| Step                                                       | Command                                                                                                  | Remarks                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                      | <b>system-view</b>                                                                                       | N/A                                                                                                                                                                                                                                                                                                              |
| 2. Enter Layer 2 Ethernet interface view, port group view. | <b>interface</b> <i>interface-type</i><br><i>interface-number</i>                                        | N/A                                                                                                                                                                                                                                                                                                              |
| 3. Configure the IPv6 source guard function on the port.   | <b>ipv6 verify source</b> { <b>ipv6-address</b>   <b>ipv6-address mac-address</b>   <b>mac-address</b> } | Not configured by default.<br>The keyword specified in the <b>ipv6 verify source</b> command is only for instructing the generation of dynamic IPv6 source guard entries. It does not affect static binding entries. When using a static binding entry, a port does not consider the keyword into consideration. |

#### NOTE:

Although dynamic IPv6 source guard entries are generated based on DHCPv6 entries, the number of dynamic IPv6 source guard entries is not necessarily the same as that of the DHCPv6 entries.

## Configuring a static IPv6 source guard entry

Static IPv6 binding entries take effect only on ports configured with the IPv6 source guard function (see "[Configuring the IPv6 source guard function](#)").

Port-based static IPv6 source guard entries and dynamic IPv6 source guard entries take precedence over global static IPv6 source guard entries. A port matches a packet against global static binding entries only when the packet does not match any port-based static binding entry or dynamic binding entry on the port.

### Configuring global static IPv6 binding entries

A global static IPv6 binding entry defines the IPv6 address and MAC address of the packets that can be forwarded by ports. It takes effect on all ports of the device.

To configure a global static IPv6 binding entry:

| Step                  | Command            | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | <b>system-view</b> | N/A     |

| Step                                             | Command                                                                                          | Remarks                                                       |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| 2. Configure a global static IPv6 binding entry. | <b>ipv6 source binding ipv6-address</b><br><i>ipv6-address mac-address</i><br><i>mac-address</i> | No global static IPv6 binding entry is configured by default. |

## Configuring port-based static IPv6 binding entries

Follow these guidelines to configure port-based static IPv6 source guard entries:

- You cannot configure the same static binding entry on one port repeatedly, but you can configure the same static binding entry on different ports.
- In an IPv6 source guard entry, the MAC address cannot be all 0s, all Fs (a broadcast MAC address), or a multicast address, and the IPv6 address must be a unicast address and cannot be all 0s, all Fs, or a loopback address.
- IP source guard does not use the VLAN information (if specified) in static IPv6 binding entries to filter packets.
- When the ND detection function is configured, be sure to specify the VLAN where ND detection is configured in static binding entries. Otherwise, ND packets will be discarded because they cannot match any static IPv6 binding entry.
- If a static binding entry to be added denotes the same binding as an existing dynamic binding entry, the new static binding entry overwrites the dynamic binding entry.

To configure a static IPv6 source guard entry on a port:

| Step                                                | Command                                                                                                                                                                                                                     | Remarks                                                           |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| 1. Enter system view.                               | <b>system-view</b>                                                                                                                                                                                                          | N/A                                                               |
| 2. Enter Layer 2 interface view.                    | <b>interface</b> <i>interface-type</i><br><i>interface-number</i>                                                                                                                                                           | N/A                                                               |
| 3. Configure a static IPv6 binding entry on a port. | <b>ipv6 source binding { ipv6-address</b><br><i>ipv6-address</i>   <b>ipv6-address</b><br><i>ipv6-address mac-address</i><br><i>mac-address</i>   <b>mac-address</b><br><i>mac-address</i> } [ <b>vlan</b> <i>vlan-id</i> ] | By default, no static IPv6 binding entry is configured on a port. |

## Setting the maximum number of IPv6 source guard entries

The maximum number of IPv6 source guard entries is used to limit the total number of static and dynamic IPv6 source guard entries on a port. When the number of IPv6 binding entries on a port reaches the maximum, the port does not allow new IPv6 binding entries any more.

If the maximum number of IPv6 binding entries to be configured is smaller than the number of existing IPv6 binding entries on the port, the maximum number can be configured successfully, and the existing entries are not affected. New IPv6 binding entries, however, cannot be added until the number of IPv6 binding entries on the port drops below the configured maximum.

To configure the maximum number of IPv6 binding entries allowed on a port:

| Step                  | Command            | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | <b>system-view</b> | N/A     |

| Step                                                                         | Command                                                           | Remarks                                                                                                        |
|------------------------------------------------------------------------------|-------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| 2. Enter Layer 2 Ethernet interface view.                                    | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                                                                                                            |
| 3. Configure the maximum number of IPv6 binding entries allowed on the port. | <b>ipv6 verify source max-entries</b><br><i>number</i>            | Optional.<br>By default, the maximum number is 1500 on the HP 5500 EI series and 640 on the HP 5500 SI series. |

## Displaying and maintaining IP source guard

For IPv4 source guard:

| Task                                      | Command                                                                                                                                                                                                                                                                                                             | Remarks               |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Display static IPv4 source guard entries. | <b>display ip source binding static</b> [ <b>interface</b><br><i>interface-type interface-number</i>  <br><b>ip-address</b> <i>ip-address</i>   <b>mac-address</b><br><i>mac-address</i> ] [ <b>slot</b> <i>slot-number</i> ] [   { <b>begin</b>  <br><b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view |
| Display IPv4 source guard entries.        | <b>display ip source binding</b> [ <b>interface</b><br><i>interface-type interface-number</i>  <br><b>ip-address</b> <i>ip-address</i>   <b>mac-address</b><br><i>mac-address</i> ] [ <b>slot</b> <i>slot-number</i> ] [   { <b>begin</b>  <br><b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]        | Available in any view |

For IPv6 source guard:

| Task                                      | Command                                                                                                                                                                                                                                                                                                                   | Remarks               |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Display static IPv6 source guard entries. | <b>display ipv6 source binding static</b> [ <b>interface</b><br><i>interface-type interface-number</i>  <br><b>ipv6-address</b> <i>ipv6-address</i>   <b>mac-address</b><br><i>mac-address</i> ] [ <b>slot</b> <i>slot-number</i> ] [   { <b>begin</b>  <br><b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view |
| Display IPv6 source guard entries.        | <b>display ipv6 source binding</b> [ <b>interface</b><br><i>interface-type interface-number</i>  <br><b>ipv6-address</b> <i>ipv6-address</i>   <b>mac-address</b><br><i>mac-address</i> ] [ <b>slot</b> <i>slot-number</i> ] [   { <b>begin</b>  <br><b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]        | Available in any view |

## IP source guard configuration examples

### Static IPv4 source guard configuration example

#### Network requirements

As shown in [Figure 120](#), Host A and Host B are connected to ports GigabitEthernet 1/0/2 and GigabitEthernet 1/0/1 of Device B respectively, Host C is connected to port GigabitEthernet 1/0/2 of

Device A, and Device B is connected to port GigabitEthernet 1/0/1 of Device A. All hosts use static IP addresses.

Configure static IPv4 source guard entries on Device A and Device B to meet the following requirements:

- On port GigabitEthernet 1/0/2 of Device A, only IP packets from Host C can pass.
- On port GigabitEthernet 1/0/1 of Device A, only IP packets from Host A can pass.
- On port GigabitEthernet 1/0/2 of Device B, only IP packets from Host A can pass.
- On port GigabitEthernet 1/0/1 of Device B, only IP packets sourced from 192.168.0.2/24 can pass. Host B can communicate with Host A by using this IP address even if it uses another network adapter.

**Figure 120 Network diagram**

## Configuration procedure

### 1. Configure Device A:

# Configure the IPv4 source guard function on GigabitEthernet 1/0/2 to filter packets based on both the source IP address and MAC address.

```
<DeviceA> system-view
```

```
[DeviceA] interface gigabitethernet 1/0/2
```

```
[DeviceA-GigabitEthernet1/0/2] ip verify source ip-address mac-address
```

# Configure GigabitEthernet 1/0/2 to allow only IP packets with the source MAC address of 0001-0203-0405 and the source IP address of 192.168.0.3 to pass.

```
[DeviceA] interface gigabitethernet 1/0/2
```

```
[DeviceA-GigabitEthernet1/0/2] ip source binding ip-address 192.168.0.3 mac-address 0001-0203-0405
```

```
[DeviceA-GigabitEthernet1/0/2] quit
```

# Configure the IPv4 source guard function on GigabitEthernet 1/0/1 to filter packets based on both the source IP address and MAC address.

```
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] ip verify source ip-address mac-address
```

# Configure GigabitEthernet 1/0/1 to allow only IP packets with the source MAC address of 0001-0203-0406 and the source IP address of 192.168.0.1 to pass.

```
[DeviceA-GigabitEthernet1/0/1] ip source binding ip-address 192.168.0.1 mac-address 0001-0203-0406
```

```
[DeviceA-GigabitEthernet1/0/1] quit
```

### 2. Configure Device B:

# Configure the IPv4 source guard function on GigabitEthernet 1/0/2 to filter packets based on both the source IP address and MAC address.

```
[DeviceB] interface gigabitethernet 1/0/2
```

```
[DeviceB-GigabitEthernet1/0/2] ip verify source ip-address mac-address
```

# Configure GigabitEthernet 1/0/2 to allow only IP packets with the source MAC address of 0001-0203-0406 and the source IP address of 192.168.0.1 to pass.

```
[DeviceB] interface gigabitethernet 1/0/2
```

```
[DeviceB-GigabitEthernet1/0/2] ip source binding ip-address 192.168.0.1 mac-address 0001-0203-0406
```

```
[DeviceB-GigabitEthernet1/0/2] quit
```

# Configure the IPv4 source guard function on GigabitEthernet 1/0/1 to filter packets based on the source IP address.

```
[DeviceB] interface gigabitethernet 1/0/1
```

```
[DeviceB-GigabitEthernet1/0/1] ip verify source ip-address
```

# Configure GigabitEthernet 1/0/1 to allow only IP packets with the source IP address of 192.168.0.2 to pass.

```
[DeviceB-GigabitEthernet1/0/1] ip source binding ip-address 192.168.0.2
```

```
[DeviceB-GigabitEthernet1/0/1] quit
```

## Verifying the configuration

# On Device A, display information about static IPv4 source guard entries. The output shows that the static IPv4 source guard entries are configured successfully.

```
[DeviceA] display ip source binding static
```

```
Total entries found: 2
```

| MAC Address    | IP Address  | VLAN | Interface | Type   |
|----------------|-------------|------|-----------|--------|
| 0001-0203-0405 | 192.168.0.3 | N/A  | GE1/0/2   | Static |
| 0001-0203-0406 | 192.168.0.1 | N/A  | GE1/0/1   | Static |

# On Device B, display information about static IPv4 source guard entries. The output shows that the static IPv4 source guard entries are configured successfully.

```
[DeviceB] display ip source binding static
```

```
Total entries found: 2
```

| MAC Address    | IP Address  | VLAN | Interface | Type   |
|----------------|-------------|------|-----------|--------|
| 0001-0203-0406 | 192.168.0.1 | N/A  | GE1/0/2   | Static |
| N/A            | 192.168.0.2 | N/A  | GE1/0/1   | Static |

## Dynamic IPv4 source guard using DHCP snooping configuration example

### Network requirements

As shown in [Figure 121](#), the device connects to the host (client) and the DHCP server through ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 respectively. The host obtains an IP address from the DHCP server.

Enable DHCP snooping on the device to record the DHCP snooping entry of the host. Enable the IPv4 source guard function on the device's port GigabitEthernet 1/0/1 to filter packets based on the DHCP snooping entry, allowing only packets from clients that obtain IP addresses through the DHCP server to pass.

For information about DHCP server configuration, see *Layer 3—IP Services Configuration Guide*.

**Figure 121 Network diagram**

## Configuration procedure

1. Configure DHCP snooping.

# Enable DHCP snooping.

```
<Device> system-view
```

```
[Device] dhcp-snooping
```

# Configure port GigabitEthernet 1/0/2, which is connected to the DHCP server, as a trusted port.

```
[Device] interface gigabitethernet1/0/2
```

```
[Device-GigabitEthernet1/0/2] dhcp-snooping trust
```

```
[Device-GigabitEthernet1/0/2] quit
```

2. Configure the IPv4 source guard function.

# Configure the IPv4 source guard function on port GigabitEthernet 1/0/1 to filter packets based on both the source IP address and MAC address.

```
[Device] interface gigabitethernet1/0/1
```

```
[Device-GigabitEthernet1/0/1] ip verify source ip-address mac-address
```

```
[Device-GigabitEthernet1/0/1] quit
```

## Verifying the configuration

# Display the IPv4 source guard entries generated on port GigabitEthernet 1/0/1.

```
[Device] display ip source binding
```

```
Total entries found: 1
```

| MAC Address    | IP Address  | VLAN | Interface | Type     |
|----------------|-------------|------|-----------|----------|
| 0001-0203-0406 | 192.168.0.1 | 1    | GE1/0/1   | DHCP-SNP |

# Display DHCP snooping entries to see whether they are consistent with the dynamic entries generated on GigabitEthernet 1/0/1.

```
[Device] display dhcp-snooping
```

```
DHCP Snooping is enabled.
```

```
The client binding table for all untrusted ports.
```

```
Type : D--Dynamic , S--Static , R--Recovering
```

```
Type IP Address MAC Address Lease VLAN SVLAN Interface
```

```
==== =====
```

```
D 192.168.0.1 0001-0203-0406 86335 1 N/A GigabitEthernet1/0/1
```

```
--- 1 dhcp-snooping item(s) found ---
```

The output shows that a dynamic IPv4 source guard entry has been generated based on the DHCP snooping entry.

# Dynamic IPv4 source guard using DHCP relay configuration example

## Network requirements

As shown in Figure 122, the host and the DHCP server are connected to the switch through interfaces VLAN-interface 100 and VLAN-interface 200 respectively. DHCP relay is enabled on the switch. The host (with the MAC address of 0001-0203-0406) obtains an IP address from the DHCP server through the DHCP relay agent.

Enable the IPv4 source guard function on the switch's VLAN-interface 100 to filter packets based on the DHCP relay entry, allowing only packets from clients that obtain IP addresses from the DHCP server to pass.

Figure 122 Network diagram

## Configuration procedure

1. Configure the IPv4 source guard function:
  - # Configure the IP addresses of the interfaces. (Details not shown.)
  - # Configure the IPv4 source guard function on VLAN-interface 100 to filter packets based on both the source IP address and MAC address.

```
<Switch> system-view
[Switch] vlan 100
[Switch-Vlan100] quit
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] ip verify source ip-address mac-address
[Switch-Vlan-interface100] quit
```
2. Configure the DHCP relay agent:
  - # Enable the DHCP service.

```
[Switch] dhcp enable
```
  - # Configure the IP address of the DHCP server.

```
[Switch] dhcp relay server-group 1 ip 10.1.1.1
```
  - # Configure VLAN-interface 100 to operate in DHCP relay mode.

```
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] dhcp select relay
```
  - # Correlate VLAN-interface 100 with DHCP server group 1.

```
[Switch-Vlan-interface100] dhcp relay server-select 1
[Switch-Vlan-interface100] quit
```

## Verifying the configuration

- # Display the generated IPv4 source guard entries.

```
[Switch] display ip source binding
```

Total entries found: 1

| MAC Address    | IP Address  | VLAN | Interface | Type     |

## Static IPv6 source guard configuration example

### Network requirements

As shown in [Figure 123](#), the host is connected to port GigabitEthernet 1/0/1 of the device. Configure a static IPv6 source guard entry for GigabitEthernet 1/0/1 of the device to allow only packets from the host to pass.

**Figure 123 Network diagram**

### Configuration procedure

# Configure the IPv6 source guard function on GigabitEthernet 1/0/1 to filter packets based on both the source IP address and MAC address.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 verify source ipv6-address mac-address
```

# Configure GigabitEthernet 1/0/1 to allow only IPv6 packets with the source MAC address of 0001-0202-0202 and the source IPv6 address of 2001::1 to pass.

```
[Device-GigabitEthernet1/0/1] ipv6 source binding ipv6-address 2001::1 mac-address
0001-0202-0202
[Device-GigabitEthernet1/0/1] quit
```

### Verifying the configuration

# On Device, display the information about static IPv6 source guard entries. The output shows that the binding entry is configured successfully.

```
[Device] display ipv6 source binding static
Total entries found: 1

```

## Dynamic IPv6 source guard using DHCPv6 snooping configuration example

### Network requirements

As shown in [Figure 124](#), the host (DHCPv6 client) and the DHCPv6 server are connected to the device through ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 respectively.

Enable DHCPv6 and DHCPv6 snooping on the device, so that the host can obtain an IP address through the DHCPv6 server and the IPv6 IP address and the MAC address of the host can be recorded in a DHCPv6 snooping entry.

Enable IPv6 source guard function on the device's port GigabitEthernet 1/0/1 to filter packets based on DHCPv6 snooping entries, allowing only packets from a client that obtains an IP address through the DHCP server to pass.

**Figure 124 Network diagram**

## Configuration procedure

- Configure DHCPv6 snooping:
  - # Enable DHCPv6 snooping globally.
 

```
<Device> system-view
[Device] ipv6 dhcp snooping enable
```
  - # Enable DHCPv6 snooping in VLAN 2.
 

```
[Device] vlan 2
[Device-vlan2] ipv6 dhcp snooping vlan enable
[Device-vlan2] quit
```
  - # Configure the port connecting to the DHCP server as a trusted port.
 

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] ipv6 dhcp snooping trust
[Device-GigabitEthernet1/0/2] quit
```
- Configure the IPv6 source guard function:
  - # Configure the IPv6 source guard function on GigabitEthernet 1/0/1 to filter packets based on both the source IP address and MAC address.
 

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 verify source ipv6-address mac-address
[Device-GigabitEthernet1/0/1] quit
```

## Verifying the configuration

# Display the dynamic IPv6 source guard entries generated on port GigabitEthernet 1/0/1.

```
[Device] display ipv6 source binding
```

```
Total entries found: 1
```

| MAC Address    | IP Address | VLAN | Interface | Type       |
|----------------|------------|------|-----------|------------|
| 040a-0000-0001 | 2001::1    | 2    | GE1/0/1   | DHCPv6-SNP |

# Display all DHCPv6 snooping entries to see whether they are consistent with the dynamic IP source guard entries generated on GigabitEthernet 1/0/1.

```
[Device] display ipv6 dhcp snooping user-binding dynamic
```

| IP Address | MAC Address    | Lease | VLAN | Interface            |
|------------|----------------|-------|------|----------------------|
| 2001::1    | 040a-0000-0001 | 286   | 2    | GigabitEthernet1/0/1 |

```
--- 1 DHCPv6 snooping item(s) found ---
```

The output shows that a dynamic IPv6 source guard entry has been generated on port GigabitEthernet 1/0/1 based on the DHCPv6 snooping entry.

# Dynamic IPv6 source guard using ND snooping configuration example

## Network requirements

As shown in Figure 125, the client is connected to the device through port GigabitEthernet 1/0/1.

Enable ND snooping on the device, establishing ND snooping entries by listening to DAD NS messages.

Enable the IPv6 source guard function on port GigabitEthernet 1/0/1 to filter packets based on the ND snooping entries, allowing only packets with a legally obtained IPv6 address to pass.

Figure 125 Network diagram

## Configuration procedure

1. Configure ND snooping:

# In VLAN 2, enable ND snooping.

```
<Device> system-view
[Device] vlan 2
[Device-vlan2] ipv6 nd snooping enable
[Device-vlan2] quit
```

2. Configure the IPv6 source guard function:

# Configure the IPv6 source guard function on GigabitEthernet 1/0/1 to filter packets based on both the source IP address and MAC address.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 verify source ipv6-address mac-address
[Device-GigabitEthernet1/0/1] quit
```

## Verifying the configuration

# Display the IPv6 source guard entries generated on port GigabitEthernet 1/0/1.

```
[Device] display ipv6 source binding
```

Total entries found: 1

| MAC Address    | IP Address | VLAN | Interface | Type   |
|----------------|------------|------|-----------|--------|
| 040a-0000-0001 | 2001::1    | 2    | GE1/0/1   | ND-SNP |

# Display the IPv6 ND snooping entries to see whether they are consistent with the dynamic IP source guard entries generated on GigabitEthernet 1/0/1.

```
[Device] display ipv6 nd snooping
```

| IPv6 Address | MAC Address    | VID | Interface | Aging Status |
|--------------|----------------|-----|-----------|--------------|
| 2001::1      | 040a-0000-0001 | 2   | GE1/0/1   | 25 Bound     |

---- Total entries: 1 ----

The output shows that a dynamic IPv6 source guard entry has generated on port GigabitEthernet 1/0/1 based on the ND snooping entry.

# Global static IP source guard configuration example

## Network requirements

As shown in [Figure 126](#), Device A is a distribution layer device. Device B is an access device. Host A in VLAN 10 and Host B in VLAN 20 communicate with each other through Device A.

- Configure Device B to discard attack packets that exploit the IP address or MAC address of Host A and Host B.
- Configure Device B to forward packets of Host A and Host B normally.

**Figure 126 Network diagram**

## Configuration procedure

# Create VLAN 10, and add port GigabitEthernet 1/0/2 to VLAN 10.

```
<DeviceB> system-view
[DeviceB] vlan 10
[DeviceB-vlan10] port gigabitethernet 1/0/2
[DeviceB-vlan10] quit
```

# Create VLAN 20, and add port GigabitEthernet 1/0/3 to VLAN 20.

```
[DeviceB] vlan 20
[DeviceB-vlan20] port gigabitethernet 1/0/3
[DeviceB-vlan20] quit
```

# Configure the link type of GigabitEthernet 1/0/1 as trunk, and permit packets of VLAN 10 and VLAN 20 to pass the port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 10 20
[DeviceB-GigabitEthernet1/0/1] quit
```

# Configure IPv4 source guard on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 to filter packets based on both the source IP address and MAC address.

```
[DeviceB] interface gigabitethernet 1/0/2
```

```
[DeviceB-GigabitEthernet1/0/2] ip verify source ip-address mac-address
[DeviceB-GigabitEthernet1/0/2] quit
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ip verify source ip-address mac-address
[DeviceB-GigabitEthernet1/0/3] quit

Configure global static IP binding entries to prevent attack packets that exploit the IP address or MAC
address of Host A and Host B from being forwarded.

[DeviceB] ip source binding ip-address 192.168.0.2 mac-address 0001-0203-0406
[DeviceB] ip source binding ip-address 192.168.1.2 mac-address 0001-0203-0407
```

## Verifying the configuration

# Display static IPv4 binding entries on Device B.

```
[DeviceB] display ip source binding static
```

Total entries found: 2

| MAC Address    | IP Address  | VLAN | Interface | Type   |
|----------------|-------------|------|-----------|--------|
| 0001-0203-0406 | 192.168.0.2 | N/A  | N/A       | Static |
| 0001-0203-0407 | 192.168.1.2 | N/A  | N/A       | Static |

After the configurations, Host A and Host B can ping each other successfully.

# Troubleshooting IP source guard

## Symptom

Failed to configure static or dynamic IP source guard on a port.

## Analysis

IP source guard is not supported on a port in an aggregation group.

## Solution

Remove the port from the aggregation group.

# Configuring ARP attack protection

Only the HP 5500 EI switches support Layer 3 Ethernet port configuration.

The term "interface" in the ARP attack protection features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

## Overview

Although ARP is easy to implement, it provides no security mechanism and is vulnerable to network attacks. An attacker can exploit ARP vulnerabilities to attack network devices in the following ways:

- Acts as a trusted user or gateway to send ARP packets so the receiving devices obtain incorrect ARP entries.
- Sends a large number of destination unreachable IP packets to have the receiving device busy with resolving destination IP addresses until its CPU is overloaded.
- Sends a large number of ARP packets to overload the CPU of the receiving device.

For more information about ARP attack features and types, see *ARP Attack Protection Technology White Paper*.

ARP attacks and viruses are threatening LAN security. This chapter introduces multiple features to detect and prevent such attacks.

## ARP attack protection configuration task list

| Task                                 | Remarks                                                                                                                                                    |

## Configuring ARP defense against IP packet attacks

If the device receives a large number of IP packets from a host addressed to unreachable destinations,

- The device sends a large number of ARP requests to the destination subnets, and thus the load of the destination subnets increases.
- The device keeps trying to resolve destination IP addresses, which increases the load on the CPU.

To protect the device from IP packet attacks, you can enable the ARP source suppression function or ARP black hole routing function.

If the packets have the same source address, you can enable the ARP source suppression function. With the function enabled, you can set a threshold for the number of ARP requests that a sending host can trigger in five seconds with packets with unresolvable destination IP addresses. When the number of ARP requests exceeds that threshold, the device suppresses the host from triggering any ARP requests in the following five seconds.

If the packets have various source addresses, you can enable the ARP black hole routing function. After receiving an IP packet whose destination IP address cannot be resolved by ARP, the device with this function enabled immediately creates a black hole route and simply drops all packets matching the route during the aging time of the black hole route.

## Configuring ARP source suppression

| Step                                                                                                                                                                    | Command                                                   | Remarks                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|-----------------------------|
| 1. Enter system view.                                                                                                                                                   | <b>system-view</b>                                        | N/A                         |
| 2. Enable ARP source suppression.                                                                                                                                       | <b>arp source-suppression enable</b>                      | Disabled by default.        |
| 3. Set the maximum number of packets with the same source IP address but unresolvable destination IP addresses that the device can receive in five consecutive seconds. | <b>arp source-suppression limit</b><br><i>limit-value</i> | Optional.<br>10 by default. |

## Enabling ARP black hole routing

| Step                              | Command                           | Remarks                          |

## Configuration example

### Network requirements

As shown in [Figure 127](#), a LAN contains two areas: an R&D area in VLAN 10 and an office area in VLAN 20. The two areas connect to the gateway (Device) through an access switch.

A large number of ARP requests are detected in the office area and are considered as the consequence of an IP flood attack. To prevent such attacks, configure ARP source suppression and ARP black hole routing.

Figure 127 Network diagram

### Configuration considerations

If the attacking packets have the same source address, you can enable the ARP source suppression function with the following steps:

1. Enable ARP source suppression.
2. Set the threshold for ARP packets from the same source address to 100. If the number of ARP requests sourced from the same IP address in five seconds exceeds 100, the device suppresses the IP packets sourced from this IP address from triggering any ARP requests within the following five seconds.

If the attacking packets have different source addresses, enable the ARP black hole routing function on the device.

### Configuration procedure

1. Configure ARP source suppression:

# Enable ARP source suppression on the device and set the threshold for ARP packets from the same source address to 100.

```
<Device> system-view
[Device] arp source-suppression enable
[Device] arp source-suppression limit 100
```

2. Configure ARP black hole routing:

# Enable ARP black hole routing on the device.

```
<Device> system-view
[Device] arp resolving-route enable
```

# Configuring ARP packet rate limit

## Introduction

The ARP packet rate limit feature allows you to limit the rate of ARP packets to be delivered to the CPU on a switch. For example, if an attacker sends a large number of ARP packets to an ARP detection enabled device, the CPU of the device will be overloaded because all of the ARP packets are redirected to the CPU for checking. As a result, the device fails to deliver other functions properly or even crashes. To solve this problem, you can configure ARP packet rate limit.

Enable this feature after the ARP detection or ARP snooping feature is configured, or use this feature to prevent ARP flood attacks.

## Configuration procedure

When the ARP packet rate exceeds the rate limit set on an interface, the device with ARP packet rate limit enabled sends trap and log messages to inform the event. To avoid too many trap and log messages, you can set the interval for sending such messages. Within each interval, the device will output the peak ARP packet rate in the trap and log messages.

Note that trap and log messages are generated only after the trap function of ARP packet rate limit is enabled. Trap and log messages will be sent to the information center of the device. You can set the parameters of the information center to determine the output rules of trap and log messages. The output rules specify whether the messages are allowed to be output and where they are bound for. For the parameter configuration of the information center, see *Network Management and Monitoring Configuration Guide*.

If you enable ARP packet rate limit on a Layer 2 aggregate interface, trap and log messages are sent when the ARP packet rate of a member port exceeds the preset threshold rate.

To configure ARP packet rate limit:

| Step                                                                                                             | Command                                                           | Remarks                                                                                                                                                                     |
|------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                                                                            | <b>system-view</b>                                                | N/A                                                                                                                                                                         |
| 2. Enable ARP packet rate limit trap.                                                                            | <b>snmp-agent trap enable arp rate-limit</b>                      | Optional.<br>Enabled by default.<br>For more information, see the <b>snmp-agent trap enable arp</b> command in <i>Network Management and Monitoring Command Reference</i> . |
| 3. Set the interval for sending trap and log messages when ARP packet rate exceeds the specified threshold rate. | <b>arp rate-limit information interval seconds</b>                | Optional.<br>60 seconds by default.                                                                                                                                         |
| 4. Enter Layer 2 Ethernet interface/Layer 2 aggregate interface view.                                            | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                                                                                                                                                                         |
| 5. Configure ARP packet rate limit.                                                                              | <b>arp rate-limit { disable   rate pps drop }</b>                 | By default, ARP packet rate limit is disabled.                                                                                                                              |

# Configuring source MAC address based ARP attack detection

With this feature enabled, the device checks the source MAC address of ARP packets delivered to the CPU. It detects an attack when one MAC address sends more ARP packets in five seconds than the specified threshold. The device adds the MAC address to the attack detection table.

Before the attack detection entry is aged out, the device uses either of the following detection modes to respond to the detected attack:

- **Monitor mode**—Generates a log message.
- **Filter mode**—Generates a log message and filters out subsequent ARP packets from the attacking MAC address.

You can also configure protected MAC addresses to exclude a gateway or server from detection. A protected MAC address is excluded from ARP attack detection even if it is an attacker.

## Configuration procedure

To configure source MAC address based ARP attack detection:

| Step                                                                                    | Command                                                                    | Remarks                                 |
|-----------------------------------------------------------------------------------------|----------------------------------------------------------------------------|-----------------------------------------|
| 1. Enter system view.                                                                   | <b>system-view</b>                                                         | N/A                                     |
| 2. Enable source MAC address based ARP attack detection and specify the detection mode. | <b>arp anti-attack source-mac { filter   monitor }</b>                     | Disabled by default.                    |
| 3. Configure the threshold.                                                             | <b>arp anti-attack source-mac threshold</b><br><i>threshold-value</i>      | Optional.<br>50 by default.             |
| 4. Configure the age timer for ARP attack detection entries.                            | <b>arp anti-attack source-mac aging-time</b> <i>time</i>                   | Optional.<br>300 seconds by default.    |
| 5. Configure protected MAC addresses.                                                   | <b>arp anti-attack source-mac exclude-mac</b><br><i>mac-address</i> <1-10> | Optional.<br>Not configured by default. |

### NOTE:

After an ARP attack detection entry expires, ARP packets sourced from the MAC address in the entry can be processed normally.

## Displaying and maintaining source MAC address based ARP attack detection

| Task                                                                                       | Command                                                                                                                                                                                       | Remarks               |
|--------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Display attacking MAC addresses detected by source MAC address based ARP attack detection. | <b>display arp anti-attack source-mac</b> { slot slot-number   <b>interface</b> interface-type interface-number } [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } regular-expression ] | Available in any view |

## Configuration example

### Network requirements

As shown in Figure 128, the hosts access the Internet through a gateway (Device). If malicious users send a large number of ARP requests to the gateway, the gateway may crash and cannot process requests from the clients. To solve this problem, configure source MAC address based ARP attack detection on the gateway.

Figure 128 Network diagram

### Configuration considerations

An attacker may forge a large number of ARP packets by using the MAC address of a valid host as the source MAC address. To prevent such attacks, configure the gateway in the following steps:

1. Enable source MAC address based ARP attack detection and specify the filter mode.
2. Set the threshold.
3. Set the age timer for detection entries.
4. Configure the MAC address of the server as a protected MAC address so that it can send ARP packets

### Configuration procedure

# Enable source MAC address based ARP attack detection and specify the filter mode.

```
<Device> system-view
```

```
[Device] arp anti-attack source-mac filter
Set the threshold to 30.
[Device] arp anti-attack source-mac threshold 30
Set the age timer for detection entries to 60 seconds.
[Device] arp anti-attack source-mac aging-time 60
Configure 0012-3f86-e94c as a protected MAC address.
[Device] arp anti-attack source-mac exclude-mac 0012-3f86-e94c
```

## Configuring ARP packet source MAC address consistency check

### Introduction

The ARP packet source MAC address consistency check feature enables a gateway device to filter out ARP packets that have a different source MAC address in the Ethernet header from the sender MAC address in the message, so that the gateway device can learn correct ARP entries.

### Configuration procedure

To enable ARP packet source MAC address consistency check:

| Step                                                       | Command                                   | Remarks             |
|------------------------------------------------------------|-------------------------------------------|---------------------|
| 1. Enter system view.                                      | <b>system-view</b>                        | N/A                 |
| 2. Enable ARP packet source MAC address consistency check. | <b>arp anti-attack valid-check enable</b> | Disabled by default |

## Configuring ARP active acknowledgement

### Introduction

The ARP active acknowledgement feature is configured on gateway devices to identify invalid ARP packets.

ARP active acknowledgement works before the gateway creates or modifies an ARP entry to avoid generating any incorrect ARP entry. For more information about its working mechanism, see *ARP Attack Protection Technology White Paper*.

### Configuration procedure

To configure ARP active acknowledgement:

| Step                  | Command            | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | <b>system-view</b> | N/A     |

| Step                                               | Command                                  | Remarks             |
|----------------------------------------------------|------------------------------------------|---------------------|
| 2. Enable the ARP active acknowledgement function. | <b>arp anti-attack active-ack enable</b> | Disabled by default |

## Configuring ARP detection

### Introduction

ARP detection enables access devices to block ARP packets from unauthorized clients to prevent user spoofing and gateway spoofing attacks.

ARP detection provides the user validity check, ARP packet validity check, and ARP restricted forwarding functions. If both ARP packet validity check and user validity check are enabled, the former one applies first, and then the latter applies.

ARP detection does not check ARP packets received from ARP trusted ports.

### Configuring user validity check

This feature enables a device to check user validity as follows:

1. Upon receiving an ARP packet from an ARP untrusted interface, the device checks the packet against the configured rules. If a match is found, the ARP packet is processed according to the matching rule; if no match is found, the device checks the packet against static IP Source Guard binding entries
2. The device compares the sender IP and MAC addresses of the ARP packet against the static IP source guard binding entries. If a match is found, the ARP packet is considered valid and is forwarded. If an entry with a matching IP address but an unmatched MAC address is found, the ARP packet is considered invalid and is discarded. If no entry with a matching IP address is found, the device compares the ARP packet's sender IP and MAC addresses against the DHCP snooping entries, 802.1X security entries, and OUI MAC addresses.
3. If a match is found from those entries, the ARP packet is considered valid and is forwarded. (For a packet to pass user validity check based on OUI MAC addresses, the sender MAC address must be an OUI MAC address and the voice VLAN must be enabled.)
4. If no match is found, the ARP packet is considered invalid and is discarded.

For more information about voice VLANs and OUI MAC addresses, see *Layer 2—LAN Switching Configuration Guide*.

#### Configuration guidelines

Follow these guidelines when you configure user validity check:

- Static IP source guard binding entries are created by using the **ip source binding** command. For more information, see "[Configuring IP source guard](#)."
- Dynamic DHCP snooping entries are automatically generated by DHCP snooping. For more information, see *Layer 3—IP Services Configuration Guide*.
- 802.1X security entries are generated by 802.1X. After a client passes 802.1X authentication and uploads its IP address to an ARP detection enabled device, the device automatically generates an 802.1X security entry. Therefore, the 802.1X client must be able to upload its IP address to the device. For more information, see "[Configuring 802.1X](#)."

- At least the configured rules, static IP source guard binding entries, DHCP snooping entries, or 802.1X security entries must be available for user validity check. Otherwise, ARP packets received from ARP untrusted ports will be discarded, except the ARP packets with an OUI MAC address as the sender MAC address when voice VLAN is enabled.
- You must specify a VLAN for an IP source guard binding entry; otherwise, no ARP packets can match the IP source guard binding entry.

## Configuration procedure

To configure user validity check:

| Step                                                                           | Command                                                                                                                                                                                                                                                 | Remarks                                                                                                                                               |
|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                                          | <b>system-view</b>                                                                                                                                                                                                                                      | N/A                                                                                                                                                   |
| 2. Set rules for user validity check.                                          | <b>arp detection</b> <i>id-number</i> { <b>permit</b>   <b>deny</b> } <b>ip</b> { <b>any</b>   <i>ip-address</i> [ <i>ip-address-mask</i> ] } <b>mac</b> { <b>any</b>   <i>mac-address</i> [ <i>mac-address-mask</i> ] } [ <b>vlan</b> <i>vlan-id</i> ] | Optional.<br>By default, no rule is configured.                                                                                                       |
| 3. Enter VLAN view.                                                            | <b>vlan</b> <i>vlan-id</i>                                                                                                                                                                                                                              | N/A                                                                                                                                                   |
| 4. Enable ARP detection for the VLAN.                                          | <b>arp detection enable</b>                                                                                                                                                                                                                             | ARP detection based on static IP source guard binding entries/DHCP snooping entries/802.1X security entries/OUI MAC addresses is disabled by default. |
| 5. Return to system view.                                                      | <b>quit</b>                                                                                                                                                                                                                                             | N/A                                                                                                                                                   |
| 6. Enter Layer 2 Ethernet interface/Layer 2 aggregate interface view.          | <b>interface</b> <i>interface-type</i> <i>interface-number</i>                                                                                                                                                                                          | N/A                                                                                                                                                   |
| 7. Configure the port as a trusted port on which ARP detection does not apply. | <b>arp detection trust</b>                                                                                                                                                                                                                              | Optional.<br>The port is an untrusted port by default.                                                                                                |

## Configuring ARP packet validity check

Perform this task to enable validity check for ARP packets received on untrusted ports and specify the following objects to be checked.

- **src-mac**—Checks whether the sender MAC address in the message body is identical to the source MAC address in the Ethernet header. If they are identical, the packet is forwarded; otherwise, the packet is discarded.
- **dst-mac**—Checks the target MAC address of ARP replies. If the target MAC address is all-zero, all-one, or inconsistent with the destination MAC address in the Ethernet header, the packet is considered invalid and discarded.
- **ip**—Checks the sender and target IP addresses of ARP replies, and the sender IP address of ARP requests. All-zero, all-one, or multicast IP addresses are considered invalid and the corresponding packets are discarded.

To configure ARP packet validity check:

| Step                                                                           | Command                                                                         | Remarks                                                |
|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------|--------------------------------------------------------|
| 1. Enter system view.                                                          | <b>system-view</b>                                                              | N/A                                                    |
| 2. Enter VLAN view.                                                            | <b>vlan</b> <i>vlan-id</i>                                                      | N/A                                                    |
| 3. Enable ARP detection for the VLAN.                                          | <b>arp detection enable</b>                                                     | Disabled by default.                                   |
| 4. Return to system view.                                                      | <b>quit</b>                                                                     | N/A                                                    |
| 5. Enable ARP packet validity check and specify the objects to be checked.     | <b>arp detection validate</b> { <b>dst-mac</b>   <b>ip</b>   <b>src-mac</b> } * | Disabled by default.                                   |
| 6. Enter Layer 2 Ethernet port/Layer 2 aggregate interface view.               | <b>interface</b> <i>interface-type</i><br><i>interface-number</i>               | N/A                                                    |
| 7. Configure the port as a trusted port on which ARP detection does not apply. | <b>arp detection trust</b>                                                      | Optional.<br>The port is an untrusted port by default. |

## Configuring ARP restricted forwarding

ARP restricted forwarding controls the forwarding of ARP packets that are received on untrusted ports and have passed ARP detection in the following cases:

- If the packets are ARP requests, they are forwarded through the trusted ports.
- If the packets are ARP responses, they are forwarded according to their destination MAC address. If no match is found in the MAC address table, they are forwarded through the trusted ports.

Before performing the following configuration, make sure you have configured the **arp detection enable** command.

To enable ARP restricted forwarding:

| Step                                 | Command                                 | Remarks             |
|--------------------------------------|-----------------------------------------|---------------------|
| 1. Enter system view.                | <b>system-view</b>                      | N/A                 |
| 2. Enter VLAN view.                  | <b>vlan</b> <i>vlan-id</i>              | N/A                 |
| 3. Enable ARP restricted forwarding. | <b>arp restricted-forwarding enable</b> | Disabled by default |

## Displaying and maintaining ARP detection

| Task                                          | Command                                                                                                                                                                                         | Remarks                |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Display the VLANs enabled with ARP detection. | <b>display arp detection</b> [ [ { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] ]                                                                               | Available in any view  |
| Display the ARP detection statistics.         | <b>display arp detection statistics</b> [ <b>interface</b> <i>interface-type</i> <i>interface-number</i> ] [ [ { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] ] | Available in any view  |
| Clear the ARP detection statistics.           | <b>reset arp detection statistics</b> [ <b>interface</b> <i>interface-type</i> <i>interface-number</i> ]                                                                                        | Available in user view |

# User validity check configuration example

## Network requirements

As shown in Figure 129, configure Switch B to perform user validity check based on 802.1X security entries for connected hosts.

Figure 129 Network diagram

## Configuration procedure

1. Add all the ports on Switch B into VLAN 10, and configure the IP address of VLAN-interface 10 on Switch A. (Details not shown.)

2. Configure Switch A as a DHCP server:

# Configure DHCP address pool 0.

```
<SwitchA> system-view
[SwitchA] dhcp enable
[SwitchA] dhcp server ip-pool 0
[SwitchA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

3. Configure Host A and Host B as 802.1X clients and configure them to upload IP addresses for ARP detection. (Details not shown.)

4. Configure Switch B:

# Enable the 802.1X function.

```
<SwitchB> system-view
[SwitchB] dot1x
[SwitchB] interface gigabitEthernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] dot1x
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitEthernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] dot1x
[SwitchB-GigabitEthernet1/0/2] quit
```

# Add local access user **test**.

```
[SwitchB] local-user test
[SwitchB-luser-test] service-type lan-access
```

```
[SwitchB-luser-test] password simple test
[SwitchB-luser-test] quit
```

# Enable ARP detection for VLAN 10.

```
[SwitchB] vlan 10
[SwitchB-vlan10] arp detection enable
```

# Configure the upstream port as a trusted port and the downstream ports as untrusted ports (a port is an untrusted port by default).

```
[SwitchB-vlan10] interface gigabitEthernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] arp detection trust
[SwitchB-GigabitEthernet1/0/3] quit
```

After the preceding configurations are complete, when ARP packets arrive at interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, they are checked against 802.1X security entries.

## User validity check and ARP packet validity check configuration example

### Network requirements

Configure Switch B to perform ARP packet validity check and user validity check based on static IP source guard binding entries and DHCP snooping entries for connected hosts.

Figure 130 Network diagram

### Configuration procedure

1. Add all the ports on Switch B to VLAN 10, and configure the IP address of VLAN-interface 10 on Switch A. (Details not shown.)
2. Configure Switch A as a DHCP server:

```
Configure DHCP address pool 0.
<SwitchA> system-view
[SwitchA] dhcp enable
[SwitchA] dhcp server ip-pool 0
```

```
[SwitchA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

3. Configure Host A as DHCP client, and Host B as user. (Details not shown.)

4. Configure Switch B:

```
Enable DHCP snooping.
```

```
<SwitchB> system-view
```

```
[SwitchB] dhcp-snooping
```

```
[SwitchB] interface gigabitethernet 1/0/3
```

```
[SwitchB-GigabitEthernet1/0/3] dhcp-snooping trust
```

```
[SwitchB-GigabitEthernet1/0/3] quit
```

```
Enable ARP detection for VLAN 10.
```

```
[SwitchB] vlan 10
```

```
[SwitchB-vlan10] arp detection enable
```

```
Configure the upstream port as a trusted port (a port is an untrusted port by default).
```

```
[SwitchB-vlan10] interface gigabitethernet 1/0/3
```

```
[SwitchB-GigabitEthernet1/0/3] arp detection trust
```

```
[SwitchB-GigabitEthernet1/0/3] quit
```

```
Configure a static IP source guard binding entry on interface GigabitEthernet 1/0/2.
```

```
[SwitchB] interface gigabitethernet 1/0/2
```

```
[SwitchB-GigabitEthernet1/0/2] ip source binding ip-address 10.1.1.6 mac-address
0001-0203-0607 vlan 10
```

```
[SwitchB-GigabitEthernet1/0/2] quit
```

```
Enable ARP packet validity check by checking the MAC addresses and IP addresses of ARP
packets.
```

```
[SwitchB] arp detection validate dst-mac ip src-mac
```

After the configurations are completed, ARP packets received on interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 have their MAC and IP addresses checked first, and then are checked against the static IP source guard binding entries and finally DHCP snooping entries.

## ARP restricted forwarding configuration example

### Network requirements

As shown in [Figure 131](#), configure ARP restricted forwarding on Switch B where ARP detection is configured so that port isolation configured on Switch B can take effect for broadcast ARP requests.

**Figure 131 Network diagram**

### Configuration procedure

1. Configure VLAN 10, add ports to VLAN 10, and configure the IP address of the VLAN-interface, as shown in [Figure 127](#). (Details not shown.)
2. Configure the DHCP server on Switch A.

# Configure DHCP address pool 0.

```
<SwitchA> system-view
[SwitchA] dhcp enable
[SwitchA] dhcp server ip-pool 0
[SwitchA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

3. Configure the DHCP client on Hosts A and B. (Details not shown.)

4. Configure Switch B.

# Enable DHCP snooping, and configure GigabitEthernet 1/0/3 as a DHCP-trusted port.

```
<SwitchB> system-view
[SwitchB] dhcp-snooping
[SwitchB] interface gigabitEthernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] dhcp-snooping trust
[SwitchB-GigabitEthernet1/0/3] quit
```

# Enable ARP detection.

```
[SwitchB] vlan 10
[SwitchB-vlan10] arp detection enable
```

# Configure GigabitEthernet 1/0/3 as an ARP-trusted port.

```
[SwitchB-vlan10] interface gigabitEthernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] arp detection trust
[SwitchB-GigabitEthernet1/0/3] quit
```

# Configure a static IP source guard entry on interface GigabitEthernet 1/0/2.

```
[SwitchB] interface gigabitEthernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ip source binding ip-address 10.1.1.6 mac-address
0001-0203-0607 vlan 10
[SwitchB-GigabitEthernet1/0/2] quit
```

# Enable the checking of the MAC addresses and IP addresses of ARP packets.

```
[SwitchB] arp detection validate dst-mac ip src-mac
```

# Configure port isolation.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port-isolate enable
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port-isolate enable
[SwitchB-GigabitEthernet1/0/2] quit
```

After the preceding configurations are complete, ARP packets received on interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 have their MAC and IP addresses checked first, and then are checked against the static IP source guard binding entries and finally DHCP snooping entries. However, ARP broadcast requests sent from Host A can pass the check on Switch B and reach Host B. Port isolation fails.

# Configure ARP restricted forwarding.

```
[SwitchB] vlan 10
[SwitchB-vlan10] arp restricted-forwarding enable
[SwitchB-vlan10] quit
```

After the configuration, Switch B forwards ARP broadcast requests from Host A to Switch A through the trusted port GigabitEthernet 1/0/3, and thus Host B cannot receive such packets. Port isolation works normally.

## Configuring ARP automatic scanning and fixed ARP

ARP automatic scanning is usually used together with the fixed ARP feature.

With ARP automatic scanning enabled on an interface, the device automatically scans neighbors on the interface, sends ARP requests to the neighbors, obtains their MAC addresses, and creates dynamic ARP entries.

Fixed ARP allows the device to change the existing dynamic ARP entries (including those generated through ARP automatic scanning) into static ARP entries. The fixed ARP feature effectively prevents ARP entries from being modified by attackers.

HP recommends that you use ARP automatic scanning and fixed ARP in a small-scale network such as a cybercafe.

## Configuration guidelines

Follow these guidelines when you configure ARP automatic scanning and fixed ARP:

- IP addresses existing in ARP entries are not scanned.
- ARP automatic scanning may take some time. To stop an ongoing scan, press **Ctrl + C**. Dynamic ARP entries are created based on ARP replies received before the scan is terminated.
- The static ARP entries changed from dynamic ARP entries have the same attributes as the manually configured static ARP entries.
- Use the **arp fixup** command to change the existing dynamic ARP entries into static ARP entries. You can use this command again to change the dynamic ARP entries learned later into static ARP entries.

- The number of static ARP entries changed from dynamic ARP entries is restricted by the number of static ARP entries that the device supports. As a result, the device may fail to change all dynamic ARP entries into static ARP entries.
- To delete a specific static ARP entry changed from a dynamic one, use the **undo arp ip-address** [ *vpn-instance-name* ] command (The HP 5500 SI switch series does not support the *vpn-instance-name* argument in the command). To delete all such static ARP entries, use the **reset arp all** or **reset arp static** command.

## Configuration procedure

To configure ARP automatic scanning and fixed ARP:

| Step                              | Command                                                                     |
|-----------------------------------|-----------------------------------------------------------------------------|
| 1. Enter system view.             | <b>system-view</b>                                                          |
| 2. Enter interface view.          | <b>interface</b> <i>interface-type</i> <i>interface-number</i>              |
| 3. Enable ARP automatic scanning. | <b>arp scan</b> [ <i>start-ip-address</i> <b>to</b> <i>end-ip-address</i> ] |
| 4. Return to system view.         | <b>quit</b>                                                                 |
| 5. Enable fixed ARP.              | <b>arp fixup</b>                                                            |

## Configuring ARP gateway protection

The ARP gateway protection feature, if configured on ports not connected with the gateway, can block gateway spoofing attacks.

When such a port receives an ARP packet, it checks whether the sender IP address in the packet is consistent with that of any protected gateway. If yes, it discards the packet. If not, it handles the packet normally.

## Configuration guidelines

Follow these guidelines when you configure ARP gateway protection:

- You can enable ARP gateway protection for up to eight gateways on a port.
- Commands **arp filter source** and **arp filter binding** cannot be both configured on a port.
- If ARP gateway protection works with ARP detection and ARP snooping, ARP gateway protection applies first.

## Configuration procedure

To configure ARP gateway protection:

| Step                                                                       | Command                                                        | Remarks |
|----------------------------------------------------------------------------|----------------------------------------------------------------|---------|
| 1. Enter system view.                                                      | <b>system-view</b>                                             | N/A     |
| 2. Enter Layer 2 Ethernet interface view/Layer 2 aggregate interface view. | <b>interface</b> <i>interface-type</i> <i>interface-number</i> | N/A     |

| Step | Command                                                                                                 | Remarks             |
|------|---------------------------------------------------------------------------------------------------------|---------------------|
| 3.   | Enable ARP gateway protection for a specified gateway.<br><br><code>arp filter source ip-address</code> | Disabled by default |

## Configuration example

### Network requirements

As shown in [Figure 132](#), Host B launches gateway spoofing attacks to Switch B. As a result, traffic that Switch B intends to send to Switch A is sent to Host B.

Configure Switch B to block such attacks.

**Figure 132 Network diagram**

### Configuration procedure

# Configure ARP gateway protection on Switch B.

```

<SwitchB> system-view
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] arp filter source 10.1.1.1
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] arp filter source 10.1.1.1

```

After the configuration is complete, Switch B will discard the ARP packets whose source IP address is that of the gateway.

## Configuring ARP filtering

To prevent gateway spoofing and user spoofing, the ARP filtering feature controls the forwarding of ARP packets on a port.

The port checks the sender IP and MAC addresses in a received ARP packet against configured ARP filtering entries. If a match is found, the packet is handled normally. If not, the packet is discarded.

## Configuration guidelines

Follow these guidelines when you configure ARP filtering:

- You can configure up to eight ARP filtering entries on a port.
- Commands **arp filter source** and **arp filter binding** cannot be both configured on a port.
- If ARP filtering works with ARP detection and ARP snooping, ARP filtering applies first.

## Configuration procedure

To configure ARP filtering:

| Step                                                                       | Command                                                           | Remarks                   |
|----------------------------------------------------------------------------|-------------------------------------------------------------------|---------------------------|
| 1. Enter system view.                                                      | <b>system-view</b>                                                | N/A                       |
| 2. Enter Layer 2 Ethernet interface view/Layer 2 aggregate interface view. | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                       |
| 3. Configure an ARP filtering entry.                                       | <b>arp filter binding</b> <i>ip-address</i><br><i>mac-address</i> | Not configured by default |

## Configuration example

### Network requirements

As shown in [Figure 133](#), the IP and MAC addresses of Host A are 10.1.1.2 and 000f-e349-1233. The IP and MAC addresses of Host B are 10.1.1.3 and 000f-e349-1234.

Configure ARP filtering on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 of Switch B to permit specific ARP packets only.

**Figure 133 Network diagram**

### Configuration procedure

# Configure ARP filtering on Switch B.

```
<SwitchB> system-view
```

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] arp filter binding 10.1.1.2 000f-e349-1233
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] arp filter binding 10.1.1.3 000f-e349-1234
```

After the configuration is complete, GigabitEthernet 1/0/1 will permit incoming ARP packets with sender IP and MAC addresses as 10.1.1.2 and 000f-e349-1233, and discard other ARP packets. GigabitEthernet 1/0/2 will permit incoming ARP packets with sender IP and MAC addresses as 10.1.1.9 and 000f-e349-1233 and discard other ARP packets. ARP packets from Host A are permitted, but those from Host B are discarded.

# Configuring ND attack defense

## Overview

The IPv6 Neighbor Discovery (ND) protocol provides rich functions, such as address resolution, neighbor reachability detection, duplicate address detection, router/prefix discovery and address autoconfiguration, and redirection. However, it does not provide any security mechanisms. Attackers can easily exploit the ND protocol to attack hosts and gateways by sending forged packets. For more information about the five functions of the ND protocol, see *Layer 3—IP Services Configuration Guide*.

The ND protocol implements its function by using five types of ICMPv6 messages:

- Neighbor Solicitation (NS)
- Neighbor Advertisement (NA)
- Router Solicitation (RS)
- Router Advertisement (RA)
- Redirect (RR)

As shown in [Figure 134](#), an attacker can attack a network by sending forged ICMPv6 messages:

- Sends forged NS/NA/RS packets with the IPv6 address of a victim host. The gateway and other hosts update the ND entry for the victim host with incorrect address information. As a result, all packets intended for the victim host are sent to the attacking host rather than the victim host.
- Sends forged RA packets with the IPv6 address of a victim gateway. As a result, all hosts attached to the victim gateway maintain incorrect IPv6 configuration parameters and ND entries.

**Figure 134 ND attack diagram**

All forged ND packets have two common features:

- The Ethernet frame header and the source link layer address option of the ND packet contain different source MAC addresses.

- The mapping between the source IPv6 address and the source MAC address in the Ethernet frame header is invalid.

To identify forged ND packets, HP developed the source MAC consistency check and ND detection features.

## Enabling source MAC consistency check for ND packets

Use source MAC consistency check on a gateway to filter out ND packets that carry different source MAC addresses in the Ethernet frame header and the source link layer address option.

Follow these guidelines when you enable source MAC consistency check for ND packets:

- If VRRP is used, disable source MAC consistency check for ND packets to prevent incorrect dropping of packets. With VRRP, the NA message always conveys a MAC address different from the Source Link-Layer Address option.
- Only the HP 5500 EI switches support VRRP.

