For the parameters configured on both sides for ORF capability negotiation, see [Table 9](#).

To enable the BGP ORF capability:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	Required
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Enable BGP route refresh for a peer or peer group.	peer { <i>group-name</i> <i>ipv6-address</i> } capability-advertise route-refresh	Enabled by default

Step	Command	Remarks
5. Enable the non-standard ORF capability for a BGP peer or peer group.	peer { <i>group-name</i> <i>ipv6-address</i> } capability-advertise orf non-standard	Optional. By default, standard BGP ORF capability defined in RFC 5291 and RFC 5292 is supported.
6. Enable the ORF IP prefix negotiation capability for a BGP peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> <i>ipv6-address</i> } capability-advertise orf ip-prefix { both receive send }	Not supported by default.

Table 9 Description of the both, send, and receive parameters and the negotiation result

Local parameter	Peer parameter	Negotiation result
send	<ul style="list-style-type: none"> • receive • both 	The ORF sending capability is enabled locally and the ORF receiving capability is enabled on the peer.
receive	<ul style="list-style-type: none"> • send • both 	The ORF receiving capability is enabled locally and the ORF sending capability is enabled on the peer.
both	both	Both the ORF sending and receiving capabilities are enabled locally and on the peer.

Enabling 4-byte AS number suppression

When a switch that supports 4-byte AS numbers sends an Open message for peer relationship establishment, the Optional parameters field of the message indicates that the AS number occupies four bytes—in the range of 1 to 4294967295. If the peer device does not support 4-byte AS numbers (for examples, it supports only 2-byte AS numbers), the peer relationship cannot be established.

After you enable the 4-byte AS number suppression function, the peer device can then process the Open message even though it does not support 4-byte AS numbers, and the BGP peer relationship can be established.

If the peer device supports 4-byte AS numbers, do not enable the 4-byte AS number suppression function; otherwise, the BGP peer relationship cannot be established.

To enable 4-byte AS number suppression:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Enable 4-byte AS number suppression.	peer { <i>group-name</i> <i>ip-address</i> } capability-advertise suppress-4-byte-as	Disabled by default.

Setting the DSCP value for IPv6 BGP packets

An IPv6 packet header contains an 8-bit Traffic class field. This field identifies the service type of IPv6 packets. As defined in RFC 2474, the first six bits set the Differentiated Services Code Point (DSCP) value and the last two bits are reserved. Network devices use the DSCP value as a reference to determine the packet priority for transmission.

You can set the DSCP value for IPv6 BGP packets.

To set the DSCP value for packets sent to an IPv6 BGP peer or peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Set the DSCP value for the BGP packets sent to the specified IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } dscp <i>dscp-value</i>	Optional. By default, the DSCP value in IPv6 BGP packets is 48.

Configuring the maximum number of load-balanced routes

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure the maximum number of load balanced routes.	balance <i>number</i>	By default, no load balancing is enabled.

Enabling MD5 authentication for TCP connections

IPv6 BGP employs TCP as the transport protocol. To enhance security, configure IPv6 BGP to perform MD5 authentication when establishing a TCP connection. If the authentication fails, no TCP connection can be established.

The MD5 authentication for establishing TCP connections does not apply to BGP packets.

The MD5 authentication requires that the two parties have the same authentication mode and password to establish a TCP connection; otherwise, no TCP connection can be established due to authentication failure.

To enable MD5 authentication for TCP connections:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Enable MD5 authentication when establishing a TCP connection to the peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } password { cipher simple } <i>password</i>	Not enabled by default.

Applying an IPsec policy to an IPv6 BGP peer or peer group

To protect routing information and defend attacks, IPv6 BGP can authenticate protocol packets by using an IPsec policy.

Outbound IPv6 BGP packets carry the Security Parameter Index (SPI) defined in the IPsec policy. A device uses the SPI carried in a received packet to match against the configured IPsec policy. If they match, the device accepts the packet; otherwise, it discards the packet and will not establish a neighbor relationship with the sending device.

Configuration prerequisites

Before you apply an IPsec policy to a peer or peer group, complete following tasks:

- Create an IPsec proposal.
- Create an IPsec policy.

For more information about IPsec policy configuration, see *Security Configuration Guide*.

Configuration guidelines

An IPsec policy used for IPv6 BGP can be only in manual mode. For more information, see *Security Configuration Guide*.

Configuration procedure

To apply an IPsec policy to a peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Apply an IPsec policy to a peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } ipsec-policy <i>policy-name</i>	Not configured by default.

Configuring a large-scale IPv6 BGP network

In a large-scale IPv6 BGP network, configuration and maintenance become inconvenient because of too many peers. Configuring peer groups makes management easier and improves route distribution efficiency. Peer group includes IBGP peer group, where peers belong to the same AS, and EBGP peer group, where peers belong to different ASs. If peers in an EBGP group belong to the same external AS, the EBGP peer group is a pure EBGP peer group, and if not, a mixed EBGP peer group.

In a peer group, all members have a common policy. Using the community attribute can make a set of IPv6 BGP routers in multiple ASs have the same policy because community sending between IPv6 BGP peers is not limited by AS.

To assure connectivity between IBGP peers, make them fully meshed, but it becomes impractical when too many IBGP peers exist. Using route reflectors or confederation can solve this issue. In a large-scale AS, both of them can be used.

Confederation configuration of IPv6 BGP is identical to that of BGP4, so it is not mentioned here.

Configuration prerequisites

Before you configure a large-scale IPv6 BGP network, complete the following tasks:

- Make peer nodes accessible to each other at the network layer.
- Enable BGP and configure a router ID.

Configuring IPv6 BGP peer group

Configuring an IBGP peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Create an IBGP peer group.	group ipv6-group-name [internal]	N/A
5. Add a peer into the group.	peer ipv6-address group ipv6-group-name [as-number as-number]	Not added by default.

Creating a pure EBGP peer group

To create a pure EBGP peer group, specify an AS number for the peer group.

If a peer was added into an EBGP peer group, you cannot specify any AS number for the peer group.

To create a pure EBGP peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Create an EBGp peer group.	group <i>ipv6-group-name</i> external	N/A
5. Configure the AS number for the peer group.	peer <i>ipv6-group-name</i> as-number <i>as-number</i>	Not configured by default.
6. Add an IPv6 peer into the peer group.	peer <i>ipv6-address</i> group <i>ipv6-group-name</i>	Not added by default.

Creating a mixed EBGp peer group

When creating a mixed EBGp peer group, you must create a peer and specify its AS number that is different from AS numbers of other peers; however, you cannot specify AS number for the EBGp peer group.

To create a mixed EBGp peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Create an EBGp peer group.	group <i>ipv6-group-name</i> external	N/A
5. Specify the AS number of an IPv6 peer.	peer <i>ipv6-address</i> as-number <i>as-number</i>	Not specified by default.
6. Add the IPv6 peer into the peer group.	peer <i>ipv6-address</i> group <i>ipv6-group-name</i>	Not added by default.

Configuring IPv6 BGP community

When configuring IPv6 BGP community, you must configure a routing policy to define the community attribute, and apply the routing policy to route advertisement. For routing policy configuration, see "[Configuring routing policies.](#)"

Advertising community attribute to an IPv6 peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A

Step	Command	Remarks
4. Advertise community attribute to an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } advertise-community	Not advertised by default.
5. Advertise extended community attribute to an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } advertise-ext-community	Not advertised by default.