To enable source MAC consistency check for ND packets:

| Step                                                   | Command                         | Remarks             |
|--------------------------------------------------------|---------------------------------|---------------------|
| 1. Enter system view.                                  | <b>system-view</b>              | N/A                 |
| 2. Enable source MAC consistency check for ND packets. | <b>ipv6 nd mac-check enable</b> | Disabled by default |

## Configuring the ND detection function

### Introduction to ND detection

Use the ND detection function on access devices to verify the source of ND packets. If an ND packet comes from a spoofing host or gateway, it is discarded.

The ND detection function operates on a per VLAN basis. In an ND detection-enabled VLAN, a port is either ND-trusted or ND-untrusted:

- An ND-trusted port does not check ND packets for address spoofing.
- An ND-untrusted port checks all ND packets but RA and RR messages in the VLAN for source spoofing. RA and RR messages are considered illegal and are discarded directly.

The ND detection function checks an ND packet by looking up the IPv6 static bindings table of the IP source guard function, ND snooping table, and DHCPv6 snooping table in the following steps:

1. Looks up the IPv6 static binding table of IP source guard, based on the source IPv6 address and the source MAC address in the Ethernet frame header of the ND packet. If an exact match is found, the ND packet is forwarded. If an entry matches the source IPv6 address but not the source MAC address, the ND packet is discarded. If no entry matches the source IPv6 address, the ND detection function continues to look up the DHCPv6 snooping table and the ND snooping table.
2. If an exact match is found in either the DHCPv6 snooping or ND snooping table, the ND packet is forwarded. If no match is found in either table, the packet is discarded. If neither the DHCPv6 snooping table nor the ND snooping table is available, the ND packet is discarded.

## Configuration guidelines

Follow these guidelines when you configure ND detection:

- To create IPv6 static bindings with IP source guard, use the **ipv6 source binding** command. For more information, see "[Configuring IP source guard](#)."
- The DHCPv6 snooping table is created automatically by the DHCPv6 snooping module. For more information, see *Layer 3—IP Services Configuration Guide*.
- The ND snooping table is created automatically by the ND snooping module. For more information, see *Layer 3—IP Services Configuration Guide*.
- ND detection performs source check by using the binding tables of IP source guard, DHCPv6 snooping, and ND snooping. To prevent an ND-untrusted port from discarding legal ND packets in an ND detection-enabled VLAN, make sure that at least one of the three functions is available.
- When creating an IPv6 static binding with IP source guard for ND detection in a VLAN, specify the VLAN ID for the binding. If not, no ND packets in the VLAN can match the binding.

## Configuration procedure

To configure ND detection:

| Step                                                                          | Command                                                           | Remarks                                                              |
|-------------------------------------------------------------------------------|-------------------------------------------------------------------|----------------------------------------------------------------------|
| 1. Enter system view.                                                         | <b>system-view</b>                                                | N/A                                                                  |
| 2. Enter VLAN view.                                                           | <b>vlan</b> <i>vlan-id</i>                                        | N/A                                                                  |
| 3. Enable ND Detection.                                                       | <b>ipv6 nd detection enable</b>                                   | Disabled by default.                                                 |
| 4. Quit system view.                                                          | <b>quit</b>                                                       | N/A                                                                  |
| 5. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view. | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                                                                  |
| 6. Configure the port as an ND-trusted port.                                  | <b>ipv6 nd detection trust</b>                                    | Optional.<br>A port does not trust sources of ND packets by default. |

## Displaying and maintaining ND detection

| Task                                                                                        | Command                                                                                                                                                                                           | Remarks                |
|---------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Display the ND detection configuration.                                                     | <b>display ipv6 nd detection</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                                                                               | Available in any view  |
| Display the statistics of discarded packets when the ND detection checks the user legality. | <b>display ipv6 nd detection statistics</b> [ <b>interface</b> <i>interface-type</i> <i>interface-number</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view  |
| Clear the statistics by ND detection.                                                       | <b>reset ipv6 nd detection statistics</b> [ <b>interface</b> <i>interface-type</i> <i>interface-number</i> ]                                                                                      | Available in user view |

# ND detection configuration example

## Network requirements

As shown in [Figure 135](#), Host A and Host B connect to Switch A, the gateway, through Switch B. Host A has the IPv6 address 10::5 and MAC address 0001-0203-0405. Host B has the IPv6 address 10::6 and MAC address 0001-0203-0607.

Enable ND detection on Switch B to filter out forged ND packets.

**Figure 135 Network diagram**

## Configuration procedure

### 1. Configuring Switch A:

# Enable IPv6 forwarding.

```
<SwitchA> system-view
```

```
[SwitchA] ipv6
```

# Create VLAN 10.

```
[SwitchA] vlan 10
```

```
[SwitchA-vlan10] quit
```

# Assign port GigabitEthernet 1/0/3 to VLAN 10.

```
[SwitchA] interface gigabitethernet 1/0/3
```

```
[SwitchA- GigabitEthernet1/0/3] port link-type trunk
```

```
[SwitchA- GigabitEthernet1/0/3] port trunk permit vlan 10
```

```
[SwitchA- GigabitEthernet1/0/3] quit
```

# Assign an IPv6 address to VLAN-interface 10.

```
[SwitchA] interface vlan-interface 10
```

```
[SwitchA-Vlan-interface10] ipv6 address 10::1/64
[SwitchA-Vlan-interface10] quit
```

## 2. Configuring Switch B:

**# Enable IPv6 forwarding.**

```
<SwitchB> system-view
[SwitchB] ipv6
```

**# Create VLAN 10.**

```
[SwitchB] vlan 10
[SwitchB-vlan10] quit
```

**# Add ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to VLAN 10.**

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port access vlan 10
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port access vlan 10
[SwitchB-GigabitEthernet1/0/2] quit
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] port link-type trunk
[SwitchB-GigabitEthernet1/0/3] port trunk permit vlan 10
[SwitchB-GigabitEthernet1/0/3] quit
```

**# Enable ND snooping for global unicast and link local addresses in VLAN 10.**

```
[SwitchB] ipv6 nd snooping enable link-local
[SwitchB] ipv6 nd snooping enable global
[SwitchB] vlan 10
[SwitchB-vlan 10] ipv6 nd snooping enable
```

**# Enable ND detection in VLAN 10.**

```
[SwitchB-vlan 10] ipv6 nd detection enable
[SwitchB-vlan 10] quit
```

**# Configure the uplink port GigabitEthernet 1/0/3 as an ND-trusted port, and the downlink ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as ND-untrusted ports (the default).**

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 nd detection trust
```

The configuration enables Switch B to check all incoming ND packets of ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 based on the ND snooping table.

# Configuring URPF (available only on the HP 5500 EI)

The term "router" in this feature refers to both routers and Layer 3 switches.

## URPF overview

### What is URPF

Unicast Reverse Path Forwarding (URPF) protects a network against source address spoofing attacks, such as denial of service (DoS) and distributed denial of service (DDoS) attacks.

Attackers launch attacks by creating a series of packets with forged source addresses. For applications using IP-address-based authentication, this type of attack allows unauthorized users to access the system in the name of authorized users, or to even access the system as the administrator. Even if the attackers cannot receive any response packets, the attacks are still disruptive to the attacked target.

**Figure 136 Attack based on source address spoofing**

As shown in [Figure 136](#), Router A sends the server (Router B) requests with a forged source IP address 2.2.2.1 at a high rate, and Router B sends packets to IP address 2.2.2.1 (Router C) in response to the requests. Consequently, both Router B and Router C are attacked.

URPF can prevent this source address spoofing attack by checking the source addresses of packets and filtering out invalid packets.

## URPF check modes

URPF provides two check modes: strict and loose.

### Strict URPF

To pass strict URPF check, the source address and receiving interface of a packet must match the destination address and output interface of a forwarding information base (FIB) entry.

In some scenarios such as asymmetrical routing, strict URPF may discard valid packets.

Strict URPF is often deployed between an internet service provider (ISP) and the connected users.

### Loose URPF

To pass loose URPF check, the source address of a packet must match the destination address of a FIB entry. Loose URPF can avoid discarding valid packets, but may let go attack packets.

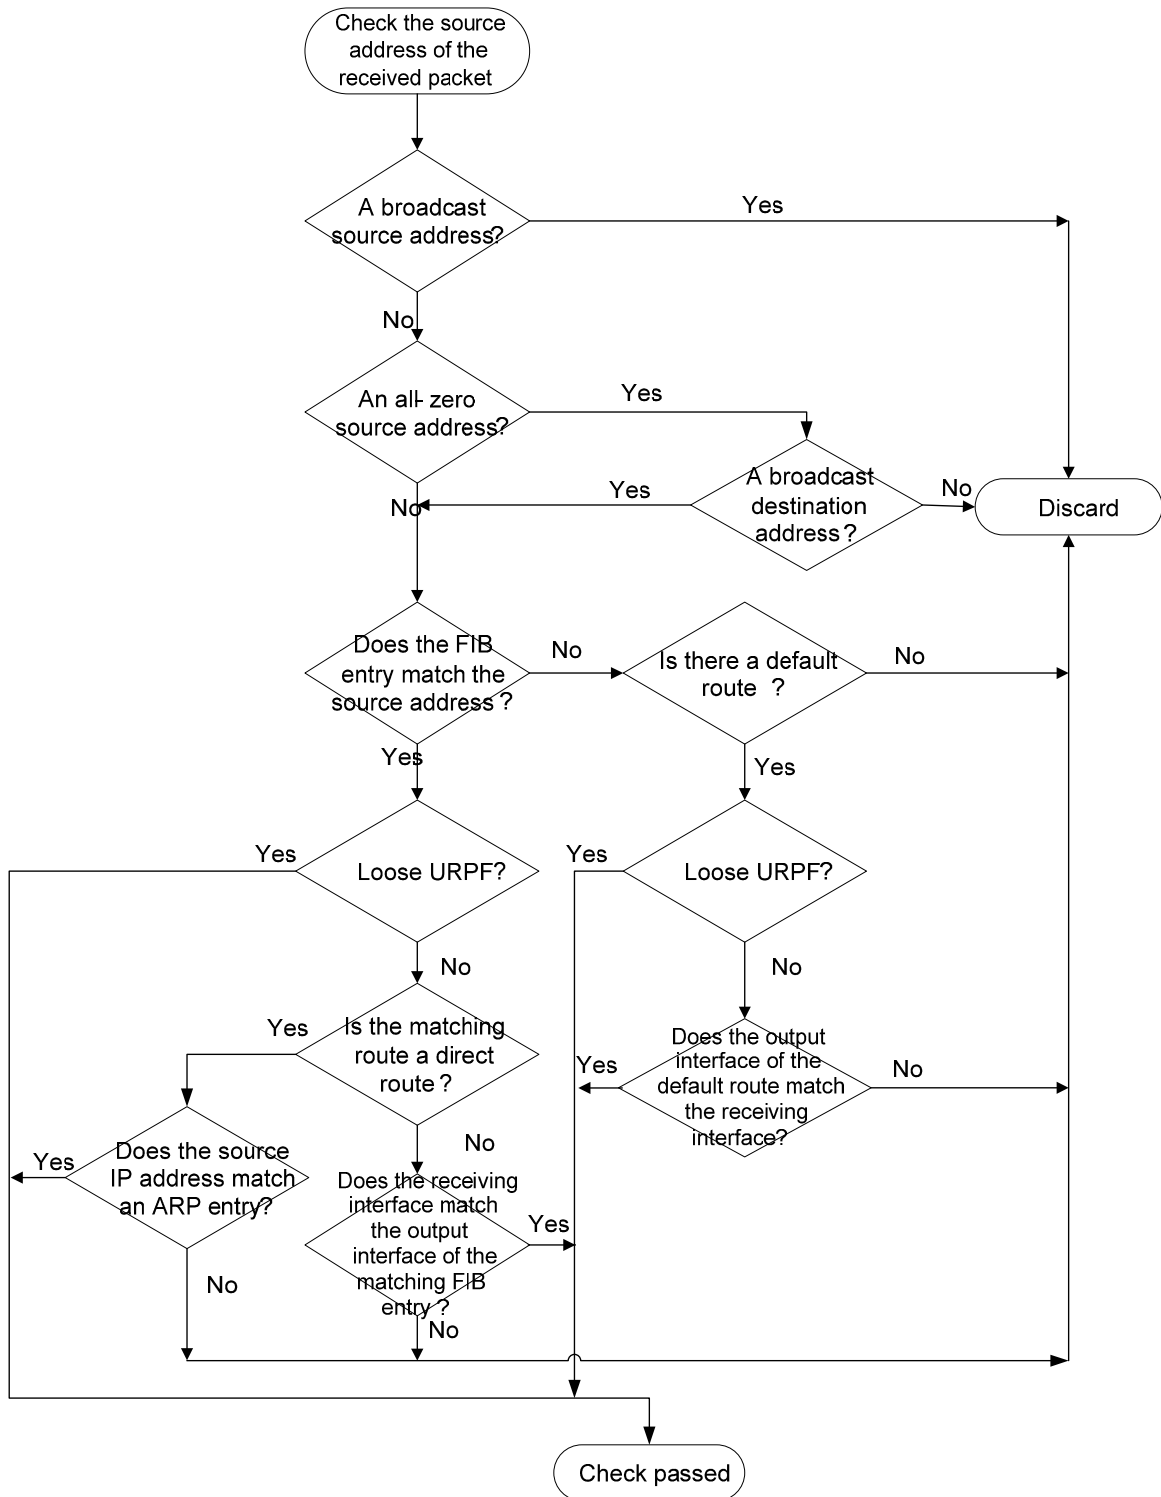

Loose URPF is often deployed between ISPs, especially in asymmetrical routing.

# How URPF works

URPF does not check multicast packets.

URPF works in the steps, as shown in [Figure 137](#).

**Figure 137 URPF work flow**

1. URPF checks the source address validity:

- Discards packets with a broadcast source address.
  - Discards packets with an all-zero source address but a non-broadcast destination address. (A packet with source address 0.0.0.0 and destination address 255.255.255.255 might be a DHCP or BOOTP packet, and is not discarded.)
  - For other packets, precede to step 2.
2. URPF checks whether the source address matches a FIB entry:
    - If yes, precede to step 3.
    - If not, precede to step 6.
  3. URPF checks whether the check mode is loose:
    - If yes, precede to step 8.
    - If not, URPF checks whether the matching route is a direct route: if yes, precede to step 5; if not, precede to step 4.
  4. URPF checks whether the receiving interface matches the output interface of the matching FIB entry.
    - If yes, precede to step 8.
    - If not, precede to step 9.
  5. URPF checks whether the source IP address matches an ARP entry.
    - If yes, precede to step 8.
    - If not, precede to step 9.
  6. URPF checks whether the FIB table has a default route.
    - If yes, precede to step 7.
    - If not, precede to step 9.
  7. URPF checks whether the check mode is loose:
    - If yes, precede to step 8.
    - If not, URPF checks whether the output interface of the default route matches the receiving interface of the packet: if yes, precede to step 8; if not, precede to step 9.
  8. The packet passes the check and is forwarded.
  9. The packet is discarded.

# Network application

Figure 138 Network diagram

Configure strict URPF between each ISP and its connected users, and loose URPF between ISPs.

## Configuring URPF

To configure URPF globally:

| Step                           | Command                           | Remarks              |
|--------------------------------|-----------------------------------|----------------------|
| 1. Enter system view.          | <b>system-view</b>                | N/A                  |
| 2. Enable URPF check globally. | <b>ip urpf { loose   strict }</b> | Disabled by default. |

### NOTE:

- The routing table size decreases by half when URPF is enabled on the HP 5500 EI switches.
- To prevent loss of routes and packets, URPF cannot be enabled if the number of route entries the switch maintains exceeds half the routing table size.

## URPF configuration example

### Network requirements

As shown in Figure 139, a client (Switch A) directly connects to the ISP switch (Switch B). Enable URPF check on Switch A and Switch B to prevent source address spoofing attacks.

**Figure 139 Network diagram**

### Configuration procedure

1. Configure Switch A:  
# Enable strict URPF check.  
<SwitchA> system-view  
[SwitchA] ip urpf strict
2. Configure Switch B:  
# Enable strict URPF check.  
<SwitchB> system-view  
[SwitchB] ip urpf strict

# Configuring SAVI

## SAVI overview

Source Address Validation (SAVI) is applied on access devices. SAVI creates a table of bindings between addresses and ports through other features such as ND snooping, DHCPv6 snooping, and IP Source Guard, and uses those bindings to check the validity of the source addresses of DHCPv6 protocol packets, ND protocol packets, and IPv6 data packets.

SAVI can be used in the following address assignment scenarios:

- DHCPv6-only: The hosts connected to the SAVI-enabled device obtain addresses only through DHCPv6.
- SLAAC-only: The hosts connected to the SAVI-enabled device obtain addresses only through Stateless Address Autoconfiguration (SLAAC).
- DHCPv6+SLAAC: The hosts connected to the SAVI-enabled device obtain addresses through DHCPv6 and SLAAC.

The following section describes SAVI configurations in these address assignment scenarios.

## Configuring global SAVI

| Step                                                                | Command                                        | Remarks                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                               | <b>system-view</b>                             | N/A                                                                                                                                                                                                                                                                                                                                                                     |
| 2. Enable the SAVI function.                                        | <b>ipv6 savi strict</b>                        | Disabled by default.                                                                                                                                                                                                                                                                                                                                                    |
| 3. Set the time to wait for a duplicate address detection (DAD) NA. | <b>ipv6 savi dad-delay</b> <i>value</i>        | Optional<br>One second by default.<br>If no DAD NA is received within the specified time when the corresponding ND snooping entry is in detect state, the ND snooping entry changes to bound state.                                                                                                                                                                     |
| 4. Set the time to wait for a DAD NS from a DHCPv6 client.          | <b>ipv6 savi dad-preparedelay</b> <i>value</i> | Optional<br>One second by default.<br>This command is used with the DHCPv6 snooping function. After DHCPv6 snooping detects that a client obtains an IPv6 address, it monitors whether the client detects IP address conflict. If DHCPv6 snooping does not receive any DAD NS from the client before the set time expires, SAVI sends a DAD NS on behalf of the client. |

---

**NOTE:**

If a port on the SAVI enabled device is down for three minutes or more, the device deletes the DHCPv6 snooping entries and ND snooping entries corresponding to the port.

---

# SAVI configuration in DHCPv6-only address assignment scenario

## Network requirements

Figure 140 Network diagram

As shown in Figure 140, Switch A is the DHCPv6 server. Switch B connects to the DHCPv6 server through interface GigabitEthernet 1/0/1, and connects to two DHCPv6 clients through interfaces GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3. The three interfaces of Switch B belong to VLAN 2. The client can obtain IP address only through DHCPv6. Configure SAVI on Switch B to automatically bind the IP addresses assigned through DHCPv6 and permit only packets from bound addresses and link-local addresses.

## Configuration considerations

Configure Switch B as follows:

- Enable SAVI.
- Enable DHCPv6 snooping. For more information about DHCPv6 snooping, see *Layer 3—IP Services Configuration Guide*.
- Enable link-local address ND snooping. For more information about ND snooping, see *Layer 3—IP Services Configuration Guide*.
- Enable ND detection in VLAN 2 to check the ND packets arrived on the ports. For more information about ND detection, see "[Configuring ND attack defense](#)."
- Configure a static IPv6 source guard binding entry on each interface connected to a client. This step is optional. If this step is not performed, SAVI does not check packets against static binding entries. For more information about static IPv6 source guard binding entries, see "[Configuring IP source guard](#)."
- Configure dynamic IPv6 source guard binding on the interfaces connected to the clients. For more information about dynamic IPv6 source guard binding, see "[Configuring IP source guard](#)."

## Packet check principles

Switch B checks DHCPv6 protocol packets from DHCPv6 clients against link-local address ND snooping entries; checks ND protocol packets against link-local address ND snooping entries, DHCPv6 snooping entries, and static binding entries; and checks the IPv6 data packets from the clients against dynamic binding entries (including link-local address ND snooping entries and DHCPv6 snooping entries) applied on the interfaces connected to the clients and against static binding entries. The items to be examined include MAC address, IPv6 address, VLAN information, and ingress port.

## Configuration procedure

# Enable SAVI.

```
<SwitchB> system-view
[SwitchB] ipv6 savi strict
```

# Enable IPv6.

```
[SwitchB] ipv6
```

# Globally enable DHCPv6 snooping.

```
[SwitchB] ipv6 dhcp snooping enable
```

# Assign interfaces GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
```

# Enable DHCPv6 snooping in VLAN 2.

```
[SwitchB-vlan2] ipv6 dhcp snooping vlan enable
[SwitchB] quit
```

# Configure interface GigabitEthernet 1/0/1 as a DHCP snooping trusted port.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
[SwitchB-GigabitEthernet1/0/1] quit
```

# Enable link-local address ND snooping and ND detection.

```
[SwitchB] ipv6 nd snooping enable link-local
[SwitchB] vlan 2
[SwitchB-vlan2] ipv6 nd snooping enable
[SwitchB-vlan2] ipv6 nd detection enable
[SwitchB-vlan2] quit
```

# Configure the dynamic IPv6 source guard binding function on downlink ports GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

```
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ipv6 verify source ipv6-address mac-address
[SwitchB-GigabitEthernet1/0/2] quit
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 verify source ipv6-address mac-address
[SwitchB-GigabitEthernet1/0/3] quit
```

# SAVI configuration in SLAAC-only address assignment scenario

## Network requirements

Figure 141 Network diagram

As shown in [Figure 141](#), Switch A serves as the gateway. Switch B connects Host A and Host B. The hosts can obtain IPv6 addresses only through SLAAC. Configure SAVI on Switch B to bind the addresses assigned through SLAAC and permit only packets from the bound addresses.

## Configuration considerations

Configure Switch B as follows:

- Enable SAVI.
- Enable global unicast address ND snooping and link-local address ND snooping. For more information about ND snooping, see *Layer 3—IP Services Configuration Guide*.
- Enable ND detection in VLAN 10 to check the ND packets arrived on the ports. For more information about ND detection, see "[Configuring ND attack defense](#)."
- Configure a static IPv6 source guard binding entry on each interface connected to a host. This step is optional. If this step is not performed, SAVI does not check packets against static binding entries. For more information about static IPv6 source guard binding entries, see "[Configuring IP source guard](#)."
- Configure dynamic IPv6 source guard binding on the interfaces connected to the hosts. For more information about dynamic IPv6 source guard binding, see "[Configuring IP source guard](#)."
- Enable DHCPv6 snooping and leave the interface connected to the gateway as its default status (non-trusted port) so that the hosts cannot obtain IP addresses through DHCPv6. For more information about DHCPv6 snooping, see *Layer 3—IP Services Configuration Guide*.

## Packet check principles

Switch B checks ND protocol packets against ND snooping entries and static binding entries; and checks the IPv6 data packets from the hosts against dynamic binding entries (including ND snooping entries) applied on the interfaces connected to the hosts and against static binding entries. The items to be examined include MAC address, IPv6 address, VLAN information, and ingress port.

## Configuration procedure

# Enable SAVI.

```
<SwitchB> system-view
[SwitchB] ipv6 savi strict
```

# Enable IPv6.

```
[SwitchB] ipv6
```

# Assign GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to VLAN 10.

```
[SwitchB] vlan 10
[SwitchB-vlan10] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
[SwitchB-vlan10] quit
```

# Enable global unicast address ND snooping and link-local address ND snooping.

```
[SwitchB] ipv6 nd snooping enable link-local
[SwitchB] ipv6 nd snooping enable global

# SAVI configuration in DHCPv6+SLAAC address assignment scenario

## Network requirements

Figure 142 Network diagram

As shown in [Figure 142](#), Switch B connects to the DHCPv6 server through interface GigabitEthernet 1/0/1 and connects to the DHCPv6 client through interface GigabitEthernet 1/0/3. Host A and Host B access Gateway (Switch A) through Switch B. Interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 on Switch B belong to VLAN 2. The hosts can obtain IP addresses through DHCPv6 or SLAAC. Configure SAVI on Switch B to permit only packets from addresses assigned through DHCPv6 and the bound addresses assigned through SLAAC.

## Configuration considerations

Configure Switch B as follows:

- Enable SAVI.
- Enable DHCPv6 snooping. For more information about DHCPv6 snooping, see *Layer 3—IP Services Configuration Guide*.
- Enable global unicast address ND snooping and link-local address ND snooping. For more information about ND snooping, see *Layer 3—IP Services Configuration Guide*.
- Enable ND detection in VLAN 2 to check the ND packets arrived on the ports. For more information about ND detection, see "[Configuring ND attack defense](#)."
- Configure a static IPv6 source guard binding entry on each interface connected to a host. This step is optional. If this step is not performed, SAVI does not check packets against static binding entries. For more information about static IPv6 source guard binding entries, see "[Configuring IP source guard](#)."
- Configure dynamic IPv6 source guard binding on the interfaces connected to the hosts. For more information about dynamic IPv6 source guard binding, see "[Configuring IP source guard](#)."

## Packet check principles

Switch B checks DHCPv6 protocol packets from DHCPv6 clients against link-local address ND snooping entries; checks ND protocol packets against ND snooping entries, DHCPv6 snooping entries, and static

binding entries; and checks the IPv6 data packets from the hosts against dynamic binding entries (including ND snooping entries and DHCPv6 snooping entries) applied on the interfaces connected to the hosts and against static binding entries. The items to be examined include MAC address, IPv6 address, VLAN information, and ingress port.

## Configuration procedure

# Enable SAVI.

```
<SwitchB> system-view
[SwitchB] ipv6 savi strict
```

# Enable IPv6.

```
[SwitchB] ipv6
```

# Enable DHCPv6 snooping.

```
[SwitchB] ipv6 dhcp snooping enable
```

# Assign interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 to VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
gigabitethernet 1/0/4 gigabitethernet 1/0/5
```

# Enable DHCPv6 snooping in VLAN 2.

```
[SwitchB-vlan2] ipv6 dhcp snooping vlan enable
[SwitchB] quit
```

# Configure interface GigabitEthernet 1/0/1 as a DHCPv6 snooping trusted port.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
[SwitchB-GigabitEthernet1/0/1] quit
```

# Enable ND snooping and ND detection.

```
[SwitchB] ipv6 nd snooping enable link-local
[SwitchB] ipv6 nd snooping enable global
[SwitchB] vlan 2
[SwitchB-vlan2] ipv6 nd snooping enable
[SwitchB-vlan2] ipv6 nd detection enable
[SwitchB-vlan2] quit
```

# Configure interface GigabitEthernet 1/0/2 as an ND detection trusted port.

```
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ipv6 nd detection trust
[SwitchB-GigabitEthernet1/0/2] quit
```

# Configure the dynamic IPv6 source guard binding function on downlink ports GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 verify source ipv6-address mac-address
[SwitchB-GigabitEthernet1/0/3] quit
[SwitchB] interface gigabitethernet 1/0/4
[SwitchB-GigabitEthernet1/0/4] ipv6 verify source ipv6-address mac-address
[SwitchB-GigabitEthernet1/0/4] quit
[SwitchB] interface gigabitethernet 1/0/5
[SwitchB-GigabitEthernet1/0/5] ipv6 verify source ipv6-address mac-address
```

# Configuring blacklist

## Overview

The blacklist feature is an attack prevention mechanism that filters packets based on the source IP address. Compared with ACL-based packet filtering, the blacklist feature is easier to configure and fast in filtering packets sourced from particular IP addresses.

The device can dynamically add and remove blacklist entries by cooperating with the login user authentication feature. When the device detects that a user tried to use FTP, Telnet, SSH, SSL, or web to log in to the device for a specific number of times but failed to log in, it considers the user an invalid user and automatically blacklists the user's IP address to filter subsequent packets sourced from that IP address. This function can effectively prevent users from cracking passwords by repeatedly trying to log in.

The device always uses the login failure threshold of 6 and sets the aging time of a dynamic blacklist entry to 10 minutes. These two settings are not configurable. User login failure reasons include wrong username, wrong password, and wrong verification code (for web users).

The device also supports adding and removing blacklist entries manually. Manually configured blacklist entries fall into two categories: permanent and non-permanent. A permanent blacklist entry is always present unless being removed manually, whereas a non-permanent blacklist entry has a limited lifetime depending on your configuration. When the lifetime of a non-permanent entry expires, the device removes the entry from the blacklist, allowing the packets of the IP address defined by the entry to pass through.

## Configuring the blacklist feature

| Step                             | Command                                                                           | Remarks                                                                                         |
|----------------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| 1. Enter system view.            | <b>system-view</b>                                                                | N/A                                                                                             |
| 2. Enable the blacklist feature. | <b>blacklist enable</b>                                                           | Disabled by default.                                                                            |
| 3. Add a blacklist entry.        | <b>blacklist ip</b> <i>source-ip-address</i><br>[ <b>timeout</b> <i>minutes</i> ] | Optional.<br>To add a permanent entry, do not specify the <b>timeout</b> <i>minutes</i> option. |

## Displaying and maintaining the blacklist

| Task                           | Command                                                                                                                                                                                                                             | Remarks               |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Display blacklist information. | <b>display blacklist</b> { <b>all</b>   <b>ip</b> <i>source-ip-address</i> [ <b>slot</b> <i>slot-number</i> ]   <b>slot</b> <i>slot-number</i> } [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view |

# Blacklist configuration example

## Network requirements

As shown in Figure 143, Host A, Host B, and Host C are internal users, and external user Host D is considered an attacker.

Configure Device to always filter packets from Host D, and to prevent internal users from guessing passwords.

Figure 143 Network diagram

## Configuration procedure

# Assign IP addresses to the interfaces of Device. (Details not shown.)

# Enable the blacklist feature.

```
<Device> system-view
[Device] blacklist enable
```

# Add the IP address of Host D 5.5.5.5 to the blacklist. Do not specify any aging time to make the entry never age out.

```
[Device] blacklist ip 5.5.5.5
```

## Verifying the configuration

If Host C tries to log in to Device through web for six times but fails to log in, the device blacklists Host C. Use the **display blacklist all** command to view all added blacklist entries.

```
[Device] display blacklist all
```

```
Blacklist information

Blacklist : enabled
Blacklist items : 2

IP Type Aging started Aging finished Dropped packets
 YYYY/MM/DD hh:mm:ss YYYY/MM/DD hh:mm:ss
5.5.5.5 manual 2011/04/09 16:02:20 Never 0
192.168.1.4 manual 2011/04/09 16:02:26 2011/04/09 16:12:26 0
```

Host D and Host C are on the blacklist. Host C will stay on the list for 10 minutes, and will then be able to try to log in again. The entry for Host D will never age out. When you do not consider Host D an attacker anymore, you can use the **undo blacklist ip 5.5.5.5** command to remove the entry.

# High availability overview

Communication interruptions can seriously affect widely-deployed value-added services such as IPTV and video conference. Therefore, the basic network infrastructures must be able to provide high availability.

The following are the effective ways to improve availability:

- Increasing fault tolerance
- Speeding up fault recovery
- Reducing impact of faults on services

## Availability requirements

Availability requirements fall into three levels based on purpose and implementation.

**Table 1 Availability requirements**

| Level | Requirement                                                  | Solution                                                                                                                                                                                                               |
|-------|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1     | Decrease system software and hardware faults                 | <ul style="list-style-type: none"><li>• <b>Hardware</b>—Simplifying circuit design, enhancing production techniques, and performing reliability tests.</li><li>• <b>Software</b>—Reliability design and test</li></ul> |
| 2     | Protect system functions from being affected if faults occur | Device and link redundancy and deployment of switchover strategies                                                                                                                                                     |
| 3     | Enable the system to recover as fast as possible             | Performing fault detection, diagnosis, isolation, and recovery technologies                                                                                                                                            |

The level 1 availability requirement should be considered during the design and production process of network devices. Level 2 should be considered during network design. Level 3 should be considered during network deployment, according to the network infrastructure and service characteristics.

## Availability evaluation

Mean Time Between Failures (MTBF) and Mean Time to Repair (MTTR) are used to evaluate the availability of a network.

### MTBF

MTBF is the predicted elapsed time between inherent failures of a system during operation. It is typically in the unit of hours. A higher MTBF means a high availability.

### MTTR

MTTR is the average time required to repair a failed system. MTTR in a broad sense also involves spare parts management and customer services.

MTTR = fault detection time + hardware replacement time + system initialization time + link recovery time + routing time + forwarding recovery time. A smaller value of each item means a smaller MTTR and a higher availability.

# High availability technologies

Increasing MTBF or decreasing MTTR can enhance the availability of a network. The high availability technologies described in this section meet the level 2 and level 3 high availability requirements by decreasing MTTR.

High availability technologies can be classified as fault detection technologies or protection switchover technologies.

## Fault detection technologies

Fault detection technologies enable detection and diagnosis of network faults. CFD, DLDP, and Ethernet OAM are data link layer fault detection technologies. BFD is a generic fault detection technology that can be used at any layer. NQA is used for diagnosis and evaluation of network quality. Monitor Link and Track work along with other high availability technologies to detect faults through a collaboration mechanism.

**Table 2 Fault detection technologies**

| Technology                             | Introduction                                                                                                                                                                                                                                                                                                     | Reference                                                                         |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| CFD                                    | Connectivity Fault Detection (CFD), which conforms to IEEE 802.1ag Connectivity Fault Management (CFM) and ITU-T Y.1731, is an end-to-end per-VLAN link layer Operations, Administration and Maintenance (OAM) mechanism used for link connectivity detection, fault verification, and fault location.           | "Configuring CFD" in <i>High Availability Configuration Guide</i>                 |
| DLDP                                   | The Device link detection protocol (DLDP) deals with unidirectional links that may occur in a network. Upon detecting a unidirectional link, DLDP, as configured, can shut down the related port automatically or prompt users to take actions to avoid network problems.                                        | "Configuring DLDP" in <i>High Availability Configuration Guide</i>                |
| Ethernet OAM                           | As a tool monitoring Layer 2 link status, Ethernet OAM is mainly used to address common link-related issues on the "last mile". You can monitor the status of the point-to-point link between two directly connected devices by enabling Ethernet OAM on them.                                                   | "Configuring Ethernet OAM" in <i>High Availability Configuration Guide</i>        |
| BFD (available only on the HP 5500 EI) | Bidirectional forwarding detection (BFD) provides a single mechanism to quickly detect and monitor the connectivity of links or IP forwarding in networks. To improve network performance, devices must quickly detect communication failures to restore communication through backup paths as soon as possible. | "Configuring BFD" in <i>High Availability Configuration Guide</i>                 |
| NQA                                    | Network Quality Analyzer (NQA) analyzes network performance, services and service quality through sending test packets, and provides you with network performance and service quality parameters such as jitter, TCP connection delay, FTP connection delay and file transfer rate.                              | "Configuring NQA" in <i>Network Management and Monitoring Configuration Guide</i> |
| Monitor Link                           | Monitor Link works together with Layer 2 topology protocols to adapt the up/down state of a downlink port to the state of an uplink port. This feature enables fast link switchover on a downstream device in response to the uplink state change on its upstream device.                                        | "Configuring Monitor Link" in <i>High Availability Configuration Guide</i>        |

| Technology | Introduction                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Reference                                                           |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| Track      | The track module is used to implement collaboration between different modules. The collaboration here involves three parts: the application modules, the track module, and the detection modules. These modules collaborate with one another through collaboration entries. That is, the detection modules trigger the application modules to perform certain operations through the track module. More specifically, the detection modules probe the link status, network performance and so on, and inform the application modules of the detection result through the track module. Once notified of network status changes, the application modules deal with the changes to avoid communication interruption and network performance degradation. | "Configuring track" in <i>High Availability Configuration Guide</i> |

## Protection switchover technologies

Protection switchover technologies aim at recovering network faults. They back up hardware, link, routing, and service information for switchover in case of network faults, to ensure continuity of network services.

**Table 3 Protection switchover technologies**

| Technology                             | Introduction                                                                                                                                                                                                                                                                                                                                                                     | Reference                                                                                        |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Ethernet Link Aggregation              | Ethernet link aggregation, most often simply called link aggregation, aggregates multiple physical Ethernet links into one logical link to increase link bandwidth beyond the limits of any one single link. This logical link is an aggregate link. It allows for link redundancy because the member physical links can dynamically back up one another.                        | "Configuring Ethernet link aggregation" in <i>Layer 2—LAN Switching Configuration Guide</i>      |
| Smart Link                             | Smart Link is a feature developed to address the slow convergence issue with STP. It provides link redundancy as well as fast convergence in a dual uplink network, allowing the backup link to take over quickly when the primary link fails.                                                                                                                                   | "Configuring Smart Link" in <i>High Availability Configuration Guide</i>                         |
| MSTP                                   | As a Layer 2 management protocol, the Multiple Spanning Tree Protocol (MSTP) eliminates Layer 2 loops by selectively blocking redundant links in a network, and in the mean time, allows for link redundancy.                                                                                                                                                                    | "Configuring spanning tree" in <i>Layer 2—LAN Switching Configuration Guide</i>                  |
| RRPP                                   | The Rapid Ring Protection Protocol (RRPP) is a link layer protocol designed for Ethernet rings. RRPP can prevent broadcast storms caused by data loops when an Ethernet ring is healthy, and rapidly restore the communication paths between the nodes in the event that a link is disconnected on the ring.                                                                     | "Configuring RRPP" in <i>High Availability Configuration Guide</i>                               |
| FRR (available only on the HP 5500 EI) | Fast Reroute (FRR) provides a quick per-link or per-node protection on an LSP. In this approach, once a link or node fails on a path, FRR comes up to reroute the path to a new link or node to bypass the failed link or node. This can happen as fast as 50 milliseconds minimizing data loss. Protocols such as RIP, OSPF, IS-IS, and static routing support this technology. | <i>Layer 3—IP Routing Configuration Guide/Configuration Guide</i> of the corresponding protocols |

| <b>Technology</b>                                    | <b>Introduction</b>                                                                                                                                                                                                                                                                                                                                                                                                                           | <b>Reference</b>                                                                                 |
|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| GR (available only on the HP 5500 EI)                | Graceful Restart (GR) ensures the continuity of packet forwarding when a protocol, such as BGP, IS-IS, OSPF, IPv6 BGP, IPv6 IS-IS, or OSPFv3, restarts or during an active/standby switchover process. It needs other devices to implement routing information backup and recovery.                                                                                                                                                           | <i>Layer 3—IP Routing Configuration Guide/Configuration Guide of the corresponding protocols</i> |
| NSR (available only on the HP 5500 EI)               | Non-stop Routing (NSR) is a new feature used to ensure non-stop data transmission during an active/standby switchover. Devices that have formed an IRF fabric support this feature. It backs up IP forwarding information from the master to the slave. Upon an active/standby switchover, NSR can complete link state recovery and route re-generation without requiring the cooperation of other devices. Only IS-IS supports this feature. | "Configuring IS-IS" in <i>Layer 3—IP Routing Configuration Guide</i>                             |
| Stateful Failover (available only on the HP 5500 EI) | Two devices back up the services of each other to ensure that the services on them are consistent. If one device fails, the other device can take over the services by using VRRP or dynamic routing protocols. Because the other device has already backed up the services, service traffic can pass through the other device, avoiding service interruption.                                                                                | "Configuring stateful failover" in <i>High Availability Configuration Guide</i>                  |
| VRRP (available only on the HP 5500 EI)              | Virtual Router Redundancy Protocol (VRRP) is an error-tolerant protocol that provides highly reliable default links on multicast and broadcast LANs such as Ethernet, avoiding network interruption due to failure of a single link.                                                                                                                                                                                                          | "Configuring VRRP" in <i>High Availability Configuration Guide</i>                               |

A single availability technology cannot solve all problems. Therefore, a combination of availability technologies, chosen on the basis of detailed analysis of network environments and user requirements, should be used to enhance network availability. For example, access-layer devices should be connected to distribution-layer devices over redundant links, and core-layer devices should be fully meshed. Also, network availability should be considered during planning prior to building a network.

# Configuring Ethernet OAM

## Ethernet OAM overview

Ethernet Operation, Administration and Maintenance (OAM) is a tool that monitors Layer 2 link status and addresses common link-related issues on the "last mile." You can use it to monitor the status of the point-to-point link between two directly connected devices.

## Major functions of Ethernet OAM

Ethernet OAM provides the following functions:

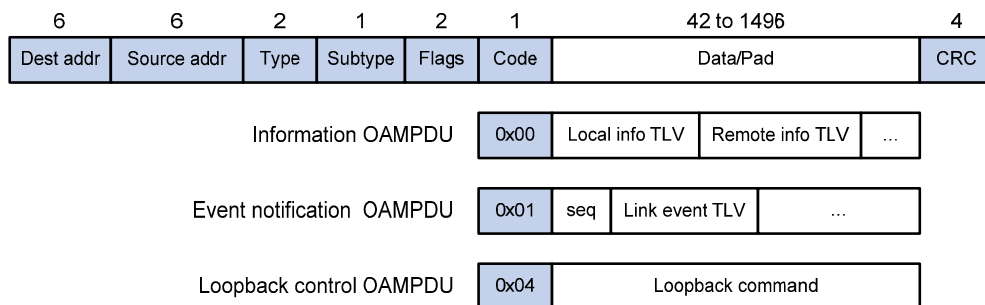

- **Link performance monitoring**—Monitors the performance indices of a link, including packet loss, delay, and jitter, and collects traffic statistics of various types
- **Fault detection and alarm**—Checks the connectivity of a link by sending OAM protocol data units (OAMPDUs) and reports to the network administrators when a link error occurs
- **Remote loopback**—Checks link quality and locates link errors by looping back OAMPDUs

## Ethernet OAMPDUs

Ethernet OAM works on the data link layer. Ethernet OAM reports the link status by periodically exchanging OAMPDUs between devices so that the administrator can effectively manage the network.

Ethernet OAMPDUs fall into the following types: Information, Event Notification, and Loopback Control.

**Figure 1 Formats of different types of Ethernet OAMPDUs**

**Table 4 Fields in an OAMPDU**

| Field       | Description                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dest addr   | Destination MAC address of the Ethernet OAMPDU<br>It is a slow protocol multicast address, 0180c2000002. Bridges cannot forward slow protocol packets, so Ethernet OAMPDUs cannot be forwarded. |
| Source addr | Source MAC address of the Ethernet OAMPDU<br>It is the bridge MAC address of the sending side and is a unicast MAC address.                                                                     |
| Type        | Type of the encapsulated protocol in the Ethernet OAMPDU<br>The value is 0x8809.                                                                                                                |

| Field   | Description                                                                           |
|---------|---------------------------------------------------------------------------------------|
| Subtype | The specific protocol being encapsulated in the Ethernet OAMPDU<br>The value is 0x03. |
| Flags   | Status information of an Ethernet OAM entity                                          |
| Code    | Type of the Ethernet OAMPDU                                                           |

**NOTE:**

Throughout this document, a port with Ethernet OAM enabled is an Ethernet OAM entity or an OAM entity.

**Table 5 Functions of different types of OAMPDUs**

| OAMPDU type               | Function                                                                                                                                                                                                                            |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Information OAMPDU        | Used for transmitting state information of an Ethernet OAM entity—including the information about the local device and remote devices and customized information—to the remote Ethernet OAM entity and maintaining OAM connections. |
| Event Notification OAMPDU | Used by link monitoring to notify the remote OAM entity when it detects problems on the link in between.                                                                                                                            |
| Loopback Control OAMPDU   | Used for remote loopback control. By inserting the information used to enable/disable loopback to a loopback control OAMPDU, you can enable/disable loopback on a remote OAM entity.                                                |

## How Ethernet OAM works

This section describes the working procedures of Ethernet OAM.

### Ethernet OAM connection establishment

Ethernet OAM connection is the basis of all the other Ethernet OAM functions. OAM connection establishment is also known as the "Discovery phase", where an Ethernet OAM entity discovers remote OAM entities and establishes sessions with them.

In this phase, interconnected OAM entities determine whether Ethernet OAM connections can be established, by exchanging Information OAMPDUs to notify the peer of their OAM configuration information and the OAM capabilities of the local nodes. An Ethernet OAM connection can be established between entities that have matching Loopback, link detecting, and link event settings. After an Ethernet OAM connection is established, Ethernet OAM takes effect on both sides.

For Ethernet OAM connection establishment, a device can operate in active Ethernet OAM mode or passive Ethernet OAM mode, but a switch role will be somewhat different depending on the mode.

**Table 6 Active Ethernet OAM mode and passive Ethernet OAM mode**

| Item                             | Active Ethernet OAM mode | Passive Ethernet OAM mode |
|----------------------------------|--------------------------|---------------------------|
| Initiating OAM Discovery         | Available                | Unavailable               |
| Responding to OAM Discovery      | Available                | Available                 |
| Transmitting Information OAMPDUs | Available                | Available                 |

| Item                                            | Active Ethernet OAM mode                           | Passive Ethernet OAM mode |
|-------------------------------------------------|----------------------------------------------------|---------------------------|
| Transmitting Event Notification OAMPDU          | Available                                          | Available                 |
| Transmitting Information OAMPDU without any TLV | Available                                          | Available                 |
| Transmitting Loopback Control OAMPDU            | Available                                          | Unavailable               |
| Responding to Loopback Control OAMPDU           | Available—if both sides operate in active OAM mode | Available                 |

**NOTE:**

- Only OAM entities operating in active OAM mode can initiate OAM connections. OAM entities operating in passive mode wait and respond to the connection requests sent by their peers.
- No OAM connection can be established between OAM entities operating in passive OAM mode.

After an Ethernet OAM connection is established, the Ethernet OAM entities on both sides exchange Information OAMPDU at the handshake packet transmission interval to check whether the Ethernet OAM connection is normal. If an Ethernet OAM entity receives no Information OAMPDU within the Ethernet OAM connection timeout time, the Ethernet OAM connection is considered disconnected.

### Link monitoring

Error detection in an Ethernet is difficult, especially when the physical connection in the network is not disconnected but network performance is degrading gradually. Link monitoring is used to detect and indicate link faults in various environments. Ethernet OAM implements link monitoring through the exchange of Event Notification OAMPDU. When detecting one of the link error events listed in [Table 7](#), the local OAM entity sends an Event Notification OAMPDU to notify the remote OAM entity. With the log information, network administrators can keep track of network status promptly.

**Table 7 Ethernet OAM link error events**

| Ethernet OAM link events    | Description                                                                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Errored symbol event        | An errored symbol event occurs when the number of detected symbol errors during a specified detection interval exceeds the predefined threshold.                   |
| Errored frame event         | An errored frame event occurs when the number of detected error frames during a specified interval exceeds the predefined threshold.                               |
| Errored frame period event  | An errored frame period event occurs if the number of frame errors in a specific number of received frames exceeds the predefined threshold.                       |
| Errored frame seconds event | An errored frame seconds event occurs when the number of error frame seconds detected on a port during a specified detection interval reaches the error threshold. |

The system transforms the period of detecting errored frame period events into the maximum number of 64-byte frames (excluding the interframe spacing and preamble) that a port can send in the specified period. The system takes the maximum number of frames sent as the period. The maximum number of frames sent is calculated using this formula: the maximum number of frames = interface bandwidth (bps) × errored frame period event detection period (in ms)/(64 × 8 × 1000).

A second in which errored frames appear is called an "errored frame second."

## Remote fault detection

Information OAMPDUs are exchanged periodically among Ethernet OAM entities across established OAM connections. In a network where traffic is interrupted due to device failures or unavailability, the flag field defined in information OAMPDUs allows an Ethernet OAM entity to send error information—the critical link event type—to its peer. You can use the log information to track ongoing link status and troubleshoot problems promptly.

**Table 8 Critical link events**

| Type           | Description                                         | OAMPDU transmission frequencies |
|----------------|-----------------------------------------------------|---------------------------------|
| Link Fault     | Peer link signal is lost.                           | Once per second                 |
| Dying Gasp     | A power failure or other unexpected error occurred. | Non-stop                        |
| Critical Event | An undetermined critical event occurred.            | Non-stop                        |

This Switch Series is able to receive information OAMPDUs carrying the critical link events listed in [Table 8](#).

Only the Gigabit fiber ports are able to send information OAMPDUs carrying Link Fault events.

This Switch Series is able to send information OAMPDUs carrying Dying Gasp events when the device is rebooted or relevant ports are manually shut down. Physical IRF ports, however, are unable to send this type of OAMPDU. For more information about physical IRF ports, see *IRF Configuration Guide*.

This Switch Series is unable to send information OAMPDUs carrying Critical Events.

## Remote loopback

Remote loopback is available only after the Ethernet OAM connection is established. With remote loopback enabled, the Ethernet OAM entity operating in active Ethernet OAM mode sends non-OAMPDUs to its peer. After receiving these frames, the peer does not forward them according to their destination addresses. Instead, it returns them to the sender along the original path.

Remote loopback enables you to check the link status and locate link failures. Performing remote loopback periodically helps to detect network faults promptly. Furthermore, performing remote loopback by network segments helps to locate network faults.

## Standards and protocols

Ethernet OAM is defined in IEEE 802.3ah (Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications).

## Ethernet OAM configuration task list

| Task                                                                     | Remarks                                                    |          |
|--------------------------------------------------------------------------|------------------------------------------------------------|----------|
| <a href="#">Configuring basic Ethernet OAM functions</a>                 | Required                                                   |          |
| <a href="#">Configuring the Ethernet OAM connection detection timers</a> | Optional                                                   |          |

|                                          | Configuring errored frame period event detection                      |
|                                          | Configuring errored frame seconds event detection                     |
| Configuring Ethernet OAM remote loopback | Enabling Ethernet OAM remote loopback                                 |
|                                          | Rejecting the Ethernet OAM remote loopback request from a remote port |

## Configuring basic Ethernet OAM functions

For Ethernet OAM connection establishment, an Ethernet OAM entity operates in active mode or passive mode. Only an Ethernet OAM entity in active mode can initiate connection establishment. After Ethernet OAM is enabled on an Ethernet port, according to its Ethernet OAM mode, the Ethernet port establishes an Ethernet OAM connection with its peer port.

To change the Ethernet OAM mode on an Ethernet OAM-enabled port, you must first disable Ethernet OAM on the port.

To configure basic Ethernet OAM functions:

| Step                                        | Command                                                           | Remarks                                               |
|---------------------------------------------|-------------------------------------------------------------------|-------------------------------------------------------|
| 1. Enter system view.                       | <b>system-view</b>                                                | N/A                                                   |
| 2. Enter Layer 2 Ethernet interface view.   | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                                                   |
| 3. Set the Ethernet OAM mode.               | <b>oam mode</b> { <b>active</b>   <b>passive</b> }                | Optional.<br>The default is active Ethernet OAM mode. |
| 4. Enable Ethernet OAM on the current port. | <b>oam enable</b>                                                 | Ethernet OAM is disabled by default.                  |

## Configuring the Ethernet OAM connection detection timers

After an Ethernet OAM connection is established, the Ethernet OAM entities on both sides exchange Information OAMPDUs at the handshake packet transmission interval to check whether the Ethernet OAM connection is normal. If an Ethernet OAM entity receives no Information OAMPDU within the Ethernet OAM connection timeout time, the Ethernet OAM connection is considered disconnected.

By adjusting the handshake packet transmission interval and the connection timeout timer, you can change the detection time resolution for Ethernet OAM connections.

After the timeout timer of an Ethernet OAM connection expires, the local OAM entity ages out its connection with the peer OAM entity, causing the OAM connection to be disconnected. HP recommends that you set the connection timeout timer to at least five times the handshake packet transmission interval, ensuring the stability of Ethernet OAM connections.

To configure the Ethernet OAM connection detection timers:

| Step                                                                  | Command                                    | Remarks                                    |
|-----------------------------------------------------------------------|--------------------------------------------|--------------------------------------------|
| 1. Enter system view.                                                 | <b>system-view</b>                         | N/A                                        |
| 2. Configure the Ethernet OAM handshake packet transmission interval. | <b>oam timer hello</b> <i>interval</i>     | Optional.<br>1000 millisecond by default.  |
| 3. Configure the Ethernet OAM connection timeout timer.               | <b>oam timer keepalive</b> <i>interval</i> | Optional.<br>5000 milliseconds by default. |

## Configuring link monitoring

After Ethernet OAM connections are established, the link monitoring periods and thresholds configured in this section take effect on all Ethernet ports automatically.

## Configuring errored symbol event detection

| Step                                                        | Command                                                    | Remarks                           |
|-------------------------------------------------------------|------------------------------------------------------------|-----------------------------------|
| 1. Enter system view.                                       | <b>system-view</b>                                         | N/A                               |
| 2. Configure the errored symbol event detection interval.   | <b>oam errored-symbol period</b> <i>period-value</i>       | Optional.<br>1 second by default. |
| 3. Configure the errored symbol event triggering threshold. | <b>oam errored-symbol threshold</b> <i>threshold-value</i> | Optional.<br>1 by default.        |

## Configuring errored frame event detection

| Step                                                       | Command                                                   | Remarks                           |
|------------------------------------------------------------|-----------------------------------------------------------|-----------------------------------|
| 1. Enter system view.                                      | <b>system-view</b>                                        | N/A                               |
| 2. Configure the errored frame event detection interval.   | <b>oam errored-frame period</b> <i>period-value</i>       | Optional.<br>1 second by default. |
| 3. Configure the errored frame event triggering threshold. | <b>oam errored-frame threshold</b> <i>threshold-value</i> | Optional.<br>1 by default.        |

## Configuring errored frame period event detection

| Step                                                              | Command                                                          | Remarks                                    |
|-------------------------------------------------------------------|------------------------------------------------------------------|--------------------------------------------|
| 1. Enter system view.                                             | <b>system-view</b>                                               | N/A                                        |
| 2. Configure the errored frame period event detection period.     | <b>oam errored-frame-period period</b> <i>period-value</i>       | Optional.<br>1000 milliseconds by default. |
| 3. Configure the errored frame period event triggering threshold. | <b>oam errored-frame-period threshold</b> <i>threshold-value</i> | Optional.<br>1 by default.                 |

# Configuring errored frame seconds event detection

## IMPORTANT:

Make sure the errored frame seconds triggering threshold is less than the errored frame seconds detection interval. Otherwise, no errored frame seconds event can be generated.

To configure errored frame seconds event detection:

| Step                                                               | Command                                                           | Remarks                            |
|--------------------------------------------------------------------|-------------------------------------------------------------------|------------------------------------|
| 1. Enter system view.                                              | <b>system-view</b>                                                | N/A                                |
| 2. Configure the errored frame seconds event detection interval.   | <b>oam errored-frame-seconds period</b> <i>period-value</i>       | Optional.<br>60 second by default. |
| 3. Configure the errored frame seconds event triggering threshold. | <b>oam errored-frame-seconds threshold</b> <i>threshold-value</i> | Optional.<br>1 by default.         |

# Configuring Ethernet OAM remote loopback

## Enabling Ethernet OAM remote loopback

### ⚠ CAUTION:

Use this function with caution, because enabling Ethernet OAM remote loopback impacts other services.

When you enable Ethernet OAM remote loopback on a port, the port sends Loopback Control OAMPDUs to a remote port, and the remote port enters the loopback state. The port then sends test frames to the remote port. By observing how many of these test frames return, you can calculate the packet loss ratio on the link to evaluate the link performance.

You can enable Ethernet OAM remote loopback on a specific port in user view, system view, or Layer 2 Ethernet interface view. The configuration effects are the same.