Applying a routing policy to routes advertised to a peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Apply a routing policy to routes advertised to an IPv6 peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } route-policy <i>route-policy-name</i> export	Not applied by default.

Configuring an IPv6 BGP route reflector

Follow these guidelines when you configure an IPv6 BGP route reflector:

Because the route reflector forwards routing information between clients, you must make clients of a route reflector fully meshed. If clients are fully meshed, HP recommends disabling route reflection between clients to reduce routing costs.

If a cluster has multiple route reflectors, you must specify the same cluster ID for these route reflectors to avoid routing loops.

To configure an IPv6 BGP route reflector:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure the router as a route reflector and specify an IPv6 peer or peer group as a client.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } reflect-client	Not configured by default.
5. Enable route reflection between clients.	reflect between-clients	Optional. Enabled by default.
6. Configure the cluster ID of the route reflector.	reflector cluster-id <i>cluster-id</i>	Optional. By default, a route reflector uses its router ID as the cluster ID.

Configuring BFD for IPv6 BGP

IPv6 BGP maintains neighbor relationships based on the keepalive timer and holdtime timer, which are set in seconds. IPv6 BGP defines that the holdtime interval must be at least three times the keepalive interval. This mechanism makes the detection of a link failure rather slow and thus causes a large quantity of packets to be dropped especially when the failed link is a high-speed link. You can enable BFD to detect the link to a peer. BFD can quickly detect any link failure and thus reduce network convergence time.

After a link failure occurs, BFD may detect the failure before the system performs GR and as a result, GR will fail. Therefore, if GR capability is enabled for IPv6 BGP, use BFD with caution. For more information about BFD, see *High Availability Configuration Guide*.

! IMPORTANT:

Before configuring BFD for IPv6 BGP, you must enable BGP.

To enable BFD for a BGP peer:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable BGP and enter BGP view.	bgp as-number	Not enabled by default.
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Enable BFD for the specified BGP peer.	peer ipv6-address bfd	Not enabled for any BGP peer by default.

Displaying and maintaining IPv6 BGP

Displaying BGP

Task	Command	Remarks
Display IPv6 BGP peer group information.	display bgp ipv6 group [<i>ipv6-group-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP advertised routing information.	display bgp ipv6 network [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP AS path information.	display bgp ipv6 paths [<i>as-regular-expression</i> { begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP peer or peer group information.	display bgp ipv6 peer [<i>group-name</i> log-info <i>ipv4-address</i> verbose <i>ipv6-address</i> { log-info verbose } verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display the prefix entries in the ORF information of the specified BGP peer.	display bgp ipv6 peer { <i>ip-address</i> <i>ipv6-address</i> } received ipv6-prefix [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP routing table information.	display bgp ipv6 routing-table [<i>ipv6-address</i> <i>prefix-length</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP routing information matching an AS path ACL.	display bgp ipv6 routing-table as-path-acl <i>as-path-acl-number</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP routing information with the specified community attribute.	display bgp ipv6 routing-table community [<i>aa:nn</i> <1-13>] [no-advertise no-export no-export-subconfed]* [whole-match] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP routing information matching an IPv6 BGP community list.	display bgp ipv6 routing-table community-list { { <i>basic-community-list-number</i> <i>comm-list-name</i> } [whole-match] <i>adv-community-list-number</i> }&<1-16> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display dampened IPv6 BGP routing information.	display bgp ipv6 routing-table dampened [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP dampening parameter information.	display bgp ipv6 routing-table dampening parameter [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP routing information originated from different ASs.	display bgp ipv6 routing-table different-origin-as [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP routing flap statistics.	display bgp ipv6 routing-table flap-info [regular-expression <i>as-regular-expression</i> [as-path-acl <i>as-path-acl-number</i> <i>ipv6-address</i> <i>prefix-length</i> [longer-match]] [{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display BGP routing information to or from an IPv4 or IPv6 peer.	display bgp ipv6 routing-table peer { <i>ipv4-address</i> <i>ipv6-address</i> } { advertised-routes received-routes } [<i>network-address</i> <i>prefix-length</i> statistic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 BGP routing information matching a regular expression.	display bgp ipv6 routing-table regular-expression <i>as-regular-expression</i>	Available in any view
Display IPv6 BGP routing statistics.	display bgp ipv6 routing-table statistic [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Resetting IPv6 BGP connections

Task	Command	Remarks
Perform soft reset on IPv6 BGP connections.	refresh bgp ipv6 { <i>ipv4-address</i> <i>ipv6-address</i> all external group <i>ipv6-group-name</i> internal } { export import }	Available in user view
Reset IPv6 BGP connections.	reset bgp ipv6 { <i>as-number</i> <i>ipv4-address</i> <i>ipv6-address</i> flap-info] all external group <i>group-name</i> internal }	Available in user view

Clearing IPv6 BGP information

Task	Command	Remarks
Clear dampened IPv6 BGP routing information and release suppressed routes.	reset bgp ipv6 dampening [<i>ipv6-address</i> / <i>prefix-length</i>]	Available in user view
Clear IPv6 BGP route flap information.	reset bgp ipv6 flap-info [<i>ipv6-address/prefix-length</i> as-path-acl <i>as-path-acl-number</i> regex <i>as-path-regexp</i>]	Available in user view

IPv6 BGP configuration examples

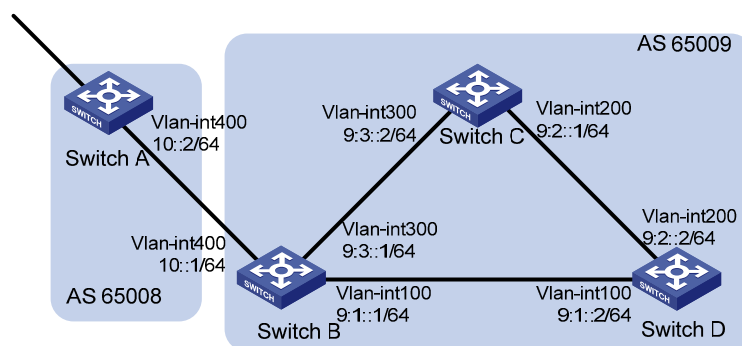

Some examples for IPv6 BGP configuration are similar to those of BGP4. For more information, see "Configuring BGP."

IPv6 BGP basic configuration example

Network requirements

All switches in Figure 115 run IPv6 BGP. Between Switch A and Switch B is an EBGP connection. Switch B, Switch C, and Switch D are fully meshed through IBGP connections.

Figure 115 Network diagram

Configuration procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure IBGP connections:
Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] bgp 65009
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] ipv6-family
[SwitchB-bgp-af-ipv6] peer 9:1::2 as-number 65009
[SwitchB-bgp-af-ipv6] peer 9:3::2 as-number 65009
[SwitchB-bgp-af-ipv6] quit
[SwitchB-bgp] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] bgp 65009
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] ipv6-family
[SwitchC-bgp-af-ipv6] peer 9:3::1 as-number 65009
[SwitchC-bgp-af-ipv6] peer 9:2::2 as-number 65009
[SwitchC-bgp-af-ipv6] quit
[SwitchC-bgp] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ipv6
[SwitchD] bgp 65009
[SwitchD-bgp] router-id 4.4.4.4
[SwitchD-bgp] ipv6-family
[SwitchD-bgp-af-ipv6] peer 9:1::1 as-number 65009
[SwitchD-bgp-af-ipv6] peer 9:2::1 as-number 65009
[SwitchD-bgp-af-ipv6] quit
[SwitchD-bgp] quit
```

3. Configure the EBGp connection:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] bgp 65008
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] ipv6-family
[SwitchA-bgp-af-ipv6] peer 10::1 as-number 65009
[SwitchA-bgp-af-ipv6] quit
[SwitchA-bgp] quit
```

Configure Switch B.

```
[SwitchB] bgp 65009
[SwitchB-bgp] ipv6-family
[SwitchB-bgp-af-ipv6] peer 10::2 as-number 65008
```

Display IPv6 peer information on Switch B.

```
[SwitchB] display bgp ipv6 peer
```

```

BGP local router ID : 2.2.2.2
Local AS number : 65009
Total number of peers : 3                Peers in established state : 3

```

Peer	AS	MsgRcvd	MsgSent	OutQ	PrefRcv	Up/Down	State
10::2	65008	3	3	0	0	00:01:16	Established
9:3::2	65009	2	3	0	0	00:00:40	Established
9:1::2	65009	2	4	0	0	00:00:19	Established

Display IPv6 peer information on Switch C.

```
[SwitchC] display bgp ipv6 peer
```

```

BGP local router ID : 3.3.3.3
Local AS number : 65009
Total number of peers : 2                Peers in established state : 2

```

Peer	AS	MsgRcvd	MsgSent	OutQ	PrefRcv	Up/Down	State
9:3::1	65009	4	4	0	0	00:02:18	Established
9:2::2	65009	4	5	0	0	00:01:52	Established

Switch A and B have established an EBGP connection; Switch B, C, and D have established IBGP connections with each other.

IPv6 BGP route reflector configuration example

Network requirements

As shown in the following figure, Switch B receives an EBGP update and sends it to Switch C, which is configured as a route reflector with two clients: Switch B and Switch D.

Switch B and Switch D do not need to establish an IBGP connection because Switch C reflects updates between them.

Figure 116 Network diagram

Configuration procedure

1. Configure IPv6 addresses for VLAN interfaces. (Details not shown.)

2. Configure IPv6 BGP basic functions:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] bgp 100
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] ipv6-family
[SwitchA-bgp-af-ipv6] peer 100::2 as-number 200
[SwitchA-bgp-af-ipv6] network 1:: 64
```

#Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] bgp 200
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] ipv6-family
[SwitchB-bgp-af-ipv6] peer 100::1 as-number 100
[SwitchB-bgp-af-ipv6] peer 101::1 as-number 200
[SwitchB-bgp-af-ipv6] peer 101::1 next-hop-local
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] bgp 200
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] ipv6-family
[SwitchC-bgp-af-ipv6] peer 101::2 as-number 200
[SwitchC-bgp-af-ipv6] peer 102::2 as-number 200
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ipv6
[SwitchD] bgp 200
[SwitchD-bgp] router-id 4.4.4.4
[SwitchD-bgp] ipv6-family
[SwitchD-bgp-af-ipv6] peer 102::1 as-number 200
```

3. Configure route reflector:

Configure Switch C as a route reflector, and configure Switch B and Switch D as its clients.

```
[SwitchC-bgp-af-ipv6] peer 101::2 reflect-client
[SwitchC-bgp-af-ipv6] peer 102::2 reflect-client
```

Use the **display bgp ipv6 routing-table** command on Switch B and Switch D; both of them learned the network 1::/64.

IPv6 BGP IPsec policy configuration example

Network requirements

As shown in the following figure,

- Configure IPv6 BGP on the switches. Switches A and B establish an IBGP relationship. Switches B and C establish an EBGP relationship.
- Configure IPsec policies on the switches to authenticate and encrypt protocol packets.

Figure 117 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure the IBGP connection:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] bgp 65008
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] ipv6-family
[SwitchA-bgp-af-ipv6] group ibgp internal
[SwitchA-bgp-af-ipv6] peer 1::2 group ibgp
[SwitchA-bgp-af-ipv6] quit
[SwitchA-bgp] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] bgp 65008
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] ipv6-family
[SwitchB-bgp-af-ipv6] group ibgp internal
[SwitchB-bgp-af-ipv6] peer 1::1 group ibgp
[SwitchB-bgp-af-ipv6] quit
[SwitchB-bgp] quit
```

3. Configure the EBGP connection:

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ipv6
[SwitchC] bgp 65009
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] ipv6-family
[SwitchC-bgp-af-ipv6] group ebgp external
[SwitchC-bgp-af-ipv6] peer 3::1 as-number 65008
[SwitchC-bgp-af-ipv6] peer 3::1 group ebgp
```

```
[SwitchC-bgp-af-ipv6] quit
[SwitchC-bgp] quit
```

Configure Switch B.

```
[SwitchB-bgp] ipv6-family
[SwitchB-bgp-af-ipv6] group ebgp external
[SwitchB-bgp-af-ipv6] peer 3::2 as-number 65009
[SwitchB-bgp-af-ipv6] peer 3::2 group ebgp
[SwitchB-bgp-af-ipv6] quit
[SwitchB-bgp] quit
```

4. Configure IPsec policies:

On Switch A, create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy001**, specify the manual mode for it, reference IPsec proposal **tran1**, set the SPIs of the inbound and outbound SAs to 12345, and the keys for the inbound and outbound SAs using ESP to abcdefg.

```
[SwitchA] ipsec proposal tran1
[SwitchA-ipsec-proposal-tran1] encapsulation-mode transport
[SwitchA-ipsec-proposal-tran1] transform esp
[SwitchA-ipsec-proposal-tran1] esp encryption-algorithm des
[SwitchA-ipsec-proposal-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-proposal-tran1] quit
[SwitchA] ipsec policy policy001 10 manual
[SwitchA-ipsec-policy-manual-policy001-10] proposal tran1
[SwitchA-ipsec-policy-manual-policy001-10] sa spi outbound esp 12345
[SwitchA-ipsec-policy-manual-policy001-10] sa spi inbound esp 12345
[SwitchA-ipsec-policy-manual-policy001-10] sa string-key outbound esp abcdefg
[SwitchA-ipsec-policy-manual-policy001-10] sa string-key inbound esp abcdefg
[SwitchA-ipsec-policy-manual-policy001-10] quit
```

On Switch B, create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy001**, specify the manual mode for it, reference IPsec proposal **tran1**, set the SPIs of the inbound and outbound SAs to 12345, and the keys for the inbound and outbound SAs using ESP to abcdefg; create an IPsec proposal named **tran2**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1; create an IPsec policy named **policy002**, specify the manual mode for it, reference IPsec proposal **tran2**, set the SPIs of the inbound and outbound SAs to 54321, and the keys for the inbound and outbound SAs using ESP to gfedcba.

```

```

5. Apply IPsec policies to IBGP peers:

Configure Switch A.

```

[SwitchA] bgp 65008
[SwitchA-bgp] ipv6-family
[SwitchA-bgp-af-ipv6] peer 1::2 ipsec-policy policy001
[SwitchA-bgp-af-ipv6] quit
[SwitchA-bgp] quit