### Configuration guidelines

- Ethernet OAM remote loopback is available only after the Ethernet OAM connection is established and can be performed only by Ethernet OAM entities operating in active Ethernet OAM mode.
- Remote loopback is available only on full-duplex links that support remote loopback at both ends.
- Ethernet OAM remote loopback must be supported by both the remote port and the sending port.
- Enabling Ethernet OAM remote loopback interrupts data communications. After Ethernet OAM remote loopback is disabled, all the ports involved will shut down and then come up. Ethernet OAM remote loopback can be disabled by any of the following actions: executing the **undo oam enable** command to disable Ethernet OAM; executing the **undo oam loopback interface** or **undo oam loopback** command to disable Ethernet OAM remote loopback; and Ethernet OAM connection timing out.
- Ethernet OAM remote loopback is only applicable to individual links. It is not applicable to link aggregation member ports or service loopback group member ports. In addition, do not assign ports where Ethernet OAM remote loopback is being performed to link aggregation groups or

service loopback groups. For more information about link aggregation groups and service loopback groups, see *Layer 2—LAN Switching Configuration Guide*.

- Enabling internal loopback test on a port in remote loopback test can terminate the remote loopback test. For more information about loopback test, see *Layer 2—LAN Switching Configuration Guide*.

## Configuration procedure

To enable Ethernet OAM remote loopback in user view:

| Task                                                    | Command                                                                 | Remarks              |
|---------------------------------------------------------|-------------------------------------------------------------------------|----------------------|
| Enable Ethernet OAM remote loopback on a specific port. | <b>oam loopback interface</b><br><i>interface-type interface-number</i> | Disabled by default. |

To enable Ethernet OAM remote loopback in system view:

| Step                                                       | Command                                                                 | Remarks              |
|------------------------------------------------------------|-------------------------------------------------------------------------|----------------------|
| 1. Enter system view.                                      | <b>system-view</b>                                                      | N/A                  |
| 2. Enable Ethernet OAM remote loopback on a specific port. | <b>oam loopback interface</b><br><i>interface-type interface-number</i> | Disabled by default. |

To enable Ethernet OAM remote loopback in Layer 2 Ethernet interface view:

| Step                                                | Command                                                           | Remarks              |
|-----------------------------------------------------|-------------------------------------------------------------------|----------------------|
| 1. Enter system view.                               | <b>system-view</b>                                                | N/A                  |
| 2. Enter Layer 2 Ethernet interface view.           | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                  |
| 3. Enable Ethernet OAM remote loopback on the port. | <b>oam loopback</b>                                               | Disabled by default. |

## Rejecting the Ethernet OAM remote loopback request from a remote port

The Ethernet OAM remote loopback function impacts other services. To solve this problem, you can disable a port from being controlled by the Loopback Control OAMPDUs sent by a remote port. The local port then rejects the Ethernet OAM remote loopback request from the remote port.

To reject the Ethernet OAM remote loopback request from a remote port:

| Step                                                                   | Command                                                           | Remarks                                                                                         |
|------------------------------------------------------------------------|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                                  | <b>system-view</b>                                                | N/A                                                                                             |
| 2. Enter Layer 2 Ethernet interface view.                              | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                                                                                             |
| 3. Reject the Ethernet OAM remote loopback request from a remote port. | <b>oam loopback reject-request</b>                                | By default, a port does not reject the Ethernet OAM remote loopback request from a remote port. |

# Displaying and maintaining Ethernet OAM configuration

| Task                                                                                                      | Command                                                                                                                                                                                                       | Remarks                |
|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Display global Ethernet OAM configuration.                                                                | <b>display oam configuration</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                                                                                           | Available in any view  |
| Display the statistics on critical events after an Ethernet OAM connection is established.                | <b>display oam critical-event</b> [ <b>interface</b> <i>interface-type interface-number</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                              | Available in any view  |
| Display the statistics on Ethernet OAM link error events after an Ethernet OAM connection is established. | <b>display oam link-event</b> { <b>local</b>   <b>remote</b> } [ <b>interface</b> <i>interface-type interface-number</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view  |
| Display the information about an Ethernet OAM connection.                                                 | <b>display oam</b> { <b>local</b>   <b>remote</b> } [ <b>interface</b> <i>interface-type interface-number</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]            | Available in any view  |
| Clear statistics on Ethernet OAM packets and Ethernet OAM link error events.                              | <b>reset oam</b> [ <b>interface</b> <i>interface-type interface-number</i> ]                                                                                                                                  | Available in user view |

## Ethernet OAM configuration example

### Network requirements

On the network shown in [Figure 2](#), perform the following operations:

- Enable Ethernet OAM on Device A and Device B to auto-detect link errors between the two devices
- Monitor the performance of the link between Device A and Device B by collecting statistics about the error frames received by Device A

**Figure 2 Network diagram**

### Configuration procedure

1. Configure Device A:

```
Configure GigabitEthernet 1/0/1 to operate in passive Ethernet OAM mode and enable Ethernet OAM for it.
```

```
<DeviceA> system-view
```

```
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] oam mode passive
[DeviceA-GigabitEthernet1/0/1] oam enable
[DeviceA-GigabitEthernet1/0/1] quit
```

# Set the errored frame detection interval to 20 seconds and set the errored frame event triggering threshold to 10.

```
[DeviceA] oam errored-frame period 20
[DeviceA] oam errored-frame threshold 10
```

## 2. Configure Device B:

# Configure GigabitEthernet 1/0/1 to operate in active Ethernet OAM mode (the default) and enable Ethernet OAM for it.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] oam mode active
[DeviceB-GigabitEthernet1/0/1] oam enable
[DeviceB-GigabitEthernet1/0/1] quit
```

## 3. Verify the configuration:

Use the **display oam configuration** command to display the Ethernet OAM configuration. For example:

# Display the Ethernet OAM configuration on Device A.

```
[DeviceA] display oam configuration
Configuration of the link event window/threshold :

Errored-symbol Event period(in seconds) : 1
Errored-symbol Event threshold : 1
Errored-frame Event period(in seconds) : 20
Errored-frame Event threshold : 10
Errored-frame-period Event period(in ms) : 1000
Errored-frame-period Event threshold : 1
Errored-frame-seconds Event period(in seconds) : 60
Errored-frame-seconds Event threshold : 1
```

Configuration of the timer :

```

Hello timer(in ms) : 1000
Keepalive timer(in ms) : 5000
```

The output shows that the detection period of errored frame events is 20 seconds, the detection threshold is 10 seconds, and all the other parameters use the default values.

You can use the **display oam critical-event** command to display the statistics of Ethernet OAM critical link events. For example:

# Display the statistics of Ethernet OAM critical link events on all the ports of Device A.

```
[DeviceA] display oam critical-event
Port : GigabitEthernet1/0/1
Link Status : Up
Event statistic :

Link Fault : 0 Dying Gasp : 0 Critical Event : 0
```

The output shows that no critical link event occurred on the link between Device A and Device B. You can use the **display oam link-event** command to display the statistics of Ethernet OAM link error events. For example:

# Display Ethernet OAM link event statistics of the remote end of Device B.

```
[DeviceB] display oam link-event remote
```

```
Port :GigabitEthernet1/0/1
```

```
Link Status :Up
```

```
OAMRemoteErrFrameEvent : (ms = milliseconds)
```

```

Event Time Stamp : 5789 Errored FrameWindow : 10(100ms)
Errored Frame Threshold : 1 Errored Frame : 3
Error Running Total : 35 Event Running Total : 17
```

The output shows that 35 errors occurred since Ethernet OAM was enabled on Device A, 17 of which are caused by error frames. The link is unstable.

# Configuring CFD

## CFD overview

Connectivity Fault Detection (CFD), which conforms to IEEE 802.1ag Connectivity Fault Management (CFM) and ITU-T Y.1731, is an end-to-end per-VLAN link layer Operations, Administration and Maintenance (OAM) mechanism used for link connectivity detection, fault verification, and fault location.

## Basic concepts in CFD

### Maintenance domain

A maintenance domain (MD) defines the network where CFD plays its role. The MD boundary is defined by some maintenance association end points (MEPs) configured on the ports. An MD is identified by its MD name.

To accurately locate faults, CFD introduces eight levels (from 0 to 7) to MDs. The bigger the number, the higher the level and the larger the area covered. Domains can touch or nest (if the outer domain has a higher level than the nested one) but cannot intersect or overlap.

MD levels facilitate fault location and make fault location more accurate. As shown in [Figure 3](#), MD\_A in light blue nests MD\_B in dark blue. If a connectivity fault is detected at the boundary of MD\_A, any of the devices in MD\_A, including Device A through Device E, may fail. If a connectivity fault is also detected at the boundary of MD\_B, the failure points may be any of Device B through Device D. If the devices in MD\_B can operate properly, at least Device C is operational.

**Figure 3 Two nested MDs**

CFD exchanges messages and performs operations on a per-domain basis. By planning MDs properly in a network, you can use CFD to rapidly locate failure points.

### Maintenance association

A maintenance association (MA) is a set of maintenance points (MPs) in an MD. An MA is identified by the "MD name + MA name." You can configure multiple MAs in an MD as needed.

An MA serves a VLAN. Packets sent by the MPs in an MA carry the relevant VLAN tag. An MP can receive packets sent by other MPs in the same MA.

## Maintenance point

An MP is configured on a port and belongs to an MA. MPs fall into two types: maintenance association end points (MEPs) and maintenance association intermediate points (MIPs).

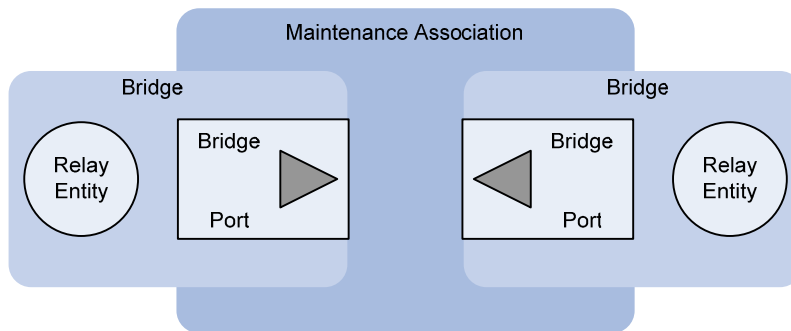

- MEP

Each MEP is identified by an integer called a "MEP ID". The MEPs of an MD define the range and boundary of the MD. The MA and MD that a MEP belongs to define the VLAN attribute and level of the packets sent by the MEP. MEPs fall into inward-facing MEPs and outward-facing MEPs.

The level of a MEP determines the levels of packets that the MEP can process. The packets transmitted from a MEP carry the level of the MEP. A MEP forwards packets at a higher level and processes packet of its level or lower. The processing procedure is specific to packets in the same VLAN. Packets of different VLANs are independent.

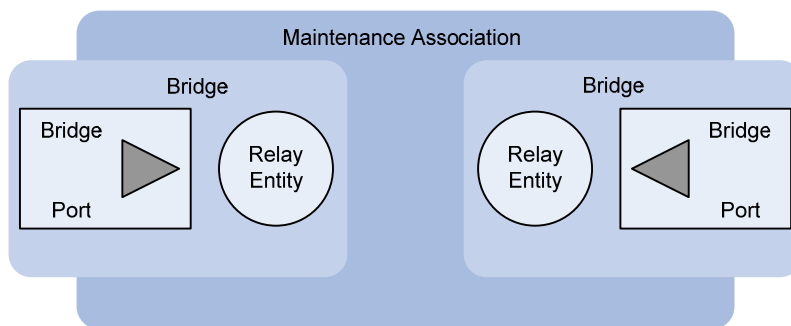

The direction of a MEP (outward-facing or inward-facing) determines the position of the MD relative to the port.

**Figure 4 Outward-facing MEP**

As shown in [Figure 4](#), an outward-facing MEP sends packets to its host port.

**Figure 5 Inward-facing MEP**

As shown in [Figure 5](#), an inward-facing MEP does not send packets to its host port. Rather, it sends packets to other ports on the device.

- MIP

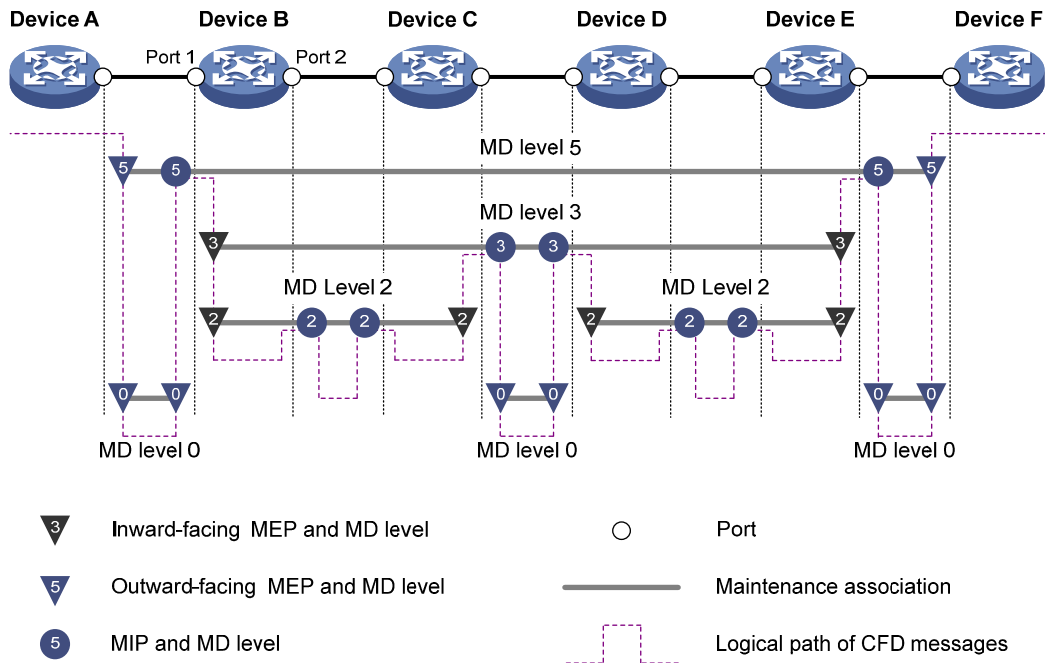

A MIP is internal to an MD. It cannot send CFD packets actively. However, it can handle and respond to CFD packets. The MA and MD to which a MIP belongs define the VLAN attribute and level of the packets received.

By cooperating with MEPs, a MIP can perform a function similar to ping and traceroute. Like a MEP, a MIP forwards packets of a different level without any processing and only processes packets of its level.

Figure 6 demonstrates a grading example of the CFD module. Six devices, labeled A through F respectively, exist. Suppose each device has two ports, and MEPs and MIPs are configured on some of these ports. Four levels of MDs are designed in this example, the bigger the number, the higher the level and the larger the area covered. In this example, Port 1 of device B is configured with the following MPs—a level 5 MIP, a level 3 inward-facing MEP, a level 2 inward-facing MEP, and a level 0 outward-facing MEP.

Figure 6 Levels of MPs

## MEP list

A MEP list is a collection of local MEPs allowed to be configured and the remote MEPs to be monitored in the same MA. It lists all the MEPs configured on different devices in the same MA. The MEPs all have unique MEP IDs. When a MEP receives from a remote device a continuity check message (CCM) that carries a MEP ID not included in the MEP list of the MA, it drops the message.

## CFD functions

CFD works effectively only in properly-configured networks. Its functions, which are implemented through the MPs, include:

- Continuity check (CC)
- Loopback (LB)
- Linktrace (LT)
- Alarm indication signal (AIS)
- Loss measurement (LM)
- Delay measurement (DM)
- Test (TST)

## Continuity check

Connectivity faults are usually caused by device faults or configuration errors. Continuity check checks the connectivity between MEPs. This function is implemented through periodic sending of continuity check messages (CCMs) by the MEPs. As a multicast message, a CCM sent by one MEP is intended to be received by all the other MEPs in the same MA. If a MEP fails to receive the CCMs within 3.5 times the sending interval, the link is considered faulty and a log is generated. When multiple MEPs send CCMs at the same time, the multipoint-to-multipoint link check is achieved. CCM frames are multicast frames.

## Loopback

Similar to ping at the IP layer, loopback verifies the connectivity between a local device and a remote device. To implement this function, the local MEP sends loopback messages (LBMs) to the remote MEP. Depending on whether the local MEP can receive a loopback reply message (LBR) from the remote MEP, the link state between the two can be verified. LBM frames and LBR frames are unicast frames.

## Linktrace

Linktrace identifies the path between the source MEP and the target MEP. This function is implemented in the following way—the source MEP sends the linktrace messages (LTMs) to the target MEP. After receiving the messages, the target MEP and the MIPs that the LTM frames pass send back linktrace reply messages (LTRs) to the source MEP. Based on the reply messages, the source MEP can identify the path to the target MEP. LTM frames are multicast frames and LTRs are unicast frames.

## AIS

The AIS function suppresses the number of error alarms reported by MEPs. If a local MEP receives no CCM frames from its peer MEP within 3.5 times the CCM transmission interval, it immediately starts to send AIS frames periodically in the opposite direction of CCM frames. Upon receiving the AIS frames, the peer MEP suppresses the error alarms locally, and continues to send the AIS frames. If the local MEP receives CCM frames within 3.5 times the CCM transmission interval, it stops sending AIS frames and restores the error alarm function. AIS frames are multicast frames.

## LM

The LM function measures the frame loss in a certain direction between a pair of MEPs. The source MEP sends loss measurement messages (LMMs) to the target MEP, the target MEP responds with loss measurement replies (LMRs), and the source MEP calculates the number of lost frames according to the counter values of the two consecutive LMRs (the current LMR and the previous LMR). LMMs and LMRs are multicast frames.

## DM

The DM function measures frame delays between two MEPs, including one-way and two-way frame delays.

1. One-way frame delay measurement

The source MEP sends a one-way delay measurement (1DM) frame, which carries the transmission time, to the target MEP. Upon receiving the 1DM frame, the target MEP records the reception time, and calculates and records the link transmission delay and jitter (delay variation) according to the transmission time and reception time. 1DM frames are multicast frames.

2. Two-way frame delay measurement

The source MEP sends a delay measurement message (DMM), which carries the transmission time, to the target MEP. Upon receiving the DMM, the target MEP responds with a delay measurement reply (DMR), which carries the reception time and transmission time of the DMM and the transmission time of the DMR. Upon receiving the DMR, the source MEP records the DMR reception

time, and calculates the link transmission delay and jitter according to the DMR reception time and DMM transmission time. DMM frames and DMR frames are multicast frames.

## TST

The TST function tests the bit errors between two MEPs. The source MEP sends a TST frame, which carries the test pattern, such as pseudo random bit sequence (PRBS) or all-zero, to the target MEP. Upon receiving the TST frame, the target MEP determines the bit errors by calculating and comparing the content of the TST frame. TST frames are unicast frames.

## Protocols and standards

- IEEE 802.1ag, *Virtual Bridged Local Area Networks Amendment 5: Connectivity Fault Management*
- ITU-T Y.1731, *OAM functions and mechanisms for Ethernet based networks*

## CFD configuration task list

For CFD to work properly, design the network by performing the following tasks:

- Grade the MDs in the entire network, and define the boundary of each MD
- Assign a name for each MD. Make sure that the same MD has the same name on different devices.
- Define the MA in each MD according to the VLAN you want to monitor
- Assign a name for each MA. Make sure that the same MA in the same MD has the same name on different devices.
- Determine the MEP list of each MA in each MD. Make sure that devices in the same MA maintain the same MEP list.
- At the edges of MD and MA, MEPs should be designed at the device port. MIPs can be designed on devices or ports that are not at the edges.

Complete the following tasks to configure CFD:

| Tasks                          | Remarks                              |                                                                                                                                    |
|--------------------------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
|                                | Enabling CFD                         | Required                                                                                                                           |
|                                | Configuring the CFD protocol version | Optional                                                                                                                           |
| Configuring basic CFD settings | Configuring service instances        | Creating a service instance with the MD name<br>Required<br>Creating a service instance without the MD name<br>Perform either task |
|                                | Configuring MEPs                     | Required                                                                                                                           |
|                                | Configuring MIP generation rules     | Required                                                                                                                           |
| Configuring CFD functions      | Configuring CC on MEPs               | Required                                                                                                                           |
|                                | Configuring LB on MEPs               | Optional                                                                                                                           |
|                                | Configuring LT on MEPs               | Optional                                                                                                                           |
|                                | Configuring AIS                      | Optional                                                                                                                           |

| Tasks                                  | Remarks  |
|----------------------------------------|----------|
| <a href="#">Configuring LM</a>         | Optional |
| <a href="#">Configuring one-way DM</a> | Optional |
| <a href="#">Configuring two-way DM</a> | Optional |
| <a href="#">Configuring TST</a>        | Optional |

**NOTE:**

Typically, a port blocked by STP cannot receive or send CFD messages except in the following cases:

- The port is configured as an outward-facing MEP.
- The port is configured as a MIP or inward-facing MEP, which can still receive and send CFD messages except CCM messages.

## Configuring basic CFD settings

### Enabling CFD

Enable CFD on all concerned devices.

To enable CFD on a device:

| Step                  | Command            | Remarks                     |
|-----------------------|--------------------|-----------------------------|
| 1. Enter system view. | <b>system-view</b> | N/A                         |
| 2. Enable CFD.        | <b>cfid enable</b> | CFD is disabled by default. |

### Configuring the CFD protocol version

Three CFD protocol versions are available: IEEE 802.1ag draft5.2 version, IEEE 802.1ag draft5.2 interim version, and IEEE 802.1ag standard version. Devices in a same MD must use the same CFD protocol version. Otherwise, they cannot exchange CFD protocol packets.

To configure the CFD protocol version:

| Step                                   | Command                                                 | Remarks                                                                 |
|----------------------------------------|---------------------------------------------------------|-------------------------------------------------------------------------|
| 1. Enter system view.                  | <b>system-view</b>                                      | N/A                                                                     |
| 2. Configure the CFD protocol version. | <b>cfid version { draft5   draft5-plus   standard }</b> | Optional.<br>By default, CFD uses the standard version of IEEE 802.1ag. |

If an MD is created by using the **cfid md** command or automatically generated by using the **cfid service-instance maid format** command on a device, you cannot switch between the standard and non-standard versions (draft5.2 version and draft5.2 interim version). However, you can switch between the draft5.2 version and draft5.2 interim version. This restriction does not apply to the device without an MD configured.

## Configuring service instances

Before configuring the MEPs and MIPs, you must first configure service instances. A service instance is a set of service access points (SAPs), and it belongs to an MA in an MD.

A service instance is indicated by an integer to represent an MA in an MD. The MD and MA define the level and VLAN attribute of the messages handled by the MPs in a service instance.

Service instances fall into two types:

- Service instance with the MD name, which takes effect in any version of CFD.
- Service instance without the MD name, which takes effect in only CFD IEEE 802.1ag.

You can create either type of service instance as needed.

### Creating a service instance with the MD name

To create a service instance with the MD name, create the MD and MA for the service instance first.

#### CAUTION:

You must create the MD, MA, and service instance by strictly following the order stated in the table.

To configure a service instance with the MD name:

| Step                                           | Command                                                                                           | Remarks                 |
|------------------------------------------------|---------------------------------------------------------------------------------------------------|-------------------------|
| 1. Enter system view.                          | <b>system-view</b>                                                                                | N/A                     |
| 2. Create an MD.                               | <b>cfld md</b> <i>md-name</i> <b>level</b> <i>level-value</i>                                     | Not created by default. |
| 3. Create an MA.                               | <b>cfld ma</b> <i>ma-name</i> <b>md</b> <i>md-name</i> <b>vlan</b> <i>vlan-id</i>                 | Not created by default. |
| 4. Create a service instance with the MD name. | <b>cfld service-instance</b> <i>instance-id</i> <b>md</b> <i>md-name</i> <b>ma</b> <i>ma-name</i> | Not created by default. |

### Creating a service instance without the MD name

When you create a service instance without the MD name, the system automatically creates the MA and MD for the service instance.

To create a service instance without the MD name:

| Step                                              | Command                                                                                                                                                                                                   | Remarks                 |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| 1. Enter system view.                             | <b>system-view</b>                                                                                                                                                                                        | N/A                     |
| 2. Create a service instance without the MD name. | <b>cfld service-instance</b> <i>instance-id</i><br><b>maid format</b> { <b>icc-based</b> <i>ma-name</i><br>  <b>string</b> <i>ma-name</i> } <b>level</b> <i>level-value</i><br><b>vlan</b> <i>vlan-id</i> | Not created by default. |

## Configuring MEPs

CFD is implemented through various operations on MEPs. As a MEP is configured on a service instance, the MD level and VLAN attribute of the service instance become the attribute of the MEP.

Before creating MEPs, configure the MEP list. An MEP list is a collection of local MEPs allowed to be configured in an MA and the remote MEPs to be monitored.

**IMPORTANT:**

You cannot create a MEP if the MEP ID is not included in the MEP list of the service instance.

To configure a MEP:

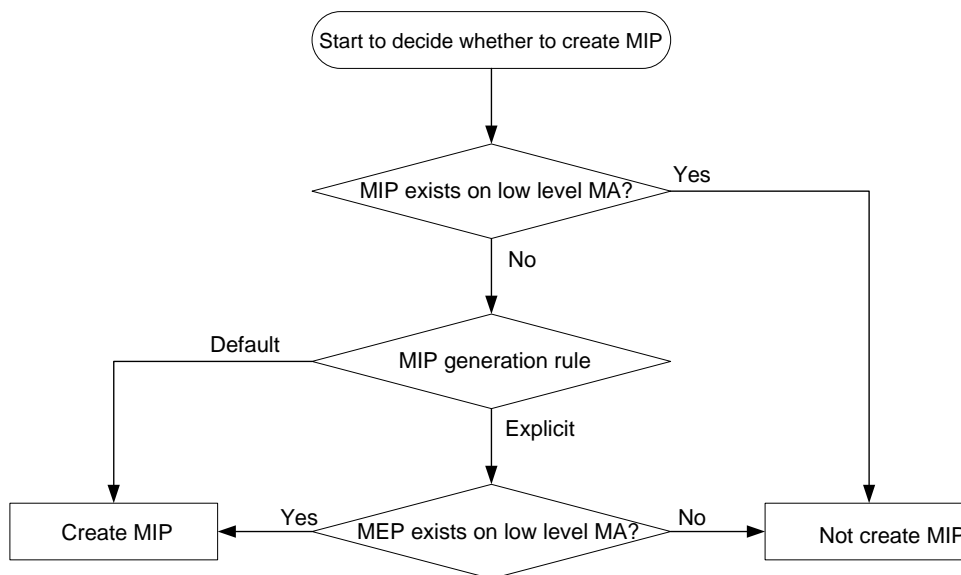

| Step                                      | Command                                                                                                         | Remarks                                |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------|----------------------------------------|
| 1. Enter system view.                     | <b>system-view</b>                                                                                              | N/A                                    |
| 2. Configure a MEP list.                  | <b>bfd meplist</b> <i>mep-list</i><br><b>service-instance</b> <i>instance-id</i>                                | By default, no MEP list is configured. |
| 3. Enter Layer 2 Ethernet interface view. | <b>interface</b> <i>interface-type</i><br><i>interface-number</i>                                               | N/A                                    |
| 4. Create a MEP.                          | <b>bfd mep</b> <i>mep-id</i> <b>service-instance</b><br><i>instance-id</i> { <b>inbound</b>   <b>outbound</b> } | Not configured by default.             |
| 5. Enable the MEP.                        | <b>bfd mep</b> <b>service-instance</b><br><i>instance-id</i> <b>mep</b> <i>mep-id</i> <b>enable</b>             | Disabled by default.                   |

## Configuring MIP generation rules

As functional entities in a service instance, MIPs respond to various CFD frames, such as LTM frames, LBM frames, 1DM frames, DMM frames, and TST frames.

MIPs are generated on each port automatically according to related MIP generation rules. If a port has no MIP, the system will check the MAs in each MD (from low to high levels) and follow the procedure described in Figure 7 to create or not to create MIPs (within the same VLAN):

**Figure 7 Procedure of creating MIPs**

You can choose appropriate MIP generation rules based on your network design.

To configure the rules for generating MIPs:

| Step                                        | Command                                                                                                | Remarks                                                                    |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| 1. Enter system view.                       | <b>system-view</b>                                                                                     | N/A                                                                        |
| 2. Configure the rules for generating MIPs. | <b>cfd mip-rule</b> { <b>explicit</b>   <b>default</b> }<br><b>service-instance</b> <i>instance-id</i> | By default, neither MIPs nor the rules for generating MIPs are configured. |

Any of the following actions or cases can cause MIPs to be created or deleted after you have configured the **cfd mip-rule** command:

- Enabling CFD (use the **cfd enable** command)
- Creating or deleting the MEPs on a port
- Changes occur to the VLAN attribute of a port
- The rule specified in the **cfd mip-rule** command changes

## Configuring CFD functions

### Configuration prerequisites

Complete basic CFD settings.

### Configuring CC on MEPs

After the CC function is configured, MEPs can send CCM frames to one another to check the connectivity between them.

You must configure CC before configuring other CFD functions.

#### CAUTION:

On different devices, the MEPs belonging to the same MD and MA should be configured with the same CCM transmission interval.

To configure CC on a MEP:

| Step                                                                    | Command                                                                                     | Remarks                                                 |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|---------------------------------------------------------|
| 1. Enter system view.                                                   | <b>system-view</b>                                                                          | N/A                                                     |
| 2. Configure the interval field value in the CCM messages sent by MEPs. | <b>cfd cc interval</b> <i>interval-value</i><br><b>service-instance</b> <i>instance-id</i>  | Optional.<br>By default, the interval field value is 4. |
| 3. Enter Layer 2 Ethernet interface view.                               | <b>interface</b> <i>interface-type</i><br><i>interface-number</i>                           | N/A                                                     |
| 4. Enable CCM sending on a MEP.                                         | <b>cfd cc service-instance</b> <i>instance-id</i><br><b>mep</b> <i>mep-id</i> <b>enable</b> | Disabled by default.                                    |

**Table 9 Relationship between the interval field value, the interval between CCM messages, and the timeout time of the remote MEP**

| The interval field value | The interval between CCM messages | The timeout time of the remote MEP |
|--------------------------|-----------------------------------|------------------------------------|
| 4                        | 1 second                          | 3.5 seconds                        |
| 5                        | 10 second                         | 35 seconds                         |
| 6                        | 60 seconds                        | 210 seconds                        |
| 7                        | 600 seconds                       | 2100 seconds                       |

## Configuring LB on MEPs

The LB function can verify the link state between the local MEP and the remote MEP or MIP.

To configure LB on a MEP:

| Task       | Command                                                                                                                                                                                       | Remarks                                                                                                                                                                   |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable LB. | <b>cfd loopback service-instance</b><br><i>instance-id mep mep-id</i> { <b>target-mep</b><br><i>target-mep-id</i>   <b>target-mac</b><br><i>mac-address</i> } [ <b>number</b> <i>number</i> ] | Disabled by default.<br>Available in any view<br>The <b>target-mep</b> <i>target-mep-id</i> option is not supported if an outward-facing MEP is configured on the switch. |

## Configuring LT on MEPs

LT can trace the path between the source and target MEPs and can also locate link faults by sending LT messages automatically. The two functions are implemented in the following way:

- To implement the first function, the source MEP first sends LTM messages to the target MEP. Based on the LTR messages in response to the LTM messages, the path between the two MEPs can be identified.
- In the latter case, after LT messages automatic sending is enabled, if the source MEP fails to receive the CCM frames from the target MEP within 3.5 times the transmission interval, the link between the two is considered faulty, and LTM frames (with the target MEP as the destination and the TTL field in the LTM frames set to the maximum value 255) will be sent out. Based on the LTRs that the MIPs return, the fault source can be located.

To configure LT on MEPs:

| Step                                                    | Command                                                                                                                                                                                                              | Remarks                                                                                                                                           |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Find the path between a source MEP and a target MEP. | <b>cfd linktrace service-instance</b><br><i>instance-id mep mep-id</i><br>{ <b>target-mep</b> <i>target-mep-id</i>  <br><b>target-mac</b> <i>mac-address</i> } [ <b>tth</b><br><i>tth-value</i> ] [ <b>hw-only</b> ] | Available in any view<br>The <b>target-mep</b> <i>target-mep-id</i> option is not supported if an outward-facing MEP is configured on the switch. |
| 2. Enter system view.                                   | <b>system-view</b>                                                                                                                                                                                                   | N/A                                                                                                                                               |
| 3. Enable LT messages automatic sending.                | <b>cfd linktrace auto-detection</b> [ <b>size</b><br><i>size-value</i> ]                                                                                                                                             | Disabled by default.                                                                                                                              |

## Configuring AIS

The AIS function suppresses the number of error alarms reported by MEPs.

To make an MEP in the service instance send AIS frames, you must configure the AIS frame transmission level to be higher than the MD level of the MEP.

Enable AIS and configure the proper AIS frame transmission level on the target MEP, so the target MEP can suppress the error alarms and send the AIS frame to the MD of a higher level. If you enable AIS but do not configure the proper AIS frame transmission level on the target MEP, the target MEP can suppress the error alarms, but cannot send the AIS frames.

To configure AIS:

| Step                                              | Command                                                                              | Remarks                           |
|---------------------------------------------------|--------------------------------------------------------------------------------------|-----------------------------------|
| 1. Enter system view.                             | <b>system-view</b>                                                                   | N/A                               |
| 2. Enable AIS.                                    | <b>cfd ais enable</b>                                                                | Disabled by default.              |
| 3. Configure the AIS frame transmission level.    | <b>cfd ais level</b> <i>level-value</i> <b>service-instance</b> <i>instance-id</i>   | Not configured by default.        |
| 4. Configure the AIS frame transmission interval. | <b>cfd ais period</b> <i>period-value</i> <b>service-instance</b> <i>instance-id</i> | Optional.<br>1 second by default. |

## Configuring LM

The LM function measures frame loss between MEPs, including the number of lost frames, the frame loss ratio, and the average number of lost frames for the source and target MEPs.

To configure LM:

| Step                  | Command                                                                                                                                                                                          | Remarks                                                                                                                                          |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view. | <b>system-view</b>                                                                                                                                                                               | N/A                                                                                                                                              |
| 2. Configure LM.      | <b>cfd slm service-instance</b> <i>instance-id</i><br><b>mep</b> <i>mep-id</i> { <b>target-mac</b> <i>mac-address</i>   <b>target-mep</b> <i>target-mep-id</i> } [ <b>number</b> <i>number</i> ] | Disabled by default.<br>The <b>target-mep</b> <i>target-mep-id</i> option is not supported if an outward-facing MEP is configured on the switch. |

### NOTE:

The LM function takes effect only in CFD IEEE 802.1ag.

## Configuring one-way DM

The one-way DM function measures the one-way frame delay between two MEPs, and monitors and manages the link transmission performance.

The one-way DM function takes effect only in CFD IEEE 802.1ag.

One-way DM requires that the clocks at the transmitting MEP and the receiving MEP be synchronized. For the purpose of frame delay variation measurement, the requirement for clock synchronization can be relaxed.

To view the test result, use the **display cfd dm one-way history** command on the target MEP.

To configure one-way DM:

| Step                     | Command                                                                                                                                                                                         | Remarks                                                                                                                                          |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.    | <b>system-view</b>                                                                                                                                                                              | N/A                                                                                                                                              |
| 2. Configure one-way DM. | <b>cfd dm one-way service-instance</b><br><i>instance-id mep mep-id</i> { <b>target-mac</b><br><i>mac-address</i>   <b>target-mep</b><br><i>target-mep-id</i> } [ <b>number</b> <i>number</i> ] | Disabled by default.<br>The <b>target-mep</b> <i>target-mep-id</i> option is not supported if an outward-facing MEP is configured on the switch. |

## Configuring two-way DM

The two-way DM function measures the two-way frame delay, average two-way frame delay, and two-way frame delay variation between two MEPs, and monitors and manages the link transmission performance.

To configure two-way DM:

| Step                     | Command                                                                                                                                                                                         | Remarks                                                                                                                                          |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.    | <b>system-view</b>                                                                                                                                                                              | N/A                                                                                                                                              |
| 2. Configure two-way DM. | <b>cfd dm two-way service-instance</b><br><i>instance-id mep mep-id</i> { <b>target-mac</b><br><i>mac-address</i>   <b>target-mep</b><br><i>target-mep-id</i> } [ <b>number</b> <i>number</i> ] | Disabled by default.<br>The <b>target-mep</b> <i>target-mep-id</i> option is not supported if an outward-facing MEP is configured on the switch. |

### NOTE:

The two-way DM function is available only under the IEEE 802.1ag standard version of CFD.

## Configuring TST

The TST function detects bit errors on a link, and monitors and manages the link transmission performance.

To configure TST:

| Step                  | Command                                                                                                                                                                                                                                                                                                                                  | Remarks                                                                                                                                          |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view. | <b>system-view</b>                                                                                                                                                                                                                                                                                                                       | N/A                                                                                                                                              |
| 2. Configure TST.     | <b>cfd tst service-instance</b> <i>instance-id</i><br><b>mep</b> <i>mep-id</i> { <b>target-mac</b><br><i>mac-address</i>   <b>target-mep</b><br><i>target-mep-id</i> } [ <b>number</b> <i>number</i> ]<br>[ <b>length-of-test</b> <i>length</i> ]<br>[ <b>pattern-of-test</b> { <b>all-zero</b>   <b>prbs</b> }<br>[ <b>with-crc</b> ] ] | Disabled by default.<br>The <b>target-mep</b> <i>target-mep-id</i> option is not supported if an outward-facing MEP is configured on the switch. |

**NOTE:**

- The TST function takes effect only in CFD IEEE 802.1ag.
- To view the test result, use the **display cfd tst** command on the target MEP.

## Displaying and maintaining CFD

| Task                                                                                         | Command                                                                                                                                                                                              | Remarks               |

| Display MA configuration information.                                                        | <b>display cfd ma</b> [ [ <i>ma-name</i> ] <b>md</b> { <i>md-name</i>   <i>level level-value</i> } ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]              | Available in any view |
| Display service instance configuration information.                                          | <b>display cfd service-instance</b> [ <i>instance-id</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                                                        | Available in any view |
| Display MEP list in a service instance.                                                      | <b>display cfd meplist</b> [ <b>service-instance</b> <i>instance-id</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                                         | Available in any view |
| Display MP information.                                                                      | <b>display cfd mp</b> [ <b>interface</b> <i>interface-type</i> <i>interface-number</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                          | Available in any view |
| Display the attribute and running information of the MEPs.                                   | <b>display cfd mep</b> <i>mep-id</i> <b>service-instance</b> <i>instance-id</i> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                                   | Available in any view |
| Display LTR information received by a MEP.                                                   | <b>display cfd linktrace-reply</b> [ <b>service-instance</b> <i>instance-id</i> [ <b>mep</b> <i>mep-id</i> ] ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]    | Available in any view |
| Display the information of a remote MEP.                                                     | <b>display cfd remote-mep</b> <b>service-instance</b> <i>instance-id</i> <b>mep</b> <i>mep-id</i> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                 | Available in any view |
| Display the content of the LTR messages received as responses to the automatically sent LTM. | <b>display cfd linktrace-reply auto-detection</b> [ <b>size</b> <i>size-value</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                               | Available in any view |
| Display the AIS configuration and information on the specified MEP.                          | <b>display cfd ais</b> [ <b>service-instance</b> <i>instance-id</i> [ <b>mep</b> <i>mep-id</i> ] ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                | Available in any view |
| Display the one-way DM result on the specified MEP.                                          | <b>display cfd dm one-way history</b> [ <b>service-instance</b> <i>instance-id</i> [ <b>mep</b> <i>mep-id</i> ] ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view |

| Task                                              | Command                                                                                                                                                                               | Remarks                |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Display the TST result on the specified MEP.      | <b>display cfd tst</b> [ <b>service-instance</b> <i>instance-id</i> [ <b>mep</b> <i>mep-id</i> ] ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view  |
| Clear the one-way DM result on the specified MEP. | <b>reset cfd dm one-way history</b> [ <b>service-instance</b> <i>instance-id</i> [ <b>mep</b> <i>mep-id</i> ] ]                                                                       | Available in user view |
| Clear the TST result on the specified MEP.        | <b>reset cfd tst</b> [ <b>service-instance</b> <i>instance-id</i> [ <b>mep</b> <i>mep-id</i> ] ]                                                                                      | Available in user view |

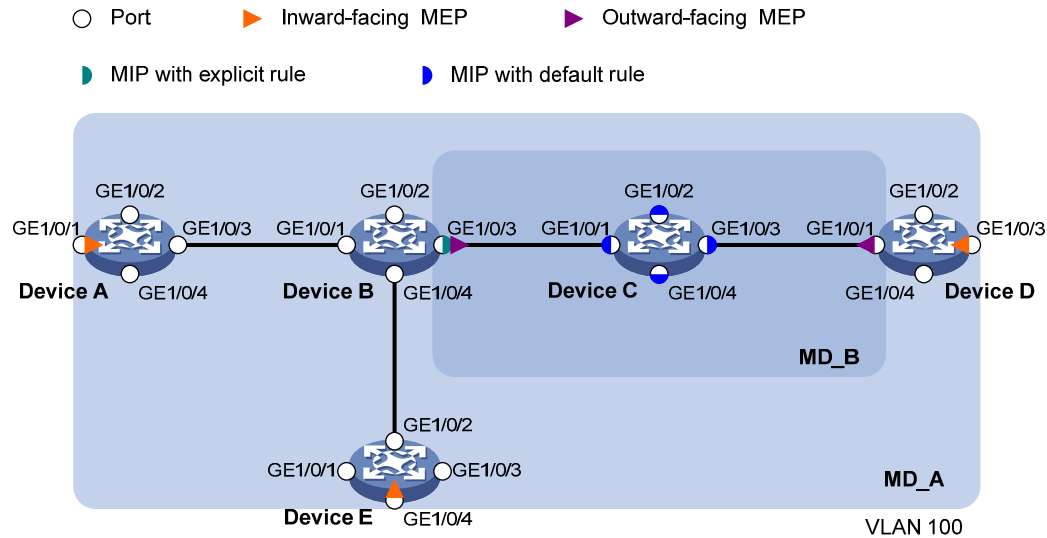

## CFD configuration example

### Network requirements

As shown in [Figure 8](#):

- The network comprises five devices and is divided into two MDs: MD\_A (level 5) and MD\_B (level 3). All ports belong to VLAN 100, and the MAs in the two MDs all serve VLAN 100. Suppose the MAC addresses of Device A through Device E are 0010-FC00-6511, 0010-FC00-6512, 0010-FC00-6513, 0010-FC00-6514, and 0010-FC00-6515.
- MD\_A has three edge ports: GigabitEthernet 1/0/1 on Device A, GigabitEthernet 1/0/3 on Device D, and GigabitEthernet 1/0/4 on Device E, and they are all inward-facing MEPs. MD\_B has two edge ports: GigabitEthernet 1/0/3 on Device B and GigabitEthernet 1/0/1 on Device D, and they are both outward-facing MEPs.
- In MD\_A, Device B is designed to have MIPs when its port is configured with low level MEPs. Port GigabitEthernet 1/0/3 is configured with MEPs of MD\_B, and the MIPs of MD\_A can be configured on this port. You should configure the MIP generation rule of MD\_A as explicit.
- The MIPs of MD\_B are designed on Device C, and are configured on all ports. You should configure the MIP generation rule as default.
- Configure CC to monitor the connectivity among all the MEPs in MD\_A and MD\_B. Configure to use LB to locate link faults, and use the AIS function to suppress the error alarms reported.
- After the status information of the entire network is obtained, use LT, LM, one-way DM, two-way DM, and TST to detect link faults.

**Figure 8 Network diagram**

### Configuration procedure

1. Configure a VLAN and assign ports to it:

On each device shown in [Figure 8](#), create VLAN 100, and assign ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to VLAN 100.

2. Enable CFD:

# Enable CFD on Device A.

```
<DeviceA> system-view
[DeviceA] cfd enable
```

Enable CFD on Device B through Device E using the same method.

3. Configure service instances:

# Create MD\_A (level 5) on Device A, create MA\_A, which serves VLAN 100, in MD\_A, and create service instance 1 for MD\_A and MA\_A.

```
[DeviceA] cfd md MD_A level 5
[DeviceA] cfd ma MA_A md MD_A vlan 100
[DeviceA] cfd service-instance 1 md MD_A ma MA_A
```

Configure Device E as you configure Device A.

# Create MD\_A (level 5) on Device B, create MA\_A, which serves VLAN 100, in MD\_A, and then create service instance 1 for MD\_A and MA\_A. In addition, create MD\_B (level 3), create MA\_B, which serves VLAN 100, in MD\_B, and then create service instance 2 for MD\_B and MA\_B.

```
[DeviceB] cfd md MD_A level 5
[DeviceB] cfd ma MA_A md MD_A vlan 100
[DeviceB] cfd service-instance 1 md MD_A ma MA_A
[DeviceB] cfd md MD_B level 3
[DeviceB] cfd ma MA_B md MD_B vlan 100
[DeviceB] cfd service-instance 2 md MD_B ma MA_B
```

Configure Device D as you configure Device B.

# Create MD\_B (level 3) on Device C, create MA\_B, which serves VLAN 100, in MD\_B, and then create service instance 2 for MD\_B and MA\_B.

```
[DeviceC] cfd md MD_B level 3
```

```
[DeviceC] cfd ma MA_B md MD_B vlan 100
[DeviceC] cfd service-instance 2 md MD_B ma MA_B
```

#### 4. Configure MEPs:

# On Device A, configure a MEP list in service instance 1. Create and enable inward-facing MEP 1001 in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceA] cfd meplist 1001 4002 5001 service-instance 1
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] cfd mep 1001 service-instance 1 inbound
[DeviceA-GigabitEthernet1/0/1] cfd mep service-instance 1 mep 1001 enable
[DeviceA-GigabitEthernet1/0/1] quit
```

# On Device B, configure a MEP list in service instances 1 and 2, respectively. Create and enable outward-facing MEP 2001 in service instance 2 on GigabitEthernet 1/0/3.

```
[DeviceB] cfd meplist 1001 4002 5001 service-instance 1
[DeviceB] cfd meplist 2001 4001 service-instance 2
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] cfd mep 2001 service-instance 2 outbound
[DeviceB-GigabitEthernet1/0/3] cfd mep service-instance 2 mep 2001 enable
[DeviceB-GigabitEthernet1/0/3] quit
```

# On Device D, configure a MEP list in service instances 1 and 2, respectively. Create and enable outward-facing MEP 4001 in service instance 2 on GigabitEthernet 1/0/1, and then create and enable inward-facing MEP 4002 in service instance 1 on GigabitEthernet 1/0/3.

```
[DeviceD] cfd meplist 1001 4002 5001 service-instance 1
[DeviceD] cfd meplist 2001 4001 service-instance 2
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] cfd mep 4001 service-instance 2 outbound
[DeviceD-GigabitEthernet1/0/1] cfd mep service-instance 2 mep 4001 enable
[DeviceD-GigabitEthernet1/0/1] quit
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] cfd mep 4002 service-instance 1 inbound
[DeviceD-GigabitEthernet1/0/3] cfd mep service-instance 1 mep 4002 enable
[DeviceD-GigabitEthernet1/0/3] quit
```

# On Device E, configure a MEP list in service instance 1. Create and enable inward-facing MEP 5001 in service instance 1 on GigabitEthernet 1/0/4.

```
[DeviceE] cfd meplist 1001 4002 5001 service-instance 1
[DeviceE] interface gigabitethernet 1/0/4
[DeviceE-GigabitEthernet1/0/4] cfd mep 5001 service-instance 1 inbound
[DeviceE-GigabitEthernet1/0/4] cfd mep service-instance 1 mep 5001 enable
[DeviceE-GigabitEthernet1/0/4] quit
```

#### 5. Configure MIPs:

# Configure the MIP generation rule in service instance 1 on Device B as explicit.

```
[DeviceB] cfd mip-rule explicit service-instance 1
```

# Configure the MIP generation rule in service instance 2 on Device C as default.

```
[DeviceC] cfd mip-rule default service-instance 2
```

#### 6. Configure CC:

# On Device A, enable the sending of CCM frames for MEP 1001 in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] cfd cc service-instance 1 mep 1001 enable
[DeviceA-GigabitEthernet1/0/1] quit
```

# On Device B, enable the sending of CCM frames for MEP 2001 in service instance 2 on GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] cfd cc service-instance 2 mep 2001 enable
[DeviceB-GigabitEthernet1/0/3] quit
```

# On Device D, enable the sending of CCM frames for MEP 4001 in service instance 2 on GigabitEthernet 1/0/1, and enable the sending of CCM frames for MEP 4002 in service instance 1 on GigabitEthernet 1/0/3.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] cfd cc service-instance 2 mep 4001 enable
[DeviceD-GigabitEthernet1/0/1] quit
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] cfd cc service-instance 1 mep 4002 enable
[DeviceD-GigabitEthernet1/0/3] quit
```

# On Device E, enable the sending of CCM frames for MEP 5001 in service instance 1 on GigabitEthernet 1/0/4.

```
[DeviceE] interface gigabitethernet 1/0/4
[DeviceE-GigabitEthernet1/0/4] cfd cc service-instance 1 mep 5001 enable
[DeviceE-GigabitEthernet1/0/4] quit
```

## 7. Configure AIS:

# Enable AIS on Device B, and configure the AIS frame transmission level as 2 and AIS frame transmission interval as 1 second in service instance 2.

```
[DeviceB] cfd ais enable
[DeviceB] cfd ais level 5 service-instance 2
[DeviceB] cfd ais period 1 service-instance 2
```

## Verifying the configuration

### 1. Verify the LB function:

When the CC function detects a link fault, use the LB function to locate the fault.

# Enable LB on Device A to check the status of the link between MEP 1001 and MEP 5001 in service instance 1.

```
[DeviceA] cfd loopback service-instance 1 mep 1001 target-mep 5001
Loopback to 0010-FC00-6515 with the sequence number start from 1001-43404:
Reply from 0010-FC00-6515: sequence number=1001-43404 time=5ms
Reply from 0010-FC00-6515: sequence number=1001-43405 time=5ms
Reply from 0010-FC00-6515: sequence number=1001-43406 time=5ms
Reply from 0010-FC00-6515: sequence number=1001-43407 time=5ms
Reply from 0010-FC00-6515: sequence number=1001-43408 time=5ms
Send:5 Received:5 Lost:0
```

After the whole network status is obtained with the CC function, use the LT function to identify the paths between source and target MEPs or locate faults.

### 2. Verify the LT function:

# Identify the path between MEP 1001 and MEP 5001 in service instance 1 on Device A.

```
[DeviceA] cfd linktrace service-instance 1 mep 1001 target-mep 5001
Linktrace to MEP 5001 with the sequence number 1001-43462
```

| MAC Address    | TTL | Last MAC       | Relay Action |
|----------------|-----|----------------|--------------|
| 0010-FC00-6515 | 63  | 0010-FC00-6512 | Hit          |

### 3. Verify the LM function:

After the CC function obtains the status information of the entire network, use the LM function to test the link status. For example:

# Test the frame loss from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd slm service-instance 1 mep 1001 target-mep 4002
Reply from 0010-FC00-6514
Far-end frame loss: 10 Near-end frame loss: 20
Reply from 0010-FC00-6514
Far-end frame loss: 40 Near-end frame loss: 40
Reply from 0010-FC00-6514
Far-end frame loss: 0 Near-end frame loss: 10
Reply from 0010-FC00-6514
Far-end frame loss: 30 Near-end frame loss: 30
```

Average

```
Far-end frame loss: 20 Near-end frame loss: 25
Far-end frame loss rate: 25% Near-end frame loss rate: 32%
Send LMMs: 5 Received: 5 Lost: 0
```

### 4. Verify the one-way DM function:

After the CC function obtains the status information of the entire network, use the one-way DM function to test the one-way frame delay of a link. For example:

# Test the one-way frame delay from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd dm one-way service-instance 1 mep 1001 target-mep 4002
Info: 5 1DM frames process is done, please check the result on the remote device.
```

# Display the one-way DM result on MEP 4002 in service instance 1 on Device D.

```
[DeviceD] display cfd dm one-way history service-instance 1 mep 4002
Service instance: 1
MEP ID: 4002
Send 1DM total number: 0
Received 1DM total number: 5
Frame delay: 10ms 9ms 11ms 5ms 5ms
Delay average: 8ms
Delay variation: 5ms 4ms 6ms 0ms 0ms
Variation average: 3ms
```

### 5. Verify the two-way DM function:

After the CC function obtains the status information of the entire network, use the two-way DM function to test the two-way frame delay of a link. For example:

# Test the two-way frame delay from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd dm two-way service-instance 1 mep 1001 target-mep 4002
Frame delay:
Reply from 0010-FC00-6514: 10ms
Reply from 0010-FC00-6514: 9ms
Reply from 0010-FC00-6514: 11ms
Reply from 0010-FC00-6514: 5ms
```

Reply from 0010-FC00-6514: 5ms

Average: 8ms

Send DMMs: 5            Received: 5            Lost: 0

Frame delay variation: 5ms 4ms 6ms 0ms 0ms

Average: 3ms

**6. Verify the TST function:**

After the CC function obtains the status information of the entire network, use the TST function to test the bit errors of a link. For example:

# Test the bit errors on the link from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd tst service-instance 1 mep 1001 target-mep 4002
```

Info: TST process is done. Please check the result on the remote device.

# Display the TST result on MEP 4002 in service instance 1 on Device D.