```

Configure Switch B.

```

[SwitchB] bgp 65008
[SwitchB-bgp] ipv6-family

```

```
[SwitchB-bgp-af-ipv6] peer 1::1 ipsec-policy policy001
[SwitchB-bgp-af-ipv6] quit
[SwitchB-bgp] quit
```

6. Apply IPsec policies to EBGp peers:

Configure Switch C.

```
[SwitchC] bgp 65009
[SwitchC-bgp] ipv6-family
[SwitchC-bgp-af-ipv6] peer ebgp ipsec-policy policy002
[SwitchC-bgp-af-ipv6] quit
[SwitchC-bgp] quit
```

Configure Switch B.

```
[SwitchB] bgp 65008
[SwitchB-bgp] ipv6-family
[SwitchB-bgp-af-ipv6] peer ebgp ipsec-policy policy002
[SwitchB-bgp-af-ipv6] quit
[SwitchB-bgp] quit
```

7. Verify the configuration:

Display detailed IPv6 BGP peer information.

```
[SwitchB] display bgp ipv6 peer verbose
      BGP Peer is 1::1, remote AS 65008,
      Type: IBGP link
      BGP version 4, remote router ID 1.1.1.1
      BGP current state: Established, Up for 00h01m51s
      BGP current event: RecvKeepalive
      BGP last state: OpenConfirm
      Port: Local - 1029 Remote - 179
      Configured: Active Hold Time: 180 sec Keepalive Time: 60 sec
      Received : Active Hold Time: 180 sec
      Negotiated: Active Hold Time: 180 sec
      Peer optional capabilities:
      Peer support bgp multi-protocol extended
      Peer support bgp route refresh capability
      Address family IPv4 Unicast: advertised and received
Received: Total 0 messages, Update messages 0
Sent: Total 0 messages, Update messages 0
Maximum allowed prefix number: 4294967295
Threshold: 75%
Minimum time between advertisement runs is 30 seconds
Optional capabilities:
Route refresh capability has been enabled
ORF advertise capability based on prefix (type 64):
Local: both
Negotiated: send
Peer Preferred Value: 0
IPsec policy name: policy001, SPI :12345
```

```

Peer Preferred Value: 0
IPsec policy name: policy002, SPI :54321
Routing policy configured:
No routing policy is configured

```

The output shows that both IBGP and EBGP neighbor relationships have been established and all protocol packets are protected by IPsec.

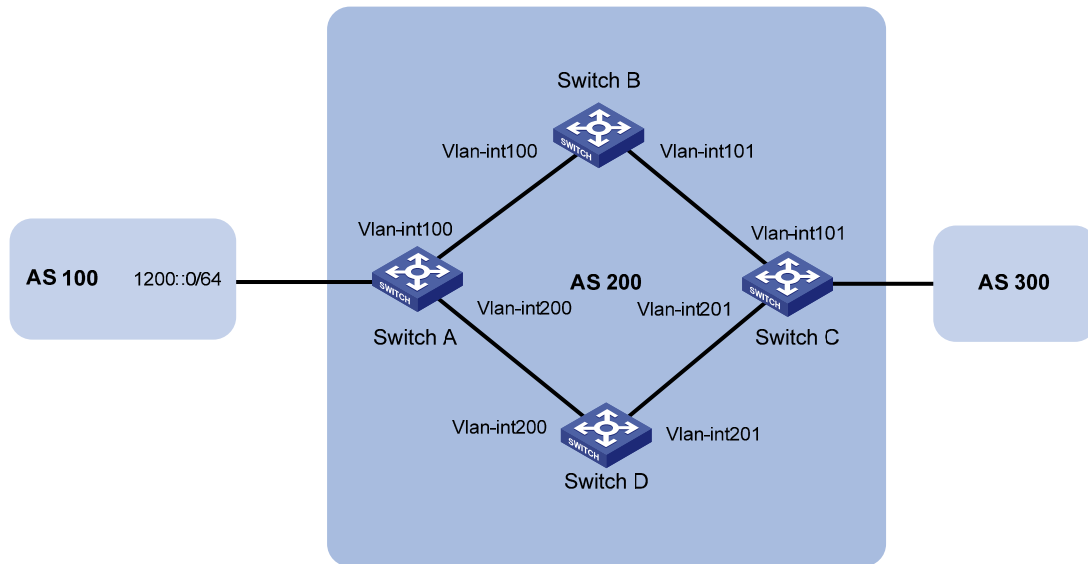

Configuring BFD for IPv6 BGP

Network requirements

As shown in [Figure 118](#),

- Configure OSPFv3 as the IGP in AS 200.
- Establish two IBGP connections between Switch A and Switch C. When both links are working, Switch C adopts the link Switch A \leftrightarrow Switch B \leftrightarrow Switch C to exchange packets with network 1200::0/64. Configure BFD over the link. Then if the link fails, BFD can quickly detect the failure and notify it to IPv6 BGP. Then the link Switch A \leftrightarrow Switch D \leftrightarrow Switch C takes effect immediately.

Figure 118 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	3000::1/64	Switch C	Vlan-int101	3001::3/64
	Vlan-int200	2000::1/64		Vlan-int201	2001::3/64
Switch B	Vlan-int100	3000::2/64	Switch D	Vlan-int200	2000::2/64
	Vlan-int101	3001::2/64		Vlan-int201	2001::2/64

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPFv3 to make sure that Switch A and Switch C are reachable to each other. (Details not shown.)
3. Configure IPv6 BGP on Switch A.

Establish two IBGP connections between Switch A and Switch C.

```
<SwitchA> system-view
[SwitchA] bgp 200
[SwitchA-bgp] ipv6-family
[SwitchA-bgp-af-ipv6] peer 3001::3 as-number 200
[SwitchA-bgp-af-ipv6] peer 2001::3 as-number 200
[SwitchA-bgp-af-ipv6] quit
```

When the two links between Switch A and Switch C are both up, Switch C adopts the link Switch A<—>Switch B<—>Switch C to exchange packets with network 1200::0/64. (Set a higher MED value for route 1200::0/64 sent to peer 2001::3 on Switch A.)

- o Create IPv6 ACL 2000 to permit 1200::0/64 to pass.

```
[SwitchA] acl ipv6 number 2000
[SwitchA-acl6-basic-2000] rule permit source 1200::0 64
[SwitchA-acl6-basic-2000] quit
```
- o Create two route policies, **apply_med_50** and **apply_med_100**. Policy **apply_med_50** sets the MED for route 1200::0/64 to 50. Policy **apply_med_100** sets that to 100.

```
[SwitchA] route-policy apply_med_50 permit node 10
[SwitchA-route-policy] if-match ipv6 address acl 2000
[SwitchA-route-policy] apply cost 50
[SwitchA-route-policy] quit
[SwitchA] route-policy apply_med_100 permit node 10
[SwitchA-route-policy] if-match ipv6 address acl 2000
[SwitchA-route-policy] apply cost 100
[SwitchA-route-policy] quit
```

- Apply routing policy **apply_med_50** to routes outgoing to peer 3001::3, and apply routing policy **apply_med_100** to routes outgoing to peer 2001::3.

```
[SwitchA] bgp 200
[SwitchA-bgp] ipv6-family
[SwitchA-bgp-af-ipv6] network 1200:: 64
[SwitchA-bgp-af-ipv6] peer 3001::3 route-policy apply_med_50 export
[SwitchA-bgp-af-ipv6] peer 2001::3 route-policy apply_med_100 export
```

Configure BFD over the link to peer 3001::3 so that when the link Switch A<—>Switch B<—>Switch C fails, BFD can quickly detect the failure and notify it to IPv6 BGP, and then the link Switch A<—>Switch D<—>Switch C takes effect immediately.

```
[SwitchA-bgp-af-ipv6] peer 3001::3 bfd
[SwitchA-bgp-af-ipv6] quit
[SwitchA-bgp] quit
```

4. Configure IPv6 BGP on Switch C:

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp] ipv6-family
[SwitchC-bgp-af-ipv6] peer 3000::1 as-number 200
[SwitchC-bgp-af-ipv6] peer 3000::1 bfd
[SwitchC-bgp-af-ipv6] peer 2000::1 as-number 200
[SwitchC-bgp-af-ipv6] quit
[SwitchC-bgp] quit
```

5. Configure BFD parameters (you can use default BFD parameters instead):

Configure Switch A.

```
[SwitchA] bfd session init-mode active
[SwitchA] interface vlan-interface 100
```

- Configure the minimum interval for transmitting BFD control packets as 500 milliseconds.

```
[SwitchA-Vlan-interface100] bfd min-transmit-interval 500
```
- Configure the minimum interval for receiving BFD control packets as 500 milliseconds.

```
[SwitchA-Vlan-interface100] bfd min-receive-interval 500
```
- Configure the detect multiplier as 7.

```
[SwitchA-Vlan-interface100] bfd detect-multiplier 7
[SwitchA-Vlan-interface100] quit
```

Configure Switch C.

```
[SwitchC] bfd session init-mode active
[SwitchC] interface vlan-interface 101
```

- Configure the minimum interval for transmitting BFD control packets as 500 milliseconds.
[SwitchC-Vlan-interface101] bfd min-transmit-interval 500
- Configure the minimum interval for receiving BFD control packets as 500 milliseconds.
[SwitchC-Vlan-interface101] bfd min-receive-interval 500
- Configure the detect multiplier as 7.
[SwitchC-Vlan-interface101] bfd detect-multiplier 7
[SwitchC-Vlan-interface101] return

6. Verify the configuration:

The following operations are made on Switch C. Operations on Switch A and Switch B are similar and are not shown.

Display detailed BFD session information.

```
<SwitchC> display bfd session verbose
```

```
Total session number: 1   Up session number: 1   Init mode: Active
```

```
IPv6 Session working under Ctrl mode:
```

```

Local Discr: 17                               Remote Discr: 13
Source IP: 3001::3
Destination IP: 3000::1
Session State: Up                             Interface: Vlan-interface101
Min Trans Inter: 500ms                       Act Trans Inter: 500ms
Min Recv Inter: 500ms                       Act Detect Inter: 3000ms
Recv Pkt Num: 57                             Send Pkt Num: 53
Hold Time: 2200ms                           Connect Type: Direct
Running Up for: 00:00:06                     Auth mode: none
Protocol: BGP6
Diag Info: No Diagnostic

```

The output shows that a BFD session is established between Switch A's VLAN-interface 100 and Switch C's VLAN-interface 101 and that BFD runs properly.

Display IPv6 peer information on Switch C, and you can see that the neighborhood between Switch A and Switch C is established.

```
<SwitchC> display bgp ipv6 peer
```

```
BGP local router ID : 1.1.1.1
```

```
Local AS number : 200
```

```
Total number of peers : 2
```

```
Peers in established state : 2
```

Peer	AS	MsgRcvd	MsgSent	OutQ	PrefRcv	Up/Down	State
2000::1	200	7	10	0	0	00:01:05	Established
3000::1	200	7	10	0	0	00:01:34	Established

Display route 1200::0/64 on Switch C, and you can see that Switch A and Switch C communicate through Switch B.

```
<SwitchC> display ipv6 routing-table 1200::0 64 verbose
```

```
Routing Table :
```

```
Summary Count : 2
```

```

Destination : 1200::
NextHop      : 3000::1
RelayNextHop : 3001::2
Neighbor     : 3000::1
Interface    : Vlan-interface101
State        : Active Adv
Tunnel ID    : 0x0
Age          : 4538sec
PrefixLength : 64
Preference   : 255
Tag          : 0H
ProcessID    : 0
Protocol     : BGP4+
Cost         : 50
Label        : NULL

```

```

Destination : 1200::
NextHop      : 2000::1
RelayNextHop : 2001::2
Neighbor     : 2000::1
Interface    : Vlan-interface201
State        : Invalid Adv
Tunnel ID    : 0x0
Age          : 4515sec
PrefixLength : 64
Preference   : 255
Tag          : 0H
ProcessID    : 0
Protocol     : BGP4+
Cost         : 100
Label        : NULL

```

The output shows that Switch C has two routes to reach network 1200::0/64: Switch C<—>Switch B<—>Switch A, which is the currently active route; Switch C<—>Switch D<—>Switch A, which is the backup route.

Enable BFD debugging on Switch C.

```

<SwitchC> debugging bfd scm
<SwitchC> debugging bfd event
<SwitchC> debugging bgp bfd
<SwitchC> terminal monitor
<SwitchC> terminal debugging

```

The following debugging information shows that Switch C can quickly detect the failure on Switch B.

```

%Nov 5 11:42:24:172 2009 SwitchC BFD/5/BFD_CHANGE_FSM: Sess[3001::3/3000::1,
13/17,VLAN101,Ctrl], Sta: UP->DOWN, Diag: 1
%Nov 5 11:42:24:172 2009 SwitchC BGP/5/BGP_STATE_CHANGED: 3000::1 state is changed
from ESTABLISHED to IDLE.
*Nov 5 11:42:24:187 2009 SwitchC RM/6/RMDEBUG: BGP_BFD: Recv BFD DOWN msg, Src IP
3001::3, Dst IP 3000::1, Instance ID 0.
*Nov 5 11:42:24:187 2009 SwitchC RM/6/RMDEBUG: BGP_BFD: Reset BGP session 3000::1
for BFD session down.
*Nov 5 11:42:24:187 2009 SwitchC RM/6/RMDEBUG: BGP_BFD: Send DELETE msg to BFD,
Connection type DIRECT, Src IP 3001::3, Dst IP 3000::1, Instance ID 0.

```

Display route 1200::0/64 on Switch C, and you can see that Switch A and Switch C communicate through Switch D.