```
[DeviceD] display cfd tst service-instance 1 mep 4002
```

Service instance: 1

MEP ID: 4002

Send TST total number: 0

Received TST total number: 5

Received from 0010-FC00-6511, sequence number 1: Bit True

Received from 0010-FC00-6511, sequence number 2: Bit True

Received from 0010-FC00-6511, sequence number 3: Bit True

Received from 0010-FC00-6511, sequence number 4: Bit True

Received from 0010-FC00-6511, sequence number 5: Bit True

# Configuring DLDAP

## DLDP overview

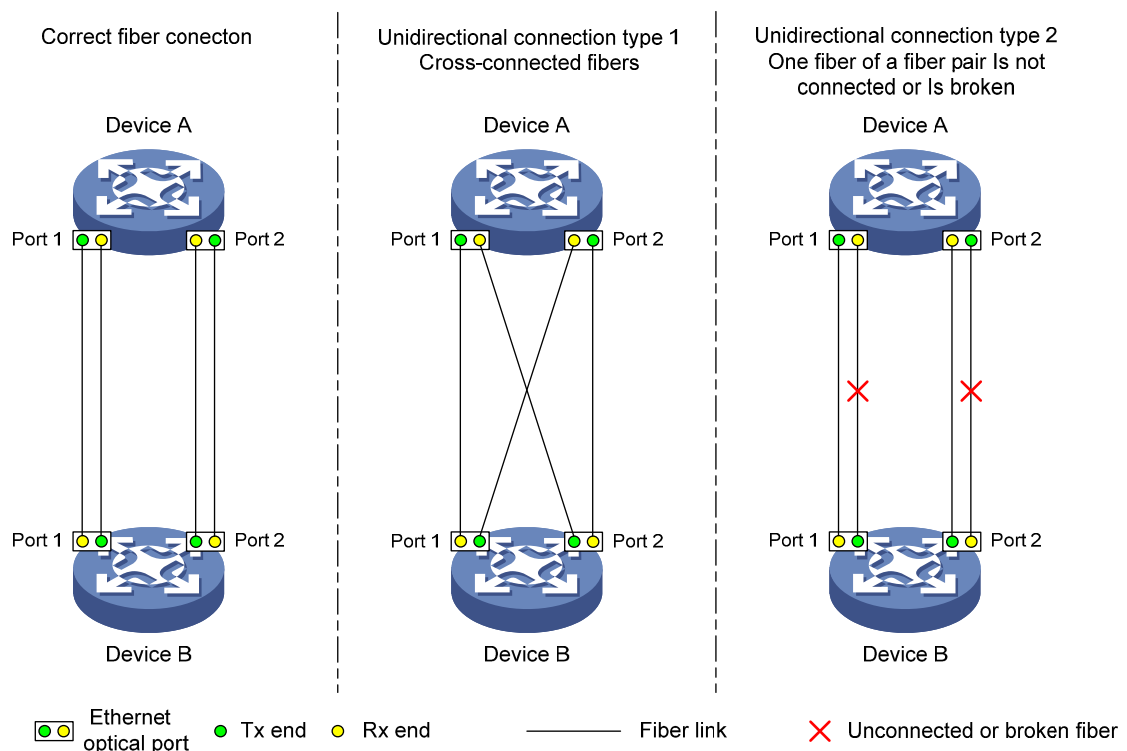

### Background

Unidirectional links occur when one end of a link can receive packets from the other end, but the other end cannot receive packets sent by the first end. Unidirectional links result in problems such as loops in an STP-enabled network.

For example, the link between two switches, Switch A and Switch B, is a bidirectional link when they are connected via a fiber pair, with one fiber used for sending packets from A to B and the other for sending packets from B to A. This link is a two-way link. If one of the fibers gets broken, the link becomes a unidirectional link (one-way link).

There are two types of unidirectional fiber links. One occurs when fibers are cross-connected. The other occurs when a fiber is not connected at one end, or when one fiber of a fiber pair gets broken. [Figure 9](#) shows a correct fiber connection and the two types of unidirectional fiber connection.

**Figure 9 Correct and incorrect fiber connections**

The Device link detection protocol (DLDP) detects unidirectional links (fiber links or twisted-pair links) and can be configured to shut down the related port automatically or prompt users to take actions to avoid network problems.

As a data link layer protocol, DLDP cooperates with physical layer protocols to monitor link status. When the auto-negotiation mechanism provided by the physical layer detects physical signals and faults, DLDP

performs operations such as identifying peer devices, detecting unidirectional links, and shutting down unreachable ports. The auto-negotiation mechanism and DLDAP work together to make sure that physical/logical unidirectional links are detected and shut down, and to prevent failure of other protocols such as STP. If both ends of a link are operating normally at the physical layer, DLDAP detects whether the link is correctly connected at the link layer and whether the two ends can exchange packets properly. This is beyond the capability of the auto-negotiation mechanism at the physical layer.

## How DLDAP works

### DLDAP link states

A device is in one of these DLDAP link states: Initial, Inactive, Active, Advertisement, Probe, Disable, and DelayDown, as described in [Table 10](#).

**Table 10 DLDAP link states**

| State         | Indicates...                                                                                                                                                                                                                                                                             |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initial       | DLDAP is disabled.                                                                                                                                                                                                                                                                       |
| Inactive      | DLDAP is enabled, and the link is down.                                                                                                                                                                                                                                                  |
| Active        | DLDAP is enabled and the link is up, or the neighbor entries have been cleared.                                                                                                                                                                                                          |
| Advertisement | All neighbors are bi-directionally reachable or DLDAP has been in active state for more than five seconds. This is a relatively stable state where no unidirectional link has been detected.                                                                                             |
| Probe         | DLDAP enters this state if it receives a packet from an unknown neighbor. In this state, DLDAP sends packets to check whether the link is unidirectional. As soon as DLDAP transits to this state, a probe timer starts and an echo timeout timer starts for each neighbor to be probed. |
| Disable       | A port enters this state when: <ul style="list-style-type: none"> <li>• A unidirectional link is detected.</li> <li>• The contact with the neighbor in enhanced mode gets lost.</li> <li>• In this state, the port does not receive or send packets other than DLDAPDUs.</li> </ul>      |
| DelayDown     | A port in the Active, Advertisement, or Probe DLDAP link state transits to this state rather than removes the corresponding neighbor entry and transits to the Inactive state when it detects a port-down event. When a port transits to this state, the DelayDown timer is triggered.   |

### DLDAP timers

**Table 11 DLDAP timers**

| DLDAP timer         | Description                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Active timer        | Determines the interval for sending Advertisement packets with RSY tags, which defaults to 1 second. By default, a device in the active DLDAP link state sends one Advertisement packet with RSY tags every second. The maximum number of advertisement packets with RSY tags that can be sent successively is 5. |
| Advertisement timer | Determines the interval for sending common advertisement packets, which defaults to 5 seconds.                                                                                                                                                                                                                    |
| Probe timer         | Determines the interval for sending Probe packets, which defaults to 1 second. By default, a device in the probe state sends one Probe packet every second. The maximum number of Probe packets that can be sent successively is 10.                                                                              |

| DLDP timer         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Echo timer         | <p>This timer is set to 10 seconds. It is triggered when a device transits to the Probe state or when an enhanced detect is launched. When the Echo timer expires and no Echo packet has been received from a neighbor device, the state of the link is set to unidirectional and the device transits to the Disable state. In this case, the device does the following:</p> <p>Sends Disable packets.</p> <p>Either prompts the user to shut down the port or shuts down the port automatically (depending on the DLDP down mode configured).</p> <p>Removes the corresponding neighbor entries.</p>                                                        |
| Entry timer        | <p>When a new neighbor joins, a neighbor entry is created and the corresponding entry timer is triggered. When a DLDP packet is received, the device updates the corresponding neighbor entry and the entry timer.</p> <p>In normal mode, if no packet is received from a neighbor when the corresponding entry timer expires, DLDP sends advertisement packets with RSY tags and removes the neighbor entry.</p> <p>In enhanced mode, if no packet is received from a neighbor when the Entry timer expires, DLDP triggers the enhanced timer.</p> <p>The setting of an Entry timer is three times that of the Advertisement timer.</p>                     |
| Enhanced timer     | <p>In enhanced mode, this timer is triggered if no packet is received from a neighbor when the entry timer expires. Enhanced timer is set to 1 second.</p> <p>After the Enhanced timer is triggered, the device sends up to eight probe packets to the neighbor at a frequency of one packet per second.</p>                                                                                                                                                                                                                                                                                                                                                 |
| DelayDown timer    | <p>A device in Active, Advertisement, or Probe DLDP link state transits to DelayDown state rather than removes the corresponding neighbor entry and transits to the Inactive state when it detects a port-down event.</p> <p>When a device transits to this state, the DelayDown timer is triggered. A device in DelayDown state only responds to port-up events.</p> <p>If a device in the DelayDown state detects a port-up event before the DelayDown timer expires, it resumes its original DLDP state. If not, when the DelayDown timer expires, the device removes the corresponding DLDP neighbor information and transits to the Inactive state.</p> |
| RecoverProbe timer | <p>This timer is set to 2 seconds. A port in the Disable state sends one RecoverProbe packet every two seconds to detect whether a unidirectional link has restored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## DLDP mode

DLDP can operate in normal or enhanced mode:

- In normal DLDP mode, when an entry timer expires, the device removes the corresponding neighbor entry and sends an Advertisement packet with the RSY tag.
- In enhanced DLDP mode, when an entry timer expires, the Enhanced timer is triggered and the device tests the neighbor by sending up to eight Probe packets at the frequency of one packet per second. If no Echo packet has been received from the neighbor when the Echo timer expires, the device transits to the Disable state.

Table 12 shows the relationship between the DLDP modes and neighbor entry aging.

**Table 12 DLDAP mode and neighbor entry aging**

| DLDAP mode          | Detecting a neighbor after the corresponding neighbor entry ages out | Removing the neighbor entry immediately after the Entry timer expires | Triggering the Enhanced timer after an Entry timer expires |
|---------------------|----------------------------------------------------------------------|-----------------------------------------------------------------------|------------------------------------------------------------|
| Normal DLDAP mode   | No                                                                   | Yes                                                                   | No                                                         |
| Enhanced DLDAP mode | Yes                                                                  | No                                                                    | Yes                                                        |

Table 13 shows the relationship between DLDAP modes and unidirectional link types.

**Table 13 DLDAP mode and unidirectional link types**

| Unidirectional link type      | Whether it occurs on fibers | Whether it occurs on copper twisted pairs | In which DLDAP mode unidirectional links can be detected                                                                                    |
|-------------------------------|-----------------------------|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Cross-connected link          | Yes                         | No                                        | Both normal and enhanced modes                                                                                                              |
| Connectionless or broken link | Yes                         | Yes                                       | Only enhanced mode. The port that can receive signals is in Disable state, and the port that does not receive signals is in Inactive state. |

Enhanced DLDAP mode is designed for addressing black holes. It prevents situations where one end of a link is up and the other is down.

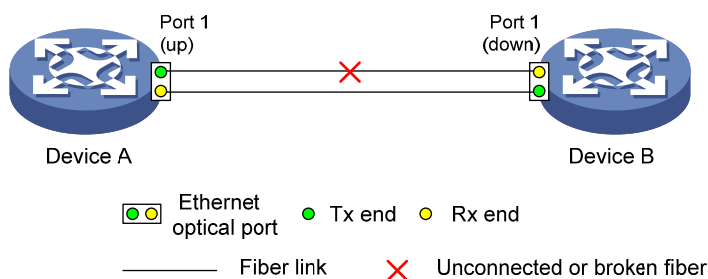

If you configure forced speed and full duplex mode on a port, the situation shown in Figure 10 may occur (take the fiber link for example). Without DLDAP enabled, the port on Device B is actually down but its state cannot be detected by common data link protocols, so the port on Device A is still up. However, in enhanced DLDAP mode, the following occurs:

The port on Device B is in Inactive DLDAP state because it is physically down.

The port on Device A tests the peer port on Device B after the Entry timer for the port on Device B expires.

The port on Device A transits to the Disable state if it does not receive an Echo packet from the port on Device B when the Echo timer expires.

**Figure 10 A scenario for the enhanced DLDAP mode**

### DLDAP authentication mode

You can use DLDAP authentication to prevent network attacks and illegal detection. There are three DLDAP authentication modes.

- Non-authentication:
  - The sending side sets the Authentication field and the Authentication type field of DLDAP packets to 0.
  - The receiving side checks the values of the two fields of received DLDAP packets and drops the packets where the two fields conflict with the corresponding local configuration.
- Simple authentication:
  - Before sending a DLDAP packet, the sending side sets the Authentication field to the user-configured password and sets the Authentication type field to 1.
  - The receiving side checks the values of the two fields in received DLDAP packets and drops any packets where the two fields conflict with the corresponding local configuration.
- MD5 authentication:
  - Before sending a packet, the sending side encrypts the user configured password using MD5 algorithm, assigns the digest to the Authentication field, and sets the Authentication type field to 2.
  - The receiving side checks the values of the two fields in received DLDAP packets and drops any packets where the two fields conflicting with the corresponding local configuration.

## DLDAP processes

1. On a DLDAP-enabled link that is in up state, DLDAP sends DLDAP packets to the peer device and processes the DLDAP packets received from the peer device. DLDAP packets sent vary with DLDAP states.

**Table 14 DLDAP packet types and DLDAP states**

| DLDAP state   | Type of DLDAP packets sent                  |
|---------------|---------------------------------------------|
| Active        | Advertisement packet with RSY tag           |
| Advertisement | Normal Advertisement packet                 |
| Probe         | Probe packet                                |
| Disable       | Disable packet and then RecoverProbe packet |

### NOTE:

A device sends Flush packets when it transits to the Initial state from the Active, Advertisement, Probe, or DelayDown state but does not send them when it transits to the Initial state from Inactive or Disable state.

2. A received DLDAP packet is processed with the following methods:
  - In any of the three authentication modes, the packet is dropped if it fails to pass the authentication.
  - The packet is dropped if the setting of the interval to send Advertisement packets it carries conflicts with the corresponding local setting.
  - Other processes are as shown in [Table 15](#).

**Table 15 Procedures for processing different types of DLDP packets received**

| Packet type                       | Processing procedure                                               |                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Advertisement packet with RSY tag | Retrieves the neighbor information                                 | If the corresponding neighbor entry does not exist, creates the neighbor entry, triggers the Entry timer, and transits to Probe state.                                                                                                                                                                                                                                                           |
|                                   |                                                                    | If the corresponding neighbor entry already exists, resets the Entry timer and transits to Probe state.                                                                                                                                                                                                                                                                                          |
| Normal Advertisement packet       | Retrieves the neighbor information                                 | If the corresponding neighbor entry does not exist, creates the neighbor entry, triggers the Entry timer, and transits to Probe state.                                                                                                                                                                                                                                                           |
|                                   |                                                                    | If the corresponding neighbor entry already exists, resets the Entry timer.                                                                                                                                                                                                                                                                                                                      |
| Flush packet                      | Determines whether or not the local port is in Disable state       | If yes, performs no processing.                                                                                                                                                                                                                                                                                                                                                                  |

| LinkDown packet | Checks whether the local port operates in Enhanced mode<br>If yes and the local port is not in Disable state, sets the state of the corresponding neighbor to unidirectional, and then checks the state of other neighbors. If all the neighbors are unidirectional, transitions the local port to the Disable state. If the state of some neighbors is unknown, waits until the state of these neighbors is determined. If bidirectional neighbors are present, removes all unidirectional neighbors. |

3. If no echo packet is received from the neighbor, DLDP performs the following processing.

**Table 16 DLDP process when no echo packet is received from the neighbor**

| No echo packet received from the neighbor                                 | Processing procedure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| In normal mode, no echo packet is received when the Echo timer expires.   | DLDP sets the state of the corresponding neighbor to unidirectional, and then checks the state of other neighbors: <ul style="list-style-type: none"> <li>If all the neighbors are unidirectional, removes all the neighbors, transitions to the Disable state, outputs log and tracking information, and sends Disable packets. In addition, depending on the user-defined DLDP down mode, shuts down the local port or prompts users to shut down the port.</li> <li>If the state of some neighbors is unknown, waits until the state of these neighbors is determined.</li> <li>If bidirectional neighbors are present, removes all unidirectional neighbors.</li> </ul> |
| In enhanced mode, no echo packet is received when the Echo timer expires. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### Link auto-recovery mechanism

If the port shutdown mode upon detection of a unidirectional link is set to **auto**, DLDP automatically sets the state of the port, where a unidirectional link is detected, to DLDP down. A DLDP down port cannot forward data traffic or send/receive any PDUs except DLDAPDUs.

On a DLDP down port, DLDP monitors the unidirectional link. Once DLDP finds out that the state of the link has restored to bidirectional, it brings up the port. The specific process is:

The DLDP down port sends out a RecoverProbe packet, which carries only information about the local port, every two seconds. Upon receiving the RecoverProbe packet, the remote end returns a RecoverEcho packet. Upon receiving the RecoverEcho packet, the local port checks whether neighbor information in the RecoverEcho packet is the same as the local port information. If they are the same, the link between the local port and the neighbor is considered to have been restored to a bidirectional link, and the port will transit from Disable state to Active state and re-establish relationship with the neighbor.

Only DLDP down ports can send and process Recover packets, including RecoverProbe packets and RecoverEcho packets. If related ports are manually shut down with the **shutdown** command, the auto-recovery mechanism will not take effect.

### DLDP neighbor state

A DLDP neighbor can be in one of the three states described in [Table 17](#).

**Table 17 Description on DLDAP neighbor states**

| <b>DLDAP neighbor state</b> | <b>Description</b>                                                                                                                                                                                                           |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unknown                     | A neighbor is in this state when it is just detected and is being probed. A neighbor is in this state only when it is being probed. It transits to Two way state or Unidirectional state after the probe operation finishes. |
| Two way                     | A neighbor is in this state after it receives response from its peer. This state indicates the link is a two-way link.                                                                                                       |
| Unidirectional              | A neighbor is in this state when the link connecting it is detected to be a unidirectional link. After a device transits to this state, the corresponding neighbor entries maintained on other devices are removed.          |

## DLDAP configuration task list

For DLDAP to work properly, enable DLDAP on both sides and make sure these settings are consistent: the interval to send Advertisement packets, DLDAP authentication mode, and password.

DLDAP does not process any link aggregation control protocol (LACP) events. The links in an aggregation are treated as individual links in DLDAP.

Make sure the DLDAP version running on devices on the two ends are the same.

Complete the following tasks to configure DLDAP:

| <b>Task</b>                                                                    | <b>Remarks</b> |
|--------------------------------------------------------------------------------|----------------|
| <a href="#">Configuring the duplex mode and speed of an Ethernet interface</a> | Required       |
| <a href="#">Enabling DLDAP</a>                                                 | Required       |
| <a href="#">Setting DLDAP mode</a>                                             | Optional       |
| <a href="#">Setting the interval to send advertisement packets</a>             | Optional       |
| <a href="#">Setting the delaydown timer</a>                                    | Optional       |
| <a href="#">Setting the port shutdown mode</a>                                 | Optional       |
| <a href="#">Configuring DLDAP authentication</a>                               | Optional       |
| <a href="#">Resetting DLDAP state</a>                                          | Optional       |

## Configuring the duplex mode and speed of an Ethernet interface

To make sure that DLDAP works properly on a link, you must configure the full duplex mode for the ports at two ends of the link, and configure a speed for the two ports, rather than letting them negotiate a speed.

For more information about the **duplex** and **speed** commands, see *Layer 2—LAN Switching Command Reference*.

# Enabling DLDAP

To properly configure DLDAP on the device, first enable DLDAP globally, and then enable it on each port.

To enable DLDAP:

| Step                                                         | Command                                                                                                                                                                               | Remarks                                                                                                                                                                                        |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                        | <b>system-view</b>                                                                                                                                                                    | N/A                                                                                                                                                                                            |
| 2. Enable DLDAP globally.                                    | <b>dldap enable</b>                                                                                                                                                                   | Globally disabled by default.                                                                                                                                                                  |
| 3. Enter Layer 2 Ethernet interface view or port group view. | Enter Layer 2 Ethernet interface view:<br><b>interface</b> <i>interface-type</i> <i>interface-number</i><br>Enter port group view:<br><b>port-group manual</b> <i>port-group-name</i> | Use either approach.<br>Configurations made in Layer 2 Ethernet interface view apply to the current port only.<br>Configurations made in port group view apply to all ports in the port group. |
| 4. Enable DLDAP.                                             | <b>dldap enable</b>                                                                                                                                                                   | Disabled on a port by default.                                                                                                                                                                 |

## NOTE:

- DLDAP takes effect only on Ethernet interfaces (fiber or copper).
- DLDAP can detect unidirectional links only after all physical links are connected. Therefore, before enabling DLDAP, make sure that optical fibers or copper twisted pairs are connected.

# Setting DLDAP mode

DLDAP operates in normal or enhanced mode.

In normal mode, DLDAP does not actively detect neighbors when the corresponding neighbor entries age out.

In enhanced mode, DLDAP actively detects neighbors when the corresponding neighbor entries age out.

To set DLDAP mode:

| Step                  | Command                                     | Remarks                         |
|-----------------------|---------------------------------------------|---------------------------------|
| 1. Enter system view. | <b>system-view</b>                          | N/A                             |
| 2. Set DLDAP mode.    | <b>dldap work-mode { enhance   normal }</b> | Optional.<br>Normal by default. |

# Setting the interval to send advertisement packets

DLDAP detects unidirectional links by sending Advertisement packets. To make sure that DLDAP can detect unidirectional links promptly without affecting network performance, set the advertisement interval appropriately depending on your network environment. The interval should be set shorter than one third of the STP convergence time. If the interval is too long, STP loops may occur before unidirectional links are detected and shut down. If the interval is too short, the number of advertisement packets will increase. HP recommends that you use the default interval in most cases.

To set the interval to send Advertisement packets:

| Step                                               | Command                   | Remarks                            |
|----------------------------------------------------|---------------------------|------------------------------------|
| 1. Enter system view.                              | <b>system-view</b>        | N/A                                |
| 2. Set the interval to send Advertisement packets. | <b>dldp interval time</b> | Optional.<br>5 seconds by default. |

**NOTE:**

- The interval for sending Advertisement packets applies to all DLDAP-enabled ports.
- To enable DLDAP to operate properly, make sure the intervals for sending Advertisement packets on both sides of a link are the same.

## Setting the delaydown timer

On some ports, when the Tx line fails, the port goes down and then comes up again, causing optical signal jitters on the Rx line. When a port goes down due to a Tx failure, the device transits to the DelayDown state instead of the Inactive state to prevent the corresponding neighbor entries from being removed. At the same time, the device triggers the DelayDown timer. If the port goes up before the timer expires, the device restores the original state; if the port remains down when the timer expires, the device transits to the Inactive state.

To set the DelayDown timer:

| Step                        | Command                          | Remarks                           |
|-----------------------------|----------------------------------|-----------------------------------|
| 1. Enter system view.       | <b>system-view</b>               | N/A                               |
| 2. Set the DelayDown timer. | <b>dldp delaydown-timer time</b> | Optional.<br>1 second by default. |

**NOTE:**

DelayDown timer setting applies to all DLDAP-enabled ports.

## Setting the port shutdown mode

On detecting a unidirectional link, the ports can be shut down in one of the following two modes:

- **Manual mode**—This mode applies to low performance networks, where normal links may be treated as unidirectional links. It protects data traffic transmission against false unidirectional links. In this mode, DLDAP only detects unidirectional links but does not automatically shut down unidirectional link ports. Instead, the DLDAP state machine generates log and traps to prompt you to manually shut down unidirectional link ports with the **shutdown** command. HP recommends that you do as prompted. Then the DLDAP state machine transits to the Disable state.
- **Auto mode**—In this mode, when a unidirectional link is detected, DLDAP transits to Disable state, generates log and traps, and sets the port state to DLDAP Down.

On a port with both remote OAM loopback and DLDAP enabled, if the port shutdown mode is auto mode, the port will be shut down by DLDAP when it receives a packet sent by itself, causing remote OAM loopback to operate improperly. To prevent this, set the port shutdown mode to manual mode.

If the device is busy, or the CPU usage is high, normal links may be treated as unidirectional links. In this case, you can set the port shutdown mode to manual mode to alleviate the impact caused by false unidirectional link report.

To set port shutdown mode:

| Step                       | Command                                                             | Remarks                              |
|----------------------------|---------------------------------------------------------------------|--------------------------------------|
| 1. Enter system view.      | <b>system-view</b>                                                  | N/A                                  |
| 2. Set port shutdown mode. | <b>dldp unidirectional-shutdown</b> { <b>auto</b>   <b>manual</b> } | Optional.<br><b>auto</b> by default. |

## Configuring DLDAP authentication

You can guard your network against attacks and malicious probes by configuring an appropriate DLDAP authentication mode, which can be simple authentication or MD5 authentication. If your network is safe, you can choose not to authenticate.

To enable DLDAP to operate properly, make sure that DLDAP authentication modes and passwords on both sides of a link are the same.

To configure DLDAP authentication:

| Step                               | Command                                                                                           | Remarks                 |
|------------------------------------|---------------------------------------------------------------------------------------------------|-------------------------|
| 1. Enter system view.              | <b>system-view</b>                                                                                | N/A                     |
| 2. Configure DLDAP authentication. | <b>dldap authentication-mode</b> { <b>none</b>   { <b>md5</b>   <b>simple</b> } <i>password</i> } | <b>none</b> by default. |

## Resetting DLDAP state

After DLDAP detects a unidirectional link on a port, the port enters Disable state. In this case, DLDAP prompts you to shut down the port manually or it shuts down the port automatically depending on the user-defined port shutdown mode. To enable the port to perform DLDAP detect again, you can reset the DLDAP state of the port by using one of the following methods:

- If the port is shut down with the **shutdown** command manually, run the **undo shutdown** command on the port.
- If DLDAP automatically shuts down the port, run the **dldap reset** command on the port to enable the port to perform DLDAP detection again. Alternatively, you can wait for DLDAP to automatically enable the port when it detects that the link has been restored to bidirectional. For how to reset the DLDAP state by using the **dldap reset** command, see "[Resetting DLDAP state in system view](#)" and "[Resetting DLDAP state in interface view/port group view](#)."

The DLDAP state that the port transits to upon the DLDAP state reset operation depends on its physical state. If the port is physically down, it transits to Inactive state; if the port is physically up, it transits to Active state.

### Resetting DLDAP state in system view

Resetting DLDAP state in system view applies to all ports of the device.

To reset DLDAP in system view:

| Step                  | Command            |
|-----------------------|--------------------|
| 1. Enter system view. | <b>system-view</b> |
| 2. Reset DLDAP state. | <b>dldap reset</b> |

### Resetting DLDAP state in interface view/port group view

Resetting DLDAP state in interface view or port group view applies to the current port or all ports in the port group.

To reset DLDAP state in interface view/port group view:

| Step                                                         | Command                                                                                                                                                                        | Remarks                                                                                                                                                                                         |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                        | <b>system-view</b>                                                                                                                                                             | N/A                                                                                                                                                                                             |
| 2. Enter Layer 2 Ethernet interface view or port group view. | Enter Layer 2 Ethernet interface view:<br><b>interface</b> <i>interface-type interface-number</i><br>Enter port group view:<br><b>port-group manual</b> <i>port-group-name</i> | Use either approach.<br>Configurations made in Layer 2 Ethernet interface view apply to the current port only. Configurations made in port group view apply to all the ports in the port group. |
| 3. Reset DLDAP state.                                        | <b>dldap reset</b>                                                                                                                                                             | N/A                                                                                                                                                                                             |

## Displaying and maintaining DLDAP

| Task                                                            | Command                                                                                                                                                       | Remarks                |
|-----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Display the DLDAP configuration of a port.                      | <b>display dldap</b> [ <i>interface-type interface-number</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]            | Available in any view  |
| Display the statistics on DLDAP packets passing through a port. | <b>display dldap statistics</b> [ <i>interface-type interface-number</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view  |
| Clear the statistics on DLDAP packets passing through a port.   | <b>reset dldap statistics</b> [ <i>interface-type interface-number</i> ]                                                                                      | Available in user view |

## DLDAP configuration examples

### Automatically shutting down unidirectional links

#### Network requirements

- As shown in [Figure 11](#), Device A and Device B are connected with two fiber pairs.
- Configure DLDAP to automatically shut down the faulty port upon detecting a unidirectional link, and automatically bring up the port after you clear the fault.

Figure 11 Network diagram

## Configuration procedure

### 1. Configure Device A:

# Enable DLDP globally.

```
<DeviceA> system-view
[DeviceA] dldp enable
```

# Configure GigabitEthernet 1/0/49 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

```
[DeviceA] interface gigabitethernet 1/0/49
[DeviceA-GigabitEthernet1/0/49] duplex full
[DeviceA-GigabitEthernet1/0/49] speed 1000
[DeviceA-GigabitEthernet1/0/49] dldp enable
[DeviceA-GigabitEthernet1/0/49] quit
```

# Configure GigabitEthernet 1/0/50 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

```
[DeviceA] interface gigabitethernet 1/0/50
[DeviceA-GigabitEthernet1/0/50] duplex full
[DeviceA-GigabitEthernet1/0/50] speed 1000
[DeviceA-GigabitEthernet1/0/50] dldp enable
[DeviceA-GigabitEthernet1/0/50] quit
```

# Set the DLDP mode to enhanced.

```
[DeviceA] dldp work-mode enhance
```

# Set the port shutdown mode to auto.

```
[DeviceA] dldp unidirectional-shutdown auto
```

### 2. Configure Device B:

# Enable DLDAP globally.

```
<DeviceB> system-view
[DeviceB] dldp enable
```

# Configure GigabitEthernet 1/0/49 to operate in full duplex mode and at 1000 Mbps, and enable DLDAP on it.

```
[DeviceB] interface gigabitethernet 1/0/49
[DeviceB-GigabitEthernet1/0/49] duplex full
[DeviceB-GigabitEthernet1/0/49] speed 1000
[DeviceB-GigabitEthernet1/0/49] dldp enable
[DeviceB-GigabitEthernet1/0/49] quit
```

# Configure GigabitEthernet 1/0/50 to operate in full duplex mode and at 1000 Mbps, and enable DLDAP on it.

```
[DeviceB] interface gigabitethernet 1/0/50
[DeviceB-GigabitEthernet1/0/50] duplex full
[DeviceB-GigabitEthernet1/0/50] speed 1000
[DeviceB-GigabitEthernet1/0/50] dldp enable
[DeviceB-GigabitEthernet1/0/50] quit
```

# Set the DLDAP mode to enhanced.

```
[DeviceB] dldp work-mode enhance
```

# Set the port shutdown mode to auto.

```
[DeviceB] dldp unidirectional-shutdown auto
```

### 3. Verify the configuration:

After the configurations are complete, you can use the **display dldp** command to display the DLDAP configuration information on ports.

# Display the DLDAP configuration information on all the DLDAP-enabled ports of Device A.

```
[DeviceA] display dldp
DLDP global status : enable
DLDP interval : 5s
DLDP work-mode : enhance
DLDP authentication-mode : none
DLDP unidirectional-shutdown : auto
DLDP delaydown-timer : 1s
The number of enabled ports is 2.
```

```
Interface GigabitEthernet1/0/49
DLDP port state : advertisement
DLDP link state : up
The neighbor number of the port is 1.
 Neighbor mac address : 0023-8956-3600
 Neighbor port index : 59
 Neighbor state : two way
 Neighbor aged time : 11
```

```
Interface GigabitEthernet1/0/50
DLDP port state : advertisement
DLDP link state : up
The neighbor number of the port is 1.
```

```
Neighbor mac address : 0023-8956-3600
Neighbor port index : 60
Neighbor state : two way
Neighbor aged time : 12
```

The output shows that both GigabitEthernet 1/0/49 and GigabitEthernet 1/0/50 are in Advertisement state, which means both links are bidirectional.

# Enable system information monitoring on Device A, and enable the display of log and trap information.

```
[DeviceA] quit
<DeviceA> terminal monitor
<DeviceA> terminal logging
<DeviceA> terminal trapping
```

The following log and trap information is displayed on Device A:

```
<DeviceA>
#Jan 18 17:36:18:798 2010 DeviceA DLDP/1/TrapOfUnidirectional: -Slot=1; Trap
1.3.6.1.4.1.25506.2.43.2.1.1 : DLDP detects a unidirectional link in port 17825792.

%Jan 18 17:36:18:799 2010 DeviceA IFNET/3/LINK_UPDOWN: GigabitEthernet1/0/49 link
status is DOWN.

%Jan 18 17:36:18:799 2010 DeviceA DLDP/3/DLDP_UNIDIRECTION_AUTO: -Slot=1; DLDP
detects a unidirectional link on port GigabitEthernet1/0/49. The transceiver has
malfunction in the Tx direction or cross-connected links exist between the local device
and its neighbor. The shutdown mode is AUTO. DLDP shuts down the port.

#Jan 18 17:36:20:189 2010 DeviceA DLDP/1/TrapOfUnidirectional: -Slot=1; Trap
1.3.6.1.4.1.25506.2.43.2.1.1 : DLDP detects a unidirectional link in port 17825793.

%Jan 18 17:36:20:189 2010 DeviceA IFNET/3/LINK_UPDOWN: GigabitEthernet1/0/50 link
status is DOWN.

%Jan 18 17:36:20:190 2010 DeviceA DLDP/3/DLDP_UNIDIRECTION_AUTO: -Slot=1; DLDP
detects a unidirectional link on port GigabitEthernet1/0/50. The transceiver has
malfunction in the Tx direction or cross-connected links exist between the local device
and its neighbor. The shutdown mode is AUTO. DLDP shuts down the port.

%Jan 15 16:54:56:040 2010 DeviceA DLDP/3/DLDP_UNIDIRECTION_AUTO_ENHANCE: -Slot=1; In
enhanced DLDP mode, port GigabitEthernet1/0/49 cannot detect its aged-out neighbor.
The transceiver has malfunction in the Tx direction or cross-connected links exist
between the local device and its neighbor. The shutdown mode is AUTO. DLDP shuts down
the port.
```

The output shows that the link status of both GigabitEthernet 1/0/49 and GigabitEthernet 1/0/50 is down, and DLDP has detected a unidirectional link on both ports and has automatically shut them down.

Assume that in this example, the unidirectional links are caused by cross-connected fibers. Correct the fiber connections on detecting the unidirectional link problem. As a result, the ports shut down by DLDP automatically recover, and Device A displays the following log information:

```
<DeviceA>
#Jan 18 17:47:33:869 2010 DeviceA IFNET/3/LINK_UPDOWN: GigabitEthernet1/0/49 link
status is UP.

#Jan 18 17:47:35:894 2010 DeviceA IFNET/3/LINK_UPDOWN: GigabitEthernet1/0/50 link
status is UP.
```

The output shows that the link status of both GigabitEthernet 1/0/49 and GigabitEthernet 1/0/50 is now up.

## Manually shutting down unidirectional links

### Network requirements

- As shown in [Figure 12](#), Device A and Device B are connected with two fiber pairs.
- Configure DLDP to send information when a unidirectional link is detected, to remind the network administrator to manually shut down the faulty port.

**Figure 12 Network diagram**

### Configuration procedure

#### 1. Configure Device A:

# Enable DLDP globally.

```
<DeviceA> system-view
[DeviceA] dldp enable
```

# Configure GigabitEthernet 1/0/49 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

```
[DeviceA] interface gigabitethernet 1/0/49
[DeviceA-GigabitEthernet1/0/49] duplex full
[DeviceA-GigabitEthernet1/0/49] speed 1000
[DeviceA-GigabitEthernet1/0/49] dldp enable
[DeviceA-GigabitEthernet1/0/49] quit
```

# Configure GigabitEthernet 1/0/50 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

```
[DeviceA] interface gigabitethernet 1/0/50
```

```
[DeviceA-GigabitEthernet1/0/50] duplex full
[DeviceA-GigabitEthernet1/0/50] speed 1000
[DeviceA-GigabitEthernet1/0/50] dldp enable
[DeviceA-GigabitEthernet1/0/50] quit
```

# Set the DLDP mode to enhanced.

```
[DeviceA] dldp work-mode enhance
```

# Set the port shutdown mode to manual.

```
[DeviceA] dldp unidirectional-shutdown manual
```

## 2. Configure Device B:

# Enable DLDP globally.

```
<DeviceB> system-view
```

```
[DeviceB] dldp enable
```

# Configure GigabitEthernet 1/0/49 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/49
[DeviceB-GigabitEthernet1/0/49] duplex full
[DeviceB-GigabitEthernet1/0/49] speed 1000
[DeviceB-GigabitEthernet1/0/49] dldp enable
[DeviceB-GigabitEthernet1/0/49] quit
```

# Configure GigabitEthernet 1/0/50 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/50
[DeviceB-GigabitEthernet1/0/50] duplex full
[DeviceB-GigabitEthernet1/0/50] speed 1000
[DeviceB-GigabitEthernet1/0/50] dldp enable
[DeviceB-GigabitEthernet1/0/50] quit
```

# Set the DLDP mode to enhanced.

```
[DeviceB] dldp work-mode enhance
```

# Set the port shutdown mode to manual.

```
[DeviceB] dldp unidirectional-shutdown manual
```

## 3. Verify the configuration:

After the configurations are complete, you can use the **display dldp** command to display the DLDP configuration information on ports.

# Display the DLDP configuration information on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
DLDP global status : enable
DLDP interval : 5s
DLDP work-mode : enhance
DLDP authentication-mode : none
DLDP unidirectional-shutdown : manual
DLDP delaydown-timer : 1s
The number of enabled ports is 2.
```

```
Interface GigabitEthernet1/0/49
DLDP port state : advertisement
DLDP link state : up
```

```
The neighbor number of the port is 1.
 Neighbor mac address : 0023-8956-3600
 Neighbor port index : 59
 Neighbor state : two way
 Neighbor aged time : 11
```

```
Interface GigabitEthernet1/0/50
 DLDP port state : advertisement
 DLDP link state : up
 The neighbor number of the port is 1.
 Neighbor mac address : 0023-8956-3600
 Neighbor port index : 60
 Neighbor state : two way
 Neighbor aged time : 12
```

The output shows that both GigabitEthernet 1/0/49 and GigabitEthernet 1/0/50 are in Advertisement state, which means both links are bidirectional.

# Enable system information monitoring on Device A, and enable the display of log and trap information.

```
[DeviceA] quit
<DeviceA> terminal monitor
<DeviceA> terminal logging
<DeviceA> terminal trapping
```

The following log and trap information is displayed on Device A:

```
<DeviceA>
#Jan 18 18:10:38:481 2010 DeviceA DLDP/1/TrapOfUnidirectional: -Slot=1; Trap
1.3.6.1.4.1.25506.2.43.2.1.1 : DLDP detects a unidirectional link in port 17825792.
```

```
%Jan 18 18:10:38:481 2010 DeviceA DLDP/3/DLDP_UNIDIRECTION_MANUAL: -Slot=1; DLDP
detects a unidirectional link on port GigabitEthernet1/0/49. The transceiver has
malfunction in the Tx direction or cross-connected links exist between the local device
and its neighbor. The shutdown mode is MANUAL. The port needs to be shut down by the
user.
```

```
#Jan 18 18:10:38:618 2010 DeviceA DLDP/1/TrapOfUnidirectional: -Slot=1; Trap
1.3.6.1.4.1.25506.2.43.2.1.1 : DLDP detects a unidirectional link in port 17825793.
```

```
%Jan 18 18:10:38:618 2010 DeviceA DLDP/3/DLDP_UNIDIRECTION_MANUAL: -Slot=1; DLDP
detects a unidirectional link on port GigabitEthernet1/0/50. The transceiver has
malfunction in the Tx direction or cross-connected links exist between the local device
and its neighbor. The shutdown mode is MANUAL. The port needs to be shut down by the
user.
```

The output shows that DLDP has detected a unidirectional link on both GigabitEthernet 1/0/49 and GigabitEthernet 1/0/50, and is asking you to shut down the faulty ports manually.

After you shut down GigabitEthernet 1/0/49 and GigabitEthernet 1/0/50, the following log information is displayed:

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/49
[DeviceA-GigabitEthernet1/0/49] shutdown
%Jan 18 18:16:12:044 2010 DeviceA IFNET/3/LINK_UPDOWN: GigabitEthernet1/0/49 link
status is DOWN.
```

```
[DeviceA-GigabitEthernet1/0/49] quit
[DeviceA] interface gigabitethernet 1/0/50
[DeviceA-GigabitEthernet1/0/50] shutdown
%Jan 18 18:18:03:583 2010 DeviceA IFNET/3/LINK_UPDOWN: GigabitEthernet1/0/50 link
status is DOWN.
```

The output shows that the link status of both GigabitEthernet 1/0/49 and GigabitEthernet 1/0/50 is down.

Assume that in this example, the unidirectional links are caused by cross-connected fibers. Correct the fiber connections, and then bring up the ports shut down earlier.

# On Device A, bring up GigabitEthernet 1/0/49 and GigabitEthernet 1/0/50:

```
[DeviceA-GigabitEthernet1/0/50] undo shutdown
[DeviceA-GigabitEthernet1/0/50]
%Jan 18 18:22:11:698 2010 DeviceA IFNET/3/LINK_UPDOWN: GigabitEthernet1/0/50 link
status is UP.
[DeviceA-GigabitEthernet1/0/50] quit
[DeviceA] interface gigabitethernet 1/0/49
[DeviceA-GigabitEthernet1/0/49] undo shutdown
[DeviceA-GigabitEthernet1/0/49]
%Jan 18 18:22:46:065 2010 DeviceA IFNET/3/LINK_UPDOWN: GigabitEthernet1/0/49 link
status is UP.
```

The output shows that the link status of both GigabitEthernet 1/0/49 and GigabitEthernet 1/0/50 is now up.

## Troubleshooting DLDAP

### Symptom

Two DLDAP-enabled devices, Device A and Device B, are connected through two fiber pairs, in which two fibers are cross-connected. The unidirectional links cannot be detected; all the four ports involved are in Advertisement state.

### Analysis

The problem can be caused by the following.

- The intervals to send Advertisement packets on Device A and Device B are not the same.
- DLDAP authentication modes/passwords on Device A and Device B are not the same.

### Solution

Make sure the interval to send Advertisement packets, the authentication mode, and the password configured on Device A and Device B are the same.

# Configuring RRPP

## RRPP overview

The Rapid Ring Protection Protocol (RRPP) is a link layer protocol designed for Ethernet rings. RRPP can prevent broadcast storms caused by data loops when an Ethernet ring is healthy, and rapidly restore the communication paths between the nodes in the event that a link is disconnected on the ring.

## Background

Metropolitan area networks (MANs) and enterprise networks usually use the ring structure to improve reliability. However, services will be interrupted if any node in the ring network fails. A ring network usually uses Resilient Packet Ring (RPR) or Ethernet rings. RPR is high in cost because it needs dedicated hardware. Contrarily, the Ethernet ring technology is more mature and economical, so it is increasingly widely used in MANs and enterprise networks.

Rapid Spanning Tree Protocol (RSTP), Per VLAN Spanning Tree (PVST), Multiple Spanning Tree Protocol (MSTP), and RRPP can eliminate Layer-2 loops. RSTP, PVST, and MSTP are mature. However, they take several seconds to converge. RRPP is an Ethernet ring-specific data link layer protocol, and it converges faster than RSTP, PVST, and MSTP. Additionally, the convergence time of RRPP is independent of the number of nodes in the Ethernet ring. RRPP can be applied to large-diameter networks.

## Basic concepts in RRPP

Figure 13 RRPP networking diagram

### RRPP domain

The interconnected devices with the same domain ID and control VLANs constitute an RRPP domain. An RRPP domain contains the following elements—primary ring, subring, control VLAN, master node, transit node, primary port, secondary port, common port, edge port, and so on.

As shown in Figure 13, Domain 1 is an RRPP domain, including two RRPP rings: Ring 1 and Ring 2. All the nodes on the two RRPP rings belong to the RRPP domain.

## RRPP ring

A ring-shaped Ethernet topology is called an "RRPP ring". RRPP rings fall into two types: primary ring and subring. You can configure a ring as either the primary ring or a subring by specifying its ring level. The primary ring is of level 0, and a subring is of level 1. An RRPP domain contains one or multiple RRPP rings, one serving as the primary ring and the others serving as subrings. A ring can be in one of the following states:

- **Health state**—All the physical links on the Ethernet ring are connected
- **Disconnect state**—Some physical links on the Ethernet ring are broken

As shown in [Figure 13](#), Domain 1 contains two RRPP rings: Ring 1 and Ring 2. The level of Ring 1 is set to 0, and that of Ring 2 is set to 1. Ring 1 is configured as the primary ring, and Ring 2 is configured as a subring.

## Control VLAN and data VLAN

### 1. Control VLAN

In an RRPP domain, a control VLAN is a VLAN dedicated to transferring Rapid Ring Protection Protocol Data Units (RRPPDUs). On a device, the ports accessing an RRPP ring belong to the control VLANs of the ring, and only such ports can join the control VLANs.

An RRPP domain is configured with two control VLANs: one primary control VLAN, which is the control VLAN for the primary ring, and one secondary control VLAN, which is the control VLAN for subrings. All subrings in the same RRPP domain share the same secondary control VLAN. After you specify a VLAN as the primary control VLAN, the system automatically configures the VLAN whose ID is the primary control VLAN ID plus one as the secondary control VLAN.

IP address configuration is prohibited on the control VLAN interfaces.

### 2. Data VLAN

A data VLAN is a VLAN dedicated to transferring data packets. Both RRPP ports and non-RRPP ports can be assigned to a data VLAN.

## Node

Each device on an RRPP ring is a node. The role of a node is configurable. RRPP has the following node roles:

- **Master node**—Each ring has one and only one master node. The master node initiates the polling mechanism and determines the operations to be performed after a change in topology.
- **Transit node**—Transit nodes include all the nodes except the master node on the primary ring and all the nodes on subrings except the master nodes and the nodes where the primary ring intersects with the subrings. A transit node monitors the state of its directly-connected RRPP links and notifies the master node of the link state changes, if any. Based on the link state changes, the master node decides the operations to be performed.
- **Edge node**—A node residing on both the primary ring and a subring at the same time. An edge node is a special transit node that serves as a transit node on the primary ring and an edge node on the subring.
- **Assistant-edge node**—A node residing on both the primary ring and a subring at the same time. An assistant-edge node is a special transit node that serves as a transit node on the primary ring and an assistant-edge node on the subring. This node works in conjunction with the edge node to detect the integrity of the primary ring and to perform loop guard.

As shown in [Figure 13](#), Ring 1 is the primary ring and Ring 2 is a subring. Device A is the master node of Ring 1, and Device B, Device C, and Device D are the transit nodes of Ring 1. Device E is the master node of Ring 2, Device B is the edge node of Ring 2, and Device C is the assistant-edge node of Ring 2.

## Primary port and secondary port

Each master node or transit node has two ports connected to an RRPP ring, one serving as the primary port and the other serving as the secondary port. You can determine the port's role.

1. In terms of functionality, the primary port and the secondary port of a master node have the following differences:
  - The primary port and the secondary port are designed to play the role of sending and receiving loop-detect packets respectively.
  - When an RRPP ring is in Health state, the secondary port of the master node will logically deny data VLANs and permit only the packets of the control VLANs.
  - When an RRPP ring is in Disconnect state, the secondary port of the master node will permit data VLANs (forward packets of data VLANs).
2. In terms of functionality, the primary port and the secondary port of a transit node have no difference. Both are designed for transferring protocol packets and data packets over an RRPP ring.

As shown in [Figure 13](#), Device A is the master node of Ring 1. Port 1 and Port 2 are the primary port and the secondary port of the master node on Ring 1 respectively. Device B, Device C, and Device D are the transit nodes of Ring 1. Their Port 1 and Port 2 are the primary port and the secondary port on Ring 1 respectively.

## Common port and edge port

The ports connecting the edge node and assistant-edge node to the primary ring are common ports. The ports connecting the edge node and assistant-edge node only to the subrings are edge ports.

As shown in [Figure 13](#), Device B and Device C lie on Ring 1 and Ring 2. Device B's Port 1 and Port 2 and Device C's Port 1 and Port 2 access the primary ring, so they are common ports. Device B's Port 3 and Device C's Port 3 access only the subring, so they are edge ports.

## RRPP ring group

To reduce Edge-Hello traffic, you can configure a group of subrings on the edge node or assistant-edge node. For more information about Edge-Hello packets, see "[RRPPDU](#)." You must configure a device as the edge node of these subrings, and another device as the assistant-edge node of these subrings. Additionally, the subrings of the edge node and assistant-edge node must connect to the same subring packet tunnels in major ring (SRPTs) so that Edge-Hello packets of the edge node of these subrings travel to the assistant-edge node of these subrings over the same link.

An RRPP ring group configured on the edge node is an edge node RRPP ring group, and an RRPP ring group configured on an assistant-edge node is an assistant-edge node RRPP ring group. Up to one subring in an edge node RRPP ring group is allowed to send Edge-Hello packets.

# RRPPDU

**Table 18 RRPPDU types and their functions**

Type	Description
Hello	The master node initiates Hello packets to detect the integrity of a ring in a network.
Link-Down	The transit node, the edge node, or the assistant-edge node initiates Link-Down packets to notify the master node of the disappearance of a ring in case of a link failure.

Type	Description
Common-Flush-FDB	The master node initiates Common-Flush-FDB (FDB stands for Forwarding Database) packets to instruct the transit nodes to update their own MAC entries and ARP/ND entries when an RRPP ring transits to Disconnect state.
Complete-Flush-FDB	The master node initiates Complete-Flush-FDB packets to instruct the transit nodes to update their own MAC entries and ARP/ND entries and release blocked ports from being blocked temporarily when an RRPP ring transits to Health state.
Edge-Hello	The edge node initiates Edge-Hello packets to examine the SRPTs between the edge node and the assistant-edge node.
Major-Fault	The assistant-edge node initiates Major-Fault packets to notify the edge node of SRPT failure when an SRPT between edge node and assistant-edge node is torn down.

**NOTE:**

RRPPDUs of subrings are transmitted as data packets in the primary ring, and RRPPDUs of the primary ring can only be transmitted within the primary ring.

## RRPP timers

When RRPP checks the link state of an Ethernet ring, the master node sends Hello packets out of the primary port according to the Hello timer and determines whether its secondary port receives the Hello packets based on the Fail timer.

- The Hello timer specifies the interval at which the master node sends Hello packets out of the primary port.
- The Fail timer specifies the maximum delay between the master node sending Hello packets out of the primary port and the secondary port receiving the Hello packets from the primary port. If the secondary port receives the Hello packets sent by the local master node before the Fail timer expires, the overall ring is in Health state. Otherwise, the ring transits into the Disconnect state.

**NOTE:**

In an RRPP domain, a transit node learns the Hello timer value and the Fail timer value on the master node through the received Hello packets, ensuring that all nodes in the ring network are consistent in the two timer settings.

## How RRPP works

### Polling mechanism

The polling mechanism is used by the master node of an RRPP ring to check the Health state of the ring network.

The master node periodically sends Hello packets out of its primary port, and these Hello packets travel through each transit node on the ring in turn:

- If the ring is complete, the secondary port of the master node will receive Hello packets before the Fail timer expires and the master node will keep the secondary port blocked.
- If the ring is torn down, the secondary port of the master node will fail to receive Hello packets before the Fail timer expires. The master node will release the secondary port from blocking data

VLANs and sending Common-Flush-FDB packets to instruct all transit nodes to update their own MAC entries and ARP/ND entries.

### Link down alarm mechanism

The transit node, the edge node or the assistant-edge node sends Link-Down packets to the master node immediately when they find any of its own ports belonging to an RRPP domain are down. Upon the receipt of a Link-Down packet, the master node releases the secondary port from blocking data VLANs and sending Common-Flush-FDB packet to instruct all the transit nodes, the edge nodes, and the assistant-edge nodes to update their own MAC entries and ARP/ND entries. After each node updates its own entries, traffic is switched to the normal link.

### Ring recovery

The master node may find that the ring is restored after a period of time after the ports belonging to the RRPP domain on the transit nodes, the edge nodes, or the assistant-edge nodes are brought up again. A temporary loop may arise in the data VLAN during this period. As a result, broadcast storm occurs.

To prevent temporary loops, non-master nodes block them immediately (and permit only the packets of the control VLAN to pass through) when they find their ports accessing the ring are brought up again. The blocked ports are activated only when the nodes are sure that no loop will be brought forth by these ports.

### Broadcast storm suppression mechanism in a multi-homed subring in case of SRPT failure

As shown in [Figure 17](#), Ring 1 is the primary ring, and Ring 2 and Ring 3 are subrings. When the two SRPTs between the edge node and the assistant-edge node are down, the master nodes of Ring 2 and Ring 3 will open their respective secondary ports, generating a loop among Device B, Device C, Device E, and Device F. As a result, a broadcast storm occurs.

To prevent generating this loop, the edge node will block the edge port temporarily. The blocked edge port is activated only when the edge node is sure that no loop will be brought forth when the edge port is activated.

### Load balancing

In a ring network, maybe traffic of multiple VLANs is transmitted at the same time. RRPP can implement load balancing for the traffic by transmitting traffic of different VLANs along different paths.

By configuring an individual RRPP domain for transmitting the traffic of the specified VLANs (protected VLANs) in a ring network, traffic of different VLANs can be transmitted according to different topologies in the ring network. In this way, load balancing is achieved.

As shown in [Figure 18](#), Ring 1 is configured as the primary ring of Domain 1 and Domain 2, which are configured with different protected VLANs. Device A is the master node of Ring 1 in Domain 1, and Device B is the master node of Ring 1 in Domain 2. With such configurations, traffic of different VLANs can be transmitted on different links to achieve load balancing in the single-ring network.

### RRPP ring group

In an edge node RRPP ring group, only an activated subring with the lowest domain ID and ring ID can send Edge-Hello packets. In an assistant-edge node RRPP ring group, any activated subring that has received Edge-Hello packets will forward these packets to the other activated subrings. With an edge node RRPP ring group and an assistant-edge node RRPP ring group configured, only one subring sends Edge-Hello packets on the edge node, and only one subring receives Edge-Hello packets on the assistant-edge node, reducing CPU workload.

As shown in [Figure 17](#), Device B is the edge node of Ring 2 and Ring 3, and Device C is the assistant-edge node of Ring 2 and Ring 3. Device B and Device C must send or receive Edge-Hello

packets frequently. If more subrings are configured or if load balancing is configured for multiple domains, Device B and Device C will send or receive a mass of Edge-Hello packets.

To reduce Edge-Hello traffic, you can assign Ring 2 and Ring 3 to an RRPP ring group configured on the edge node Device B and assign Ring 2 and Ring 3 to an RRPP ring group configured on Device C. After such configurations, if all rings are activated, only Ring 2 on Device B sends Edge-Hello packets.

## Typical RRPP networking

Here are several typical networking applications.

### Single ring

As shown in [Figure 14](#), only a single ring exists in the network topology. You only need to define an RRPP domain.

**Figure 14 Schematic diagram for a single-ring network**

### Tangent rings

As shown in [Figure 15](#), two or more rings are in the network topology and only one common node exists between rings. You must define an RRPP domain for each ring.

Figure 15 Schematic diagram for a tangent-ring network

### Intersecting rings

As shown in Figure 16, two or more rings are in the network topology and two common nodes exist between rings. You only need to define an RRPP domain and configure one ring as the primary ring and the other rings as subrings.

Figure 16 Schematic diagram for an intersecting-ring network

### Dual homed rings

As shown in Figure 17, two or more rings are in the network topology and two similar common nodes exist between rings. You only need to define an RRPP domain and configure one ring as the primary ring and the other rings as subrings.

**Figure 17 Schematic diagram for a dual-homed-ring network**

### Single-ring load balancing

In a single-ring network, you can achieve load balancing by configuring multiple domains.

As shown in Figure 18, Ring 1 is configured as the primary ring of both Domain 1 and Domain 2. Domain 1 and Domain 2 are configured with different protected VLANs. In Domain 1, Device A is configured as the master node of Ring 1. In Domain 2, Device B is configured as the master node of Ring 1. Such configurations enable the ring to block different links based on VLANs, and single-ring load balancing is achieved.

**Figure 18 Schematic diagram for a single-ring load balancing network**

### Intersecting-ring load balancing

In an intersecting-ring network, you can also achieve load balancing by configuring multiple domains.

As shown in Figure 19, Ring 1 is the primary ring, and Ring 2 is the subring in both Domain 1 and Domain 2. Domain 1 and Domain 2 are configured with different protected VLANs. Device A is configured as the master node of Ring 1 in Domain 1. Device D is configured as the master node of Ring 1 in Domain 2. Device E is configured as the master node of Ring 2 in both Domain 1 and Domain 2. However, different ports on Device E are blocked in Domain 1 and Domain 2. With the configurations, you can enable traffic of different VLANs to travel over different paths in the subring and primary ring to achieve intersecting-ring load balancing.

Figure 19 Schematic diagram for an intersecting-ring load balancing network

## Protocols and standards

RFC 3619 *Extreme Networks' Ethernet Automatic Protection Switching (EAPS) Version 1* is related to RRPP.

## RRPP configuration task list

You can create RRPP domains based on service planning, specify control VLANs and data VLANs for each RRPP domain, and then determine the ring roles and node roles based on the traffic paths in each RRPP domain.

Complete the following tasks to configure RRPP:

Task	Remarks
Creating an RRPP domain	Required Perform this task on all nodes in the RRPP domain.
Configuring control VLANs	Required Perform this task on all nodes in the RRPP domain.
Configuring protected VLANs	Required Perform this task on all nodes in the RRPP domain.
Configuring RRPP rings	Configuring RRPP ports Required Perform this task on all nodes in the RRPP domain.
	Configuring RRPP nodes Required Perform this task on all nodes in the RRPP domain.
Activating an RRPP domain	Required Perform this task on all nodes in the RRPP domain.
Configuring RRPP timers	Optional Perform this task on the master node in the RRPP domain.

Task	Remarks
Configuring an RRPP ring group	Optional Perform this task on the edge node and assistant-edge node in the RRPP domain.

**NOTE:**

- RRPP does not have an auto election mechanism, so you must configure each node in the ring network properly for RRPP to monitor and protect the ring network.
- Before configuring RRPP, you must construct a ring-shaped Ethernet topology physically.

## Creating an RRPP domain

When creating an RRPP domain, specify a domain ID, which uniquely identifies an RRPP domain. All devices in the same RRPP domain must be configured with the same domain ID.

Perform this configuration on devices you want to configure as nodes in the RRPP domain.

To create an RRPP domain:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Create an RRPP domain, and enter RRPP domain view.	<b>rrpp domain <i>domain-id</i></b>

## Configuring control VLANs

Before configuring RRPP rings in an RRPP domain, configure the same control VLANs for all nodes in the RRPP domain first.

Perform this configuration on all nodes in the RRPP domain to be configured.

## Configuration guidelines

- When you configure existing VLANs as control VLANs, the system prompts errors.
- To ensure proper forwarding of RRPPDUs, do not enable 802.1Q in 802.1Q (QinQ) or VLAN mapping on the control VLANs.
- To make sure RRPPDUs can be sent and received correctly, do not configure the default VLAN of a port accessing an RRPP ring as the primary control VLAN or the secondary control VLAN.
- To transparently transmit RRPPDUs on a device not configured with RRPP, you must ensure only the two ports connecting the device to the RRPP ring permit the packets of the control VLANs. Otherwise, the packets from other VLANs may go into the control VLANs in transparent transmission mode and strike the RRPP ring.

## Configuration procedure

To configure control VLANs:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Enter RRPP domain view.	<b>rrpp domain</b> <i>domain-id</i>
3. Configure the primary control VLAN for the RRPP domain.	<b>control-vlan</b> <i>vlan-id</i>

## Configuring protected VLANs

Before configuring RRPP rings in an RRPP domain, configure the same protected VLANs for all nodes in the RRPP domain first. All VLANs that the RRPP ports are assigned to should be protected by the RRPP domains.

You can configure protected VLANs through referencing Multiple Spanning Tree Instances (MSTIs). Before configuring protected VLANs, configure the mappings between MSTIs and the VLANs to be protected (a device working in PVST mode automatically maps VLANs to MSTIs). For more information about MSTIs and PVST, see *Layer 2—LAN Switching Configuration Guide*.

Perform this configuration on all nodes in the RRPP domain to be configured.

To configure protected VLANs:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter MST region view.	<b>stp region-configuration</b>	Not required if the device is operating in PVST mode. For more information about the command, see <i>Layer 2—LAN Switching Command Reference</i> .
3. Configure the VLAN-to-instance mapping table.	Approach 1: <b>instance</b> <i>instance-id</i> <b>vlan</b> <i>vlan-list</i> Approach 2: <b>vlan-mapping modulo</b> <i>modulo</i>	Optional. Use either approach. All VLANs in an MST region are mapped to MSTI 0 (the CIST) by default. Not required if the device is operating in PVST mode. For more information about the commands, see <i>Layer 2—LAN Switching Command Reference</i> .
4. Activate MST region configuration manually.	<b>active region-configuration</b>	Not required if the device is operating in PVST mode. For more information about the command, see <i>Layer 2—LAN Switching Command Reference</i> .

Step	Command	Remarks
5.	Display the currently activated configuration information of the MST region. <b>display stp region-configuration</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Optional. Available in any view. The command output includes VLAN-to-instance mappings. For more information about the command, see <i>Layer 2—LAN Switching Command Reference</i> .
6.	Return to system view. <b>quit</b>	Not required if the device is operating in PVST mode.
7.	Enter RRPP domain view. <b>rrpp domain</b> <i>domain-id</i>	N/A
8.	Configure protected VLANs for the RRPP domain. <b>protected-vlan reference-instance</b> <i>instance-id-list</i>	By default, no protected VLAN is configured for an RRPP domain.

**NOTE:**

When configuring load balancing, you must configure different protected VLANs for different RRPP domains.

## Configuring RRPP rings

When configuring an RRPP ring, you must make some configurations on the ports connecting each node to the RRPP ring before configuring the nodes.

RRPP ports (connecting devices to an RRPP ring) must be Layer-2 Ethernet ports or Layer-2 aggregate interfaces and cannot be member ports of any aggregation group, service loopback group, or smart link group.

After configuring a Layer-2 aggregate interface as an RRPP port, you can still assign ports to or remove ports from the aggregation group corresponding to the interface.

## Configuring RRPP ports

Perform this configuration on each node's ports intended for accessing RRPP rings.

### Configuration guidelines

- RRPP ports always allow packets of the control VLANs to pass through.
- For more information about the **port link-type trunk**, **port trunk permit vlan**, and **undo stp enable** commands, see *Layer 2—LAN Switching Command Reference*.
- The 802.1p priority of trusted packets on the RRPP ports must be configured, so that RRPP packets take higher precedence than data packets when passing through the RRPP ports. For more information about the **qos trust dot1p** command, see *ACL and QoS Command Reference*.
- Do not enable OAM remote loopback function on an RRPP port. Otherwise, it may cause a temporary broadcast storm.
- Do not configure a port accessing an RRPP ring as the destination port of a mirroring group.
- Do not configure physical-link-state change suppression time on a port accessing an RRPP ring to accelerate topology convergence. For more information, see the **undo link-delay** command (*Layer 2—LAN Switching Command Reference*).

## Configuration procedure

To configure RRPP ports:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregation interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the link type of the interface as trunk.	<b>port link-type trunk</b>	By default, the link type of an interface is access.
4. Assign the trunk port to the protected VLANs of the RRPP domain.	<b>port trunk permit vlan</b> { <i>vlan-id-list</i>   <b>all</b> }	By default, a trunk port allows only packets of VLAN 1 to pass through.
5. Disable the spanning tree feature.	<b>undo stp enable</b>	Enabled by default.
6. Configure the port to trust the 802.1p precedence of the received packets.	<b>qos trust dot1p</b>	By default, the port priority is trusted.

## Configuring RRPP nodes

If a device carries multiple RRPP rings in an RRPP domain, only one ring can be configured as the primary ring on the device, and the role of the device on a subring can only be an edge node or an assistant-edge node.

### Specifying a master node

Perform this configuration on a device to be configured as a master node.

To specify a master node:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Enter RRPP domain view.	<b>rrpp domain</b> <i>domain-id</i>
3. Specify the current device as the master node of the ring, and specify the primary port and the secondary port.	<b>ring</b> <i>ring-id</i> <b>node-mode master</b> [ <b>primary-port</b> <i>interface-type interface-number</i> ] [ <b>secondary-port</b> <i>interface-type interface-number</i> ] <b>level</b> <i>level-value</i>

### Specifying a transit node

Perform this configuration on a device to be configured as a transit node.

To specify a transit node:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Enter RRPP domain view.	<b>rrpp domain</b> <i>domain-id</i>
3. Specify the current device as a transit node of the ring, and specify the primary port and the secondary port.	<b>ring</b> <i>ring-id</i> <b>node-mode transit</b> [ <b>primary-port</b> <i>interface-type interface-number</i> ] [ <b>secondary-port</b> <i>interface-type interface-number</i> ] <b>level</b> <i>level-value</i>

## Specifying an edge node

When configuring an edge node, you must first configure the primary ring before configuring the subrings.

Perform this configuration on a device to be configured as an edge node.

To specify an edge node:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Enter RRPP domain view.	<b>rrpp domain</b> <i>domain-id</i>
3. Specify the current device as a transit node of the primary ring, and specify the primary port and the secondary port.	<b>ring</b> <i>ring-id</i> <b>node-mode transit</b> [ <b>primary-port</b> <i>interface-type interface-number</i> ] [ <b>secondary-port</b> <i>interface-type interface-number</i> ] <b>level</b> <i>level-value</i>
4. Specify the current device as the edge node of a subring, and specify the edge port.	<b>ring</b> <i>ring-id</i> <b>node-mode edge</b> [ <b>edge-port</b> <i>interface-type interface-number</i> ]

## Specifying an assistant-edge node

When configuring an assistant-edge node, you must first configure the primary ring before configuring the subrings.

Perform this configuration on a device to be configured as an assistant-edge node.

To specify an assistant-edge node:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Enter RRPP domain view.	<b>rrpp domain</b> <i>domain-id</i>
3. Specify the current device as a transit node of the primary ring, and specify the primary port and the secondary port.	<b>ring</b> <i>ring-id</i> <b>node-mode transit</b> [ <b>primary-port</b> <i>interface-type interface-number</i> ] [ <b>secondary-port</b> <i>interface-type interface-number</i> ] <b>level</b> <i>level-value</i>
4. Specify the current device as the assistant-edge node of the subring, and specify an edge port.	<b>ring</b> <i>ring-id</i> <b>node-mode assistant-edge</b> [ <b>edge-port</b> <i>interface-type interface-number</i> ]

# Activating an RRPP domain

To activate an RRPP domain on the current device, enable the RRPP protocol and RRPP rings for the RRPP domain on the current device.

To prevent Hello packets of subrings from being looped on the primary ring, enable the primary ring on its master node before enabling the subrings on their separate master nodes. On an edge node or assistant-edge node, enable/disable the primary ring and subrings separately:

- Enable the primary ring of an RRPP domain before enabling the subrings of the RRPP domain.
- Disable the primary ring of an RRPP domain after disabling all subrings of the RRPP domain.

Perform this operation on all nodes in the RRPP domain.

To activate an RRPP domain:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enable RRPP.	<b>rrpp enable</b>	Disabled by default.
3. Enter RRPP domain view.	<b>rrpp domain</b> <i>domain-id</i>	N/A
4. Enable the specified RRPP ring.	<b>ring</b> <i>ring-id</i> <b>enable</b>	Disabled by default.

## Configuring RRPP timers

Perform this configuration on the master node of an RRPP domain.

To configure RRPP timers:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter RRPP domain view.	<b>rrpp domain</b> <i>domain-id</i>	N/A
3. Configure the Hello timer and Fail timer for the RRPP domain.	<b>timer hello-timer</b> <i>hello-value</i> <b>fail-timer</b> <i>fail-value</i>	By default, the Hello timer value is 1 second, and the Fail timer value is 3 seconds.

### NOTE:

- The Fail timer value must be equal to or greater than three times the Hello timer value.
- To avoid temporary loops when the primary ring fails in a dual-homed-ring network, make sure that the difference between the Fail timer value on the master node of the subring and that on the master node of the primary ring is greater than twice the Hello timer value of the master node of the subring.

## Configuring an RRPP ring group

To reduce Edge-Hello traffic, adopt the RRPP ring group mechanism by assigning subrings with the same edge node/assistant-edge node to an RRPP ring group. An RRPP ring group must be configured on both the edge node and the assistant-edge node and can only be configured on these two types of nodes.

Perform this configuration on both the edge node and the assistant-edge node in an RRPP domain.

## Configuration restrictions and guidelines

- You can assign a subring to only one RRPP ring group. Make sure the RRPP ring group configured on the edge node and the RRPP ring group configured on the assistant-edge node contain the same subrings. Otherwise, the RRPP ring group cannot operate properly.
- Make sure the subrings in an RRPP ring group share the same edge node and assistant-edge node and that the edge node and the assistant edge node have the same SRPTs.
- Make sure a device plays the same role on the subrings in an RRPP ring group. The role can be the edge node or the assistant-edge node.
- Make sure the RRPP ring group on the edge node and the RRPP ring group on the assistant-edge node have the same configurations and activation status.

- Make sure that all subrings in an RRPP ring group have the same SRPTs. If the SRPTs of these subrings are configured or modified differently, the RRPP ring group cannot operate properly.

## Configuration procedure

To configure an RRPP ring group:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Create an RRPP ring group and enter RRPP ring group view.	<b>rrpp ring-group</b> <i>ring-group-id</i>
3. Assign the specified subrings to the RRPP ring group.	<b>domain</b> <i>domain-id</i> <b>ring</b> <i>ring-id-list</i>

## Displaying and maintaining RRPP

Task	Command	Remarks
Display brief RRPP information.	<b>display rrpp brief</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view
Display RRPP group configuration information.	<b>display rrpp ring-group</b> [ <i>ring-group-id</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view
Display detailed RRPP information.	<b>display rrpp verbose domain</b> <i>domain-id</i> [ <b>ring</b> <i>ring-id</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view
Display RRPP statistics.	<b>display rrpp statistics domain</b> <i>domain-id</i> [ <b>ring</b> <i>ring-id</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view
Clear RRPP statistics.	<b>reset rrpp statistics domain</b> <i>domain-id</i> [ <b>ring</b> <i>ring-id</i> ]	Available in user view

## RRPP configuration examples

### Single ring configuration example

#### Networking requirements

As shown in [Figure 20](#),

- Device A, Device B, Device C, and Device D form RRPP domain 1. Specify the primary control VLAN of RRPP domain 1 as VLAN 4092. RRPP domain 1 protects VLANs 1 through 30.
- Device A, Device B, Device C, and Device D form primary ring 1.
- Specify Device A as the master node of primary ring 1, GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port.
- Specify Device B, Device C, and Device D as the transit nodes of primary ring 1. Specify their GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port.

Figure 20 Network diagram

## Configuration procedure

### 1. Configure Device A:

# Create VLANs 1 through 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

# Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, disable the spanning tree feature, and set the trusted packet priority type to 802.1p priority. Configure the two ports as trunk ports, and assign them to VLANs 1 through 30.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo link-delay
[DeviceA-GigabitEthernet1/0/1] undo stp enable
[DeviceA-GigabitEthernet1/0/1] qos trust dot1p
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] undo link-delay
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] qos trust dot1p
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

# Create RRPP domain 1. Configure VLAN 4092 as the primary control VLAN of RRPP domain 1, and configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA] rrpp domain 1
[DeviceA-rrpp-domain1] control-vlan 4092
```

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the
primary port and GigabitEthernet 1/0/2 as the secondary port, and enable ring 1.
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

# Enable RRPP.

```
[DeviceA] rrpp enable
```

## 2. Configure Device B:

# Create VLANs 1 through 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

# Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, disable the spanning tree feature, and set the trusted packet priority type to 802.1p priority. Configure the two ports as trunk ports, and assign them to VLANs 1 through 30.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] undo link-delay
[DeviceB-GigabitEthernet1/0/1] undo stp enable
[DeviceB-GigabitEthernet1/0/1] qos trust dot1p
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] undo link-delay
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] qos trust dot1p
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

# Create RRPP domain 1. Configure VLAN 4092 as the primary control VLAN of RRPP domain 1, and configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceB] rrpp domain 1
[DeviceB-rrpp-domain1] control-vlan 4092
[DeviceB-rrpp-domain1] protected-vlan reference-instance 1
```

# Configure Device B as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port, and enable ring 1.

```
[DeviceB-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain1] ring 1 enable
[DeviceB-rrpp-domain1] quit
```

# Enable RRPP.

```
[DeviceB] rrpp enable
```

3. Configure Device C:

The configuration on Device C is similar to that on Device B and is not shown here.

4. Configure Device D:

The configuration on Device D is similar to that on Device B and is not shown here.

5. Verify the configuration:

Use the **display** command to view RRPP configuration and operational information on each device.

## Intersecting ring configuration example

### Networking requirements

As shown in [Figure 21](#),

- Device A, Device B, Device C, Device D, and Device E form RRPP domain 1. VLAN 4092 is the primary control VLAN of RRPP domain 1, and RRPP domain 1 protects VLANs 1 through 30.
- Device A, Device B, Device C, and Device D form primary ring 1, and Device B, Device C and Device E form subring 2.
- Device A is the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.
- Device E is the master node of subring 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.
- Device B is the transit node of primary ring 1 and the edge node of subring 2, and GigabitEthernet 1/0/3 is the edge port.
- Device C is the transit node of primary ring 1 and the assistant-edge node of subring 1, and GigabitEthernet 1/0/3 is the edge port.
- Device D is the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.

**Figure 21 Network diagram**

### Configuration procedure

1. Configure Device A:

# Create VLANs 1 through 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

# Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, disable the spanning tree feature, and set the trusted packet priority type to 802.1p priority. Configure the two ports as trunk ports, and assign them to VLANs 1 through 30.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo link-delay
[DeviceA-GigabitEthernet1/0/1] undo stp enable
[DeviceA-GigabitEthernet1/0/1] qos trust dot1p
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] undo link-delay
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] qos trust dot1p
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

# Create RRPP domain 1. Configure VLAN 4092 as the primary control VLAN of RRPP domain 1, and configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA] rrpp domain 1
[DeviceA-rrpp-domain1] control-vlan 4092
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

# Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port, and enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

# Enable RRPP.

```
[DeviceA] rrpp enable
```

## 2. Configure Device B:

# Create VLANs 1 through 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

# Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3, disable the spanning tree feature, and set the trusted packet priority type to 802.1p priority. Configure the three ports as trunk ports, and assign them to VLANs 1 through 30.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] undo link-delay
[DeviceB-GigabitEthernet1/0/1] undo stp enable
[DeviceB-GigabitEthernet1/0/1] qos trust dot1p
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] undo link-delay
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] qos trust dot1p
[DeviceB-GigabitEthernet1/0/2] port link-type trunk

[DeviceE-rrpp-domain1] ring 2 enable
[DeviceE-rrpp-domain1] quit
```

# Enable RRPP.

```
[DeviceE] rrpp enable
```

#### 6. Verify the configuration:

Use the **display** command to view RRPP configuration and operational information on each device.

## Dual homed rings configuration example

### Networking requirements

As shown in [Figure 22](#),

- Device A through Device H form RRPP domain 1. Specify the primary control VLAN of RRPP domain 1 as VLAN 4092, and specify that RRPP domain 1 protects VLANs 1 through 30.
- Device A through Device D form primary ring 1. Device A, Device B, and Device E form subring 2. Device A, Device B, and Device F form subring 3. Device C, Device D, and Device G form subring 4. Device C, Device D, and Device H form subring 5.
- Specify Device A as the master node of primary ring 1, GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Specify Device E as the master node of subring 2, GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Specify Device F as the master node of subring 3, GigabitEthernet 1/0/1 as the primary port and

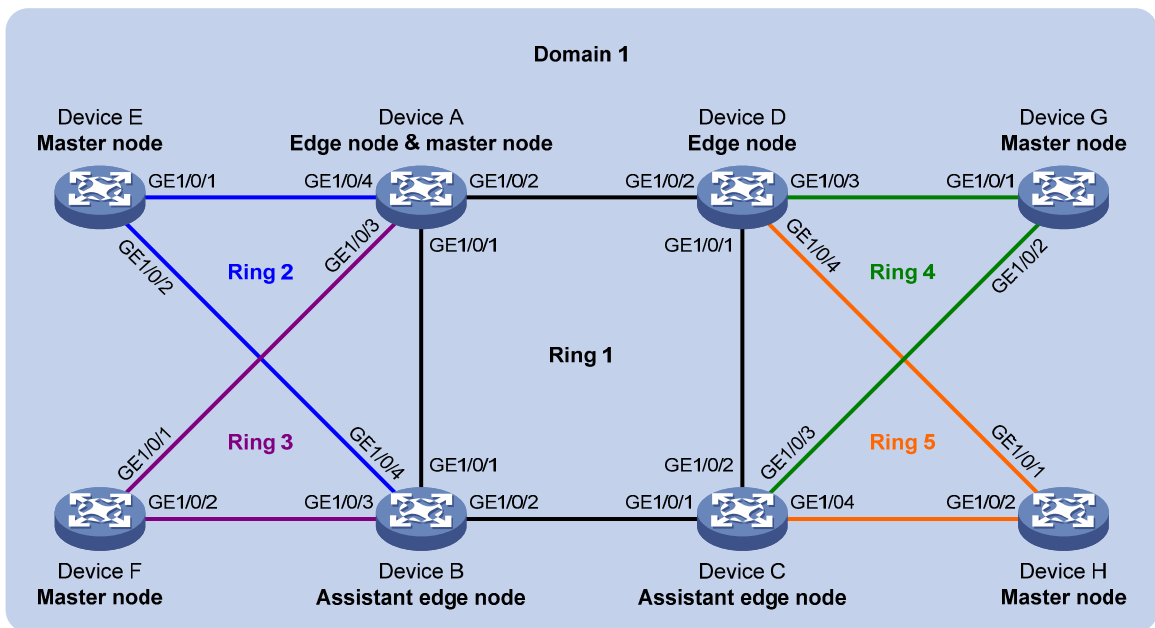

GigabitEthernet 1/0/2 as the secondary port. Specify Device G as the master node of subring 4, GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Specify Device H as the master node of subring 5, GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port.

- Specify Device A as the edge node of the connected subrings, its GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 as the edge ports. Specify Device D as the transit node of the primary ring and edge node of the connected subrings, its GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 as the edge ports. Specify Device B and Device C as the transit node of the primary ring and assistant-edge nodes of the connected subrings, their GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 as the edge ports.

**NOTE:**

Configure the primary and secondary ports on the master nodes properly to make sure that other protocols still work normally when data VLANs are denied by the secondary ports.

**Figure 22 Network diagram**

**Configuration procedure**

- Configure Device A:

# Create VLANs 1 through 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

# Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4, disable the spanning tree feature, and set the trusted packet priority type

to 802.1p priority. Configure the four ports as trunk ports, and assign them to VLANs 1 through 30.

```
[DeviceA] interface gigabitethernet 1/0/1

```

# Configure Device H as the master node of subring 5, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port, and enable subring 5.

```
[DeviceH-rrpp-domain1] ring 5 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 1
[DeviceH-rrpp-domain1] ring 5 enable
[DeviceH-rrpp-domain1] quit
```

# Enable RRPP.

```
[DeviceH] rrpp enable
```

#### 9. Verify the configuration:

Use the **display** command to view RRPP configuration and operational information on each device.

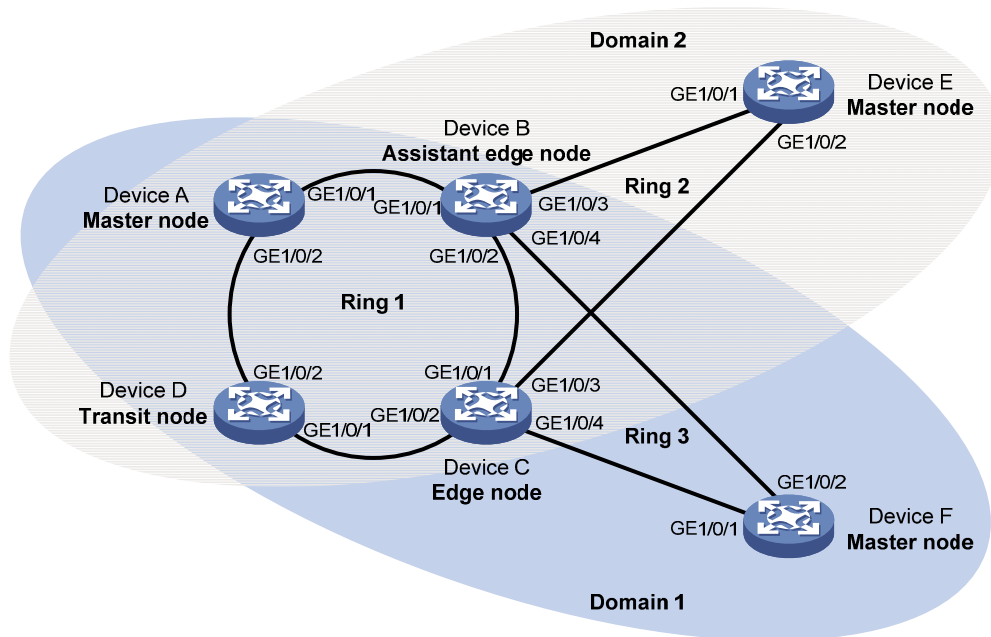

## Intersecting-ring load balancing configuration example

### Networking requirements

As shown in [Figure 23](#),

- Device A, Device B, Device C, Device D, and Device F form RRPP domain 1, and VLAN 100 is the primary control VLAN of the RRPP domain. Device A is the master node of the primary ring, Ring 1; Device D is the transit node of Ring 1; Device F is the master node of the subring Ring 3; Device C is the edge node of the subring Ring 3; Device B is the assistant-edge node of the subring Ring 3.
- Device A, Device B, Device C, Device D, and Device E form RRPP domain 2, and VLAN 105 is the primary control VLAN of the RRPP domain. Device A is the master node of the primary ring, Ring 1; Device D is the transit node of Ring 1; Device E is the master node of the subring Ring 2; Device C is the edge node of the subring Ring 2; Device B is the assistant-edge node of the subring Ring 2.
- Specify VLAN 1 as the protected VLAN of domain 1 and VLAN 2 the protected VLAN of domain 2. You can implement VLAN-based load balancing on Ring 1.
- Because the edge node and assistant-edge node of Ring 2 are the same as those of Ring 3 and the two subrings have the same SRPTs, you can add Ring 2 and Ring 3 to the RRPP ring group to reduce Edge-Hello traffic.

Figure 23 Network diagram

## Configuration procedure

### 1. Configure Device A:

# Create VLANs 1 and 2, map VLAN 1 to MSTI 1 and VLAN 2 to MSTI 2, and activate MST region configuration.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 2
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1
[DeviceA-mst-region] instance 2 vlan 2
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

# Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, disable the spanning tree feature, and set the trusted packet priority type to 802.1p priority. Configure the two ports as trunk ports, and assign them to VLAN 1 and VLAN 2.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo link-delay
[DeviceA-GigabitEthernet1/0/1] undo stp enable
[DeviceA-GigabitEthernet1/0/1] qos trust dot1p
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 2
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] undo link-delay
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] qos trust dot1p
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 2
```

```

[DeviceA-GigabitEthernet1/0/2] quit
Create RRPP domain 1. Configure VLAN 100 as the primary control VLAN of RRPP domain 1,
and configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.
[DeviceA] rrpp domain 1
[DeviceA-rrpp-domain1] control-vlan 100
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the
primary port and GigabitEthernet 1/0/2 as the secondary port, and enable ring 1.
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
Create RRPP domain 2, configure VLAN 105 as the primary control VLAN of RRPP domain 2,
and configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.
[DeviceA] rrpp domain 2
[DeviceA-rrpp-domain2] control-vlan 105
[DeviceA-rrpp-domain2] protected-vlan reference-instance 2
Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/2 as the
master port and GigabitEthernet 1/0/1 as the secondary port, and enable ring 1.
[DeviceA-rrpp-domain2] ring 1 node-mode master primary-port gigabitethernet 1/0/2
secondary-port gigabitethernet 1/0/1 level 0
[DeviceA-rrpp-domain2] ring 1 enable
[DeviceA-rrpp-domain2] quit
Enable RRPP.
[DeviceA] rrpp enable

```

## 2. Configure Device B:

```

Create VLANs 1 and 2, map VLAN 1 to MSTI 1 and VLAN 2 to MSTI 2, and activate MST region
configuration.
<DeviceB> system-view
[DeviceB] vlan 1 to 2
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1
[DeviceB-mst-region] instance 2 vlan 2
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1 and
GigabitEthernet 1/0/2, disable the spanning tree feature, and set the trusted packet priority type
to 802.1p priority. Configure the two ports as trunk ports, and assign them to VLAN 1 and VLAN
2.

[DeviceC-rrpp-domain2] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceC-rrpp-domain2] ring 1 enable

Configure Device C as the edge node of subring 2 in RRPP domain 2, with GigabitEthernet
1/0/3 as the edge port, and enable subring 2.
[DeviceC-rrpp-domain2] ring 2 node-mode edge edge-port gigabitethernet 1/0/3
[DeviceC-rrpp-domain2] ring 2 enable
[DeviceC-rrpp-domain2] quit

Enable RRPP.

```

```
[DeviceC] rrpp enable
```

#### 4. Configure Device D:

# Create VLANs 1 and 2, map VLAN 1 to MSTI 1 and VLAN 2 to MSTI 2, and activate MST region configuration.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 2
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1
[DeviceD-mst-region] instance 2 vlan 2
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

# Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, disable the spanning tree feature, and set the trusted packet priority type to 802.1p priority. Configure the two ports as trunk ports, and assign them to VLAN 1 and VLAN 2.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] undo link-delay
[DeviceD-GigabitEthernet1/0/1] undo stp enable
[DeviceD-GigabitEthernet1/0/1] qos trust dot1p
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 2
[DeviceD-GigabitEthernet1/0/1] quit
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] undo link-delay
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] qos trust dot1p
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 2
[DeviceD-GigabitEthernet1/0/2] quit
```

# Create RRPP domain 1. Configure VLAN 100 as the primary control VLAN of RRPP domain 1, and configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceD] rrpp domain 1
[DeviceD-rrpp-domain1] control-vlan 100
[DeviceD-rrpp-domain1] protected-vlan reference-instance 1
```

# Configure Device D as the transit node of primary ring 1 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port, and enable ring 1.

```
[DeviceD-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain1] ring 1 enable
[DeviceD-rrpp-domain1] quit
```

# Create RRPP domain 2. Configure VLAN 105 as the primary control VLAN of RRPP domain 2, and configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceD] rrpp domain 2
[DeviceD-rrpp-domain2] control-vlan 105
[DeviceD-rrpp-domain2] protected-vlan reference-instance 2
```

# Configure Device D as the transit node of primary ring 1 in RRPP domain 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port, and enable ring 1.

```
[DeviceD-rrpp-domain2] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain2] ring 1 enable
[DeviceD-rrpp-domain2] quit
```

**# Enable RRPP.**

```
[DeviceD] rrpp enable
```

## 5. Configure Device E:

**# Create VLAN 2, map VLAN 2 to MSTI 2, and activate MST region configuration.**

```
<DeviceE> system-view
[DeviceE] vlan 2
[DeviceE-vlan2] quit
[DeviceE] stp region-configuration
[DeviceE-mst-region] instance 2 vlan 2
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

**# Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, disable the spanning tree feature, and set the trusted packet priority type to 802.1p priority. Configure the two ports as trunk ports, remove them from VLAN 1, assign them to VLAN 2, and configure VLAN 2 as their default VLAN.**

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] undo link-delay
[DeviceE-GigabitEthernet1/0/1] undo stp enable
[DeviceE-GigabitEthernet1/0/1] qos trust dot1p
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
[DeviceE-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 2
[DeviceE-GigabitEthernet1/0/1] port trunk pvid vlan 2
[DeviceE-GigabitEthernet1/0/1] quit
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] undo link-delay
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] qos trust dot1p
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceE-GigabitEthernet1/0/2] port trunk pvid vlan 2
[DeviceE-GigabitEthernet1/0/2] quit
```

**# Create RRPP domain 2. Configure VLAN 105 as the primary control VLAN, and configure the VLAN mapped to MSTI 2 as the protected VLAN.**

```
[DeviceE] rrpp domain 2
[DeviceE-rrpp-domain2] control-vlan 105
[DeviceE-rrpp-domain2] protected-vlan reference-instance 2
```

**# Configure Device E as the master mode of subring 2 in RRPP domain 2, with GigabitEthernet 1/0/2 as the primary port and GigabitEthernet 1/0/1 as the secondary port, and enable ring 2.**

```
[DeviceE-rrpp-domain2] ring 2 node-mode master primary-port gigabitethernet 1/0/2
secondary-port gigabitethernet 1/0/1 level 1
[DeviceE-rrpp-domain2] ring 2 enable
[DeviceE-rrpp-domain2] quit
```

# Enable RRPP.

```
[DeviceE] rrpp enable
```

## 6. Configure Device F:

# Create VLAN 1, map VLAN 1 to MSTI 1, and activate MST region configuration.

```
<DeviceF> system-view
```

```
[DeviceF] vlan 1
```

```
[DeviceF-vlan1] quit
```

```
[DeviceF] stp region-configuration
```

```
[DeviceF-mst-region] instance 1 vlan 1
```

```
[DeviceF-mst-region] active region-configuration
```

```
[DeviceF-mst-region] quit
```

# Cancel the physical state change suppression interval setting on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, disable the spanning tree feature, and set the trusted packet priority type to 802.1p priority. Configure the two ports as trunk ports, and assign them to VLAN 1.

```
[DeviceF] interface gigabitethernet 1/0/1
```

```
[DeviceF-GigabitEthernet1/0/1] undo link-delay
```

```
[DeviceF-GigabitEthernet1/0/1] undo stp enable
```

```
[DeviceF-GigabitEthernet1/0/1] qos trust dot1p
```

```
[DeviceF-GigabitEthernet1/0/1] port link-type trunk
```

```
[DeviceF-GigabitEthernet1/0/1] port trunk permit vlan 1
```

```
[DeviceF-GigabitEthernet1/0/1] quit
```

```
[DeviceF] interface gigabitethernet 1/0/2
```

```
[DeviceF-GigabitEthernet1/0/2] undo link-delay
```

```
[DeviceF-GigabitEthernet1/0/2] undo stp enable
```

```
[DeviceF-GigabitEthernet1/0/2] qos trust dot1p
```

```
[DeviceF-GigabitEthernet1/0/2] port link-type trunk
```

```
[DeviceF-GigabitEthernet1/0/2] port trunk permit vlan 1
```

```
[DeviceF-GigabitEthernet1/0/2] quit
```

# Create RRPP domain 1. Configure VLAN 100 as the primary control VLAN, and configure the VLAN mapped to MSTI 1 as the protected VLAN.

```
[DeviceF] rrpp domain 1
```

```
[DeviceF-rrpp-domain1] control-vlan 100
```

```
[DeviceF-rrpp-domain1] protected-vlan reference-instance 1
```

# Configure Device F as the master node of subring 3 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port, and enable subring 3.

```
[DeviceF-rrpp-domain1] ring 3 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 1
```

```
[DeviceF-rrpp-domain1] ring 3 enable
```

```
[DeviceF-rrpp-domain1] quit
```

# Enable RRPP.

```
[DeviceF] rrpp enable
```

## 7. RRPP ring group configurations on Device B and Device C after the configurations.

# Create RRPP ring group 1 on Device B. Add subrings 2 and 3 to the RRPP ring group.

```
[DeviceB] rrpp ring-group 1
```

```
[DeviceB-rrpp-ring-group1] domain 2 ring 2
```

```
[DeviceB-rrpp-ring-group1] domain 1 ring 3
```

# Create RRPP ring group 1 on Device C, and add subrings 2 and 3 to the RRPP ring group.

```
[DeviceC] rrpp ring-group 1
[DeviceC-rrpp-ring-group1] domain 2 ring 2
[DeviceC-rrpp-ring-group1] domain 1 ring 3
```

8. Verify the configuration:

Use the **display** command to view RRPP configuration and operational information on each device.

## Troubleshooting

### Symptom

When the link state is normal, the master node cannot receive Hello packets, and the master node unblocks the secondary port.

### Analysis

The reasons may be:

- RRPP is not enabled on some nodes in the RRPP ring.
- The domain ID or primary control VLAN ID is not the same for the nodes in the same RRPP ring.
- Some ports are abnormal.

### Solution

- Use the **display rrpp brief** command to examine whether RRPP is enabled for all nodes. If it is not, use the **rrpp enable** command and the **ring enable** command to enable RRPP and RRPP rings for all nodes.
- Use the **display rrpp brief** command to examine whether the domain ID and primary control VLAN ID are the same for all nodes. If they are not, set the same domain ID and primary control VLAN ID for the nodes.
- Use the **display rrpp verbose** command to examine the link state of each port in each ring.
- Use the **debugging rrpp** command on each node to examine whether a port receives or transmits Hello packets. If it does not, Hello packets are lost.

# Configuring Smart Link

## Smart Link overview

### Background

To avoid single-point failures and guarantee network reliability, downstream devices are usually dual-homed to upstream devices, as shown in [Figure 24](#).

**Figure 24 Diagram for a dual uplink network**

To remove network loops on a dual-homed network, you can use a spanning tree protocol or the Rapid Ring Protection Protocol (RRPP). The problem with STP, however, is that STP convergence time is long, which makes it not suitable for users who have high demand on convergence speed. RRPP can meet users' demand on convergence speed, but it involves complicated networking and configurations and is mainly used in ring-shaped networks.

For more information about STP and RRPP, see *Layer 2—LAN Switching Configuration Guide* and "[Configuring RRPP](#)."

Smart Link is a feature developed to address the slow convergence issue with STP. It provides link redundancy as well as fast convergence in a dual uplink network, allowing the backup link to take over quickly when the primary link fails. To sum up, Smart Link has the following features:

- Dedicated to dual uplink networks
- Subsecond convergence
- Easy to configure

## Terminology

### Smart link group

A smart link group consists of only two member ports: the master and the slave ports. At a time, only one port is active for forwarding, and the other port is blocked and in standby state. When link failure occurs on the active port due to port shutdown or presence of unidirectional link for example, the standby port becomes active to take over and the original active port transits to the blocked state.

As shown in [Figure 24](#), Port1 and Port2 of Device C and Port1 and Port2 of Device D each form a smart link group, with Port1 being active and Port2 being standby.

### Master/slave port

Master port and slave port are two port roles in a smart link group. When both ports in a smart link group are up, the master port preferentially transits to the forwarding state, and the slave port stays in standby state. Once the master port fails, the slave port takes over to forward traffic. As shown in [Figure 24](#), you can configure Port1 of Device C and Port1 of Device D as master ports, and Port2 of Device C and Port2 of Device D slave ports.

### Master/slave link

The link that connects the master port in a smart link group is the master link. The link that connects the slave port is the slave link.

### Flush message

Flush messages are used by a smart link group to notify other devices to refresh their MAC address forwarding entries and ARP/ND entries when link switchover occurs in the smart link group. Flush messages are common multicast data packets, and will be dropped by a blocked receiving port.

### Protected VLAN

A smart link group controls the forwarding state of some data VLANs (protected VLANs). Different smart link groups on a port control different protected VLANs. The state of the port in a protected VLAN is determined by the state of the port in the smart link group.

### Transmit control VLAN

The transmit control VLAN is used for transmitting flush messages. When link switchover occurs, the devices (such as Device C and Device D in [Figure 24](#)) broadcast flush messages within the transmit control VLAN.

### Receive control VLAN

The receive control VLAN is used for receiving and processing flush messages. When link switchover occurs, the devices (such as Device A, Device B, and Device E in [Figure 24](#)) receive and process flush messages in the receive control VLAN and refresh their MAC address forwarding entries and ARP/ND entries.

# How Smart Link works

## Link backup mechanism

As shown in [Figure 24](#), the link on Port1 of Device C is the master link, and the link on Port2 of Device C is the slave link. Typically, Port1 is in forwarding state, and Port2 is in standby state. When the master link fails, Port2 takes over to forward traffic and Port1 is blocked and placed in standby state.

---

### NOTE:

When a port switches to the forwarding state, the system outputs log information to notify the user of the port state change.

---

## Topology change mechanism

Because link switchover can outdate the MAC address forwarding entries and ARP/ND entries on all devices, you need a forwarding entry update mechanism to ensure proper transmission. By far, the following two update mechanisms are provided:

- Uplink traffic-triggered MAC address learning, where update is triggered by uplink traffic. This mechanism is applicable to environments with devices not supporting Smart Link, including devices of other vendors'.
- Flush update where a Smart Link-enabled device updates its information by transmitting flush messages over the backup link to its upstream devices. This mechanism requires the upstream devices to be capable of recognizing Smart Link flush messages to update its MAC address forwarding entries and ARP/ND entries.

## Role preemption mechanism

As shown in [Figure 24](#), the link on Port1 of Device C is the master link, and the link on Port2 of Device C is the slave link. Once the master link fails, Port1 is automatically blocked and placed in standby state, and Port2 takes over to forward traffic. When the master link recovers, one of the following occurs:

- If the smart link group is not configured with role preemption, to keep traffic forwarding stable, Port1 that has been blocked due to link failure does not immediately take over to forward traffic. Rather, it stays blocked until the next link switchover.
- If the smart link group is configured with role preemption, Port1 takes over to forward traffic as soon as its link recovers, and Port2 is automatically blocked and placed in standby state.

## Load sharing mechanism

A ring network may carry traffic of multiple VLANs. Smart Link can forward traffic of different VLANs in different smart link groups, implementing load sharing.

To implement load sharing, you can assign a port to multiple smart link groups (each configured with different protected VLANs), making sure that the state of the port is different in these smart link groups. In this way, traffic of different VLANs can be forwarded along different paths.

You can configure protected VLANs for a smart link group by referencing Multiple Spanning Tree Instances (MSTIs).

# Smart Link collaboration mechanisms

## Collaboration between Smart Link and Monitor Link

Smart Link cannot sense by itself when faults occur on the uplink of the upstream devices, or when faults are cleared. To monitor the uplink status of the upstream devices, you can configure the Monitor Link

function to monitor the uplink ports of the upstream devices. Monitor Link adapts the up/down state of downlink ports to the up/down state of uplink ports, triggering Smart Link to perform link switchover on the downstream device.

For more information about Monitor Link, see "[Configuring Monitor Link](#)."

### Collaboration between Smart Link and CC of CFD

Smart Link cannot sense by itself when faults (for example, unidirectional link, misconnected fibers, and packet loss) occur on the intermediate devices or network paths, or when faults are cleared. To check the link status, Smart Link ports must use link detection protocols. When a fault is detected or cleared, the link detection protocols inform Smart Link to switch over the links.

With the collaboration between Smart Link and the Continuity Check (CC) function of Connectivity Fault Detection (CFD) configured, CFD notifies the ports of fault detection events on the basis of detection VLANs and detection ports. A port responds to a continuity check event only when the control VLAN of the smart link group to which it belongs matches the detection VLAN.

For more information about the CC function of CFD, see "[Configuring CFD](#)."

## Smart Link configuration task list

A smart link device is a device that supports Smart Link and is configured with a smart link group and a transmit control VLAN for flush message transmission. Device C and Device D in [Figure 24](#) are two examples of smart link devices.

An associated device is a device that supports Smart Link and receives flush messages sent from the specified control VLAN. Device A, Device B, and Device E in [Figure 24](#) are examples of associated devices.

Complete the following tasks to configure Smart Link:

Task	Remarks	
Configuring a Smart Link device	<a href="#">Configuring protected VLANs for a smart link group</a>	Required
	<a href="#">Configuring member ports for a smart link group</a>	Required
	<a href="#">Configuring role preemption for a smart link group</a>	Optional
	<a href="#">Enabling the sending of flush messages</a>	Optional
	<a href="#">Configuring the collaboration between Smart Link and CC of CFD</a>	Optional
Configuring an associated device	<a href="#">Enabling the receiving of flush messages</a>	Required

## Configuring a Smart Link device

### Configuration prerequisites

- Before configuring a port as a smart link group member, shut down the port to prevent loops. You can bring up the port only after completing the smart link group configuration.

- Disable the spanning tree feature and RRP on the ports that you want to add to the smart link group, and make sure that the ports are not member ports of any aggregation group or service loopback group.

**NOTE:**

A loop may occur on the network during the time when the spanning tree feature is disabled but Smart Link has not yet taken effect on a port.

## Configuring protected VLANs for a smart link group

You can configure protected VLANs for a smart link group by referencing MSTIs. Before configuring the protected VLANs, configure the mappings between MSTIs and the VLANs to be protected. (In PVST mode, the system automatically maps VLANs to MSTIs.) For more information about MSTI and PVST, see *Layer 2—LAN Switching Configuration Guide*.

To configure the protected VLANs for a smart link group:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter MST region view.	<b>stp region-configuration</b>	Not required in PVST mode. For more information about the command, see <i>Layer 2—LAN Switching Command Reference</i> .
3. Configure the VLAN-to-instance mapping table.	Approach 1: <b>instance instance-id vlan vlan-list</b> Approach 2: <b>vlan-mapping modulo modulo</b>	Optional. Use either approach. All VLANs in an MST region are mapped to CIST (MSTI 0) by default. Not required in PVST mode. For more information about the commands, see <i>Layer 2—LAN Switching Command Reference</i> .
4. Activate MST region configuration manually.	<b>active region-configuration</b>	Not required in PVST mode. For more information about the command, see <i>Layer 2—LAN Switching Command Reference</i> .
5. Display the currently activated configuration information of the MST region.	<b>display stp region-configuration [   { begin   exclude   include } regular-expression ]</b>	Optional. Available in any view. You can view the VLANs mapped to the MSTIs. For more information about the command, see <i>Layer 2—LAN Switching Command Reference</i> .
6. Return to system view.	<b>quit</b>	Not required in PVST mode.
7. Create a smart link group, and enter smart link group view.	<b>smart-link group group-id</b>	N/A

Step	Command	Remarks
8. Configure protected VLANs for the smart link group.	<b>protected-vlan reference-instance</b> <i>instance-id-list</i>	By default, no protected VLAN is configured for a smart link group.

## Configuring member ports for a smart link group

You can configure member ports for a smart link group either in smart link group view or in interface view. The configurations made in these two views have the same effect.

### In smart link group view

To configure member ports for a smart link group in smart link group view:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Create a smart link group, and enter smart link group view.	<b>smart-link group</b> <i>group-id</i>
3. Configure member ports for a smart link group.	<b>port</b> <i>interface-type interface-number</i> { <b>master</b>   <b>slave</b> }

### In interface view

To configure member ports for a smart link group in interface view:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Enter Layer 2 Ethernet interface view or layer 2 aggregate interface view.	<b>interface</b> <i>interface-type interface-number</i>
3. Configure member ports for a smart link group.	<b>port smart-link group</b> <i>group-id</i> { <b>master</b>   <b>slave</b> }

## Configuring role preemption for a smart link group

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Create a smart link group, and enter smart link group view.	<b>smart-link group</b> <i>group-id</i>	N/A
3. Enable role preemption.	<b>preemption mode role</b>	By default, the device works in the non-preemption mode.
4. Configure the preemption delay.	<b>preemption delay</b> <i>delay-time</i>	Optional. 1 second by default.

#### NOTE:

The preemption delay configuration takes effect only after role preemption is enabled.

## Enabling the sending of flush messages

The control VLAN configured for a smart link group must be different from that configured for any other smart link group.

Make sure the configured control VLAN already exists, and assign the smart link group member ports to the control VLAN.

The control VLAN of a smart link group should also be one of its protected VLANs. Do not remove the control VLAN. Otherwise, flush messages cannot be sent properly.

To enable the sending of flush messages:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Create a smart link group, and enter smart link group view.	<b>smart-link group</b> <i>group-id</i>	N/A
3. Enable flush update in the specified control VLAN.	<b>flush enable</b> [ <b>control-vlan</b> <i>vlan-id</i> ]	Optional. By default, flush update is enabled, and VLAN 1 is the control VLAN.

## Configuring the collaboration between Smart Link and CC of CFD

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter Layer 2 Ethernet interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the collaboration between Smart Link and the CC function of CFD on the port.	<b>port smart-link group</b> <i>group-id</i> <b>track cfd cc</b>	Optional. By default, the collaboration between Smart Link and the CC function of CFD is not configured.

### NOTE:

When configuring the collaboration between Smart Link and the CC function of CFD on a smart link member port, make sure that the control VLAN of the smart link group to which the port belongs matches the detection VLAN of the CC function of CFD.

# Configuring an associated device

## Configuration prerequisites

Disable the spanning tree feature on the associated device's ports that connect to the member ports of the smart link group; otherwise, the ports will discard flush messages when they are not in the forwarding state in case of a topology change.

## Enabling the receiving of flush messages

You do not need to enable all ports on the associated devices to receive flush messages sent from the transmit control VLAN; you only need to enable those on the master and slave links between the smart link device and the destination device.

### Configuration guidelines

- Configure all the control VLANs to receive flush messages.
- If no control VLAN is specified for processing flush messages, the device forwards the received flush messages without processing them.
- Make sure the receive control VLAN is the same as the transmit control VLAN configured on the smart link device. If they are not the same, the associated device will forward the received flush messages directly without any processing.
- Do not remove the control VLANs. Otherwise, flush messages cannot be sent properly.
- Make sure the control VLANs are existing VLANs, and assign the ports capable of receiving flush messages to the control VLANs.

### Configuration procedure

To enable the receiving of flush messages:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the control VLANs for receiving flush messages.	<b>smart-link flush enable</b> [ <b>control-vlan</b> <i>vlan-id-list</i> ]	By default, no control VLAN exists for receiving flush messages.

## Displaying and maintaining Smart Link

Task	Command	Remarks
Display smart link group information.	<b>display smart-link group</b> { <i>group-id</i>   <b>all</b> } [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view
Display information about the received flush messages.	<b>display smart-link flush</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view

Task	Command	Remarks
Clear the statistics about flush messages.	<b>reset smart-link statistics</b>	Available in user view

## Smart Link configuration examples

### Single smart link group configuration example

#### Network requirements

As shown in Figure 25, Device C and Device D are smart link devices, and Device A, Device B, and Device E are associated devices. Traffic of VLANs 1 through 30 on Device C and Device D are dually uplinked to Device A.

Configure Smart Link on Device C and Device D for dual uplink backup.

Figure 25 Network diagram

#### Configuration procedure

##### 1. Configure Device C:

# Create VLANs 1 through 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

# Shut down GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, disable the spanning tree feature on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 separately, configure them as trunk ports, and assign them to VLANs 1 through 30.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

```

[DeviceC-GigabitEthernet1/0/1] undo stp enable
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit

```

**# Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs.**

```

[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1

```

**# Configure GigabitEthernet 1/0/1 as the master port and GigabitEthernet 1/0/2 as the slave port for smart link group 1.**

```

[DeviceC-smlk-group1] port gigabitethernet1/0/1 master
[DeviceC-smlk-group1] port gigabitethernet1/0/2 slave

```

**# Enable flush message sending in smart link group 1, and configure VLAN 10 as the transmit control VLAN.**

```

[DeviceC-smlk-group1] flush enable control-vlan 10
[DeviceC-smlk-group1] quit

```

**# Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 again.**

```

[DeviceB-GigabitEthernet1/0/2] quit

```

# Configure GigabitEthernet 1/0/3 as a trunk port, and assign it to VLANs 1 through 30. Disable the spanning tree feature and enable flush message receiving on it, and configure VLAN 10 as the receive control VLAN.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/3] undo stp enable
[DeviceB-GigabitEthernet1/0/3] smart-link flush enable control-vlan 10
[DeviceB-GigabitEthernet1/0/3] quit
```

#### 4. Configure Device E:

# Create VLANs 1 through 30.

```
<DeviceE> system-view
[DeviceE] vlan 1 to 30
```

# Configure GigabitEthernet 1/0/1 as a trunk port, and assign it to VLANs 1 through 30. Enable flush message receiving on it, and configure VLAN 10 and VLAN 20 as the receive control VLANs.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceE-GigabitEthernet1/0/1] quit
```

# Configure GigabitEthernet 1/0/2 as a trunk port, and assign it to VLANs 1 through 30. Disable the spanning tree feature and enable flush message receiving on it, and configure VLAN 10 as the receive control VLAN.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10
[DeviceE-GigabitEthernet1/0/2] quit
```

# Configure GigabitEthernet 1/0/3 as a trunk port, and assign it to VLANs 1 through 30. Disable the spanning tree feature and enable flush message receiving on it, and configure VLAN 20 as the receive control VLAN.

```
[DeviceE] interface gigabitethernet 1/0/3
[DeviceE-GigabitEthernet1/0/3] port link-type trunk
[DeviceE-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/3] undo stp enable
[DeviceE-GigabitEthernet1/0/3] smart-link flush enable control-vlan 20
[DeviceE-GigabitEthernet1/0/3] quit
```

#### 5. Configure Device A:

# Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

# Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports, and assign them to VLANs 1 through 30. Enable flush message receiving on them, and configure VLAN 10 and VLAN 20 as the receive control VLANs.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceA-GigabitEthernet1/0/1] quit
```

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 20
[DeviceA-GigabitEthernet1/0/2] quit
```

## 6. Verify the configuration:

You can use the **display smart-link group** command to display the smart link group configuration on a device.

# Display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group 1
Smart link group 1 information:
Device ID: 000f-e23d-5af0
Preemption mode: NONE
Preemption delay: 1(s)
Control VLAN: 10
Protected VLAN: Reference Instance 1
```

Member	Role	State	Flush-count	Last-flush-time
GigabitEthernet1/0/1	MASTER	ACTVIE	5	16:37:20 2010/02/21
GigabitEthernet1/0/2	SLAVE	STANDBY	1	17:45:20 2010/02/21

You can use the **display smart-link flush** command to display the flush messages received on a device.

# Display the flush messages received on Device B.

```
[DeviceB] display smart-link flush
Received flush packets : 5
Receiving interface of the last flush packet : GigabitEthernet1/0/3
Receiving time of the last flush packet : 16:25:21 2009/02/21
Device ID of the last flush packet : 000f-e23d-5af0
Control VLAN of the last flush packet : 10
```

## Multiple smart link groups load sharing configuration example

### Network requirements

As shown in [Figure 26](#), Device C is a smart link device, and Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 200 on Device C are dually uplinked to Device A by Device B and Device D.

Implement dual uplink backup and load sharing on Device C: traffic of VLANs 1 through 100 is uplinked to Device A by Device B; traffic of VLANs 101 through 200 is uplinked to Device A by Device D.