```

<SwitchC> display ipv6 routing-table 1200::0 64 verbose
Routing Table :
Summary Count : 1
Destination : 1200::
NextHop      : 2000::1
RelayNextHop : 2001::2
PrefixLength : 64
Preference   : 255
Tag          : 0H

```

Neighbor	: 2000::1	ProcessID	: 0
Interface	: Vlan-interface201	Protocol	: BGP4+
State	: Active Adv	Cost	: 100
Tunnel ID	: 0x0	Label	: NULL
Age	: 4635sec		

The output shows that Switch C has one route to reach network 1200::0/64, that is, Switch C<—>Switch D<—>Switch A.

Troubleshooting IPv6 BGP configuration

IPv6 BGP peer relationship not established

Symptom

Display BGP peer information by using the **display bgp ipv6 peer** command. The state of the connection to the peer cannot become established.

Analysis

To become IPv6 BGP peers, any two routers must establish a TCP session using port 179 and exchange open messages successfully.

Processing steps

1. Use the **display current-configuration** command to check that the peer's AS number is correct.
2. Use the **display bgp ipv6 peer** command to check that the peer's IPv6 address is correct.
3. If a loopback interface is used, check that the loopback interface is specified with the **peer connect-interface** command.
4. If the peer is not directly connected, check that the **peer ebgp-max-hop** command is configured.
5. Check that a valid route to the peer is available.
6. Use the **ping** command to check the connectivity to the peer.
7. Use the **display tcp ipv6 status** command to check the TCP connection.
8. Check whether an ACL for disabling TCP port 179 is configured.

Configuring routing policies

Hardware compatibility

The HP 5500 SI Switch Series does not support OSPF, BGP, IS-IS, OSPFv3, IPv6 BGP, IPv6 IS-IS, or FRR.

Introduction to routing policy

Routing policies are used to receive, advertise, and redistribute only specific routes and modify the attributes of some routes.

Routing policy in this chapter involves both IPv4 routing policy and IPv6 routing policy.

A routing policy is used to filter routes when they are received, advertised, or redistributed and modify the attributes of some routes.

Routing policy application

A routing policy has the following applications:

- Filters advertised routes.
- Filters received routes.
- Filters redistributed routes.
- Modifies or sets the attributes of some routes.

Routing policy implementation

To configure a routing policy, you must do the following:

1. Define some filters based on the attributes of routing information, such as destination address, and the advertising router's address.
2. Apply the filters to the routing policy.

You can use multiple filters to define match criteria. For detailed information, see "[Filters](#)."

Filters

You can use the following types of filters: ACL, IP prefix list, AS path ACL, community list, extended community list, and routing policy.

ACL

ACL involves IPv4 ACL and IPv6 ACL. An ACL is configured to match the destinations or next hops of routing information.

For more information about ACL, see *ACL and QoS Configuration Guide*.

IP prefix list

IP prefix list involves IPv4 prefix list and IPv6 prefix list.

An IP prefix list is configured to match the destination address of routing information. You can use the **gateway** option to allow only routing information from certain routers to be received. For **gateway** option information, see "[Configuring RIP](#)" and "[Configuring OSPF](#)."

An IP prefix list, identified by name, can comprise multiple items. Each item, identified by an index number, can specify a prefix range to match. An item with a smaller index number is matched first. If one item is matched, the IP prefix list is passed, and the packet will not go to the next item.

AS-PATH list

An AS-PATH list, configured based on the BGP AS PATH attribute, can only be used to match BGP routing information.

For more information about AS-PATH list, see "[Configuring BGP](#)."

Community list

A community list, configured based on the BGP community attribute, can only be used to match BGP routing information.

For more information about community list, see "[Configuring BGP](#)."

Extended community list

An extended community list, configured based on the BGP extended community attribute (Route-Target for VPN and Source of Origin), can only be used to match BGP routing information.

Routing policy

A routing policy is used to match routing information and modify the attributes of permitted routes. It can reference the filters to define its own match criteria.

A routing policy can comprise multiple nodes, which are in logic OR relationship. Each routing policy node is a match unit, and a node with a smaller number is matched first. Once a node is matched, the routing policy is passed and the packet will not go to the next node.

A routing policy node comprises a set of **if-match**, **apply**, and **continue** clauses.

- The **if-match** clauses define the match criteria. The matching objects are some attributes of routing information. The **if-match** clauses of a routing policy node is in a logical AND relationship. A packet must match all the **if-match** clauses of the node to pass it.
- The **apply** clauses of the node specify the actions to be taken on the permitted packets, such as modifying a route attribute.
- The **continue** clause specifies the next routing policy node to be matched. With this clause configured, when a route matches the current routing policy node, it continues to match against the specified next node in the same routing policy. The **continue** clause combines the **if-match** and **apply** clauses of the two nodes to improve flexibility of the routing policy.

Follow these guidelines when you configure **if-match**, **apply**, and **continue** clauses:

- If you want to implement route filtering only, you do not need to configure **apply** clauses.
- If you do not configure any **if-match** clauses for a permit-mode node, the node permits all routes to pass.
- Configure a permit-mode node containing no **if-match** or **apply** clauses behind multiple deny-mode nodes to allow unmatched routes to pass.

Defining filters

Configuration prerequisites

Before you configure this task, you must determine IP-prefix list name, matching address range, and extcommunity list sequence number.

Defining an IP-prefix list

Defining an IPv4 prefix list

Identified by name, an IPv4 prefix list can comprise multiple items. Each item specifies a prefix range to match and is identified by an index number.

An item with a smaller index number is matched first. If one item is matched, the IP prefix list is passed, and the routing information will not go to the next item.

To define an IPv4 prefix list:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Define an IPv4 prefix list.	ip ip-prefix <i>ip-prefix-name</i> [index <i>index-number</i>] { deny permit } <i>ip-address mask-length</i> [greater-equal <i>min-mask-length</i>] [less-equal <i>max-mask-length</i>]	Not defined by default.

If all the items are set to the **deny** mode, no routes can pass the IPv4 prefix list. You must define the **permit** 0.0.0.0 0 **less-equal** 32 item following multiple **deny** items to allow other IPv4 routing information to pass.

For example, the following configuration filters routes 10.1.0.0/16, 10.2.0.0/16, and 10.3.0.0/16, but allows other routes to pass.

```
<Sysname> system-view
[Sysname] ip ip-prefix abc index 10 deny 10.1.0.0 16
[Sysname] ip ip-prefix abc index 20 deny 10.2.0.0 16
[Sysname] ip ip-prefix abc index 30 deny 10.3.0.0 16
[Sysname] ip ip-prefix abc index 40 permit 0.0.0.0 0 less-equal 32
```

Defining an IPv6 prefix list

Identified by name, each IPv6 prefix list can comprise multiple items. Each item specifies a prefix range to match and is identified by an index number.

An item with a smaller index number is matched first. If one item is matched, the IPv6 prefix list is passed, and the routing information will not go to the next item.

To define an IPv6 prefix list:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Define an IPv6 prefix list.	ip ipv6-prefix <i>ipv6-prefix-name</i> [index <i>index-number</i>] { deny permit } <i>ipv6-address prefix-length</i> [greater-equal <i>min-prefix-length</i>] [less-equal <i>max-prefix-length</i>]	Not defined by default.

If all items are set to the **deny** mode, no routes can pass the IPv6 prefix list. You must define the **permit** :: 0 **less-equal** 128 item following multiple **deny** items to allow other IPv6 routing information to pass.

For example, the following configuration filters routes 2000:1::/48, 2000:2::/48, and 2000:3::/48, but allows other routes to pass.