Figure 26 Network diagram

## Configuration procedure

### 1. Configure Device C:

# Create VLAN 1 through VLAN 200. Map VLANs 1 through 100 to MSTI 1. Map VLANs 101 through 200 to MSTI 2, and activate MST region configuration.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 200
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 100
[DeviceC-mst-region] instance 2 vlan 101 to 200
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

# Shut down GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, disable the spanning tree feature on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 separately, configure the ports as trunk ports, and assign them to VLAN 1 through VLAN 200.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
[DeviceC-GigabitEthernet1/0/1] undo stp enable
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/2] quit
```

# Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

# Configure GigabitEthernet 1/0/1 as the master port and GigabitEthernet 1/0/2 as the slave port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet1/0/1 master
[DeviceC-smlk-group1] port gigabitethernet1/0/2 slave
```

# Enable role preemption in smart link group 1, enable flush message sending, and configure VLAN 10 as the transmit control VLAN.

```
[DeviceC-smlk-group1] preempt mode role
[DeviceC-smlk-group-1] flush enable control-vlan 10
[DeviceC-smlk-group-1] quit
```

# Create smart link group 2, and configure all VLANs mapped to MSTI 2 as the protected VLANs for smart link group 2.

```
[DeviceC] smart-link group 2
[DeviceC-smlk-group2] protected-vlan reference-instance 2
```

# Configure GigabitEthernet 1/0/1 as the slave port and GigabitEthernet 1/0/2 as the master port for smart link group 2.

```
[DeviceC-smlk-group2] port gigabitethernet1/0/2 master
[DeviceC-smlk-group2] port gigabitethernet1/0/1 slave
```

# Enable role preemption in smart link group 2, enable flush message sending, and configure VLAN 110 as the transmit control VLAN.

```
[DeviceC-smlk-group2] preempt mode role
[DeviceC-smlk-group2] flush enable control-vlan 110
[DeviceC-smlk-group2] quit
```

# Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 again.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

## 2. Configure Device B:

# Create VLAN 1 through VLAN 200.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 200
```

# Configure GigabitEthernet 1/0/1 as a trunk port and assign it to VLANs 1 through 200. Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/1] quit
```

# Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLANs 1 through 200. Disable the spanning tree feature and enable flush message receiving on it, and configure VLAN 10 and VLAN 110 as the receive control VLANs.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/2] quit
```

## 3. Configure Device D:

# Create VLAN 1 through VLAN 200.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 200
```

# Configure GigabitEthernet 1/0/1 as a trunk port and assign it to VLANs 1 through 200. Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/1] quit
```

# Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLANs 1 through 200. Disable the spanning tree feature and enable flush message receiving on it, and configure VLAN 10 and VLAN 110 as the receive control VLANs.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/2] quit
```

#### 4. Configure Device A:

# Create VLAN 1 through VLAN 200.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 200
```

# Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports and assign them to VLANs 1 through 200. Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2

Receiving time of the last flush packet : 16:25:21 2010/02/21
Device ID of the last flush packet : 000f-e23d-5af0
Control VLAN of the last flush packet : 10

```

## Smart Link and CFD collaboration configuration example

### Network requirements

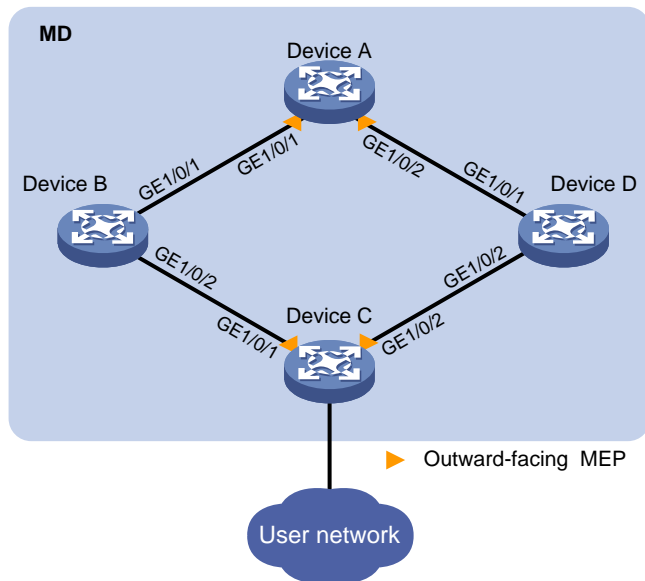

As shown in [Figure 27](#), Device A, Device B, Device C, and Device D form a maintenance domain (MD) of level 5. Device C is a smart link device, and Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 200 on Device C is dually uplinked to Device A by Device B and Device D.

Configure the CFD CC function for Smart Link, so that; Traffic of VLANs 1 through 100 is uplinked to Device A by Device C through GigabitEthernet 1/0/1 (master port of smart link group 1). Traffic of VLANs 101 through 200 is uplinked to Device A by Device C through GigabitEthernet 1/0/2 (master port of smart link group 2). When the link between Device C and Device A fails, traffic is rapidly switched to the slave port of each smart link group, and switched back to the master ports after the fault is cleared.

For more information about CFD, see "[Configuring CFD](#)."

Figure 27 Network diagram

## Configuration procedure

### 1. Configure Device A:

# Create VLAN 1 through VLAN 200.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 200
```

# Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports and assign them to VLANs 1 through 200. Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceA-GigabitEthernet1/0/2] quit
```

# Enable CFD and create an MD of level 5.

```
[DeviceA] cfd enable
[DeviceA] cfd md MD level 5
```

# Create MA **MA\_A** for the MD and configure the MA to serve VLAN 10, and create service instance 1 for the MD and MA.

```
[DeviceA] cfd ma MA_A md MD vlan 10
[DeviceA] cfd service-instance 1 md MD ma MA_A
```

# Create a MEP list in service instance 1, create and enable outward-facing MEP 1002, and enable CCM sending in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceA] cfd meplist 1001 1002 service-instance 1
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] cfd mep 1002 service-instance 1 outbound
[DeviceA-GigabitEthernet1/0/1] cfd mep service-instance 1 mep 1002 enable
[DeviceA-GigabitEthernet1/0/1] cfd cc service-instance 1 mep 1002 enable
[DeviceA-GigabitEthernet1/0/1] quit
```

# Create MA **MA\_B** for the MD and configure the MA to serve VLAN 110, and create service instance 2 for the MD and MA.

```
[DeviceA] cfd ma MA_B md MD vlan 110
[DeviceA] cfd service-instance 2 md MD ma MA_B
```

# Create a MEP list in service instance 2, create and enable outward-facing MEP 1002, and enable CCM sending in service instance 2 on GigabitEthernet 1/0/2.

```
[DeviceA] cfd meplist 2001 2002 service-instance 2
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] cfd mep 2002 service-instance 2 outbound
[DeviceA-GigabitEthernet1/0/2] cfd mep service-instance 2 mep 2002 enable
[DeviceA-GigabitEthernet1/0/2] cfd cc service-instance 2 mep 2002 enable
[DeviceA-GigabitEthernet1/0/2] quit
```

## 2. Configure Device B:

# Create VLAN 1 through VLAN 200.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 200
```

# Configure GigabitEthernet 1/0/1 as a trunk port and assign it to VLANs 1 through 200. Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/1] quit
```

# Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLANs 1 through 200. Disable the spanning tree feature and enable flush message receiving on it, and configure VLAN 10 and VLAN 110 as the receive control VLANs.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/2] quit
```

## 3. Configure Device C:

# Create VLAN 1 through VLAN 200, map VLANs 1 through 100 to MSTI 1, and VLANs 101 through 200 to MSTI 2, and activate MST region configuration.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 200
[DeviceC] stp region-configuration

```

# Configure the collaboration between the master port GigabitEthernet 1/0/1 of smart link group 1 and the CC function of CFD, and bring up the port.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] port smart-link group 1 track cfd cc
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
```

# Configure the collaboration between the master port GigabitEthernet 1/0/2 of smart link group 2 and the CC function of CFD, and bring up the port.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/1] port smart-link group 2 track cfd cc
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

#### 4. Configure Device D:

# Create VLAN 1 through VLAN 200.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 200
```

# Configure GigabitEthernet 1/0/1 as a trunk port and assign it to VLANs 1 through 200. Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/1] quit
```

# Configure GigabitEthernet 1/0/2 as a trunk port and assign it to VLANs 1 through 200. Disable the spanning tree feature and enable flush message receiving on it, and configure VLAN 10 and VLAN 110 as the receive control VLANs.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/2] quit
```

5. Verify the configuration:

Suppose the optical fiber between Device A and Device B fails. You can use the **display smart-link group** command to display the smart link group configuration on a device.

# Display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group all
Smart link group 1 information:
Device ID: 000f-e23d-5af0
Preemption mode: ROLE
Preemption delay: 1(s)
Control VLAN: 10
Protected VLAN: Reference Instance 1
Member Role State Flush-count Last-flush-time

GigabitEthernet1/0/1 MASTER DOWN 5 16:37:20 2010/02/21
GigabitEthernet1/0/2 SLAVE ACTVIE 3 17:45:20 2010/02/21

Smart link group 2 information:
Device ID: 000f-e23d-5af0
Preemption mode: ROLE
Preemption delay: 1(s)
Control VLAN: 110
Protected VLAN: Reference Instance 2
Member Role State Flush-count Last-flush-time

GigabitEthernet1/0/2 MASTER ACTVIE 5 16:37:20 2010/02/21
GigabitEthernet1/0/1 SLAVE STANDBY 1 17:45:20 2010/02/21
```

The output shows that master port GigabitEthernet 1/0/1 of smart link group 1 fails, and slave port GigabitEthernet 1/0/2 is in forwarding state.

# Configuring Monitor Link

## Monitor Link overview

Monitor Link is a port collaboration function. Monitor Link usually works together with Layer 2 topology protocols. The idea is to monitor the states of uplink ports and adapt the up/down state of downlink ports to the up/down state of uplink ports, triggering link switchover on the downstream device in time, as shown in [Figure 28](#).

**Figure 28 Monitor Link application scenario**

## Terminology

### Monitor link group

A monitor link group is a set of uplink and downlink ports. A port can belong to only one monitor link group. As shown in [Figure 28](#), ports Port1 and Port2 of Device B and those of Device D each form a monitor link group. Port1 on both devices are uplink ports, and Port2 on both devices are downlink ports.

### Uplink/Downlink ports

Uplink port and downlink port are two port roles in monitor link groups:

- Uplink ports are the monitored ports. The state of a monitor link group adapts to that of its member uplink ports. When a monitor link group contains no uplink port or when all the uplink ports are down, the monitor link group becomes down. As long as one member uplink port is up, the monitor link group stays up.

- Downlink ports are the monitoring ports. The state of the downlink ports in a monitor link group adapts to that of the monitor link group. When the state of a monitor link group changes, the state of its member downlink ports change accordingly. The state of the downlink ports in a monitor link group is always consistent with that of the monitor link group.

## Uplink/Downlink

The uplink is the link that connects the uplink ports in a monitor link group, and the downlink is the link that connects the downlink ports.

## How Monitor Link works

A monitor link group works independently of other monitor link groups. When a monitor link group contains no uplink port or when all its uplink ports are down, the monitor link group goes down and forces all downlink ports down at the same time. When any uplink port goes up, the monitor link group goes up and brings up all the downlink ports.

HP does not recommend manually shutting down or bringing up the downlink ports in a monitor link group.

# Configuring Monitor Link

## Configuration prerequisites

Make sure that the port is not the member port of any aggregation group or service loopback group.

## Creating a monitor link group

Step	Command
1. Enter system view.	<b>system-view</b>
2. Create a monitor link group, and enter monitor link group view.	<b>monitor-link group</b> <i>group-id</i>

## Configuring monitor link group member ports

You can configure member ports for a monitor link group either in monitor link group view or interface view. The configurations made in these two views lead to the same result.

You can assign a Layer 2 Ethernet port or Layer 2 aggregate interface to a monitor link group as a member port.

A port can be assigned to only one monitor link group.

Configure uplink ports prior to downlink ports to avoid undesired down/up state changes on the downlink ports.

### In monitor link group view

To configure member ports for a monitor link group in monitor link group view:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Enter monitor link group view.	<b>monitor-link group</b> <i>group-id</i>
3. Configure member ports for the monitor link group.	<b>port</b> <i>interface-type interface-number</i> { <b>uplink</b>   <b>downlink</b> }

### In interface view

To configure member ports for a monitor link group in interface view:

Step	Command
1. Enter system view.	<b>system-view</b>
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.	<b>interface</b> <i>interface-type interface-number</i>
3. Configure the current interface as a member of a monitor link group.	<b>port monitor-link group</b> <i>group-id</i> { <b>uplink</b>   <b>downlink</b> }

## Displaying and maintaining Monitor Link

Task	Command	Remarks
Display monitor link group information.	<b>display monitor-link group</b> { <i>group-id</i>   <b>all</b> } [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view

## Monitor Link configuration example

### Network requirements

As shown in [Figure 29](#), Device C is a smart link device, and Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 30 on Device C is dual-uplinked to Device A through a smart link group.

Implement dual uplink backup on Device C, and make sure that when the link between Device A and Device B (or Device D) fails, Device C can sense the link fault and perform uplink switchover in the smart link group.

For more information about Smart Link, see "[Configuring Smart Link](#)."

Figure 29 Network diagram

## Configuration procedure

### 1. Configure Device C:

# Create VLANs 1 through 30, map these VLANs to MSTI 1, and activate MST region configuration.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

# Disable the spanning tree feature on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 separately, configure them as trunk ports, and assign them to VLANs 1 through 30.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo stp enable
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

# Create smart link group 1, and configure all the VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

# Configure GigabitEthernet 1/0/1 as the master port and GigabitEthernet 1/0/2 as the slave port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 master
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 slave
```

# Enable the smart link group to transmit flush messages.

```
[DeviceC-smlk-group1] flush enable
[DeviceC-smlk-group1] quit
```

## 2. Configure Device A:

# Create VLANs 1 through 30.

```
<DeviceA> system-view
```

```
[DeviceA] vlan 1 to 30
```

# Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports, assign them to VLANs 1 through 30, and enable flush message receiving on them.

```
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable
```

```
[DeviceA-GigabitEthernet1/0/1] quit
```

```
[DeviceA] interface gigabitethernet 1/0/2
```

```
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
```

```
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

```
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable
```

```
[DeviceA-GigabitEthernet1/0/2] quit
```

## 3. Configure Device B:

# Create VLANs 1 through 30.

```
<DeviceB> system-view
```

```
[DeviceB] vlan 1 to 30
```

# Configure GigabitEthernet 1/0/1 as a trunk port, assign it to VLANs 1 through 30, and enable flush message receiving on it.

```
[DeviceB] interface gigabitethernet 1/0/1
```

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable
```

```
[DeviceB-GigabitEthernet1/0/1] quit
```

# Configure GigabitEthernet 1/0/2 as a trunk port, assign it to VLANs 1 through 30, disable the spanning tree feature, and enable flush message receiving on it.

```
[DeviceB] interface gigabitethernet 1/0/2
```

```
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

```
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable
```

```
[DeviceB-GigabitEthernet1/0/2] quit
```

# Create monitor link group 1, and then configure GigabitEthernet 1/0/1 as an uplink port and GigabitEthernet 1/0/2 as a downlink port for monitor link group 1.

```
[DeviceB] monitor-link group 1
```

```
[DeviceB-mtlk-group1] port gigabitethernet 1/0/1 uplink
```

```
[DeviceB-mtlk-group1] port gigabitethernet 1/0/2 downlink
```

```
[DeviceB-mtlk-group1] quit
```

## 4. Configure Device D:

# Create VLANs 1 through 30.

```
<DeviceD> system-view
```

```
[DeviceD] vlan 1 to 30
```

# Configure GigabitEthernet 1/0/1 as a trunk port, assign it to VLANs 1 through 30, and enable flush message receiving on it.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable
[DeviceD-GigabitEthernet1/0/1] quit
```

# Configure GigabitEthernet 1/0/2 as a trunk port, assign it to VLANs 1 through 30, disable the spanning tree feature, and enable flush message receiving on it.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable
[DeviceD-GigabitEthernet1/0/2] quit
```

# Create monitor link group 1, and then configure GigabitEthernet 1/0/1 as an uplink port and GigabitEthernet 1/0/2 as a downlink port for monitor link group 1.

```
[DeviceD] monitor-link group 1
[DeviceD-mtlk-group1] port gigabitethernet 1/0/1 uplink
[DeviceD-mtlk-group1] port gigabitethernet 1/0/2 downlink
[DeviceD-mtlk-group1] quit
```

#### 5. Verify the configuration:

Use the **display monitor-link group** command to display the monitor link group information on devices. For example, when GigabitEthernet 1/0/2 on Device A goes down due to a link fault:

# Display information about monitor link group 1 on Device B.

```
[DeviceB] display monitor-link group 1
Monitor link group 1 information:
Group status: UP
Last-up-time: 16:37:20 2009/4/21
Last-down-time: 16:35:26 2009/4/21
Member Role Status

GigabitEthernet1/0/1 UPLINK UP
GigabitEthernet1/0/2 DOWNLINK UP
```

# Display information about monitor link group 1 on Device D.

```
[DeviceD] display monitor-link group 1
Monitor link group 1 information:
Group status: DOWN
Last-up-time: 16:35:27 2009/4/21
Last-down-time: 16:37:19 2009/4/21
Member Role Status

GigabitEthernet1/0/1 UPLINK DOWN
GigabitEthernet1/0/2 DOWNLINK DOWN
```

# Configuring VRRP (available only on the HP 5500 EI)

- The term *router* in this document refers to both routers and Layer 3 switches.
- You can perform interface-specific VRRP configuration only on Layer 3 Ethernet interfaces, VLAN interfaces, and Layer 3 aggregate interfaces, unless otherwise specified. You can set an Ethernet port as a Layer 3 interface by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).
- VRRP cannot be configured on interfaces in aggregation groups.

## VRRP overview

Typically, as shown in [Figure 30](#), you can configure a default route with the gateway as the next hop for every host on a network segment. All packets destined to other network segments are sent over the default route to the gateway, which then forwards the packets. However, when the gateway fails, all the hosts that use the gateway as the default next-hop router fail to communicate with external networks.

**Figure 30 LAN networking**

Configuring a default route for network hosts facilitates your configuration, but also requires high performance stability of the device that acts as the gateway. Using more egress gateways is a common way to improve system reliability, but introduces the problem of routing among the egresses.

Virtual Router Redundancy Protocol (VRRP) is designed to address this problem. VRRP adds a group of routers that can act as network gateways to a VRRP group, which forms a virtual router. Routers in the VRRP group elect a master through the VRRP election mechanism to act as a gateway, and hosts on a LAN only need to configure the virtual router as their default network gateway.

VRRP is an error-tolerant protocol, which improves the network reliability and simplifies configurations on hosts. On a multicast and broadcast LAN such as Ethernet, VRRP provides highly reliable default links without configuration changes (such as dynamic routing protocols, route discovery protocols) when a router fails, and prevent network interruption because of a single link failure.

VRRP operates in either of the following modes:

- **Standard protocol mode**—Includes two versions VRRPv2 and VRRPv3 based on RFCs. VRRPv2 is based on IPv4, and VRRPv3 is based on IPv6. The two versions implement the same functions but are applied in different network environments. For more information, see "[VRRP standard protocol mode](#)."
- **Load balancing mode**—Extends the standard protocol mode and realizes load balancing. For more information, see "[VRRP load balancing mode](#)."

## VRRP standard protocol mode

### Introduction to VRRP group

VRRP combines a group of routers (including a master and multiple backups) on a LAN into a virtual router called VRRP group.

A VRRP group has the following features:

- A virtual router has a virtual IP address. A host on the LAN only needs to know the IP address of the virtual router and uses the IP address as the next hop of the default route.
- Every host on the LAN communicates with external networks through the virtual router.
- Routers in the VRRP group elect a master that acts as the gateway according to their priorities. The other routers function as the backups. When the master fails, to make sure that the hosts in the network segment can uninterruptedly communicate with the external networks, the backups in the VRRP group elect a new gateway to undertake the responsibility of the failed master.

**Figure 31 Network diagram**

As shown in [Figure 31](#), Router A, Router B, and Router C form a virtual router, which has its own IP address. Hosts on the Ethernet use the virtual router as the default gateway.

The router with the highest priority among the three routers is elected as the master to act as the gateway, and the other two are backups.

The IP address of the virtual router can be either an unused IP address on the segment where the VRRP group resides or the IP address of an interface on a router in the VRRP group. In the latter case, the router is called the IP address owner.

Only one IP address owner can be configured for a VRRP group.

A router in a VRRP group can be in master, backup, or initialize status.

## VRRP priority

VRRP determines the role (master or backup) of each router in a VRRP group by priority. A router with a higher priority is more likely to become the master.

VRRP priority is in the range of 0 to 255. The greater the number, the higher the priority. Priorities 1 to 254 are configurable. Priority 0 is reserved for special uses and priority 255 for the IP address owner. When a router acts as the IP address owner, its running priority is always 255. That is, the IP address owner in a VRRP group acts as the master as long as it works properly.

## Operation mode

A router in a VRRP group operates in either of the following modes:

- **Non-preemptive mode**—When a router in the VRRP group becomes the master, it stays as the master as long as it operates normally, even if a backup is assigned a higher priority later.
- **Preemptive mode**—When a backup finds its priority higher than that of the master, the backup sends VRRP advertisements to start a new master election in the VRRP group and becomes the master. Accordingly, the original master becomes a backup.

## Authentication mode

To avoid attacks from unauthorized users, VRRP adds authentication keys into packets for authentication. VRRP provides the following authentication modes:

- **simple**—Simple text authentication

A router sending a packet fills an authentication key into the packet, and the router receiving the packet compares its local authentication key with that of the received packet. If the two authentication keys are the same, the received VRRP packet is considered legitimate. Otherwise, the received packet is considered invalid.

- **md5**—MD5 authentication

A router computes the digest of a packet to be sent by using the authentication key and MD5 algorithm and saves the result in the authentication header. The router that receives the packet performs the same operation by using the authentication key and MD5 algorithm, and compares the result with the content in the authentication header. If the results are the same, the router that receives the packet considers the packet an authentic and valid VRRP packet. Otherwise, the router considers the packet invalid.

On a secure network, you can choose not to set the authentication mode.

## VRRP timers

VRRP timers include VRRP advertisement interval timer and VRRP preemption delay timer.

### VRRP advertisement interval timer

The master in a VRRP group periodically sends VRRP advertisements to inform the other routers in the VRRP group that it operates properly.

You can adjust the interval for sending VRRP advertisements by setting the VRRP advertisement interval timer. If a backup receives no advertisements in a period three times the interval, the backup regards itself as the master and sends VRRP advertisements to start a new master election.

## VRRP preemption delay timer

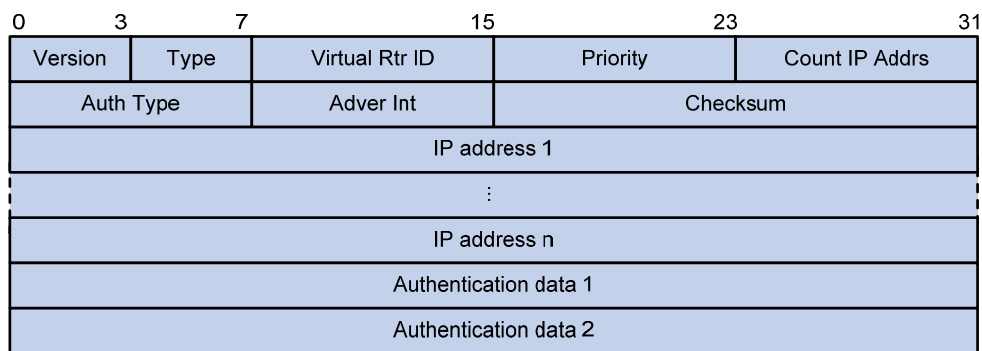

To avoid frequent state changes among members in a VRRP group and provide the backups enough time to collect information (such as routing information), each backup waits for a period of time (the preemption delay time) after it receives an advertisement with the priority lower than the local priority, then sends VRRP advertisements to start a new master election in the VRRP group and becomes the master.

## Packet format

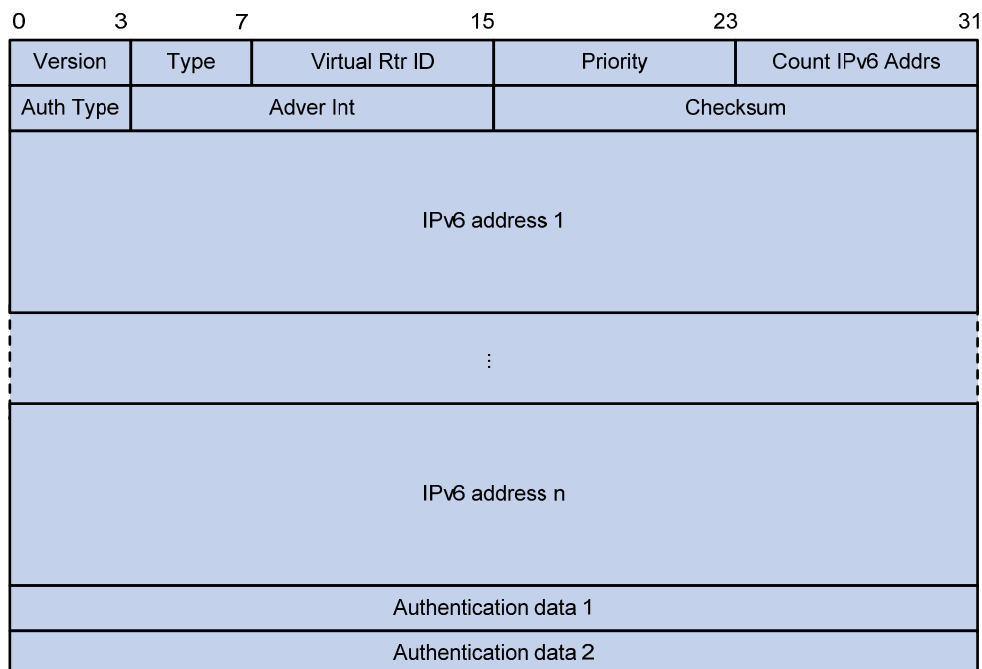

The master multicasts VRRP packets periodically to declare its existence. VRRP packets are also used for checking the parameters of the virtual router and electing the master.

VRRP packets are encapsulated in IP packets, with the protocol number being 112. [Figure 32](#) shows the format of a VRRPv2 packet and [Figure 33](#) shows the format of a VRRPv3 packet.

**Figure 32 Format of a VRRPv2 packet**

**Figure 33 Format of a VRRPv3 packet**

A VRRP packet comprises the following fields:

- **Version**—Version number of the protocol, 2 for VRRPv2 and 3 for VRRPv3.
- **Type**—Type of the VRRPv2 or VRRPv3 packet. Only one VRRP packet type is present, that is, VRRP advertisement, which is represented by 1.
- **Virtual Rtr ID (VRID)**—ID of the virtual router, that is, ID of the VRRP group. It ranges from 1 to 255.
- **Priority**—Priority of the router in the VRRP group, in the range of 0 to 255. A greater value represents a higher priority.
- **Count IP Adrs/Count IPv6 Adrs**—Number of virtual IPv4 or IPv6 addresses for the VRRP group. A VRRP group can have multiple virtual IPv4 or IPv6 addresses.
- **Auth Type**—Authentication type. 0 means no authentication, 1 means simple text authentication, and 2 means MD5 authentication. VRRPv3 does not support MD5 authentication.
- **Adver Int**—Interval for sending advertisement packets. For VRRPv2, the interval is in seconds and defaults to 1. For VRRPv3, the interval is in centiseconds and defaults to 100.
- **Checksum**—16-bit checksum for validating the data in VRRP packets.
- **IP Address/IPv6 Address**—Virtual IPv4 or IPv6 address entry of the VRRP group. The Count IP Adrs or Count IPv6 Adrs field defines the number of the virtual IP v4 or IPv6 addresses.
- **Authentication Data**—Authentication key. This field is used only for simple authentication and is 0 for any other authentication modes.

## Principles of VRRP

- Routers in a VRRP group determine their roles by priority. The router with the highest priority is the master, and the others are the backups. The master periodically sends VRRP advertisements to notify the backups that it is operating properly, and each of the backups starts a timer to wait for advertisements from the master.
- In preemptive mode, when a backup receives a VRRP advertisement, it compares the priority in the packet with its own priority. If the priority of the backup is higher, the backup becomes the master. Otherwise, it remains as a backup. With the preemptive mode, a VRRP group always has a router with the highest priority as the master for packet forwarding.
- In non-preemptive mode, a router in the VRRP group remains as a master or backup as long as the master does not fail. A backup does not become the master even if it is configured with a higher priority. The non-preemptive mode helps avoid frequent switchover between the master and backups.
- If the timer of a backup expires but the backup still does not receive any VRRP advertisement, it considers that the master fails. In this case, the backup considers itself as the master and sends VRRP advertisements to start a new master election.

The VRRP group configuration might be different on routers, and network problems might exist, so multiple master routers might exist in one VRRP group. These master routers will elect one master according to their priorities and IP addresses. The router with the highest priority wins the election. If a tie exists in the priority, the router with the highest IP address wins.

After a backup router receives an advertisement, it compares its priority against that carried in the advertisement. If its priority is higher than that carried in the advertisement, it takes over the master.

## VRRP tracking

To enable the VRRP tracking function, configure the routers in the VRRP group to operate in preemptive mode first, so that only the router with the highest priority can always operate as the master for packet forwarding.

## Tracking a specified interface

The interface tracking function expands the backup functionality of VRRP. It provides backup not only when the interface to which a VRRP group is assigned fails but also when other interfaces (such as uplink interfaces) on the router become unavailable.

If the uplink interface of a router in a VRRP group fails, usually the VRRP group cannot be aware of the uplink interface failure. If the router is the master of the VRRP group, hosts on the LAN are not able to access external networks because of the uplink failure. This problem can be solved by tracking a specified uplink interface. If the tracked uplink interface is down or removed, the priority of the master is automatically decreased by a specified value and a higher priority router in the VRRP group becomes the master.

## Monitoring a track entry

By monitoring a track entry, you can:

- Monitor an uplink and change the priority of the router according to the state of the uplink. If the uplink fails, hosts in the LAN cannot access external networks through the router. In this case, the state of the monitored track entry is negative and the priority of the router decreases by a specified value. Then, a higher priority router in the VRRP group becomes the master to maintain the proper communication between the hosts in the LAN and external networks.
- Monitor the master on a backup. When the master fails, the backup immediately preempts as the master to maintain normal communication.

For more information about track entries, see "[Configuring track](#)."

# VRRP application (taking IPv4-based VRRP for example)

## Master/backup

In master/backup mode, only the master forwards packets. When the master fails, a new master is elected from the backups. This mode requires only one VRRP group, in which each router holds a different priority and the one with the highest priority becomes the master, as shown in [Figure 34](#).

**Figure 34 VRRP in master/backup mode**

Assume that Router A is the master and therefore can forward packets to external networks, whereas Router B and Router C are backups and are thus in the state of listening. If Router A fails, Router B and Router C elect for a new master to forward packets to hosts on the LAN.

## Load sharing

More than one VRRP group can be created on an interface of a router to allow the router to be the master of one VRRP group but a backup of another at the same time.

In load sharing mode, multiple routers provide services simultaneously. This mode requires two or more VRRP groups, each of which comprises a master and one or more backups. The masters of the VRRP groups are assumed by different routers, as shown in Figure 35.

Figure 35 VRRP in load sharing mode

A router can be in multiple VRRP groups and hold a different priority in a different group.

As shown in Figure 35, the following VRRP groups are present:

- **VRRP group 1**—Router A is the master; Router B and Router C are the backups.
- **VRRP group 2**—Router B is the master; Router A and Router C are the backups.
- **VRRP group 3**—Router C is the master; Router A and Router B are the backups.

For load sharing among Router A, Router B, and Router C, hosts on the LAN need to be configured to use VRRP group 1, 2, and 3 as the default gateways. When you configure VRRP priorities, make sure that each router holds such a priority in each VRRP group that it will take the expected role in the group.

## VRRP load balancing mode

### Overview

When VRRP is operating in standard protocol mode, only the master can forward packets and the backups are in the state of listening. You can create multiple VRRP groups to share the load among multiple routers, but hosts on the LAN need to be configured with different gateways, thus making the configuration complicated.

In load balancing mode, VRRP provides load balancing in addition to virtual gateway redundancy by mapping a virtual IP address to multiple virtual MAC addresses to assign each router in a VRRP group

one virtual MAC address. In this way, each router in this VRRP group can respond to ARP requests (in an IPv4 network) or ND requests (in an IPv6 network) from corresponding hosts, so that different hosts can send packets to different routers, and each router in the VRRP group can forward packets. In load balancing mode, you need to create only one VRRP group to balance load among multiple routers, instead of allowing one router to bear the load but other routers to stay idle.

VRRP load balancing mode is based on VRRP standard protocol mode, so mechanisms, such as master election, preemption, and tracking functions, in the standard protocol mode are also supported in the load balancing mode. In addition, VRRP load balancing mode has new mechanisms, which are introduced in the following sections.

## Assigning virtual MAC addresses

When VRRP is operating in load balancing mode, the master assigns virtual MAC addresses to the routers in the VRRP group and answers the ARP requests or ND requests from different hosts. The backup routers, however, do not answer the ARP requests or ND requests from the hosts.

Assume that a VRRP group is operating in an IPv4 network. The following describes how the load balancing mode works:

1. The master assigns virtual MAC addresses to the routers (including the master itself and the backups) in the VRRP group. For example, as shown in [Figure 36](#), the virtual IP address of the VRRP group is 10.1.1.1/24; Router A is the master; Router B and Router C are the backups. Router A assigns 000f-e2ff-0011 to itself, and 000f-e2ff-0012 to Router B.

**Figure 36 Allocating virtual MAC addresses**

2. After receiving an ARP request destined for the virtual IP address of the VRRP group from a host, the master, based on the load balancing algorithm, uses a corresponding virtual MAC address to answer the ARP request. For example, as shown [Figure 37](#), when Host A sends an ARP request to retrieve the MAC address of gateway 10.1.1.1, the master (Router A), after receiving the request, returns the virtual MAC address of Router A to Host A; when Host B sends an ARP request to retrieve the MAC address of gateway 10.1.1.1, the master (Router A), after receiving the request, returns the virtual MAC address of Router B to Host B.

Figure 37 Answering ARP requests

3. Different hosts send packets to different routers according to the requested virtual MAC addresses. For example, as shown in Figure 38, Host A regards the virtual MAC address of Router A as the gateway MAC address, so it sends packets to Router A for forwarding; Host B regards the virtual MAC address of Router B as the gateway MAC address, so it sends packets to Router B for forwarding.

Figure 38 Sending packets to different routers for forwarding

# Virtual forwarder

## Creating a virtual forwarder

Virtual MAC addresses help different hosts transmit packets to different routers in a VRRP group. To enable the routers in the VRRP group to forward the packets, be sure to create virtual forwarders (VFs) on the routers. Each VF associates with a virtual MAC address in the VRRP group and forwards packets destined to this virtual MAC address.

The following describes how VFs are created on the routers in a VRRP group:

1. The master assigns virtual MAC addresses to all routers in the VRRP group. After learning its virtual MAC address, a router in the VRRP group creates a VF that corresponds to this MAC address, and becomes the owner of this VF.
2. The router advertises the VF information to the other routers in the VRRP group.
3. After receiving the VF advertisement, each of the other routers creates the advertised VF.

As described in the preceding steps, each router in the VRRP group creates not only a VF corresponding to its virtual MAC address, but also VFs advertised by the other routes in the VRRP group..

## VF weight and priority

The weight of a VF indicates the forwarding capability of a router. A higher weight indicates a higher forwarding capability. When the weight is lower than the lower limit of failure, the router cannot be capable of forwarding packets for the hosts.

The priority of a VF determines the VF state. Among the VFs that correspond to the same virtual MAC address on different routers in the VRRP group, the VF with the highest priority is in the active state and is known as the active virtual forwarder (AVF), which forwards packets; other VFs are in the listening state and are known as the listening virtual forwarders (LVFs), which monitor the state of the AVF. The priority value of a VF ranges from 0 to 255, where 255 is reserved for the VF owner. If the weight of a VF owner is higher than or equal to the lower limit of failure, the priority value of the VF owner is 255.

The priority value of a VF is calculated based on its weight:

- If the weight of a VF is higher than or equal to the lower limit of failure, and the router where the VF resides is the owner of the VF, the priority value of the VF is 255.
- If the weight of a VF is higher than or equal to the lower limit of failure, but the router where the VF resides is not the owner of the VF, the priority value of the VF is  $\text{weight}/(\text{number of local AVFs} + 1)$
- If the weight of a VF is lower than the lower limit of failure, the priority value of the VF is 0.

## VF backup

The VFs corresponding to a virtual MAC address on different routers in the VRRP group back up one another.

Figure 39 VF information

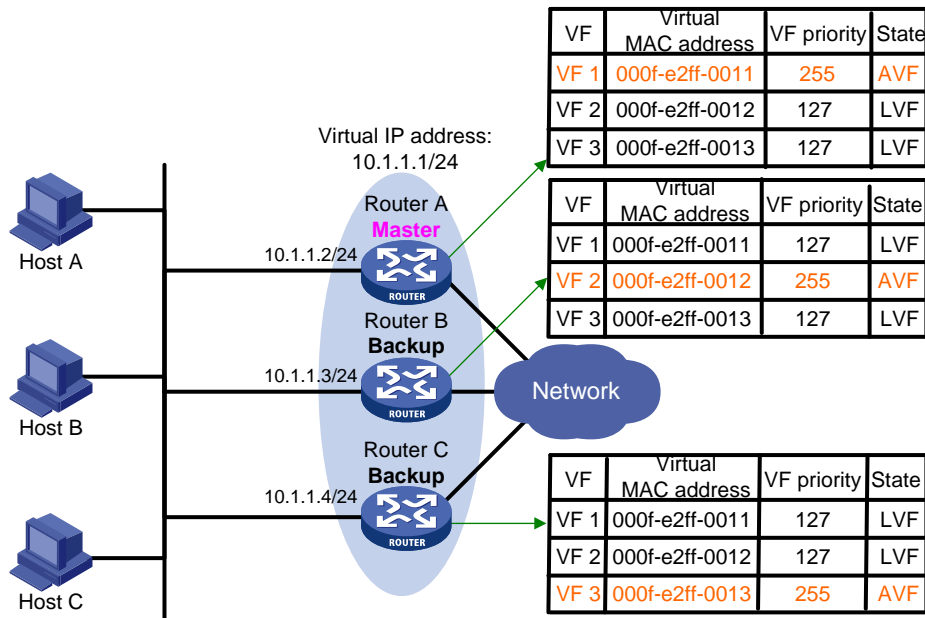

Figure 39 illustrates the VF information on each router in the VRRP group and how the routers back up one another. The master, Router A, assigns virtual MAC addresses 000f-e2ff-0011, 000f-e2ff-0012, and 000f-e2ff-0013 to itself, Router B, and Router C, respectively. The VFs corresponding to these three virtual MAC addresses, VF 1, VF 2, and VF 3, are created on each of the three routers, and the VFs corresponding to the same virtual MAC address on different routers back up one another. For example, VF 1 on Router A, Router B, and Router C can implement backup.

- Router A is the owner of VF 1, and the priority value of VF 1 on Router A is 255. In this case, VF 1 on Router A acts as the AVF to forward the packets destined for virtual MAC address 000f-e2ff-0011.
- The priority value of VF 1 on Router B and Router C is  $\text{weight}/(\text{number of local AVFs} + 1)$ , that is,  $255/(1 + 1) = 127$ , which is lower than that of VF 1 on Router A. In this case, VF 1 on both Router B and Router C acts as the LVF to listen to the status of VF 1 on Router A.
- When VF 1 on Router A fails, VF 1 on Router B and Router C elects the one with a higher priority value as the new AVF, responsible for forwarding the packets destined for virtual MAC address 000f-e2ff-0011.

**NOTE:**

A VF always operates in preemptive mode. When an LVF finds its priority value higher than that in the advertisement sent by the AVF, the LVF declares itself as the AVF.

**VF timers**

When the AVF on a router fails, the newly elected AVF on another router creates a redirect timer and a timeout timer for the failed AVF.

- **Redirect Timer**—Before this timer times out, the master still uses the virtual MAC address corresponding to the failed AVF to respond to ARP/ND requests from the hosts, and the VF owner can share traffic load if the VF owner resumes normal operation within this time. When this timer times out, the master stops using the virtual MAC address corresponding to the failed AVF to respond to ARP/ND requests from the hosts.

- **Timeout Timer**—The duration that the new AVF takes over the VF owner. Before this timer times out, all the routers in the VRRP group keep the failed AVF, and the new AVF forwards the packets destined for the virtual MAC address corresponding to the failed AVF. When this timer times out, all the routers in the VRRP group remove the failed AVF, and the new AVF stops forwarding the packets destined for the virtual MAC address corresponding to the failed AVF.

## VF tracking

The AVF forwards packets destined to the MAC address of the AVF. If the uplink of the AVF fails and no LVF is notified to take over the AVF's work, hosts (on the LAN) that use the MAC address of the AVF as their gateway MAC address cannot access the external network.

This problem can be solved by the VF tracking function. You can monitor the uplink state by using network quality analyzer (NQA) and bidirectional forwarding detection (BFD), and establish the collaboration between the VF and the NQA or between the VF and the BFD through the tracking function. When the uplink fails, the state of the monitored track entry changes to negative and the weight of the VF decreases by a specified value. Then, the VF with a higher priority becomes the AVF and forwards packets.

The VF tracking function can also work on an LVF to monitor its corresponding AVF on another router. When the AVF fails, the LVF immediately takes over the AVF to ensure uninterrupted network communications.

## Packet types

VRRP standard protocol mode defines only VRRP advertisement. Only the master in a VRRP group periodically sends VRRP advertisements, and the backups do not send VRRP advertisements.

VRRP load balancing mode defines the following types of packets:

- **Advertisement**—VRRP advertises VRRP group state and information about the VF that is in the active state. Both the master and the backups periodically send VRRP advertisements.
- **Request**—If a backup is not the VF owner, it sends a request to ask the master to assign a virtual MAC address.
- **Reply**—When receiving a request, the master sends a reply to the backup router to assign a virtual MAC address. After receiving the reply, the backup router creates a VF that corresponds to the virtual MAC address, and then becomes the owner of this VF.
- **Release**—When a VF owner fails, the router that takes over its responsibility sends a release after a specified period of time to notify the other routers in the VRRP group to delete the VF of the failed VF owner.

---

### NOTE:

The format of these packets is similar to that of the advertisement in VRRP standard protocol mode except that a packet used in load balancing mode is appended with option field, which contains information for load balancing.

---

# Configuring VRRP for IPv4

## VRRP for IPv4 configuration task list

To form a VRRP group, perform the following configurations on each device in the VRRP group.

Complete these tasks to configure VRRP for IPv4:

Task	Remarks
Configuring a VRRP operation mode	Optional
Specifying the type of MAC addresses mapped to virtual IP addresses	Optional When VRRP is operating in load balancing mode, this configuration is not effective.
Creating a VRRP group and configuring virtual IP address	Required
Configuring router priority, preemptive mode and tracking function	Optional
Configuring VF tracking	Optional The VF tracking function is effective only when VRRP is operating in load balancing mode.
Configuring VRRP packet attributes	Optional
Enabling the trap function for VRRP	Optional

## Configuring a VRRP operation mode

VRRP can operate in either of the following modes:

- **Standard protocol mode**—When VRRP is operating in this mode, only the master in a VRRP group is responsible for forwarding packets.
- **Load balancing mode**—When VRRP is operating in this mode, all the routers (master and backups) that have the AVF in a VRRP group can forward packets, thus implementing load balancing.

After the VRRP operation mode is specified on a router, all VRRP groups on the router operate in the specified operation mode.

To configure a VRRP operation mode:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Configure a VRRP operation mode.	Configure VRRP to operate in standard protocol mode: <b>undo vrrp mode</b> Configure VRRP to operate in load balancing mode: <b>vrrp mode load-balance</b>	Use either command. By default, VRRP operates in standard protocol mode.

## Specifying the type of MAC addresses mapped to virtual IP addresses

After you specify the type of MAC addresses mapped to the virtual IP addresses of VRRP groups and create a VRRP group, the master in the VRRP group uses the specified type of MAC address as the source MAC address for sending packets and uses the specified type of MAC address to answer ARP requests

from hosts so that the hosts in the internal network can learn the mapping between the IP address and the MAC address.

The following types of MAC addresses are available to be mapped to the virtual IP address of a VRRP group:

- **Virtual MAC to virtual IP mapping**—By default, a virtual MAC address is automatically created for a VRRP group when the VRRP group is created, and the virtual IP address of the VRRP group is mapped to the virtual MAC address. When such a mapping is adopted, the hosts in the internal network do not need to update the mapping between the IP address and MAC address when the master changes.
- **Real MAC to virtual IP mapping**—In case that an IP address owner exists in a VRRP group, if the virtual IP address is mapped to the virtual MAC address, two MAC addresses are mapped to one IP address. To avoid such a problem, map the virtual IP address of the VRRP group to the real MAC address of an interface to forward the packets from a host to the IP address owner.

### Configuration guidelines

- When VRRP is operating in load balancing mode, a virtual IP address is always mapped to a virtual MAC address regardless of which type of MAC addresses are specified to be mapped to virtual IP addresses.
- Specify the type of the MAC addresses mapped to the virtual IP addresses before creating a VRRP group. Otherwise, you cannot change the type of the MAC addresses mapped to virtual IP addresses.
- If VRRP groups with the same ID are created on multiple interfaces of a device, and the VRRP advertisements of these VRRP groups are to be sent through QinQ networks, HP recommends you to map the real MAC addresses of the interfaces to the virtual IP addresses of these VRRP groups. Otherwise, the VRRP advertisements of these VRRP groups cannot be sent successfully.

### Configuration procedure

To specify the type of MAC addresses mapped to virtual IP addresses:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Specify the type of MAC addresses mapped to virtual IP addresses.	<b>vrrp method { real-mac   virtual-mac }</b>	Optional. Virtual MAC address by default.

## Creating a VRRP group and configuring virtual IP address

When creating a VRRP group on an interface, configure a virtual IP address for the VRRP group. If the interface connects to multiple sub-networks, you can configure multiple virtual IP addresses for the VRRP group to realize router backup on different sub-networks.

A VRRP group is automatically created when you specify the first virtual IP address for the VRRP group. If you specify another virtual IP address for the VRRP group later, the virtual IP address is added to the virtual IP address list of the VRRP group.

Do not create VRRP groups on the VLAN interface of a super VLAN. Otherwise, network performance might be affected.

## Configuration guidelines

- When VRRP is operating in standard protocol mode, the virtual IP address of a VRRP group can be either an unused IP address on the segment where the VRRP group resides or the IP address of an interface on a router in the VRRP group. In the latter case, the router is called the IP address owner.
- When a router is the IP address owner in a VRRP group, HP recommends you not to use the IP address of the interface (virtual IP address of the VRRP group) to establish a neighbor relationship with the adjacent router, that is, not to use the **network** command to enable OSPF on the interface. For more information about **network** command, see *Layer 3—IP Routing Command Reference*.
- When VRRP is operating in load balancing mode, the virtual IP address of a VRRP group cannot be the same as the IP address of any interface in the VRRP group. In other words, in load balancing mode, the VRRP group does not have an IP address owner.
- A VRRP group is removed after you remove all the virtual IP addresses configured for it. In addition, configurations on that VRRP group do not take effect any longer.
- Removal of the VRRP group on the IP address owner causes IP address collision. To solve the collision, modify the IP address of the interface on the IP address owner first and then remove the VRRP group from the interface.
- The virtual IP address of a VRRP group cannot be 0.0.0.0, 255.255.255.255, loopback addresses, non class A/B/C addresses or other illegal IP addresses such as 0.0.0.1.
- A VRRP group operates properly only when the configured virtual IP address and the interface IP address belong to the same segment and are legal host addresses. If the configured virtual IP address and the interface IP address do not belong to the same network segment, or the configured IP address is the network address or network broadcast address of the network segment to which the interface IP address belongs, the state of the VRRP group is always **initialize** though you can perform the configuration successfully. In this case, VRRP does not take effect.

## Configuration prerequisites

Before creating a VRRP group and configuring a virtual IP address on an interface, configure an IP address for the interface and make sure that it is in the same network segment as the virtual IP address to be configured.

## Configuration procedure

To create a VRRP group and configure a virtual IP address:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter the specified interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
3. Create a VRRP group and configure a virtual IP address for the VRRP group.	<b>vrrp vrid</b> <i>virtual-router-id</i> <b>virtual-ip</b> <i>virtual-address</i>	VRRP group is not created by default.

# Configuring router priority, preemptive mode and tracking function

## Configuration guidelines

- The running priority of an IP address owner is always 255 and you do not need to configure it. An IP address owner always operates in preemptive mode.
- If you configure an interface to be tracked or a track entry to be monitored on a router that is the IP address owner in a VRRP group, the configuration does not take effect. If the router is not the IP address owner in the VRRP group later, the configuration takes effect.
- If the state of a tracked interface changes from down or removed to up, the priority of the router where the interface resides is automatically restored.
- If the state of a track entry changes from negative or invalid to positive, the priority of the router where the track entry is configured is automatically restored.

## Configuration prerequisites

Before you configure router priority, preemptive mode and tracking function, create a VRRP group on an interface and configure a virtual IP address for it.

## Configuration procedure

By configuring router priority, preemptive mode, interface tracking, or a track entry, you can determine which router in the VRRP group serves as the master.

To configure router priority, preemptive mode and the tracking function:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure router priority in the VRRP group.	<b>vrrp vrid</b> <i>virtual-router-id</i> <b>priority</b> <i>priority-value</i>	Optional. 100 by default.
4. Configure the router in the VRRP group to operate in preemptive mode and configure preemption delay.	<b>vrrp vrid</b> <i>virtual-router-id</i> <b>preempt-mode</b> [ <b>timer delay</b> <i>delay-value</i> ]	Optional. The router in the VRRP group operates in preemptive mode and the preemption delay is 0 seconds by default.
5. Configure the interface to be tracked.	<b>vrrp vrid</b> <i>virtual-router-id</i> <b>track</b> <b>interface</b> <i>interface-type</i> <i>interface-number</i> [ <b>reduced</b> <i>priority-reduced</i> ]	Optional. No interface is being tracked by default.
6. Configure VRRP to track a specified track entry.	<b>vrrp vrid</b> <i>virtual-router-id</i> <b>track</b> <i>track-entry-number</i> [ <b>reduced</b> <i>priority-reduced</i>   <b>switchover</b> ]	Optional. Not configured by default.

# Configuring VF tracking

## Configuration guidelines

- You can configure the VF tracking function when VRRP is operating in either standard protocol mode or load balancing mode. However, the VF tracking function is effective only when VRRP is operating in load balancing mode.
- By default, the weight of a VF is 255, and its lower limit of failure is 10.
- If the weight of a VF owner is higher than or equal to the lower limit of failure, the priority of the VF owner is always 255 and does not change with the weight value. Therefore, in case of an uplink failure, another VF takes over the VF owner's work and becomes the AVF only when the weight of the VF owner decreases by a properly specified value and becomes lower than the lower limit of failure. In other words, the weight of the VF owner decreases by more than 245.

## Configuration prerequisites

Before you configure the VF tracking function, create a VRRP group and configure a virtual IP address for it.

## Configuration procedure

VRRP operates in load balancing mode. Assume that you have configured the VF tracking function to monitor the track entry and specified the value by which the weight decreases. When the status of the track entry becomes negative, the weight values of all VFs on the router decrease by the specified value. When the status of the track entry becomes positive or invalid, the weight values of all VFs on the router restore their original values.

If you configure the VF tracking function on an LVF to monitor its corresponding AVF on a specified router, the LVF can take over the AVF immediately when the status of the track entry becomes negative, to ensure uninterrupted network communications.

To configure VF tracking:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter the specified interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure VF tracking.	Configure the VF tracking function to monitor a specified track entry and specify the value by which the weight decreases: <b>vrrp vrid</b> <i>virtual-router-id</i> <b>weight</b> <b>track</b> <i>track-entry-number</i> [ <b>reduced</b> <i>weight-reduced</i> ] Configure the VF tracking function to monitor an AVF on a specified router: <b>vrrp vrid</b> <i>virtual-router-id</i> <b>track</b> <i>track-entry-number</i> <b>forwarder-switchover member-ip</b> <i>ip-address</i>	Use either approach. The VF tracking function is not configured by default.

# Configuring VRRP packet attributes

## Configuration guidelines

- You might configure different authentication modes and authentication keys for the VRRP groups on an interface. However, the members of the same VRRP group must use the same authentication mode and authentication key.
- Excessive traffic might cause a backup to trigger a change of its status because the backup does not receive any VRRP advertisements for a specified period of time. To solve this problem, prolong the time interval to send VRRP advertisements.
- Configuring different intervals for sending VRRP advertisements on the routers in a VRRP group might cause a backup to trigger a change of its status because the backup does not receive any VRRP advertisements for a specified period of time. To solve this problem, configure the same interval for sending VRRP advertisements on each router in the VRRP group.

## Configuration prerequisites

Before you configure the relevant attributes of VRRP packets, create a VRRP group and configure a virtual IP address for it.

## Configuration procedure

To configure VRRP packet attributes:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Set the Differentiated Services Code Point (DSCP) value for VRRP packets.	<b>vrrp dscp</b> <i>dscp-value</i>	Optional. 48 by default.
3. Enter the specified interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
4. Configure the authentication mode and authentication key when the VRRP groups send and receive VRRP packets.	<b>vrrp vrid</b> <i>virtual-router-id</i> <b>authentication-mode</b> { <b>md5</b>   <b>simple</b> } [ <b>cipher</b> ] <i>key</i>	Optional. Authentication is not performed by default.
5. Configure the time interval for the master in the VRRP group to send VRRP advertisements.	<b>vrrp vrid</b> <i>virtual-router-id</i> <b>timer advertise</b> <i>adver-interval</i>	Optional. 1 second by default.
6. Disable TTL check on VRRP packets.	<b>vrrp un-check ttl</b>	Optional. Enabled by default. You do not need to create a VRRP group before executing this command.

## Enabling the trap function for VRRP

When the trap function is enabled for VRRP, VRRP generates traps with severity level **errors** to report its key events. The traps are sent to the information center of the device, where you can configure whether to output the trap information and the output destination. For how to configure the information center, see *Network Management and Monitoring Configuration Guide*.

To enable the trap function for VRRP:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enable the trap function for VRRP.	<b>snmp-agent trap enable vrrp</b> [ <b>authfailure</b>   <b>newmaster</b> ]	Optional. Enabled by default.

For more information about the **snmp-agent trap enable vrrp** command, see the **snmp-agent trap enable** command in *Network Management and Monitoring Command Reference*.

## Displaying and maintaining VRRP for IPv4

Task	Command	Remarks
Display VRRP group status.	<b>display vrrp</b> [ <b>verbose</b> ] [ <b>interface</b> <i>interface-type interface-number</i> [ <b>vrid</b> <i>virtual-router-id</i> ] ] [ { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view
Display VRRP group statistics.	<b>display vrrp statistics</b> [ <b>interface</b> <i>interface-type interface-number</i> [ <b>vrid</b> <i>virtual-router-id</i> ] ] [ { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view
Clear VRRP group statistics.	<b>reset vrrp statistics</b> [ <b>interface</b> <i>interface-type interface-number</i> [ <b>vrid</b> <i>virtual-router-id</i> ] ]	Available in user view

## Configuring VRRP for IPv6

### VRRP for IPv6 configuration task list

Task	Remarks
Configuring a VRRP operation mode	Optional
Specifying the type of MAC addresses mapped to virtual IPv6 addresses	Optional When VRRP is operating in load balancing mode, this configuration is not effective.
Creating a VRRP group and configuring a virtual IPv6 address	Required
Configuring router priority, preemptive mode and tracking function	Optional
Configuring VF tracking	Optional The VF tracking function is effective only when VRRP is operating in load balancing mode.
Configuring VRRP packet attributes	Optional

## Specifying the type of MAC addresses mapped to virtual IPv6 addresses

After you specify the type of MAC addresses mapped to the virtual IPv6 address of VRRP groups and create a VRRP group, the master in the VRRP group uses the specified type of MAC address as the source MAC address for sending packets and uses the specified type of MAC address to answer ND requests from hosts so that the hosts in the internal network can learn the mapping between the IPv6 address and the MAC address.

The following types of MAC addresses are available to be mapped to the virtual IPv6 address of a VRRP group:

- **Virtual MAC to virtual IP mapping**—By default, a virtual MAC address is automatically created for a VRRP group when the VRRP group is created, and the virtual IPv6 address of the VRRP group is mapped to the virtual MAC address. When such a mapping is adopted, the hosts in the internal network do not need to update the mapping between the IPv6 address and the MAC address when the master changes.
- **Real MAC to virtual IP mapping**—In case that an IP address owner exists in a VRRP group, if the virtual IPv6 address is mapped to the virtual MAC address, two MAC addresses are mapped to one IPv6 address. To avoid such a problem, map the virtual IPv6 address of the VRRP group to the real MAC address of an interface to forward the packets from a host to the IP address owner.

When VRRP is operating in load balancing mode, a virtual IPv6 address is always mapped to a virtual MAC address regardless of which type of MAC addresses are specified to be mapped to virtual IPv6 addresses.