```
<Sysname> system-view
[Sysname] ip ipv6-prefix abc index 10 deny 2000:1:: 48
[Sysname] ip ipv6-prefix abc index 20 deny 2000:2:: 48
[Sysname] ip ipv6-prefix abc index 30 deny 2000:3:: 16
[Sysname] ip ipv6-prefix abc index 40 permit :: 0 less-equal 128
```

Defining an AS path list

You can define multiple items for an AS path list that is identified by number. The relationship between items is logical OR. If a route matches one of these items, it passes the AS path list.

To define an AS path list:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Define an AS path ACL.	ip as-path <i>as-path-number</i> { deny permit } <i>regular-expression</i>	Not defined by default.

Defining a community list

You can define multiple items for a community list that is identified by number. During matching, the relationship between items is logic OR. If routing information matches one of these items, it passes the community list.

To define a community list:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Define a community list.	<ul style="list-style-type: none"> Define a basic community list: ip community-list { <i>basic-comm-list-num</i> basic <i>comm-list-name</i> } { deny permit } [<i>community-number-list</i>] [internet no-advertise no-export no-export-subconfed] * Define an advanced community list: ip community-list { <i>adv-comm-list-num</i> advanced <i>comm-list-name</i> } { deny permit } <i>regular-expression</i> 	Use either approach. Not defined by default.

Defining an extended community list

You can define multiple items for an extended community list that is identified by number. During matching, the relation between items is logic OR. If routing information matches one of these items, it passes the extended community list.

To define an extended community list:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Define an extended community list.	ip extcommunity-list <i>ext-comm-list-number</i> { deny permit } { rt <i>route-target</i> }&<1-16>	Not defined by default.

Configuring a routing policy

A routing policy is used to filter routing information and modify attributes of matching routing information. The match criteria of a routing policy can be configured by referencing the appropriate filters.

A routing policy can comprise multiple nodes, and each routing policy node contains the following:

- **if-match clauses**—Define the match criteria that routing information must satisfy. The matching objects are some attributes of routing information.
- **apply clauses**—Specify the actions to be taken on routing information that has satisfied the match criteria, such as route attribute modification.
- **continue clauses**—Specify the next routing policy node to be matched. With this clause configured, when a route matches the current routing policy node, it continues to match against the specified next node in the same routing policy.

Configuration prerequisites

Before configuring this task, you need to configure the filters and routing protocols. You also need to decide on the name of the routing policy and node numbers, match criteria, and attributes to be modified.

Creating a routing policy

Follow these guidelines when you create a routing policy:

- If a routing policy node has the **permit** keyword specified, routing information matching all the **if-match** clauses of the node will be handled using the **apply** clauses of this node, without needing to match against the next node. If routing information does not match the node, it goes to the next node for a match.
- If a routing policy node has the **deny** keyword specified, the **apply** clauses of the node is not executed. When routing information matches all the **if-match** clauses of the node, it cannot pass the node, or go to the next node. If route information cannot match all the **if-match** clauses of the node, it goes to the next node for a match.
- When a routing policy has more than one node, at least one node must be configured with the **permit** keyword. If the routing policy is used to filter routing information, routing information that does not meet any node cannot pass the routing policy. If all nodes of the routing policy are set with the **deny** keyword, no routing information can pass it.

To create a routing policy:

Step	Command
1. Enter system view.	system-view
2. Create a routing policy, specify a node for it, and enter routing policy view.	route-policy <i>route-policy-name</i> { deny permit } node <i>node-number</i>

Defining if-match clauses

Follow these guidelines when you define **if-match** clauses:

- The **if-match** clauses of a routing policy node are in logic AND relationship. Routing information must satisfy all of its **if-match** clauses before being executed with its **apply** clauses. If an **if-match** command exceeds the maximum length, multiple identical **if-match** clauses are generated. These clauses are in logical OR relationship. Routing information only needs to match one of them.
- You can specify any number of **if-match** clauses for a routing policy node. If no **if-match** clause is specified, and the routing policy node is in **permit** mode, all routing information can pass the node. If it is in **deny** mode, no routing information can pass it.
- If the ACL referenced by an **if-match** clause does not exist, the clause is always satisfied; if no rules of the referenced ACL are matched or the matching rule is inactive, the clause is not satisfied.
- An ACL specified in an **if-match** clause must be a non-VPN ACL.
- The **if-match** commands for matching IPv4 destination, next hop, and source address are different from those for matching IPv6 ones.
- BGP does not support criteria for matching against outbound interfaces of routing information.

To define **if-match** clauses:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter routing policy view.	route-policy <i>route-policy-name</i> { deny permit } node <i>node-number</i>	N/A
3. Define match criteria for IPv4 routes.	<ul style="list-style-type: none"> • Match IPv4 routing information specified in the ACL: if-match acl <i>acl-number</i> • Match IPv4 routing information specified in the IP prefix list: if-match ip-prefix <i>ip-prefix-name</i>. • Match IPv4 routing information whose next hop or source is specified in the ACL or IP prefix list: if-match ip { next-hop route-source } { acl <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } 	Optional. Not configured by default.
4. Match IPv6 routing information whose next hop or source is specified in the ACL or IP prefix list.	if-match ipv6 { address next-hop route-source } { acl <i>acl-number</i> prefix-list <i>ipv6-prefix-name</i> }	Optional. Not configured by default.

Step	Command	Remarks
5. Match BGP routing information whose AS path attribute is specified in the AS path lists.	if-match as-path <i>AS-PATH-number</i> &<1-16>	Optional. Not configured by default.
6. Match BGP routing information whose community attribute is specified in the community lists.	if-match community { { <i>basic-community-list-number</i> <i>comm-list-name</i> } [whole-match] <i>adv-community-list-number</i> }&<1-16>	Optional. Not configured by default.
7. Match routes having the specified cost.	if-match cost <i>value</i>	Optional. Not configured by default.
8. Match BGP routing information whose extended community attribute is specified in the extended community list(s).	if-match extcommunity <i>ext-comm-list-number</i> &<1-16>	Optional. Not configured by default.
9. Match routing information having specified outbound interface(s).	if-match interface { <i>interface-type</i> <i>interface-number</i> }&<1-16>	Optional. Not configured by default.
10. Match routing information having the specified route type.	if-match route-type { external-type1 external-type1or2 external-type2 internal is-is-level-1 is-is-level-2 nssa-external-type1 nssa-external-type1or2 nssa-external-type2 } *	Optional. Not configured by default.
11. Match RIP, OSPF, and IS-IS routing information having the specified tag value.	if-match tag <i>value</i>	Optional. Not configured by default.

Defining apply clauses

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter routing policy view.	route-policy <i>route-policy-name</i> { deny permit } node <i>node-number</i>	Not created by default.
3. Set the AS-PATH attribute for BGP routing information.	apply as-path <i>as-number</i> &<1-10> [replace]	Optional. Not set by default.
4. Delete the community attribute of BGP routing information using the community list.	apply comm-list { <i>comm-list-number</i> <i>comm-list-name</i> } delete	Optional. Not configured by default.
5. Set the community attribute for BGP routing information.	apply community { none additive { <i>community-number</i> &<1-16> <i>aa:nn</i> &<1-16> } internet no-advertise no-export no-export-subconfed } * [additive] }	Optional. Not set by default.

Step	Command	Remarks
6. Set a cost for routing information.	apply cost [+ -] <i>value</i>	Optional. Not set by default.
7. Set a cost type for routing information.	apply cost-type [external internal type-1 type-2]	Optional. Not set by default.
8. Set the extended community attribute for BGP routing.	apply extcommunity { { rt route-target } &<1-16> [additive] }	Optional. Not set by default.
9. Set the next hop.	<ul style="list-style-type: none"> Set the next hop for IPv4 routes: apply ip-address next-hop <i>ip-address</i> Set the next hop for IPv6 routes: apply ipv6 next-hop <i>ipv6-address</i> 	Optional. Not set by default. The setting does not apply to redistributed routing information. The apply ip-address next-hop and apply ipv6 next-hop commands do not apply to redistributed IPv4 and IPv6 routes.
10. Inject routing information to a specified ISIS level.	apply isis { level-1 level-1-2 level-2 }	Optional. Not configured by default.
11. Set the local preference for BGP routing information.	apply local-preference <i>preference</i>	Optional. Not set by default.
12. Set the origin attribute for BGP routing information.	apply origin { egp <i>as-number</i> igp incomplete }	Optional. Not set by default.
13. Set the preference for the routing protocol.	apply preference <i>preference</i>	Optional. Not set by default.
14. Set a preferred value for BGP routing information.	apply preferred-value <i>preferred-value</i>	Optional. Not set by default.
15. Set a tag value for RIP, OSPF, or IS-IS routing information.	apply tag <i>value</i>	Optional. Not set by default.
16. Configure FRR.	apply fast-reroute { backup-interface <i>interface-type interface-number</i> [backup-nexthop <i>ip-address</i>] }	Optional. Not configured by default.

NOTE:

The difference between IPv4 and IPv6 **apply** clauses is the command for setting the next hop for routing information.

Defining a continue clause

Follow these guidelines when you define a **continue** clause:

- If you configure the same type of **apply** clauses that set different values (including the **apply community** and **apply extcommunity** clauses with the **additive** keyword) on nodes that are

combined by the **continue** clause, the **apply** clause configured on the last matching node takes effect.

- If you configure the **apply community** clause for multiple nodes that are combined by the **continue** clause, the **apply comm-list delete** clause configured on the current node cannot delete the community attributes of preceding nodes.

To define a **continue** clause:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a routing policy and enter routing policy view.	route-policy <i>route-policy-name</i> { deny permit } node <i>node-number</i>	Not created by default.
3. Specify the next routing policy node to be matched.	continue [<i>node-number</i>]	Optional. Not configured by default. The node number specified must be larger than the current node number.

Displaying and maintaining the routing policy

Task	Command	Remarks
Display BGP AS-PATH list information.	display ip as-path [<i>as-path-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP community list information.	display ip community-list [<i>basic-community-list-number</i> <i>adv-community-list-number</i> <i>comm-list-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP extended community list information.	display ip extcommunity-list [<i>ext-comm-list-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv4 prefix list statistics.	display ip ip-prefix [<i>ip-prefix-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 prefix list statistics.	display ip ipv6-prefix [<i>ipv6-prefix-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing policy information.	display route-policy [<i>route-policy-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear IPv4 prefix list statistics.	reset ip ip-prefix [<i>ip-prefix-name</i>]	Available in user view
Clear IPv6 prefix list statistics.	reset ip ipv6-prefix [<i>ipv6-prefix-name</i>]	Available in user view

Routing policy configuration examples

Applying a routing policy to IPv4 route redistribution

Network requirements

As shown in Figure 119, Switch B exchanges routing information with Switch A using OSPF, and with Switch C using IS-IS.

On Switch B, enable route redistribution from IS-IS to OSPF, and apply a routing policy to set the cost of route 172.17.1.0/24 to 100 and the tag of route 172.17.2.0/24 to 20.

Figure 119 Network diagram

Configuration procedure

1. Specify IP addresses for interfaces. (Details not shown.)
2. Configure IS-IS:

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis
[SwitchC-isis-1] is-level level-2
[SwitchC-isis-1] network-entity 10.0000.0000.0001.00
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-vlan-interface200] isis enable
[SwitchC-vlan-interface200] quit
[SwitchC] interface vlan-interface 201
[SwitchC-vlan-interface201] isis enable
[SwitchC-vlan-interface201] quit
[SwitchC] interface vlan-interface 202
[SwitchC-vlan-interface202] isis enable
[SwitchC-vlan-interface202] quit
[SwitchC] interface vlan-interface 203
[SwitchC-vlan-interface203] isis enable
[SwitchC-vlan-interface203] quit
```