Specify the type of the MAC addresses mapped to the virtual IPv6 addresses before creating a VRRP group. Otherwise, you cannot change the type of the MAC addresses mapped to virtual IPv6 addresses.

To specify the type of MAC addresses mapped to virtual IPv6 addresses:

Step	Command	Remarks
1. Enter system view.	<code>system-view</code>	N/A
2. Specify the type of MAC addresses mapped to virtual IPv6 addresses.	<code>vrrp ipv6 method { real-mac   virtual-mac }</code>	Optional. Virtual MAC address by default.

## Creating a VRRP group and configuring a virtual IPv6 address

When creating a VRRP group, configure a virtual IPv6 address for the VRRP group. You can configure multiple virtual IPv6 addresses for a VRRP group.

A VRRP group is automatically created when you specify the first virtual IPv6 address for the VRRP group. If you specify another virtual IPv6 address for the VRRP group later, the virtual IPv6 address is added to the virtual IPv6 address list of the VRRP group.

Do not create VRRP groups on the VLAN interface of a super VLAN. Otherwise, network performance might be affected.

### Configuration guidelines

- When a router is the IP address owner in a VRRP group, HP recommends you not to use the IPv6 address of the interface (virtual IPv6 address of the VRRP group) to establish an OSPFv3 neighbor relationship with the adjacent router, that is, not to use the **ospfv3 area** command to enable

OSPFv3 on the interface. For more information about **ospfv3 area** command, see *Layer 3—IP Routing Command Reference*.

- When VRRP is operating in load balancing mode, the virtual IPv6 address of a VRRP group cannot be the same as the IPv6 address of any interface in the VRRP group. In other words, a VRRP group does not have an IP address owner in load balancing mode.
- A VRRP group is removed after you remove all the virtual IPv6 addresses in it. In addition, configurations on that VRRP group do not take effect any longer.
- Removal of the VRRP group on the IP address owner causes IP address collision. To resolve the collision, change the IPv6 address of the interface on the IP address owner first and then remove the VRRP group from the interface.

## Configuration prerequisites

Before creating a VRRP group and configuring a virtual IPv6 address on an interface, configure an IPv6 address for the interface and make sure that it is in the same network segment as the virtual IPv6 address to be configured.

## Configuration procedure

To create a VRRP group and configure its virtual IPv6 address:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter the specified interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
3. Create a VRRP group and configure its virtual IPv6 address, which is a link local address.	<b>vrrp ipv6 vrid</b> <i>virtual-router-id</i> <b>virtual-ip</b> <i>virtual-address</i> <b>link-local</b>	No VRRP group is created by default. The first virtual IPv6 address of the VRRP group must be a link local address. Only one link local address is allowed in a VRRP group, and must be removed the last.
4. Configure the VRRP group with a virtual IPv6 address, which is a global unicast address.	<b>vrrp ipv6 vrid</b> <i>virtual-router-id</i> <b>virtual-ip</b> <i>virtual-address</i>	Optional. By default, no global unicast address is configured as the virtual IPv6 address of a VRRP group.

# Configuring router priority, preemptive mode and tracking function

## Configuration guidelines

- The running priority of an IP address owner is always 255 and you do not need to configure it. An IP address owner always operates in preemptive mode.
- Interface tracking is not configurable on an IP address owner.
- If you configure an interface to be tracked or a track entry to be monitored on a router that is the IP address owner in a VRRP group, the configuration does not take effect. If the router is not the IP address owner in the VRRP group later, the configuration takes effect.

- If the state of a tracked interface changes from down or removed to up, the priority of the router that owns the interface is automatically restored.
- If the state of a track entry changes from negative or invalid to positive, the priority of the router where the track entry is configured is automatically restored.

## Configuration prerequisites

Before you configure router priority, preemptive mode and tracking function, create a VRRP group and configure its virtual IPv6 address.

## Configuration procedure

By configuring router priority, preemptive mode, interface tracking, or a track entry, determine which router in the VRRP group serves as the master.

To configure router priority, preemptive mode and interface tracking:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter the specified interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the priority of the router in the VRRP group.	<b>vrrp ipv6 vrid</b> <i>virtual-router-id</i> <b>priority</b> <i>priority-value</i>	Optional. 100 by default.
4. Configure the router in the VRRP group to operate in preemptive mode and configure preemption delay of the VRRP group.	<b>vrrp ipv6 vrid</b> <i>virtual-router-id</i> <b>preempt-mode</b> [ <b>timer delay</b> <i>delay-value</i> ]	Optional. The router in the VRRP group operates in preemptive mode and the preemption delay is zero seconds by default.
5. Configure the interface to be tracked.	<b>vrrp ipv6 vrid</b> <i>virtual-router-id</i> <b>track</b> <b>interface</b> <i>interface-type</i> <i>interface-number</i> [ <b>reduced</b> <i>priority-reduced</i> ]	Optional. No interface is being tracked by default.
6. Configure VRRP to track a specified track entry.	<b>vrrp ipv6 vrid</b> <i>virtual-router-id</i> <b>track</b> <i>track-entry-number</i> [ <b>reduced</b> <i>priority-reduced</i>   <b>switchover</b> ]	Optional. Not configured by default.

## Configuring VF tracking

### Configuration guidelines

- You can configure the VF tracking function when VRRP is operating in either standard protocol mode or load balancing mode. However, the VF tracking function is effective only when VRRP is operating in load balancing mode.
- By default, the weight of a VF is 255, and its lower limit of failure is 10.
- If the weight of a VF owner is higher than or equal to the lower limit of failure, the priority of the VF owner is always 255 and does not change with the weight value. Therefore, if an uplink fails, another VF takes over the VF owner's work and becomes the AVF only when the weight of the VF owner decreases by a properly specified value and becomes lower than the lower limit of failure. In other words, the weight of the VF owner decreases by more than 245.

## Configuration prerequisites

Before you configure the VF tracking function, create a VRRP group and configure a virtual IPv6 address for it.

## Configuration procedure

VRRP operates in load balancing mode. Assume that you have configured the VF tracking function to monitor a track entry and specified the value by which the weight decreases. When the status of the track entry becomes negative, the weight values of all VFs on the router decrease by the specified value. When the status of the track entry becomes positive or invalid, the weight values of all VFs on the router restore their original values.

If you configure the VF tracking function on an LVF to monitor its corresponding AVF on a specified router, the LVF can take over the AVF immediately when the status of the track entry becomes negative, to ensure uninterrupted network communications.

To configure VF tracking:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enter the specified interface view.	<b>interface</b> <i>interface-type interface-number</i>	N/A
3. Configure VF tracking.	<p>Configure the VF tracking function to monitor a specified track entry and specify the value by which the weight decreases: <b>vrp ipv6 vrid</b> <i>virtual-router-id</i> <b>weight track</b> <i>track-entry-number</i> [ <b>reduced</b> <i>weight-reduced</i> ]</p> <p>Configure the VF tracking function to monitor an AVF on a specified router: <b>vrp ipv6 vrid</b> <i>virtual-router-id</i> <b>track</b> <i>track-entry-number</i> <b>forwarder-switchover</b> <b>member-ip</b> <i>ipv6-address</i></p>	<p>Use either approach. The VF tracking function is not configured by default.</p>

## Configuring VRRP packet attributes

### Configuration guidelines

- You might configure different authentication modes and authentication keys for the VRRP groups on an interface. However, the members of the same VRRP group must use the same authentication mode and authentication key.
- Excessive traffic might cause a backup to trigger a change of its status because the backup does not receive any VRRP advertisements for a specified period of time. To solve this problem, prolong the time interval to send VRRP advertisements.
- Configuring different intervals for sending VRRP advertisements on the routers in a VRRP group might cause a backup to trigger a change of its status because the backup does not receive any VRRP advertisements for a specified period of time. To solve this problem, configure the same interval for sending VRRP advertisements on each router in the VRRP group.

### Configuration prerequisites

Before you configure the relevant attributes of VRRP packets, create a VRRP group and configure a virtual IPv6 address.

## Configuration procedure

To configure VRRP packet attributes:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Set the DSCP value for VRRP packets.	<b>vrrp ipv6 dscp</b> <i>dscp-value</i>	Optional. 56 by default.
3. Enter the specified interface view.	<b>interface</b> <i>interface-type</i> <i>interface-number</i>	N/A
4. Configure the authentication mode and authentication key when the VRRP groups send or receive VRRP packets.	<b>vrrp ipv6 vrid</b> <i>virtual-router-id</i> <b>authentication-mode</b> <b>simple</b> [ <b>cipher</b> ] <i>key</i>	Optional. Authentication is not performed by default.
5. Configure the time interval for the master in the VRRP group to send VRRP advertisement.	<b>vrrp ipv6 vrid</b> <i>virtual-router-id</i> <b>timer</b> <b>advertise</b> <i>adver-interval</i>	Optional. 100 centiseconds by default.

## Displaying and maintaining VRRP for IPv6

Task	Command	Remarks
Display VRRP group status.	<b>display vrrp ipv6</b> [ <b>verbose</b> ] [ <b>interface</b> <i>interface-type interface-number</i> [ <b>vrid</b> <i>virtual-router-id</i> ] ] [ { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view
Display VRRP group statistics.	<b>display vrrp ipv6 statistics</b> [ <b>interface</b> <i>interface-type interface-number</i> [ <b>vrid</b> <i>virtual-router-id</i> ] ] [ { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view
Clear VRRP group statistics.	<b>reset vrrp ipv6 statistics</b> [ <b>interface</b> <i>interface-type</i> <i>interface-number</i> [ <b>vrid</b> <i>virtual-router-id</i> ] ]	Available in user view

## IPv4-based VRRP configuration examples

### Single VRRP group configuration example

#### Network requirements

- Host A wants to access Host B on the Internet, using 202.38.160.111/24 as its default gateway.
- Switch A and Switch B belong to VRRP group 1 with the virtual IP address of 202.38.160.111/24.
- When Switch A operates normally, packets sent from Host A to Host B are forwarded by Switch A; when Switch A fails, packets sent from Host A to Host B are forwarded by Switch B.

**Figure 40 Network diagram**

## Configuration procedure

### 1. Configure Switch A:

# Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 202.38.160.1 255.255.255.0
```

# Create VRRP group 1 and set its virtual IP address to 202.38.160.111.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 202.38.160.111
```

# Set the priority of Switch A in VRRP group 1 to 110, which is higher than that of Switch B (100), so that Switch A can become the master.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

# Configure Switch A to operate in preemptive mode so that it can become the master whenever it works normally, and configure the preempt delay as five seconds to avoid frequent status switchover.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5
```

### 2. Configure Switch B:

# Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-Vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 202.38.160.2 255.255.255.0
```

# Create VRRP group 1 and set its virtual IP address to 202.38.160.111.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 202.38.160.111
```

# Set Switch B to operate in preemptive mode. The preempt delay is five seconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5
```

### 3. Verify the configuration:

After the configuration, Host B can be pinged successfully on Host A. To verify your configuration, use the **display vrrp verbose** command.

# Display the detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 1
 Admin Status : Up State : Master
 Config Pri : 110 Running Pri : 110
 Preempt Mode : Yes Delay Time : 5
 Auth Type : None
 Virtual IP : 202.38.160.111
 Virtual MAC : 0000-5e00-0101
 Master IP : 202.38.160.1
```

# Display the detailed information about VRRP group 1 on Switch B.

```
[SwitchB-Vlan-interface2] display vrrp verbose
IPv4 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 1
 Admin Status : Up State : Backup
 Config Pri : 100 Running Pri : 100
 Preempt Mode : Yes Delay Time : 5
 Become Master : 4200ms left
 Auth Type : None
 Virtual IP : 202.38.160.111
 Master IP : 202.38.160.1
```

The output shows that in VRRP group 1 Switch A is the master, Switch B is the backup and packets sent from Host A to Host B are forwarded by Switch A.

When Switch A fails, you can still ping through Host B on Host A. Use the **display vrrp verbose** command to view the detailed information about the VRRP group on Switch B.

# When Switch A fails, the detailed information about VRRP group 1 on Switch B is displayed.

```
[SwitchB-Vlan-interface2] display vrrp verbose
IPv4 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 1
 Admin Status : Up State : Master
 Config Pri : 100 Running Pri : 100
```

```
Preempt Mode : Yes Delay Time : 5
Auth Type : None
Virtual IP : 202.38.160.111
Virtual MAC : 0000-5e00-0101
Master IP : 202.38.160.2
```

The output shows that when Switch A fails, Switch B becomes the master, and packets sent from Host A to Host B are forwarded by Switch B.

# After Switch A resumes normal operation, use the **display vrrp verbose** command to display the detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 1
 Admin Status : Up State : Master
 Config Pri : 110 Running Pri : 110
 Preempt Mode : Yes Delay Time : 5
 Auth Type : None
 Virtual IP : 202.38.160.111
 Virtual MAC : 0000-5e00-0101
 Master IP : 202.38.160.1
```

The output shows that after Switch A resumes normal operation, it becomes the master, and packets sent from host A to host B are forwarded by Switch A.

## VRRP interface tracking configuration example

### Network requirements

- Host A wants to access Host B on the Internet, using 202.38.160.111/24 as its default gateway.
- Switch A and Switch B belong to VRRP group 1 with the virtual IP address of 202.38.160.111/24.
- If Switch A operates normally, packets sent from Host A to Host B are forwarded by Switch A. If VLAN-interface 3 through which Switch A connects to the Internet is not available, packets sent from Host A to Host B are forwarded by Switch B.
- To prevent attacks to the VRRP group from illegal users by using spoofed packets, configure the authentication mode as plain text to authenticate the VRRP packets in VRRP group 1, and specify the authentication key as **hello**.

Figure 41 Network diagram

## Configuration procedure

### 1. Configure Switch A:

# Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 202.38.160.1 255.255.255.0
```

# Create a VRRP group 1 and set its virtual IP address to 202.38.160.111.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 202.38.160.111
```

# Configure the priority of Switch A in the VRRP group to 110, which is higher than that of Switch B (100), so that Switch A can become the master.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

# Configure the authentication mode of the VRRP group as **simple** and authentication key as **hello**.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
```

# Set the interval for Master to send VRRP advertisement to four seconds.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 timer advertise 4
```

# Configure Switch A to operate in preemptive mode, so that it can become the master whenever it works normally; configure the preemption delay as five seconds to avoid frequent status switchover.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5
```

# Set VLAN interface 3 on Switch A to be tracked, and configure the amount by which the priority value decreases to be more than 10 (30 in this example), so that when VLAN-interface 3 fails, the priority of Switch A in VRRP group 1 decreases to a value lower than 100 and thus Switch B can become the master.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track interface vlan-interface 3 reduced 30
```

### 2. Configure Switch B:

# Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
```

```

[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 202.38.160.2 255.255.255.0
Create a VRRP group 1 and set its virtual IP address to 202.38.160.111.
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 202.38.160.111
Configure the authentication mode of the VRRP group as simple and authentication key as hello.
[SwitchB-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
Set the interval for master to send VRRP advertisement to four seconds.
[SwitchB-Vlan-interface2] vrrp vrid 1 timer advertise 4
Configure Switch B to operate in preemptive mode, so that Switch B can become the master after
the priority of Switch A decreases to a value lower than 100. Configure the preemption delay as
five seconds to avoid frequent status switchover.
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5

```

### 3. Verify the configuration:

After the configuration, Host B can be pinged successfully on Host A. To verify your configuration, use the **display vrrp verbose** command.

# Display the detailed information about VRRP group 1 on Switch A.

```

[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 4
 Admin Status : Up State : Master
 Config Pri : 110 Running Pri : 110
 Preempt Mode : Yes Delay Time : 5
 Auth Type : Simple Key : *****
 Virtual IP : 202.38.160.111
 Virtual MAC : 0000-5e00-0101
 Master IP : 202.38.160.1
VRRP Track Information:
 Track Interface: Vlan3 State : Up Pri Reduced : 30

```

# Display the detailed information about VRRP group 1 on Switch B.

```

[SwitchB-Vlan-interface2] display vrrp verbose
IPv4 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 4
 Admin Status : Up State : Backup
 Config Pri : 100 Running Pri : 100
 Preempt Mode : Yes Delay Time : 5
 Become Master : 2200ms left
 Auth Type : Simple Key : *****

```

```
Virtual IP : 202.38.160.111
Master IP : 202.38.160.1
```

The output shows that in VRRP group 1 Switch A is the master, Switch B is the backup and packets sent from Host A to Host B are forwarded by Switch A.

If interface VLAN-interface 3 through which Switch A connects to the Internet is not available, you can still ping Host B successfully on Host A. To view the detailed information about the VRRP group, use the **display vrrp verbose** command.

# If VLAN-interface 3 on Switch A is not available, the detailed information about VRRP group 1 on Switch A is displayed.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 4
 Admin Status : Up State : Backup
 Config Pri : 110 Running Pri : 80
 Preempt Mode : Yes Delay Time : 5
 Become Master : 2200ms left
 Auth Type : Simple Key : *****
 Virtual IP : 202.38.160.111
 Master IP : 202.38.160.2
VRRP Track Information:
 Track Interface: Vlan3 State : Down Pri Reduced : 30
```

# When VLAN-interface 3 on Switch A is not available, the detailed information about VRRP group 1 on Switch B is displayed.

```
[SwitchB-Vlan-interface2] display vrrp verbose
IPv4 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 4
 Admin Status : Up State : Master
 Config Pri : 100 Running Pri : 100
 Preempt Mode : Yes Delay Time : 5
 Auth Type : Simple Key : *****
 Virtual IP : 202.38.160.111
 Virtual MAC : 0000-5e00-0101
 Master IP : 202.38.160.2
```

The output shows that when VLAN-interface 3 on Switch A is not available, the priority of Switch A is reduced to 80 and it becomes the backup. Switch B becomes the master and packets sent from Host A to Host B are forwarded by Switch B.

# VRRP with multiple VLANs configuration example

## Network requirements

- Hosts in VLAN 2 use 202.38.160.100/25 as their default gateway and hosts in VLAN 3 use 202.38.160.200/25 as their default gateway.
- Switch A and Switch B belong to both VRRP group 1 and VRRP group 2. The virtual IP address of VRRP group 1 is 202.38.160.100/25, and that of VRRP group 2 is 202.38.160.200/25.
- In VRRP group 1, Switch A has a higher priority than Switch B. In VRRP group 2, Switch B has a higher priority than Switch A. In this case, hosts in VLAN 2 and VLAN 3 can communicate with external networks through Switch A and Switch B, respectively, and when Switch A or Switch B fails, the hosts can use the other switch to communicate with external networks to avoid communication interruption.

Figure 42 Network diagram

## Configuration procedure

### 1. Configure Switch A:

# Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 202.38.160.1 255.255.255.128
```

# Create a VRRP group 1 and set its virtual IP address to 202.38.160.100.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 202.38.160.100
```

# Configure the priority of Switch A in VRRP group 1 as 110, which is higher than that of Switch B (100), so that Switch A can become the master in VRRP group 1.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

```
[SwitchA-Vlan-interface2] quit
```

# Configure VLAN 3.

```
[SwitchA] vlan 3
[SwitchA-vlan3] port gigabitethernet 1/0/6
```

```
[SwitchA-vlan3] quit
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ip address 202.38.160.130 255.255.255.128
Create a VRRP group 2 and set its virtual IP address to 202.38.160.200.
[SwitchA-Vlan-interface3] vrrp vrid 2 virtual-ip 202.38.160.200
```

## 2. Configure Switch B:

### # Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 202.38.160.2 255.255.255.128
Create a VRRP group 1 and set its virtual IP address to 202.38.160.100.
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 202.38.160.100
[SwitchB-Vlan-interface2] quit
```

### # Configure VLAN 3.

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/6
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] ip address 202.38.160.131 255.255.255.128
Create a VRRP group 2 and set its virtual IP address to 202.38.160.200.
[SwitchB-Vlan-interface3] vrrp vrid 2 virtual-ip 202.38.160.200
Configure the priority of Switch B in VRRP group 2 to 110, which is higher than that of Switch A (100), so that Switch B can become the master in VRRP group 2.
[SwitchB-Vlan-interface3] vrrp vrid 2 priority 110
```

## 3. Verify the configuration:

To verify your configuration, use the **display vrrp verbose** command.

# Display the detailed information about the VRRP group on Switch A.

```
[SwitchA-Vlan-interface3] display vrrp verbose
IPv4 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 2
Interface Vlan-interface2

 Admin Status : Up State : Master
 Config Pri : 110 Running Pri : 110
 Preempt Mode : Yes Delay Time : 0
 Auth Type : None
 Virtual IP : 202.38.160.200
 Virtual MAC : 0000-5e00-0102
 Master IP : 202.38.160.131

```

The output shows that in VRRP group 1 Switch A is the master, Switch B is the backup and hosts with the default gateway of 202.38.160.100/25 accesses the Internet through Switch A; in VRRP group 2 Switch A is the backup, Switch B is the master and hosts with the default gateway of 202.38.160.200/25 accesses the Internet through Switch B.

## VRRP load balancing mode configuration example

### Network requirements

- Switch A, Switch B, and Switch C belong to VRRP group 1 with the virtual IP address of 10.1.1.1/24.
- Hosts on network segment 10.1.1.0/24 use 10.1.1.1/24 as their default gateway. Use the VRRP group to make sure that when a gateway (Switch A, Switch B, or Switch C) fails, the hosts on the LAN can access external networks through another gateway.
- VRRP group 1 is operating in load balancing mode to make good use of network resources.
- Configure a track entry on Switch A, Switch B, and Switch C to monitor their own VLAN-interface 3. When the interface on Switch A, Switch B, or Switch C fails, the weight of the corresponding switch decreases so that another switch with a higher weight can take over.

- Configure track entries on Switch C to monitor Switch A and Switch B. When Switch A or Switch B fails, Switch C immediately takes over the AVF on Switch A or Switch B.

Figure 43 Network diagram

## Configuration procedure

### 1. Configure Switch A:

# Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
```

# Configure VRRP to operate in load balancing mode.

```
[SwitchA] vrrp mode load-balance
```

# Create VRRP group 1 and configure its virtual IP address as 10.1.1.1.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 10.1.1.2 24
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.1
```

# Set the priority of Switch A in VRRP group 1 to 120, which is higher than that of Switch B (110) and that of Switch C (100), so that Switch A can become the master.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 120
```

# Configure Switch A to operate in preemptive mode, so that it can become the master whenever it works normally; configure the preemption delay as five seconds to avoid frequent status switchover.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5
[SwitchA-Vlan-interface2] quit
```

# Create track entry 1 to associate with the physical status of VLAN-interface 3 on Switch A. When the track entry becomes negative, it means that the interface fails.

```
[SwitchA] track 1 interface vlan-interface 3
```

# Configure VF tracking to monitor track entry 1 and specify the value by which the weight decreases, making the weight of Switch A decrease by more than 245 (250 in this example) when track entry 1 turns to negative. In such a case, another router with a higher weight can take over.

```
[SwitchA] interface vlan-interface 2
```

```
[SwitchA-Vlan-interface2] vrrp vrid 1 weight track 1 reduced 250
```

## 2. Configure Switch B:

# Configure VLAN 2.

```
<SwitchB> system-view
```

```
[SwitchB] vlan 2
```

```
[SwitchB-vlan2] port gigabitethernet 1/0/5
```

```
[SwitchB-vlan2] quit
```

# Configure VRRP to operate in load balancing mode.

```
[SwitchB] vrrp mode load-balance
```

# Create VRRP group 1 and configure its virtual IP address as 10.1.1.1.

```
[SwitchB] interface vlan-interface 2
```

```
[SwitchB-Vlan-interface2] ip address 10.1.1.3 24
```

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.1
```

# Set the priority of Switch B in VRRP group 1 to 110, which is higher than that of Switch C (100), so that Switch B can become the master when Switch A fails.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 priority 110
```

# Set Switch B to operate in preemptive mode. The preemption delay is five seconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5
```

```
[SwitchB-Vlan-interface2] quit
```

# Create track entry 1 to associate with the physical status of VLAN-interface 3 on Switch B. When the track entry becomes negative, it means that the interface fails.

```
[SwitchB] track 1 interface vlan-interface 3
```

# Configure VF tracking to monitor track entry 1 and specify the value by which the weight decreases, making the weight of Switch B decrease by more than 245 (250 in this example) when track entry 1 turns to negative. In such a case, another router with a higher weight can take over.

```
[SwitchB] interface vlan-interface 2
```

```
[SwitchB-Vlan-interface2] vrrp vrid 1 weight track 1 reduced 250
```

## 3. Configure Switch C:

# Configure VLAN 2.

```
<SwitchC> system-view
```

```
[SwitchC] vlan 2
```

```
[SwitchC-vlan2] port gigabitethernet 1/0/5
```

```
[SwitchC-vlan2] quit
```

# Configure VRRP to operate in load balancing mode.

```
[SwitchC] vrrp mode load-balance
```

# Create VRRP group 1 and configure its virtual IP address as 10.1.1.1.

```
[SwitchC] interface vlan-interface 2
```

```
[SwitchC-Vlan-interface2] ip address 10.1.1.4 24
```

```
[SwitchC-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.1
```

# Set Switch C to operate in preemptive mode. The preemption delay is five seconds.

```
[SwitchC-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5
[SwitchC-Vlan-interface2] quit
```

# Create track entry 1 to associate with the physical status of VLAN-interface 3 on Switch C. When the track entry becomes negative, it means that the interface fails.

```
[SwitchC] track 1 interface vlan-interface 3
```

# Configure VF tracking to monitor track entry 1 and specify the value by which the weight decreases, making the weight of Switch C decrease by more than 245 (250 in this example) when track entry 1 turns to negative. In such a case, another router with a higher weight can take over.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] vrrp vrid 1 weight track 1 reduced 250
[SwitchC-Vlan-interface2] quit
```

# Create track entries 2 and 3 to monitor Switch A and Switch B, respectively. If a track entry becomes negative, it indicates that the corresponding switch fails.

```
[SwitchC] bfd echo-source-ip 1.2.3.4
[SwitchC] track 2 bfd echo interface vlan-interface 2 remote ip 10.1.1.2 local ip 10.1.1.4
[SwitchC] track 3 bfd echo interface vlan-interface 2 remote ip 10.1.1.3 local ip 10.1.1.4
```

# Configure VF tracking to monitor track entry 2. When track entry 2 becomes negative, the LVF on Switch C whose corresponding AVF is on the switch with the IP address of 10.1.1.2 immediately becomes active. Switch C takes over the AVF on Switch A.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] vrrp vrid 1 track 2 forwarder-switchover member-ip 10.1.1.2
```

# Configure VF tracking to monitor track entry 3. When track entry 2 becomes negative, the LVF on Switch C whose corresponding AVF is on the switch with the IP address of 10.1.1.3 immediately becomes active. Switch C takes over the AVF on Switch B.

```
[SwitchC-Vlan-interface2] vrrp vrid 1 track 3 forwarder-switchover member-ip 10.1.1.3
```

#### 4. Verify the configuration:

After the configuration, Host A can ping the external network. To verify your configuration, use the **display vrrp verbose** command.

# Display the detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose

```

The output shows that when Switch B fails, Switch C becomes the master, and Forwarder 02 on Switch C immediately becomes active. Switch C takes over the AVF on Switch B.

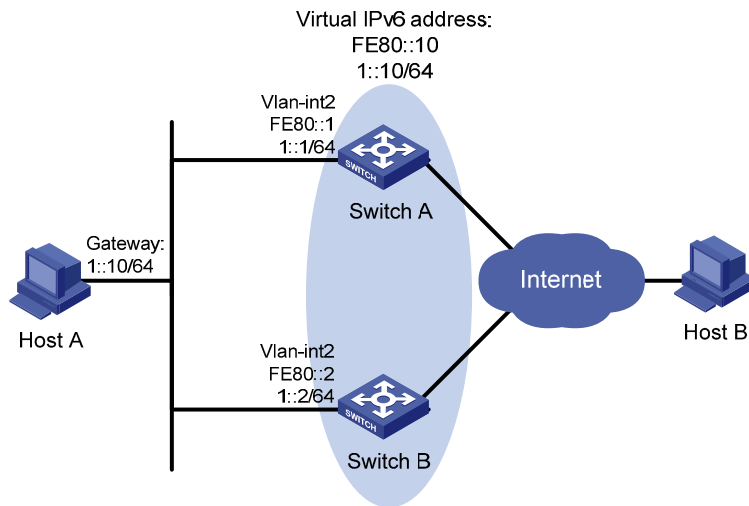

## IPv6-based VRRP configuration examples

### Single VRRP group configuration example

#### Network requirements

- Switch A and Switch B belong to VRRP group 1 with the virtual IP addresses of 1::10/64 and FE80::10.
- Host A wants to access Host B on the Internet, and learns 1::10/64 as its default gateway through RA messages sent by the switches.
- When Switch A operates normally, packets sent from Host A to Host B are forwarded by Switch A; when Switch A fails, packets sent from Host A to Host B are forwarded by Switch B.

Figure 44 Network diagram

## Configuration procedure

### 1. Configure Switch A:

# Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
[SwitchA-Vlan-interface2] ipv6 address 1::1 64
```

# Create a VRRP group 1 and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

# Set the priority of Switch A in VRRP group 1 to 110, which is higher than that of Switch B (100), so that Switch A can become the master.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
```

# Configure Switch A to operate in preemptive mode so that it can become the master whenever it works normally, and configure the preemption delay as five seconds to avoid frequent status switchover.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode timer delay 5
```

# Enable Switch A to send RA messages, so that Host A can learn the default gateway address.

```
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
```

### 2. Configure Switch B:

# Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
```

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
Create a VRRP group 1 and set its virtual IPv6 addresses to FE80::10 and 1::10.
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
Configure Switch B to operate in preemptive mode, with the preemption delay set to 5 seconds.
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode timer delay 5
Enable Switch B to send RA messages, so that Host A can learn the default gateway address.
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode timer delay 5
```

### 3. Verify the configuration:

After the configuration, Host B can be pinged successfully on Host A. To verify your configuration, use the **display vrrp ipv6 verbose** command.

# Display the detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp ipv6 verbose
IPv6 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC

 Config Pri : 100 Running Pri : 100
 Preempt Mode : Yes Delay Time : 5
 Become Master : 4200ms left
 Auth Type : None
 Virtual IP : FE80::10
 1::10
 Master IP : FE80::1
```

The output shows that in VRRP group 1 Switch A is the master, Switch B is the backup and packets sent from Host A to Host B are forwarded by Switch A.

When Switch A fails, you can still successfully ping Host B on Host A. To view the detailed information about the VRRP group on Switch B, use the **display vrrp ipv6 verbose** command.

# When Switch A fails, the detailed information about VRRP group 1 on Switch B is displayed.

```
[SwitchB-Vlan-interface2] display vrrp ipv6 verbose
IPv6 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 100
 Admin Status : Up State : Master
 Config Pri : 100 Running Pri : 100
 Preempt Mode : Yes Delay Time : 5
 Auth Type : None
 Virtual IP : FE80::10
 1::10
 Virtual MAC : 0000-5e00-0201
 Master IP : FE80::2
```

The output shows that when Switch A fails, Switch B becomes the master, and packets sent from Host A to Host B are forwarded by Switch B.

# After Switch A resumes normal operation, use the **display vrrp ipv6 verbose** command to display the detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp ipv6 verbose
IPv6 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 100
 Admin Status : Up State : Master
 Config Pri : 110 Running Pri : 110
 Preempt Mode : Yes Delay Time : 5
 Auth Type : None
 Virtual IP : FE80::10
 1::10
 Virtual MAC : 0000-5e00-0201
 Master IP : FE80::1
```

The output shows that after Switch A resumes normal operation, it becomes the master, and packets sent from host A to host B are forwarded by Switch A.

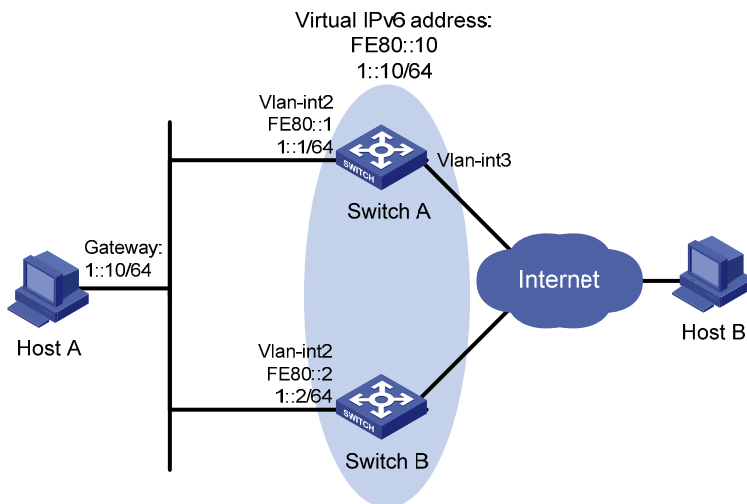

## VRRP interface tracking configuration example

### Network requirements

- Switch A and Switch B belong to VRRP group 1 with the virtual IP addresses of 1::10/64 and FE80::10.
- Host A wants to access Host B on the Internet, and learns 1::10/64 as its default gateway through RA messages sent by the switches.

- When Switch A operates normally, packets sent from Host A to Host B are forwarded by Switch A. If VLAN-interface 3 through which Switch A connects to the Internet is not available, packets sent from Host A to Host B are forwarded by Switch B.
- To prevent attacks to the VRRP group from illegal users by using spoofed packets, configure the authentication mode as plain text to authenticate the VRRP packets in VRRP group 1, and specify the authentication key as **hello**.

**Figure 45 Network diagram**

## Configuration procedure

### 1. Configure Switch A:

# Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
[SwitchA-Vlan-interface2] ipv6 address 1::1 64
```

# Create a VRRP group 1 and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

# Set the priority of Switch A in VRRP group 1 to 110, which is higher than that of Switch B (100), so that Switch A can become the master.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
```

# Set the authentication mode for VRRP group 1 to **simple** and authentication key to **hello**.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 authentication-mode simple hello
```

# Set the VRRP advertisement interval to 400 centiseconds.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 timer advertise 400
```

# Configure Switch A to operate in preemptive mode, so that it can become the master whenever it works normally; configure the preemption delay as five seconds to avoid frequent status switchover.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode timer delay 5
Set VLAN-interface 3 on Switch A to be tracked, and configure the amount by which the priority
value decreases to be more than 10 (30 in this example), so that when VLAN interface 3 fails, the
priority of Switch A in VRRP group 1 decreases to a value lower than 100 and thus Switch B can
become the master.
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 track interface vlan-interface 3 reduced
30
Enable Switch A to send RA messages, so that Host A can learn the default gateway address.
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
```

## 2. Configure Switch B:

# Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
```

# Create a VRRP group 1 and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

# Set the authentication mode for VRRP group 1 to **simple** and authentication key to **hello**.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 authentication-mode simple hello
```

# Set the VRRP advertisement interval to 400 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 timer advertise 400
```

# Configure Switch B to operate in preemptive mode, so that Switch B can become the master after the priority of Switch A decreases to a value lower than 100. Configure the preemption delay as five seconds to avoid frequent status switchover.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode timer delay 5
```

# Enable Switch B to send RA messages, so that Host A can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
```

## 3. Verify the configuration:

After the configuration, Host B can be pinged successfully on Host A. To verify the configuration, use the **display vrrp ipv6 verbose** command.

# Display the detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp ipv6 verbose
IPv6 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 400
 Admin Status : Up State : Master
 Config Pri : 110 Running Pri : 110
 Preempt Mode : Yes Delay Time : 5
```

```

Auth Type : Simple Key : *****
Virtual IP : FE80::10
 1::10
Virtual MAC : 0000-5e00-0201
Master IP : FE80::1

```

VRRP Track Information:

```

Track Interface: Vlan3 State : Up Pri Reduced : 30

```

# Display the detailed information about VRRP group 1 on Switch B.

```
[SwitchB-Vlan-interface2] display vrrp ipv6 verbose
```

IPv6 Standby Information:

```

Run Mode : Standard
Run Method : Virtual MAC

```

Total number of virtual routers : 1

Interface Vlan-interface2

```

VRID : 1 Adver Timer : 400
Admin Status : Up State : Backup
Config Pri : 100 Running Pri : 100
Preempt Mode : Yes Delay Time : 5
Become Master : 4200ms left
Auth Type : Simple Key : *****
Virtual IP : FE80::10
 1::10
Master IP : FE80::1

```

The output shows that in VRRP group 1 Switch A is the master, Switch B is the backup and packets sent from Host A to Host B are forwarded by Switch A.

When interface VLAN-interface 3 on Switch A is not available, you can still ping Host B successfully on Host A. To view the detailed information about the VRRP group, use the **display vrrp ipv6 verbose** command.

# When interface VLAN-interface 3 on Switch A is not available, the detailed information about VRRP group 1 on Switch A is displayed.

```
[SwitchA-Vlan-interface2] display vrrp ipv6 verbose
```

IPv6 Standby Information:

```

Run Mode : Standard
Run Method : Virtual MAC

```

Total number of virtual routers : 1

Interface Vlan-interface2

```

VRID : 1 Adver Timer : 400
Admin Status : Up State : Backup
Config Pri : 110 Running Pri : 80
Preempt Mode : Yes Delay Time : 5
Become Master : 4200ms left
Auth Type : Simple Key : *****
Virtual IP : FE80::10
 1::10
Master IP : FE80::2

```

VRRP Track Information:

```

Track Interface: Vlan3 State : Down Pri Reduced : 30

```

# When interface VLAN-interface 3 on Switch A is not available, the detailed information about VRRP group 1 on Switch B is displayed.

```
[SwitchB-Vlan-interface2] display vrrp ipv6 verbose
IPv6 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
Total number of virtual routers : 1
Interface Vlan-interface2
 VRID : 1 Adver Timer : 400
 Admin Status : Up State : Master
 Config Pri : 100 Running Pri : 100
 Preempt Mode : Yes Delay Time : 5
 Auth Type : Simple Key : *****
 Virtual IP : FE80::10
 1::10
 Virtual MAC : 0000-5e00-0201
 Master IP : FE80::2
```

The output shows that when VLAN-interface 3 on Switch A is not available, the priority of Switch A is reduced to 80 and Switch A becomes the backup. Switch B becomes the master and packets sent from Host A to Host B are forwarded by Switch B.

## VRRP with multiple VLANs configuration example

### Network requirements

- Switch A and Switch B belong to both VRRP group 1 and VRRP group 2. The virtual IPv6 addresses of VRRP group 1 are 1::10/64 and FE80::10, and those of VRRP group 2 are 2::10/64 and FE90::10.
- Hosts in VLAN 2 learn 1::10/64 as their default gateway and hosts in VLAN 3 learn 2::10/64 as their default gateway through RA messages sent by the switches.
- In VRRP group 1, Switch A has a higher priority than Switch B. In VRRP group 2, Switch B has a higher priority than Switch A. In this case, hosts in VLAN 2 and VLAN 3 can communicate with external networks through Switch A and Switch B, respectively, and when Switch A or Switch B fails, the hosts can use the other switch to communicate with external networks to avoid communication interruption.

**Figure 46 Network diagram**

## Configuration procedure

### 1. Configure Switch A:

# Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
[SwitchA-Vlan-interface2] ipv6 address 1::1 64
```

# Create VRRP group 1 and set its virtual IPv6 addresses to FE80::10 to 1::10.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

# Set the priority of Switch A in VRRP group 1 to 110, which is higher than that of Switch B (100), so that Switch A can become the master in VRRP group 1.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
[SwitchA-Vlan-interface2] quit
```

# Enable Switch A to send RA messages, so that hosts in VLAN 2 can learn the default gateway address.

```
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
[SwitchA-Vlan-interface2] quit
```

# Configure VLAN 3.

```
[SwitchA] vlan 3
[SwitchA-vlan3] port gigabitethernet 1/0/6
[SwitchA-vlan3] quit
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ipv6 address fe90::1 link-local
[SwitchA-Vlan-interface3] ipv6 address 2::1 64
```

```
Create VRRP group 2 and set its virtual IPv6 addresses to FE90::10 and 2::10.
[SwitchA-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip fe90::10 link-local
[SwitchA-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip 2::10
Enable Switch A to send RA messages, so that hosts in VLAN 3 can learn the default gateway
address.
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
```

## 2. Configure Switch B:

```
Configure VLAN 2.
```

```
<SwitchB> system-view
[SwitchB] ipv6
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
```

```
Create VRRP group 1 and set its virtual IPv6 addresses to FE80::10 and 1::10.
```

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
[SwitchB-Vlan-interface2] quit
```

```
Enable Switch B to send RA messages, so that hosts in VLAN 2 can learn the default gateway
address.
```

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
[SwitchB-Vlan-interface2] quit
```

```
Configure VLAN 3.
```

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/6
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] ipv6 address fe90::2 link-local
[SwitchB-Vlan-interface3] ipv6 address 2::2 64
```

```
Create VRRP group 2 and set its virtual IPv6 addresses to FE90::10 and 2::10.
```

```
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip fe90::10 link-local
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip 2::10
```

```
Set the priority of Switch B in VRRP group 2 to 110, which is higher than that of Switch A (100),
so that Switch B can become the master in VRRP group 2.
```

```
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 priority 110
```

```
Enable Switch B to send RA messages, so that hosts in VLAN 3 can learn the default gateway
address.
```

```
[SwitchB-Vlan-interface3] undo ipv6 nd ra halt
```

## 3. Verify the configuration:

To verify the configuration, use the **display vrrp ipv6 verbose** command.

```
Display the detailed information about the VRRP group on Switch A.
```

```
[SwitchA-Vlan-interface3] display vrrp ipv6 verbose
IPv6 Standby Information:
 Run Mode : Standard
 Run Method : Virtual MAC
```

Total number of virtual routers : 2

Interface Vlan-interface2

Master IP	: FE90::2		

The output shows that in VRRP group 1 Switch A is the master, Switch B is the backup and hosts with the default gateway of 1::10/64 accesses the Internet through Switch A; in VRRP group 2 Switch A is the backup, Switch B is the master and hosts with the default gateway of 2::10/64 accesses the Internet through Switch B.

## VRRP load balancing mode configuration example

### Network requirements

- Switch A, Switch B, and Switch C belong to VRRP group 1 with the virtual IPv6 addresses of FE80::10 and 1::10.
- Hosts on network segment 1::/64 learn 1::10 as their default gateway through RA messages sent by the switches. Use the VRRP group to make sure that when a gateway (Switch A, Switch B, or Switch C) fails, the hosts on the LAN can access the external network through another gateway.
- VRRP group 1 is operating in load balancing mode to make good use of network resources.
- Configure a track entry on Switch A, Switch B, and Switch C to monitor their own VLAN-interface 3. When the interface on Switch A, Switch B, or Switch C fails, the weight of the corresponding switch decreases so that another switch with a higher weight can take over.

Figure 47 Network diagram

### Configuration procedure

1. Configure Switch A:  

```
Configure VLAN 2.
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
```

```

Configure VRRP to operate in load balancing mode.
[SwitchA] vrrp mode load-balance
Create VRRP group 1 and configure its virtual IPv6 addresses as FE80::10 and 1::10.
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
[SwitchA-Vlan-interface2] ipv6 address 1::1 64
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
Set the priority of Switch A in VRRP group 1 to 120, which is higher than that of Switch B (110)
and that of Switch C (100), so that Switch A can become the master.
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 120
Configure Switch A to operate in preemptive mode so that it can become the master whenever
it works normally; configure the preemption delay as five seconds to avoid frequent status
switchover.
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode timer delay 5
Enable Switch A to send RA messages so that hosts on network segment 1::/64 can learn the
default gateway address.
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
[SwitchA-Vlan-interface2] quit
Create track entry 1 to associate with the physical status of VLAN-interface 3 on Switch A. When
the track entry becomes negative, it means that the interface fails.
[SwitchA] track 1 interface vlan-interface 3
Configure VF tracking to monitor track entry 1 and specify the value by which the weight
decreases, making the weight of Switch A decrease by more than 245 (250 in this example) when
track entry 1 turns to negative. In such a case, another router with a higher weight can take over.
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 weight track 1 reduced 250

```

## 2. Configure Switch B:

```

Configure VLAN 2.
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
Configure VRRP to operate in load balancing mode.
[SwitchB] vrrp mode load-balance
Create VRRP group 1 and configure its virtual IPv6 addresses as FE80::10 and 1::10.
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
Set the priority of Switch B in VRRP group 1 to 110, which is higher than that of Switch C (100)
so that Switch B can become the master when Switch A fails.
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
Set Switch B to operate in preemptive mode and set the preemption delay to five seconds.
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode timer delay 5

```

# Enable Switch B to send RA messages so that hosts on network segment 1::/64 can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
[SwitchB-Vlan-interface2] quit
```

# Create track entry 1 to associate with the physical status of VLAN-interface 3 on Switch B. When the track entry becomes negative, it means that the interface fails.

```
[SwitchB] track 1 interface vlan-interface 3
```

# Configure VF tracking to monitor track entry 1 and specify the value by which the weight decreases, making the weight of Switch B decrease by more than 245 (250 in this example) when track entry 1 turns to negative. In such a case, another router with a higher weight can take over.

```
[SwitchB] interface vlan-interface 2
```

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 weight track 1 reduced 250
```

### 3. Configure Switch C:

# Configure VLAN 2.

```
<SwitchC> system-view
```

```
[SwitchC] vlan 2
```

```
[SwitchC-vlan2] port gigabitethernet 1/0/5
```

```
[SwitchC-vlan2] quit
```

# Configure VRRP to operate in load balancing mode.

```
[SwitchC] vrrp mode load-balance
```

# Create VRRP group 1 and configure its virtual IPv6 addresses as FE80::10 and 1::10.

```
[SwitchC] interface vlan-interface 2
```

```
[SwitchC-Vlan-interface2] ipv6 address fe80::3 link-local
```

```
[SwitchC-Vlan-interface2] ipv6 address 1::3 64
```

```
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
```

```
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

# Set Switch C to operate in preemptive mode and set the preemption delay to five seconds.

```
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode timer delay 5
```

# Enable Switch C to send RA messages, so that hosts on network segment 1::/64 can learn the default gateway address.

```
[SwitchC-Vlan-interface2] undo ipv6 nd ra halt
```

```
[SwitchC-Vlan-interface2] quit
```

# Create track entry 1 to associate with the physical status of VLAN-interface 3 on Switch C. When the track entry becomes negative, it means that the interface fails.

```
[SwitchC] track 1 interface vlan-interface 3
```

# Configure VF tracking to monitor track entry 1 and specify the value by which the weight decreases, making the weight of Switch C decrease by more than 245 (250 in this example) when track entry 1 turns to negative. In such a case, another router with a higher weight can take over.

```
[SwitchC] interface vlan-interface 2
```

```
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 weight track 1 reduced 250
```

### 4. Verify the configuration:

After the configuration, Host A can ping the external network. To verify the configuration, use the **display ipv6 vrrp verbose** command.

# Display the detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp ipv6 verbose
```

```

Forwarder Weight Track Information:

Track Object : 1 State : Positive Weight Reduced : 250

The output shows that when VLAN interface 3 on Switch A fails, the weight of the AVF on Switch A decreases to 5, which is lower than the lower limit of failure. All VFs on Switch A turn to initialized state and cannot be used for packet forwarding. The VF corresponding to MAC address 000f-e2ff-4011 on Switch C becomes the AVF, and Switch C takes over Switch A for packet forwarding.