Configure Switch B.

```

<SwitchB> system-view
[SwitchB] isis
[SwitchB-isis-1] is-level level-2
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis enable
[SwitchB-Vlan-interface200] quit

```

3. Configure OSPF and route redistribution:

Configure OSPF on Switch A.

```

<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit

```

On Switch B, configure OSPF and enable route redistribution from IS-IS.

```

[SwitchB] ospf
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] import-route isis 1
[SwitchB-ospf-1] quit

```

Display the OSPF routing table on Switch A to view redistributed routes.

```

[SwitchA] display ospf routing

```

```

          OSPF Process 1 with Router ID 192.168.1.1
          Routing Tables

```

```

Routing for Network

```

Destination	Cost	Type	NextHop	AdvRouter	Area
192.168.1.0/24	1562	Stub	192.168.1.1	192.168.1.1	0.0.0.0

```

Routing for ASEs

```

Destination	Cost	Type	Tag	NextHop	AdvRouter
172.17.1.0/24	1	Type2	1	192.168.1.2	192.168.2.2
172.17.2.0/24	1	Type2	1	192.168.1.2	192.168.2.2
172.17.3.0/24	1	Type2	1	192.168.1.2	192.168.2.2
192.168.2.0/24	1	Type2	1	192.168.1.2	192.168.2.2

```

Total Nets: 5

```

```

Intra Area: 1 Inter Area: 0 ASE: 4 NSSA: 0

```

4. Configure filtering lists:

Configure ACL 2002 to permit route 172.17.2.0/24.

```

[SwitchB] acl number 2002
[SwitchB-acl-basic-2002] rule permit source 172.17.2.0 0.0.0.255
[SwitchB-acl-basic-2002] quit

```

```
# Configure IP prefix list prefix-a to permit route 172.17.1.0/24.
[SwitchB] ip ip-prefix prefix-a index 10 permit 172.17.1.0 24
```

5. Configure a routing policy:

```
[SwitchB] route-policy isis2ospf permit node 10
[SwitchB-route-policy] if-match ip-prefix prefix-a
[SwitchB-route-policy] apply cost 100
[SwitchB-route-policy] quit
[SwitchB] route-policy isis2ospf permit node 20
[SwitchB-route-policy] if-match acl 2002
[SwitchB-route-policy] apply tag 20
[SwitchB-route-policy] quit
[SwitchB] route-policy isis2ospf permit node 30
[SwitchB-route-policy] quit
```

6. Apply the routing policy to route redistribution:

On Switch B, apply the routing policy when redistributing routes.

```
[SwitchB] ospf
[SwitchB-ospf-1] import-route isis 1 route-policy isis2ospf
[SwitchB-ospf-1] quit
```

Display the OSPF routing table on Switch A. The cost of route 172.17.1.0/24 is 100, the tag of route 172.17.1.0/24 is 20.

```
[SwitchA] display ospf routing
```

```
OSPF Process 1 with Router ID 192.168.1.1
Routing Tables
```

Routing for Network

Destination	Cost	Type	NextHop	AdvRouter	Area
192.168.1.0/24	1	Transit	192.168.1.1	192.168.1.1	0.0.0.0

Routing for ASEs

Applying a routing policy to IPv6 route redistribution

Network requirements

As shown in [Figure 120](#):

- Enable RIPng on Switch A and Switch B.
- On Switch A, configure three static routes, and apply a routing policy to static route redistribution to permit routes 20::0/32 and 40::0/32, and deny route 30::0/32.
- Display RIPng routing table information on Switch B to verify the configuration.