# When the timeout timer (about 1800 seconds) expires, display the detailed information about VRRP group 1 on Switch C.

```
[SwitchC-Vlan-interface2] display vrrp ipv6 verbose
```

```

The output shows that when Switch A fails, Switch B becomes the master because its priority is higher than that of Switch C.

# Troubleshooting VRRP

## The screen frequently displays error prompts.

### Analysis

This error is probably caused by:

- Inconsistent configuration of the devices in the VRRP group.
- A device is attempting to send illegitimate VRRP packets.

### Solution

- In the first case, modify the configuration.
- In the latter case, resort to non-technical measures.

## Multiple masters are present in the same VRRP group.

### Analysis

- Multiple masters coexist for a short period: This is normal and requires no manual intervention.
- Multiple masters coexist for a long period: This is because devices in the VRRP group cannot receive VRRP packets, or the received VRRP packets are illegal.

### Solution

Ping between these masters, and do the following:

- If the ping fails, check network connectivity.
- If the ping succeeds, check that their configurations are consistent in terms of number of virtual IP addresses, virtual IP addresses, advertisement interval, and authentication.

## Frequent VRRP state transition.

### Analysis

The VRRP advertisement interval is set too short.

### Solution

Increase the interval to sent VRRP advertisement or introduce a preemption delay.

---

# Configuring stateful failover (available only on the HP 5500 EI)

## Stateful failover overview

Some customers require the key entries or access points of their networks, such as the Internet access point of an enterprise or a database server of a bank, to be highly reliable to ensure continuous data transmission. Deploying only one device (even with high reliability) in such a network risks a single point of failure, as shown in [Figure 48](#). Stateful failover can solve this problem.

**Figure 48 Network with one device deployed**

## Operating procedure

Stateful failover involves service backup and traffic switchover. The operating procedure of stateful failover is as follows:

1. As shown in [Figure 49](#), Device A and Device B connects to each other over a failover link.
2. The two devices exchange state negotiation messages periodically through the failover link. After the two devices enter the synchronized state, they back up the sessions of each other to make sure that the sessions on them are consistent.
3. If one device fails, the other device can take over the services by using VRRP or a dynamic routing protocol (such as OSPF) to avoid service interruption.

In this document, the stateful failover feature supports backing up only portal services.

Figure 49 Network diagram for stateful failover

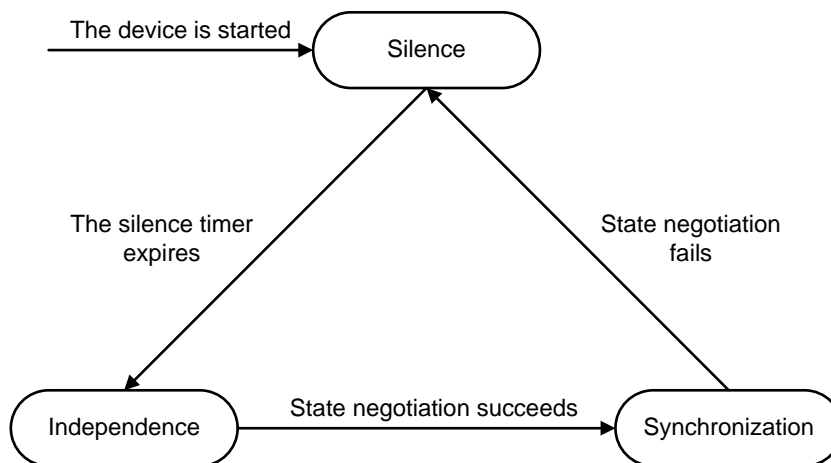

## Stateful failover states

Stateful failover has the following states:

- **Silence**—Indicates that the device has just started, or is transiting from synchronization state to independence state.
- **Independence**—Indicates that the silence timer has expired, but no failover link is established.
- **Synchronization**—Indicates that the device has completed state negotiation with the other device and is ready for service backup.

Figure 50 Stateful failover state relations

## Introduction to stateful failover configuration

To implement stateful failover on two devices, perform the following configurations:

- **Routing configuration.** Configure VRRP or a dynamic routing protocol on the devices and the uplink/downlink devices to make sure that the traffic can automatically switch to the other device when a device fails.

- Service backup configuration, which can implement real-time service backup between the two devices.

This configuration guide only introduces the service backup configuration.

Complete the following tasks to configure stateful failover:

Task	Remarks
<a href="#">Enabling stateful failover</a>	Required
<a href="#">Configuring the backup VLAN</a>	Required
Service module related configurations	Optional You must perform further configurations on the device before it can automatically back up portal service information to the backup device. For more information, see <i>Security Configuration Guide</i> .

## Enabling stateful failover

When you enable stateful failover with the **dhbk enable backup-type { dissymmetric-path | symmetric-path }** command:

- If you specify the **dissymmetric-path** keyword, the two devices operate in active/active mode. Sessions enter and leave the internal network through different devices to achieve load sharing.
- If you specify the **symmetric-path** keyword, the two devices operate in active/standby mode. Sessions enter and leave the internal network through one device.

Select a keyword based on the network environment and resources, and specify the same keyword for both devices.

To enable stateful failover:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Enable stateful failover in a specified mode.	<b>dhbk enable backup-type { dissymmetric-path   symmetric-path }</b>	Disabled by default.

## Configuring the backup VLAN

After you specify a VLAN as a backup VLAN, the interfaces added to the VLAN can serve as stateful failover interfaces to transmit stateful failover packets.

The device identifies stateful failover packets by the VLAN tag and private protocol number, and broadcasts them in the backup VLAN to the peer. Do not configure other services for the backup VLAN (such as MAC VLAN or Voice VLAN); otherwise, the operation of stateful failover may be affected.

The interfaces assigned to a backup VLAN can forward other packets besides stateful failover packets.

To configure a backup VLAN:

Step	Command	Remarks
1. Enter system view.	<b>system-view</b>	N/A
2. Create a VLAN and assign interfaces to the VLAN.	See <i>Layer 2—LAN Switching Configuration Guide</i> .	N/A
3. Return to system view.	<b>quit</b>	N/A
4. Specify the VLAN as a backup VLAN.	<b>dhbk vlan <i>vlan-id</i></b>	Not specified by default.

## Displaying and maintaining stateful failover

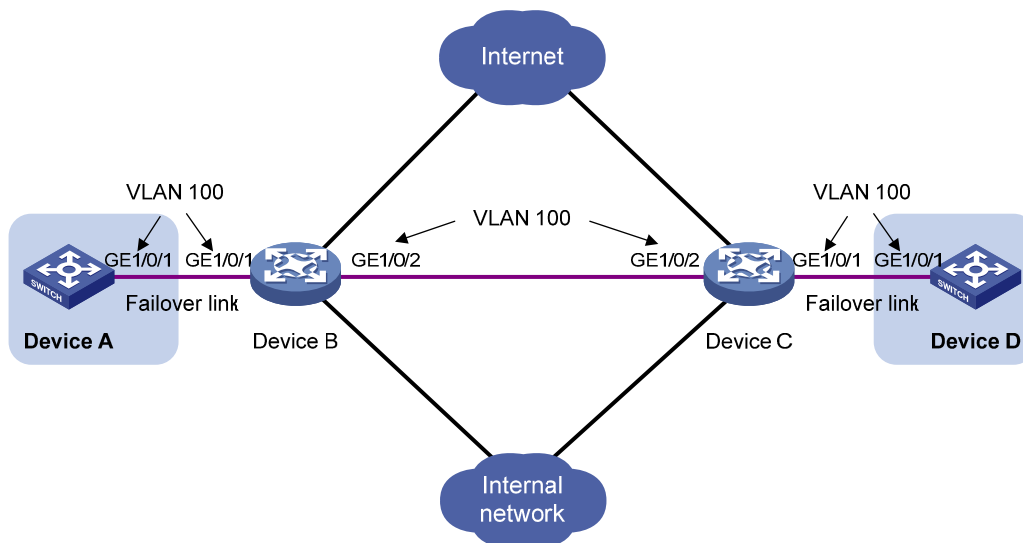

Task	Command	Remarks
Display the running status and related information of stateful failover.	<b>display dhbk status</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]	Available in any view

## Stateful failover configuration example

### Network requirements

In [Figure 51](#), Device B and Device C serve as the internal gateways of an enterprise network. Device A and Device D, respectively attached to Device B and Device C, provide portal access authentication for internal users. Configure stateful failover between Device A and Device D. When one device fails, the other device takes over the services to ensure service continuity.

**Figure 51 Network diagram**

### Configuration procedure

1. Configure Device A:  

```
Create VLAN 100.
<DeviceA> system-view
```

- ```
[DeviceA] vlan 100
# Assign GigabitEthernet 1/0/1 to VLAN 100.
[DeviceA-vlan100] port gigabitethernet 1/0/1
[DeviceA-vlan100] quit
# Specify VLAN 100 as a backup VLAN.
[DeviceA] dhbk vlan 100
# Enable symmetric-path mode stateful failover.
[DeviceA] dhbk enable backup-type symmetric-path
```
2. Configure Device B:

```
# Create VLAN 100.
<DeviceB> system-view
[DeviceB] vlan 100
# Assign GigabitEthernet 1/0/1 to VLAN 100.
[DeviceB-vlan100] port gigabitethernet 1/0/1
[DeviceB-vlan100] quit
# Assign GigabitEthernet 1/0/2 to VLAN 100.
Because Device B and Device C may exchange packets of multiple VLANs, configure
GigabitEthernet 1/0/2 as a trunk port and permit packets of VLAN 100 to pass.
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 100
Please wait... Done.
```
 3. The configurations on Device C are similar to those on Device B. (Details not shown.)
 4. The configurations on Device D are similar to those on Device A. (Details not shown.)

Configuration guidelines

When you configure stateful failover, follow these guidelines:

- Stateful failover can be implemented only between two devices rather than among more than two devices.
- The same numbered interfaces must exist on the two devices. Otherwise, session backup fails. For example, if Device A uses GigabitEthernet 1/0/1 and GigabitEthernet 1/0/3 to forward backup data, Device B must also use GigabitEthernet 1/0/1 and GigabitEthernet 1/0/3.

Configuring BFD (available only on the HP 5500 EI)

The term *router* in the BFD features refers to both routers and Layer 3 switches.

The term *interface* in the BFD features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

BFD overview

Devices must quickly detect communication failures so that measures can be taken promptly to ensure service continuity and enhance network availability.

The main fault detection methods include the following:

- **Hardware detection**—Detects link failures by sending hardware detection signals, such as synchronous digital hierarchy (SDH) alarms. Hardware detection can quickly detect link failures, but not all media types support hardware detection.
- **Hello mechanism**—Devices can use the hello mechanism of a routing protocol to detect link failures, which has a failure detection rate in seconds. On a high-speed interface, such as a Gigabit interface, a failure that lasts for one second will cause a large quantity of data to be dropped. The hello mechanism is unacceptable for delay-sensitive services such as voice service. Moreover, this detection method largely relies on the routing protocol.
- **Other detection methods**—Some protocols provide dedicated detection mechanisms. However, they cannot be deployed for inter-system communications.

Bidirectional forwarding detection (BFD) provides a single mechanism to monitor links. With BFD, devices can quickly detect communication failures and restore communications through backup paths.

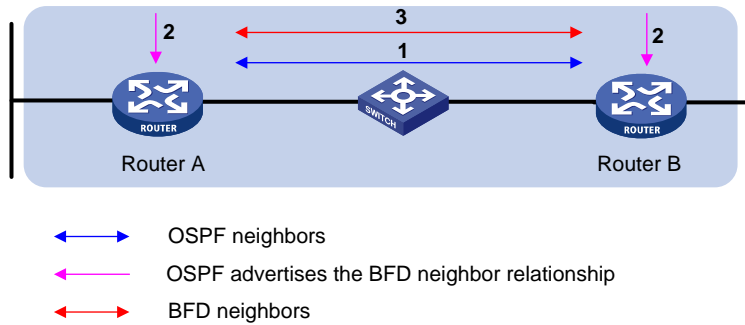

How BFD works

BFD provides a general-purpose, standard, medium- and protocol-independent fast failure detection mechanism. It can uniformly and quickly detect the failures of the bidirectional forwarding paths between two routers for protocols, such as routing protocols.

BFD provides no neighbor discovery mechanism. Protocols that BFD services notify BFD of routers to which it needs to establish sessions. After a session is established, if no BFD control packet is received from the peer within the negotiated BFD interval, BFD notifies a failure to the protocol, which takes appropriate measures.

Operation of BFD

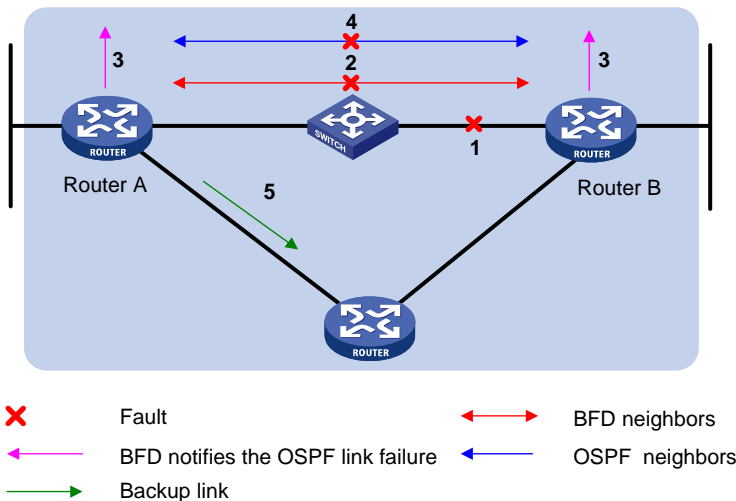

Figure 52 BFD session establishment (on OSPF routers)

The process of BFD session establishment is as follows:

1. A protocol sends hello messages to discover neighbors and establish neighborships.
2. After establishing neighborships, the protocol notifies BFD of the neighbor information, including destination and source addresses.
3. BFD uses the information to establish BFD sessions.

Figure 53 BFD fault detection (on OSPF routers)

The process of BFD fault detection is as follows:

1. BFD detects a link failure.
2. BFD clears the neighbor session.
3. BFD notifies the protocol of the failure.
4. The protocol terminates the neighborship on the link.
5. If a backup link is available, the protocol will use it to forward packets.

NOTE:

No detection time resolution is defined in the BFD draft. Most devices supporting BFD provide detection measured in milliseconds.

BFD detection methods

- **Single-hop detection**—Detects the IP connectivity between two directly connected systems.
- **Multi-hop detection**—Detects any of the paths between two systems. These paths have multiple hops and may be overlapped.
- **Bidirectional detection**—Sends detection packets at two sides of a bidirectional link to detect the bidirectional link status, finding link failures in milliseconds. (BFD LSP detection is a special case in which BFD control packets are sent in one direction, and the peer device reports the link status through other links.)

BFD session modes

- **Control packet mode**—Both ends of the link exchange BFD control packets to monitor link status.
- **Echo mode**—One end of the link sends Echo packets to the other end, which then forwards the packets back to the originating end, monitoring link status in both directions.

BFD operating modes

Before a BFD session is established, BFD has the following operating modes—active and passive.

- **Active mode**—BFD actively sends BFD control packets regardless of whether any BFD control packet is received from the peer.
- **Passive mode**—BFD does not send control packets until a BFD control packet is received from the peer.

At least one end must operate in the active mode for a BFD session to be established.

After a BFD session is established, both ends must operate in the asynchronous mode—Both endpoints periodically send BFD control packets to each other. BFD considers the session down if it receives no BFD control packets within a specific interval.

NOTE:

When a BFD session is maintained by sending Echo packets, the session is independent of the operating mode.

Dynamic BFD parameter changes

After a BFD session is established, both ends can negotiate the related BFD parameters, such as the minimum transmit interval, minimum receive interval, initialization mode, and packet authentication mode. After that, both ends use the negotiated parameters, without affecting the current session state.

Authentication modes

BFD provides the following authentication methods:

- **Simple**—Simple authentication
- **MD5**—MD5 (Message Digest 5) authentication
- **SHA1**—SHA1 (Secure Hash Algorithm 1) authentication

BFD packet format

BFD control packets are encapsulated into UDP packets with port number 3784 for single-hop detection or port number 4784 for multi-hop detection (it can also be 3784 based on the configuration task). BFD echo packets have a similar format to BFD control packets (except that the *Desired Min TX Interval* and *Required Min RX Interval* fields are null), with UDP port number 3785.

Figure 54 BFD packet format

| | | | |
|-------------------------------|------|----------|------------------------|
| 0 | 7 | 23 | 31 |
| Vers | Diag | Sta | P F C A D R |
| Detect Mult | | Length | |
| My Discriminator | | | |
| Your Discriminator | | | |
| Desired Min TX Interval | | | |
| Required Min RX Interval | | | |
| Required Min Echo RX Interval | | | |
| Auth Type | | Auth Len | Authentication Data... |

- **Vers**—Protocol version. The protocol version is 1.
- **Diag**—This bit indicates the reason for the last transition of the local session from **up** to some other state. Table 19 lists the states.

Table 19 Diag bit values

| Diag | Description |
|------|--------------------------------|
| 0 | No Diagnostic |
| 1 | Control Detection Time Expired |
| 2 | Echo Function Failed |
| 3 | Neighbor Signaled Session Down |
| 4 | Forwarding Plane Reset |
| 5 | Path Down |
| 6 | Concatenated Path Down |
| 7 | Administratively Down |
| 8 | Reverse Concatenated Path Down |
| 9~31 | Reserved for future use |

- **State (Sta)**—Current BFD session state. Its value can be 0 for AdminDown, 1 for Down, 2 for Init, and 3 for Up.
- **Poll (P)**—If set, the transmitting system is requesting verification of connectivity, or of a parameter change. If clear, the transmitting system is not requesting verification.
- **Final (F)**—If set, the transmitting system is responding to a received BFD control packet that had the Poll (P) bit set. If clear, the transmitting system is not responding to a Poll.
- **Control Plane Independent (C)**—If set, the transmitting system's BFD implementation does not share fate with its control plane (BFD is implemented in the forwarding plane and can continue to function through disruptions in the control plane.) If clear, the transmitting system's BFD implementation shares fate with its control plane.
- **Authentication Present (A)**—If set, the Authentication Section is present, and the session is to be authenticated.
- **Demand (D)**—If set, Demand mode is active in the transmitting system (the system wishes to operate in Demand mode, knows that the session is up in both directions, and is directing the remote system to cease the periodic transmission of BFD Control packets). If clear, Demand mode is not active in the transmitting system.

- **Reserved (R)**—This byte must be set to zero on transmit and ignored on receipt.
- **Detect Mult**—Detection time multiplier.
- **Length**—Length of the BFD control packet, in bytes.
- **My Discriminator**—A unique, nonzero discriminator value generated by the transmitting system, used to demultiplex multiple BFD sessions between the same pair of systems.
- **Your Discriminator**—The discriminator received from the remote system. This field reflects back the received value of My Discriminator or is 0 if that value is unknown.
- **Desired Min TX Interval**—This is the minimum interval, in microseconds, that the local system would like to use when transmitting BFD control packets. The value zero is reserved.
- **Required Min RX Interval**—This is the minimum interval, in microseconds, between received BFD control packets that this system is capable of supporting. If this value is zero, the transmitting system does not want the remote system to send any periodic BFD control packets.
- **Required Min Echo RX Interval**—This is the minimum interval, in microseconds, between received BFD echo packets that this system is capable of supporting. If this value is zero, the transmitting system does not support the receipt of BFD echo packets.
- **Auth Type**—The authentication type in use, if the Authentication Present (A) bit is set.
- **Auth Len**—The length, in bytes, of the authentication section, including the Auth Type and Auth Len fields.

Supported features

- OSPF. For more information, see *Layer 3—IP Routing Configuration Guide*.
- OSPFv3. For more information, see *Layer 3—IP Routing Configuration Guide*.
- IS-IS. For more information, see *Layer 3—IP Routing Configuration Guide*.
- IPv6 IS-IS. For more information, see *Layer 3—IP Routing Configuration Guide*.
- RIP. For more information, see *Layer 3—IP Routing Configuration Guide*.
- Static routing. For more information, see *Layer 3—IP Routing Configuration Guide*.
- BGP. For more information, see *Layer 3—IP Routing Configuration Guide*.
- IPv6 BGP. For more information, see *Layer 3—IP Routing Configuration Guide*.
- PIM. For more information, see *IP Multicast Configuration Guide*.
- IPv6 PIM. For more information, see *IP Multicast Configuration Guide*.
- Track. For more information, see "[Configuring track](#)."
- IP fast reroute (FRR). Currently, IP FRR is supported by OSPF, RIP, IS-IS, and static routing. For more information, see *Layer 3—IP Routing Configuration Guide*.

Protocols and standards

- draft-ietf-bfd-base-09, *Protocol Independent Bidirectional Forwarding Detection*
- draft-ietf-bfd-v4v6-1 hop-10, *BFD for IPv4 and IPv6 (Single Hop)*
- draft-ietf-bfd-multihop-08, *BFD for Multihop Paths*
- draft-ietf-bfd-generic-05, *Generic Application of BFD*

Configuring BFD basic functions

The BFD basic functions configuration is the basis for configuring BFD for other protocols.

Configuration prerequisites

Before configuring BFD basic functions, complete the following tasks:

- Configure the network layer addresses of the interfaces so that adjacent nodes are reachable to each other at the network layer
- Configure the routing protocols that support BFD

Configuration procedure

To configure BFD basic functions:

| Step | Command | Remarks |
|---|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Specify the mode for establishing a BFD session. | bfd session init-mode { active passive } | Optional.
active by default. |
| 3. Configure the destination port number for multi-hop BFD control packets. | bfd multi-hop destination-port port-number | Optional.
4784 by default. |
| 4. Configure the source IP address of echo packets. | bfd echo-source-ip ip-address | Optional.
The source IP address should not be on the same network segment as any local interface's IP address. Otherwise, a large number of ICMP redirect packets may be sent from the peer, resulting in link congestion. |
| 5. Enter interface view. | interface interface-type interface-number | N/A |
| 6. Configure the minimum interval for receiving BFD echo packets. | bfd min-echo-receive-interval value | Optional.
For relevant information, see the description of the <i>Required Min Echo RX Interval</i> field in " BFD packet format ."
400 milliseconds by default. |
| 7. Configure the minimum interval for transmitting BFD control packets. | bfd min-transmit-interval value | Optional.
For relevant information, see the description of the <i>Desired Min TX Interval</i> field in " BFD packet format ."
400 milliseconds by default. |

| Step | Command | Remarks |
|--|---|---|
| 8. Configure the minimum interval for receiving BFD control packets. | bfd min-recv-interval <i>value</i> | Optional.
For relevant information, see the description of the <i>Required Min RX Interval</i> field in "BFD packet format."
400 milliseconds by default. |
| 9. Configure the detection time multiplier. | bfd detect-multiplier <i>value</i> | Optional.
For relevant information, see the description of the <i>Detect Mult</i> field in "BFD packet format."
5 by default. |
| 10. Configure the authentication mode on the interface. | bfd authentication-mode { md5 <i>key-id</i> [cipher] <i>key</i> sha1 <i>key-id</i> [cipher] <i>key</i> simple <i>key-id</i> [cipher] <i>password</i> } | Optional.
By default, the interface operates in the non-authentication mode. |

In Figure 52 for example, if you configure the Desired Min TX Interval as 100 milliseconds, Required Min RX Interval as 300 milliseconds, and Detect Mult as 5 on Router A, and configure the Desired Min TX Interval as 150 milliseconds, Required Min RX Interval as 400 milliseconds, and Detect Mult as 10 on Router B,

- The actual transmitting interval on Router A is 400 milliseconds, which is the greater value between the minimum interval for transmitting BFD control packets on Router A (100 milliseconds) and the minimum interval for receiving BFD control packets on Router B (400 milliseconds).
- The actual transmitting interval on Router B is 300 milliseconds, which is the greater value between the minimum interval for transmitting BFD control packets on Router B (150 milliseconds) and the minimum interval for receiving BFD control packets on Router A (300 milliseconds).
- The actual detection time on Router A is 3000 milliseconds, which is 10×300 milliseconds (Detect Mult on Router B \times actual transmitting interval on Router B).
- The actual detection time on Router B is 2000 milliseconds, which is 5×400 milliseconds (Detect Mult on Router A \times actual transmitting interval on Router A).

Displaying and maintaining BFD

| Task | Command | Remarks |
|---|---|------------------------|
| Display information about BFD-enabled interfaces. | display bfd interface [verbose] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display information about enabled BFD debugging. | display bfd debugging-switches [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display BFD session information. | display bfd session [slot <i>slot-number</i> [all verbose] verbose] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Clear BFD session statistics. | reset bfd session statistics [slot <i>slot-number</i>] | Available in user view |

Configuring track

Only the HP 5500 EI Switch Series supports BFD, VRRP, and PBR configurations.

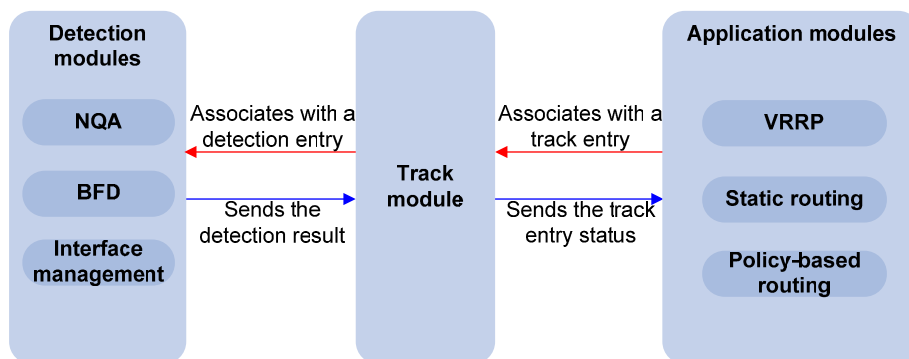

Track overview

Introduction to collaboration

The track module works between application and detection modules, as shown in [Figure 55](#). It shields the differences between various detection modules from application modules.

Collaboration is enabled after you associate the track module with a detection module and an application module. The detection module probes specific objects such as interface status, link status, network reachability, and network performance, and informs the track module of detection results. The track module sends the detection results to the associated application module. When notified of changes of the tracked object, the application modules can react to avoid communication interruption and network performance degradation.

Figure 55 Collaboration through the track module

Collaboration fundamentals

The track module collaborates with detection modules and application modules:

- Collaboration between the track module and a detection module
- Collaboration between the track module and an application module

Collaboration between the track module and a detection module

The detection module sends the detection result of the associated tracked object to the track module. Depending on the result, the track module changes the status of the track entry:

- If the tracked object functions normally, for example, the target interface is up or the target network is reachable, the state of the track entry is Positive.
- If the tracked object functions abnormally, for example, the target interface is down or the target network is unreachable, the state of the track entry is Negative.
- If the detection result is not valid, for example, the NQA test group that is associated with the track entry does not exist, the state of the track entry is Invalid.

The following detection modules can be associated with the track module:

- NQA
- BFD (available only on the HP 5500 EI)
- Interface management module

Collaboration between the track module and an application module

After being associated with an application module, when the status of the track entry changes, the track module notifies the application module, which then takes proper actions.

The following application modules can be associated with the track module:

- Virtual Router Redundancy Protocol (VRRP) (available only on the HP 5500 EI)
- Static routing
- Policy-based routing (available only on the HP 5500 EI)

In some cases, the status of a track entry changes while a route is still recovering. This leads to problems if the track module immediately notifies the application modules of the status change and the application modules begin using the route before it is ready.

For example, the master in a VRRP group monitors the uplink interface through the track module. When the uplink interface fails, the track module notifies the master to reduce its priority so that a backup with a higher priority can preempt as the master to forward packets. When failed uplink interface recovers, if the track module immediately notifies the original master to restore its priority, the master immediately will forward packets to that interface; however, this result in packet forwarding failure because the uplink route has not yet been recovered.

To solve this problem, configure a delay before the track module notifies the application modules of the track entry status changes.

Collaboration application example

The following is an example of collaboration between NQA, track, and static routing.

Configure a static route with next hop 192.168.0.88 on the device. If the next hop is reachable, the static route is valid. If the next hop becomes unreachable, the static route should become invalid. For this purpose, configure collaboration between the NQA, track, and static routing modules:

1. Create an NQA test group to monitor the reachability of IP address 192.168.0.88.
2. Create a track entry and associate it with the NQA test group. When the next hop 192.168.0.88 is reachable, the track entry is in Positive state. When the next hop becomes unreachable, the track entry is in Negative state.
3. Associate the track entry with the static route. When the track entry turns to the Positive state, the static route is valid. When the associated track entry turns to the Negative state, the static route is invalid.

Track configuration task list

To implement the collaboration function, establish associations between the track module and the detection modules, and between the track module and the application modules.

Complete these tasks to configure the track module:

| Task | Remarks |
|---|--|
| Associating the track module with a detection module | Associating track with NQA |
| | Associating track with BFD (available only on the HP 5500 EI) |
| | Associating track with interface management |
| Associating the track module with an application module | Associating track with VRRP (available only on the HP 5500 EI) |
| | Associating track with static routing |
| | Associating track with PBR (available only on the HP 5500 EI) |

Associating the track module with a detection module

Associating track with NQA

NQA supports multiple test types to analyze network performance, services, service quality. For example, an NQA test group can periodically detect whether a destination is reachable, or whether the TCP connection to a TCP server can be set up.

An NQA test group functions as follows when it is associated with a track entry:

- If the consecutive failures reach the specified threshold, the NQA module tells the track module that the tracked object malfunctions. Then the track module sets the track entry to the Negative state.
- If the specified threshold is not reached, the NQA module tells the track module that the tracked object functions normally. The track module then sets the track entry to the Positive state.

For more information about NQA, see *Network Management and Monitoring Configuration Guide*.

To associate track with NQA:

| Step | Command | Remarks |
|--|---|---------------------------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Create a track entry, associate it with an NQA reaction entry, and specify the delay time for the track module to notify the associated application module when the track entry status changes. | track track-entry-number nqa entry admin-name operation-tag reaction item-number [delay { negative negative-time positive positive-time } *] | No track entry is created by default. |

NOTE:

If the specified NQA test group or the reaction entry in the track entry does not exist, the status of the track entry is Invalid.

Associating track with BFD (available only on the HP 5500 EI)

BFD supports the control packet mode and echo mode. Only echo-mode BFD can be associated with a track entry.

The BFD functions as follows when it is associated with a track entry:

- If the BFD detects that the link fails, it informs the track entry of the link failure. The track module then sets the track entry to the Negative state.
- If the BFD detects that the link is normal, the track module sets the track entry to the Positive state.

For more information about BFD, see "[Configuring BFD \(available only on the HP 5500 EI\)](#)."

Configuration prerequisites

Before you associate track with BFD, configure the source address of the BFD echo packets.

Configuration procedure

To associate track with BFD:

| Step | Command | Remarks |
|--|--|---------------------------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Create a track entry, associate it with the BFD session, and specify the delay time for the track module to notify the associated application module when the track entry status changes. | track track-entry-number bfd echo interface interface-type interface-number remote ip remote-ip local ip local-ip [delay { negative negative-time positive positive-time } *] | No track entry is created by default. |

NOTE:

When associating track with BFD, do not configure the virtual IP address of a VRRP group as the local or remote address of a BFD session.

Associating track with interface management

The interface management module monitors the physical status or network-layer protocol status of the interface. The interface management module functions as follows when it is associated with a track entry:

- When the physical or network-layer protocol status of the interface changes to up, the interface management module informs the track module of the change and the track module sets the track entry to Positive.
- When the physical or network-layer protocol status of the interface changes to down, the interface management module informs the track module of the change and the track module sets the track entry to Negative.

To associate track with interface management:

| Step | Command | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |

| Step | Command | Remarks |
|---|---|--|
| 2. Associate track with interface management. | <p>Create a track entry, associate it with the interface management module to monitor the physical status of an interface, and specify the delay time for the track module to notify the associated application module when the track entry status changes:</p> <pre>track track-entry-number interface interface-type interface-number [delay { negative negative-time positive positive-time } *]</pre> <p>Create a track entry, associate it with the interface management module to monitor the Layer 3 protocol status of an interface, and specify the delay time for the track module to notify the associated application module when the track entry status changes:</p> <pre>track track-entry-number interface interface-type interface-number protocol { ipv4 ipv6 } [delay { negative negative-time positive positive-time } *]</pre> | <p>Use either approach.</p> <p>No track entry is created by default.</p> |

Associating the track module with an application module

Associating track with VRRP (available only on the HP 5500 EI)

VRRP is an error-tolerant protocol. It adds a group of routers that can act as network gateways to a VRRP group, which forms a virtual router. Routers in the VRRP group elect the master acting as the gateway according to their priorities. A router with a higher priority is more likely to become the master. The other routers function as the backups. When the master fails, the backups in the VRRP group elect a new gateway to undertake the responsibility of the failed master. This ensures that the hosts in the network segment can uninterruptedly communicate with external networks.

When VRRP is operating in standard protocol mode or load balancing mode, associate the track module with the VRRP group to implement the following actions:

- Change the priority of a router according to the status of the uplink. If a fault occurs on the uplink of the router, the VRRP group cannot be aware of the uplink failure. If the router is the master, hosts in the LAN cannot access the external network. This problem can be solved by establishing a track-VRRP group association. Use the detection modules to monitor the status of the uplink of the router and establish collaborations between the detection modules, track module and VRRP. When the uplink fails, the detection modules notify the track module to change the status of the monitored track entry to Negative, and the priority of the master then decreases by a specific value, allowing a higher priority router in the VRRP group to become the master, and maintaining proper communication between the hosts in the LAN and the external network.
- Monitor the master on a backup. If a fault occurs on the master, the backup operating in switchover mode will switch to the master immediately to maintain normal communication.

When VRRP is operating in load balancing mode, associate the track module with the VRRP Virtual Forwarder (VF) to implement the following functions:

- Change the priority of the active VF (AVF) according to its uplink state. When the uplink of the AVF fails, the track entry changes to Negative state and the weight of the AVF decreases by a specific value so that the VF with a higher priority becomes the new AVF to forward packets.

- Monitor the AVF status from the listening VF (LVF), which refers to the VF in listening state. When the AVF fails, the LVF that is operating in switchover mode becomes the new AVF to ensure continuous forwarding.

VRRP tracking is not valid on an IP address owner. An IP address owner refers to a router when the IP address of the virtual router is the IP address of an interface on the router in the VRRP group.

For more information about VRRP, see "[Configuring VRRP \(available only on the HP 5500 EI\)](#)."

To associate track with VRRP group:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 3. Create a VRRP group and configure its virtual IP address. | vrrp vrid <i>virtual-router-id</i> virtual-ip
<i>virtual-address</i> | No VRRP group is created by default. |
| 4. Associate a track entry with a VRRP group. | vrrp [ipv6] vrid <i>virtual-router-id</i>
track <i>track-entry-number</i> [reduced
<i>priority-reduced</i> switchover] | No track entry is specified for a VRRP group by default.
This command is supported when VRRP is operating in both standard protocol mode and load balancing mode. |

To associate track with VRRP VF:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 3. Create a VRRP group and configure its virtual IP address. | vrrp vrid <i>virtual-router-id</i> virtual-ip
<i>virtual-address</i> | No VRRP group is created by default. |
| 4. Associate track with VRRP VF. | Associate a track entry with the VRRP VF:
vrrp [ipv6] vrid <i>virtual-router-id</i>
weight track <i>track-entry-number</i>
[reduced <i>weight-reduced</i>]
Configure the LVF to monitor the AVF status through the track entry:
vrrp [ipv6] vrid <i>virtual-router-id</i>
track <i>track-entry-number</i>
forwarder-switchover member-ip
<i>ip-address</i> | Use at least one command.
By default, no track entry is specified for a VF.
This command is configurable when VRRP is operating in standard mode or load balancing mode. However, this function takes effect only when VRRP is operating in load balancing mode. |

NOTE:

- When the status of the track entry changes from Negative to Positive or Invalid, the associated router or VF restores its priority automatically.
- You can associate a nonexistent track entry with a VRRP group or VF. The association takes effect only after you use the **track** command to create the track entry.

Associating track with static routing

A static route is a manually configured route. With a static route configured, packets to the specified destination are forwarded through the path specified by the administrator.

The disadvantage of using static routes is that they cannot adapt to network topology changes. Faults or topological changes in the network can make the routes unreachable, causing network breaks.

To prevent this problem, configure another route to back up the static route. When the static route is reachable, packets are forwarded through the static route. When the static route is unreachable, packets are forwarded through the backup route, avoiding network breaks and enhancing network reliability.

To check the accessibility of a static route in real time, establish association between the track and the static route.

If you specify the next hop but not the egress interface when configuring a static route, you can establish collaborations among the static route, the track module, and detection modules. This enables you to check the accessibility of the static route by the status of the track entry.

- The Positive state of the track entry shows that the next hop of the static route is reachable and that the configured static route is valid.
- The Negative state of the track entry shows that the next hop of the static route is not reachable and that the configured static route is invalid.
- The Invalid state of the track entry shows that the accessibility of the next hop of the static route is unknown and that the static route is valid.

If the track module detects the next hop accessibility of the static route in a private network through NQA, the VPN instance name of the next hop of the static route must be consistent with that configured for the NQA test group. Otherwise, the accessibility detection cannot function properly.

If a static route needs route recursion, the associated track entry must monitor the next hop of the recursive route instead of that of the static route; otherwise, a valid route may be considered invalid.

For more information about static route configuration, see *Layer 3—IP Routing Configuration Guide*.

To associate track with static routing:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Associate the static route with a track entry to check the accessibility of the next hop. | <p>Approach 1:</p> <pre>ip route-static dest-address { mask mask-length } { next-hop-address vpn-instance d-vpn-instance-name next-hop-address } track track-entry-number [preference preference-value] [tag tag-value] [description description-text]</pre> <p>Approach 2:</p> <pre>ip route-static vpn-instance s-vpn-instance-name&<1-6> dest-address { mask mask-length } { next-hop-address track track-entry-number [public] vpn-instance d-vpn-instance-name next-hop-address track track-entry-number } [preference preference-value] [tag tag-value] [description description-text]</pre> | <p>Use either approach.</p> <p>Not configured by default.</p> <p>Only the HP 5500 EI Switch Series supports the vpn-instance keyword.</p> |

NOTE:

You can associate a nonexistent track entry with a static route. The association takes effect only after you use the **track** command to create the track entry.

Associating track with PBR (available only on the HP 5500 EI)

Policy-based routing (PBR) is a routing mechanism based on user-defined policies. Different from the traditional destination-based routing mechanism, PBR enables you to use a policy (based on the source address and other criteria) to route packets.

PBR cannot detect the availability of any action taken on packets. When an action is not available, packets processed by the action may be discarded. For example, configure PBR to forward packets that match certain criteria through a specific next hop. When the specified next hop fails, PBR cannot sense the failure, and continues to forward matching packets to the next hop.

This problem can be solved by associating track with PBR, which improves the flexibility of PBR application, and enables PBR to sense topology changes.

After you associate a track entry with an apply clause, the detection module associated with the track entry sends the detection result of the availability of the object (an interface or an IP address) specified in the apply clause.

- The Positive state of the track entry shows that the object is available, and the apply clause is valid.
- The Negative state of the track entry shows that the object is not available, and the apply clause is invalid.
- The Invalid state of the track entry shows that the apply clause is valid.

The following objects can be associated with a track entry:

- Next hop
- Default next hop

For more information about PBR, see *Layer 3—IP Routing Configuration Guide*.

Configuration prerequisites

Before you associate track with PBR, create a policy or a policy node and configure the match criteria as well.

Configuration procedure

To associate track with PBR:

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Create a policy or policy node and enter PBR policy node view. | policy-based-route <i>policy-name</i> [deny permit] node <i>node-number</i> | Required |
| 3. Define an ACL match criterion. | if-match acl <i>acl-number</i> | Optional
By default, no packets are filtered. |

| Step | Command | Remarks |
|------------------------------|---|---|
| 4. Associate track with PBR. | Set the next hop and associate it with a track entry:
apply ip-address next-hop <i>ip-address</i>
[direct] [track <i>track-entry-number</i>]
[<i>ip-address</i> [direct] [track <i>track-entry-number</i>]]

Set the default next hop, and associate it with a track entry:
apply ip-address default next-hop
<i>ip-address</i> [track <i>track-entry-number</i>]
[<i>ip-address</i> [track <i>track-entry-number</i>]] | Configure at least one of the commands. |

NOTE:

You can associate a nonexistent track entry with PBR. The association takes effect only after you use the **track** command to create the track entry.

Displaying and maintaining track entries

| Task | Command | Remarks |
|---|--|-----------------------|
| Display information about the specified or all track entries. | display track { <i>track-entry-number</i> all } [[{ begin exclude include } <i>regular-expression</i>]] | Available in any view |

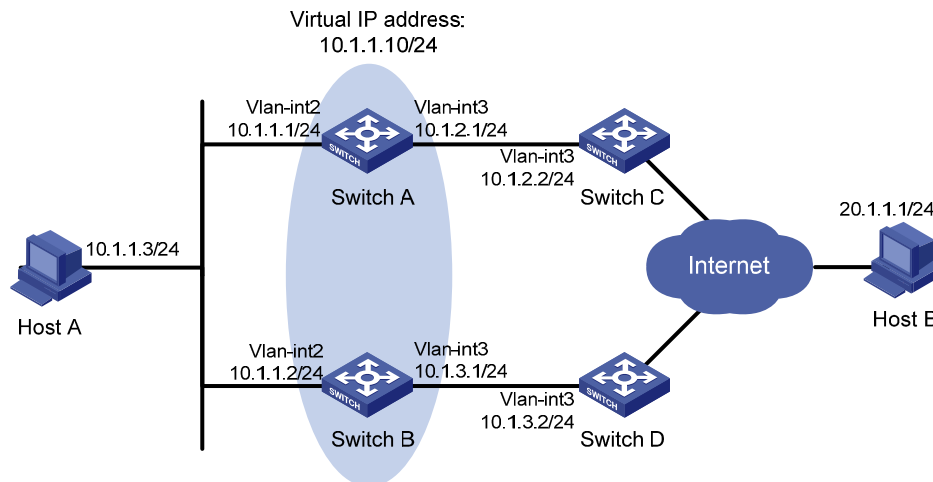

Track configuration examples

VRRP-track-NQA collaboration configuration example (the master monitors the uplink) (available only on the HP 5500 EI)

Network requirements

- As shown in [Figure 56](#), Host A needs to access Host B on the Internet. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1, whose virtual IP address is 10.1.1.10.
- When Switch A works properly, packets from Host A to Host B are forwarded through Switch A. When VRRP finds that a fault is on the uplink of Switch A through NQA, packets from Host A to Host B are forwarded through Switch B.

Figure 56 Network diagram

Configuration procedure

1. Create VLANs, and assign corresponding ports to the VLANs. Configure the IP address of each VLAN interface as shown in Figure 56. (Details not shown.)

2. Configure an NQA test group on Switch A:

```
<SwitchA> system-view
# Create an NQA test group with the administrator name admin and the operation tag test.
[SwitchA] nqa entry admin test
# Configure the test type as ICMP-echo.
[SwitchA-nqa-admin-test] type icmp-echo
# Configure the destination address as 10.1.2.2.
[SwitchA-nqa-admin-test-icmp-echo] destination ip 10.1.2.2
# Set the test frequency to 100 ms.
[SwitchA-nqa-admin-test-icmp-echo] frequency 100
# Configure reaction entry 1, specifying that five consecutive probe failures trigger the track module.
[SwitchA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[SwitchA-nqa-admin-test-icmp-echo] quit
# Start the NQA test.
[SwitchA] nqa schedule admin test start-time now lifetime forever
```

3. Configure a track entry on Switch A:

```
# Configure track entry 1, and associate it with reaction entry 1 of the NQA test group (with the administrator admin, and the operation tag test).
```

```
[SwitchA] track 1 nqa entry admin test reaction 1
```

4. Configure VRRP on Switch A:

```
# Create VRRP group 1, and configure the virtual IP address 10.1.1.10 for the group.
```

```
[SwitchA] interface vlan-interface 2
```

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

```
# Set the priority of Switch A in VRRP group 1 to 110.
```

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

```

# Set the authentication mode of VRRP group 1 to simple, and the authentication key to hello.
[SwitchA-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
# Configure the master to send VRRP packets at an interval of five seconds.
[SwitchA-Vlan-interface2] vrrp vrid 1 timer advertise 5
# Configure Switch A to operate in preemptive mode, and set the preemption delay to five
seconds.
[SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5
# Configure to monitor track entry 1, and specify the priority decrement to 30.
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 reduced 30

```

5. Configure VRRP on Switch B:

```

<SwitchB> system-view
[SwitchB] interface vlan-interface 2
# Create VRRP group 1, and configure the virtual IP address 10.1.1.10 for the group.
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
# Set the authentication mode of VRRP group 1 to simple, and the authentication key to hello.
[SwitchB-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
# Configure the master to send VRRP packets at an interval of five seconds.
[SwitchB-Vlan-interface2] vrrp vrid 1 timer advertise 5
# Configure Switch B to operate in preemptive mode, and set the preemption delay to five
seconds.
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5

```

6. Verify the configuration:

After configuration, ping Host B on Host A, and you can see that Host B is reachable. Use the **display vrrp** command to view the configuration result.

Display detailed information about VRRP group 1 on Switch A.

```

[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Standby Information:

  VRID          : 1                Adver Timer   : 5
  Admin Status  : Up                State          : Master
  Config Pri    : 100               Running Pri    : 100
  Preempt Mode  : Yes               Delay Time     : 5
  Auth Type     : Simple            Key            : hello
  Virtual IP    : 10.1.1.10
  Virtual MAC   : 0000-5e00-0101
  Master IP     : 10.1.1.2

```

The output shows that when a fault is on the link between Switch A and Switch C, the priority of Switch A decreases to 80. Switch A becomes the backup, and Switch B becomes the master. Packets from Host A to Host B are forwarded through Switch B.

Configuring BFD for a VRRP backup to monitor the master (available only on the HP 5500 EI)

Network requirements

- As shown in Figure 57, Switch A and Switch B belong to VRRP group 1, whose virtual IP address is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10. When Switch A works properly, the hosts in the LAN access the external network through Switch A. When Switch A fails, the hosts in the LAN access the external network through Switch B.
- If BFD is not configured, when the master in a VRRP group fails, the backup cannot become the master until the configured timeout timer expires. The timeout is generally three to four seconds, which makes the switchover slow. To solve this problem, VRRP uses BFD to probe the state of the master. Once the master fails, the backup can become the new master in milliseconds.

Figure 57 Network diagram

Configuration procedure

1. Create VLANs, and assign corresponding ports to the VLANs. Configure the IP address of each VLAN interface as shown in Figure 57. (Details not shown.)
2. Configure VRRP on Switch A:

```
<SwitchA> system-view  
[SwitchA] interface vlan-interface 2
```

Create VRRP group 1, and configure the virtual IP address 192.168.0.10 for the group. Set the priority of Switch A in VRRP group 1 to 110.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
[SwitchA-Vlan-interface2] return
```

3. Configure BFD on Switch B:

Configure the source address of BFD echo packets as 10.10.10.10.

```
<SwitchB> system-view
[SwitchB] bfd echo-source-ip 10.10.10.10
```

4. Create the track entry to be associated with the BFD session on Switch B:

Create track entry 1 to be associated with the BFD session to check whether Switch A is reachable.

```
[SwitchB] track 1 bfd echo interface vlan-interface 2 remote ip 192.168.0.101 local
ip 192.168.0.102
```

5. Configure VRRP on Switch B:

Create VRRP group 1, and configure the virtual IP address 192.168.0.10 for the group. VRRP group 1 monitors the status of track entry 1. When the status of the track entry becomes Negative, Switch B quickly becomes the master.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
[SwitchB-Vlan-interface2] vrrp vrid 1 track 1 switchover
[SwitchB-Vlan-interface2] return
```

6. Verify the configuration:

Display the detailed information about VRRP group 1 on Switch A.

```
<SwitchA> display vrrp verbose

```

VRRP Track Information:

```
Track Object    : 1             State : Positive           Switchover
```

Display information about track entry 1 on Switch B.

```
<SwitchB> display track 1
```

Track ID: 1

Status: Positive

Duration: 0 days 0 hours 0 minutes 32 seconds

Notification delay: Positive 0, Negative 0 (in seconds)

Reference object:

BFD session:

Packet type: Echo

Interface : Vlan-interface2

Remote IP : 192.168.0.101

Local IP : 192.168.0.102

The output shows that when the status of the track entry becomes Positive, Switch A is the master, and Switch B the backup.

Enable VRRP state debugging and BFD event debugging on Switch B.

```
<SwitchB> terminal debugging
```

```
<SwitchB> terminal monitor
```

```
<SwitchB> debugging vrrp state
```

```
<SwitchB> debugging bfd event
```

When Switch A fails, the following output is displayed on Switch B.

```
*Dec 17 14:44:34:142 2008 SwitchB BFD/7/EVENT:Send sess-down Msg,
[Src:192.168.0.102,Dst:192.168.0.101,Vlan-interface2,Echo], instance:0,
protocol:Track
```

```

```

VRRP Track Information:

Track Object : 1 State : Negative Switchover

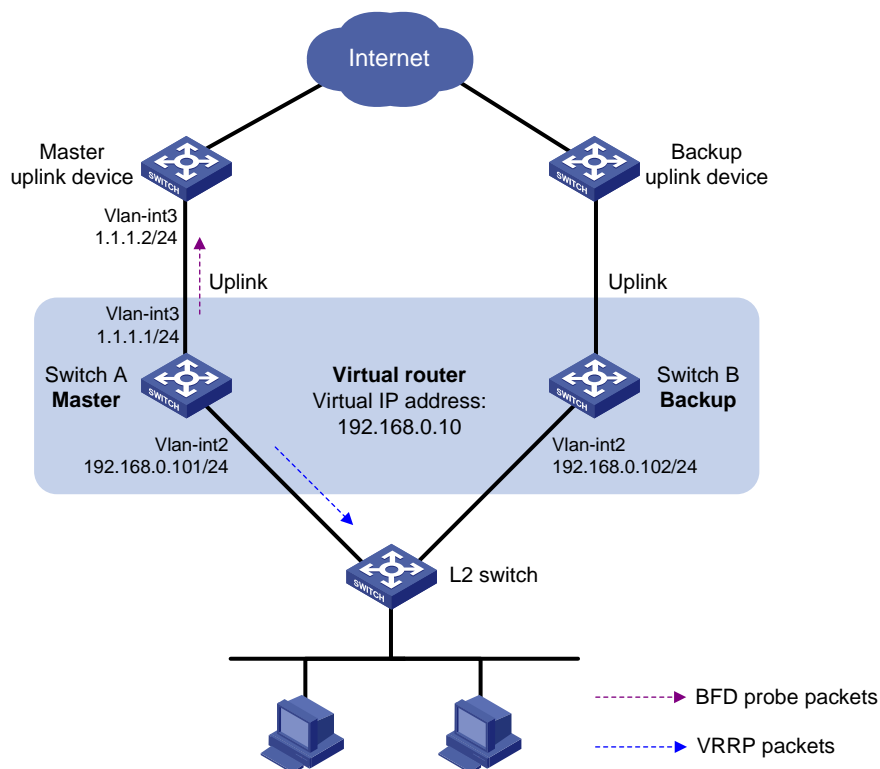

The output shows that when BFD detects that Switch A fails, it notifies VRRP through the track module to change the status of Switch B to master without waiting for a period three times the advertisement interval, so that a backup can quickly preempt as the master.

Configuring BFD for the VRRP master to monitor the uplinks (available only on the HP 5500 EI)

Network requirements

- As shown in Figure 58, Switch A and Switch B belong to VRRP group 1, whose virtual IP address is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.
- When Switch A works properly, the hosts in the LAN access the external network through Switch A. When Switch A detects that the uplink is down through BFD, it decreases its priority so that Switch B can preempt as the master, ensuring that the hosts in the LAN can access the external network through Switch B.

Figure 58 Network diagram

Configuration procedure

1. Create VLANs, and assign corresponding ports to the VLANs. Configure the IP address of each VLAN interface as shown in Figure 58. (Details not shown.)
2. Configure BFD on Switch A:
Configure the source address of BFD echo packets as 10.10.10.10.
<SwitchA> system-view

```
[SwitchA] bfd echo-source-ip 10.10.10.10
```

3. Create a track entry to be associated with the BFD session on Switch A:

```
# Create track entry 1 to be associated with the BFD session to check whether the uplink device with the IP address 1.1.1.2 is reachable.
```

```
[SwitchA] track 1 bfd echo interface vlan-interface 3 remote ip 1.1.1.2 local ip 1.1.1.1
```

4. Configure VRRP on Switch A:

```
# Create VRRP group 1, and configure the virtual IP address of the group as 192.168.0.10. Configure the priority of Switch A in VRRP group 1 as 110. Configure VRRP group 1 to monitor the status of track entry 1. When the status of the track entry becomes Negative, the priority of Switch A decreases by 20.
```

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 reduced 20
[SwitchA-Vlan-interface2] return
```

5. Configure VRRP on Switch B:

```
# Create VRRP group 1, and configure the virtual IP address of the group as 192.168.0.10.
```

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
[SwitchB-Vlan-interface2] return
```

6. Verify the configuration:

```
# Display the detailed information about the VRRP group on Switch A.
```

```
<SwitchA> display vrrp verbose
IPv4 Standby Information:

```

The output shows that when Switch A detects that the uplink fails through BFD, it decreases its priority by 20 to make sure that Switch B can preempt as the master.

Static routing-track-NQA collaboration configuration example

Network requirements

As shown in [Figure 59](#), Switch A, Switch B, Switch C, and Switch D are connected to two segments 20.1.1.0/24 and 30.1.1.0/24. Configure static routes on these switches so that the two segments can communicate with each other, and configure route backup to improve reliability of the network.

Switch A is the default gateway of the hosts in segment 20.1.1.0/24. Two static routes to 30.1.1.0/24 exist on Switch A, with the next hop being Switch B and Switch C, respectively. These two static routes back up each other as follows:

- The static route with Switch B as the next hop has a higher priority, and is the master route. If this route is available, Switch A forwards packets to 30.1.1.0/24 through Switch B.
- The static route with Switch C as the next hop acts as the backup route.
- Configure static routing-track-NQA collaboration to determine whether the master route is available in real time. If the master route is unavailable, the backup route takes effect, and Switch A forwards packets to 30.1.1.0/24 through Switch C.

Similarly, Switch D is the default gateway of the hosts in segment 30.1.1.0/24. Two static routes to 20.1.1.0/24 exist on Switch D, with the next hop being Switch B and Switch C, respectively. These two static routes back up each other as follows:

- The static route with Switch B as the next hop has a higher priority, and is the master route. If this route is available, Switch D forwards packets to 20.1.1.0/24 through Switch B.
- The static route with Switch C as the next hop acts as the backup route.
- Configure static routing-track-NQA collaboration to determine whether the master route is available in real time. If the master route is unavailable, the backup route takes effect, and Switch D forwards packets to 20.1.1.0/24 through Switch C.

Figure 59 Network diagram

Configuration procedure

1. Create VLANs, and assign corresponding ports to the VLANs. Configure the IP address of each VLAN interface as shown in Figure 59. (Details not shown.)
2. Configure Switch A:

Configure a static route to 30.1.1.0/24, with the address of the next hop as 10.1.1.2 and the default priority 60. This static route is associated with track entry 1.

```
<SwitchA> system-view
```

```
[SwitchA] ip route-static 30.1.1.0 24 10.1.1.2 track 1
```

Configure a static route to 30.1.1.0/24, with the address of the next hop as 10.3.1.3 and the priority 80.

```
[SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
```

Configure a static route to 10.2.1.4, with the address of the next hop as 10.1.1.2.

```
[SwitchA] ip route-static 10.2.1.4 24 10.1.1.2
```

Create an NQA test group with the administrator **admin** and the operation tag **test**.

```
[SwitchA] nqa entry admin test
```

Configure the test type as ICMP-echo.

```
[SwitchA-nqa-admin-test] type icmp-echo
```

Configure the destination address of the test as 10.2.1.4 and the next hop address as 10.1.1.2 to check the connectivity of the path from Switch A to Switch B and then to Switch D through NQA.

```
[SwitchA-nqa-admin-test-icmp-echo] destination ip 10.2.1.4
```

```
[SwitchA-nqa-admin-test-icmp-echo] next-hop 10.1.1.2
```

Configure the test frequency as 100 ms.

```
[SwitchA-nqa-admin-test-icmp-echo] frequency 100
```

Configure reaction entry 1, specifying that five consecutive probe failures trigger the track module.

```
[SwitchA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
```

```
threshold-type consecutive 5 action-type trigger-only
```

```
[SwitchA-nqa-admin-test-icmp-echo] quit
```

Start the NQA test.

```
[SwitchA] nqa schedule admin test start-time now lifetime forever
```

```
# Configure track entry 1, and associate it with reaction entry 1 of the NQA test group (with the administrator admin, and the operation tag test).
```

```
[SwitchA] track 1 nqa entry admin test reaction 1
```

3. Configure Switch B:

```
# Configure a static route to 30.1.1.0/24, with the address of the next hop as 10.2.1.4.
```

```
<SwitchB> system-view
```

```
[SwitchB] ip route-static 30.1.1.0 24 10.2.1.4
```

```
# Configure a static route to 20.1.1.0/24, with the address of the next hop as 10.1.1.1.
```

```
[SwitchB] ip route-static 20.1.1.0 24 10.1.1.1
```

4. Configure Switch C:

```
# Configure a static route to 30.1.1.0/24, with the address of the next hop as 10.4.1.4.
```

```
<SwitchC> system-view
```

```
[SwitchC] ip route-static 30.1.1.0 24 10.4.1.4
```

```
# Configure a static route to 20.1.1.0/24, with the address of the next hop as 10.3.1.1.
```

```
[SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
```

5. Configure Switch D:

```
# Configure a static route to 20.1.1.0/24, with the address of the next hop as 10.2.1.2 and the default priority 60. This static route is associated with track entry 1.
```

```
<SwitchD> system-view
```

```
[SwitchD] ip route-static 20.1.1.0 24 10.2.1.2 track 1
```

```
# Configure a static route to 20.1.1.0/24, with the address of the next hop as 10.4.1.3 and the priority 80.
```

```
[SwitchD] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
```

```
# Configure a static route to 10.1.1.1, with the address of the next hop as 10.2.1.2.
```

```
[SwitchD] ip route-static 10.1.1.1 24 10.2.1.2
```

```
# Create an NQA test group with the administrator admin and the operation tag test.
```

```
[SwitchD] nqa entry admin test
```

```
# Configure the test type as ICMP-echo.
```

```
[SwitchD-nqa-admin-test] type icmp-echo
```

```
# Configure the destination address of the test as 10.1.1.1 and the next hop address as 10.2.1.2 to check the connectivity of the path from Switch D to Switch B and then to Switch A through NQA.
```

```
[SwitchD-nqa-admin-test-icmp-echo] destination ip 10.1.1.1
```

```
[SwitchD-nqa-admin-test-icmp-echo] next-hop 10.2.1.2
```

```
# Configure the test frequency as 100 ms.
```

```
[SwitchD-nqa-admin-test-icmp-echo] frequency 100
```

```
# Configure reaction entry 1, specifying that five consecutive probe failures trigger the track module.
```

```
[SwitchD-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
```

```
threshold-type consecutive 5 action-type trigger-only
```

```
[SwitchD-nqa-admin-test-icmp-echo] quit
```

```
# Start the NQA test.
```

```
[SwitchD] nqa schedule admin test start-time now lifetime forever
```

```
# Configure track entry 1, and associate it with reaction entry 1 of the NQA test group (with the administrator admin, and the operation tag test).
```

```
[SwitchD] track 1 nqa entry admin test reaction 1
```

6. Verify the configuration:

Display information about the track entry on Switch A.

```
[SwitchA] display track all
```

```
Track ID: 1
  Status: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Notification delay: Positive 0, Negative 0 (in seconds)
  Reference object:
    NQA entry: admin test
    Reaction: 1
```

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table
```

```
Routing Tables: Public
```

```
          Destinations : 10          Routes : 10
Destination/Mask    Proto Pre  Cost           NextHop         Interface
10.1.1.0/24         Direct 0    0             10.1.1.1        Vlan2

30.1.1.0/24         Static 60   0             10.1.1.2        Vlan2
127.0.0.0/8         Direct 0    0             127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0             127.0.0.1       InLoop0
```

The output shows the NQA test result: the master route is available (the status of the track entry is Positive), and Switch A forwards packets to 30.1.1.0/24 through Switch B.

Remove the IP address of interface VLAN-interface 2 on Switch B.

```
<SwitchB> system-view
```

```
[SwitchB] interface vlan-interface 2
```

```
[SwitchB-Vlan-interface2] undo ip address
```

Display information about the track entry on Switch A.

```
[SwitchA] display track all
```

```
Track ID: 1
  Status: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Notification delay: Positive 0, Negative 0 (in seconds)
  Reference object:
    NQA entry: admin test
    Reaction: 1
```

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table
```

```
Routing Tables: Public
```

```
          Destinations : 10          Routes : 10
```

| Destination/Mask | Proto | Pre | Cost | NextHop | Interface |
|------------------|--------|-----|------|-----------|-----------|
| 10.1.1.0/24 | Direct | 0 | 0 | 10.1.1.1 | Vlan2 |
| 10.1.1.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 10.2.1.0/24 | Static | 60 | 0 | 10.1.1.2 | Vlan2 |
| 10.3.1.0/24 | Direct | 0 | 0 | 10.3.1.1 | Vlan3 |
| 10.3.1.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 20.1.1.0/24 | Direct | 0 | 0 | 20.1.1.1 | Vlan6 |
| 20.1.1.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 30.1.1.0/24 | Static | 80 | 0 | 10.3.1.3 | Vlan3 |
| 127.0.0.0/8 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 127.0.0.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |

The output shows the NQA test result: the master route is unavailable (the status of the track entry is Negative). The backup static route takes effect and Switch A forwards packets to 30.1.1.0/24 through Switch C.

When the master route fails, the hosts in 20.1.1.0/24 can still communicate with the hosts in 30.1.1.0/24.

```
[SwitchA] ping -a 20.1.1.1 30.1.1.1
PING 30.1.1.1: 56 data bytes, press CTRL_C to break
  Reply from 30.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
  Reply from 30.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
  Reply from 30.1.1.1: bytes=56 Sequence=3 ttl=254 time=1 ms
  Reply from 30.1.1.1: bytes=56 Sequence=4 ttl=254 time=2 ms
  Reply from 30.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms
--- 30.1.1.1 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 1/1/2 ms
```

The output on Switch D is similar to that on Switch A. When the master route fails, the hosts in 30.1.1.0/24 can still communicate with the hosts in 20.1.1.0/24.

```
[SwitchB] ping -a 30.1.1.1 20.1.1.1
PING 20.1.1.1: 56 data bytes, press CTRL_C to break
  Reply from 20.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
  Reply from 20.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms

--- 20.1.1.1 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 1/1/2 ms
```

Static routing-Track-BFD collaboration configuration example (available only on the HP 5500 EI)

Network requirements

As shown in [Figure 60](#), Switch A, Switch B, and Switch C are connected to two segments 20.1.1.0/24 and 30.1.1.0/24. Configure static routes on these routers so that the two segments can communicate with each other, and configure route backup to improve reliability of the network.

Switch A is the default gateway of the hosts in segment 20.1.1.0/24. Two static routes to 30.1.1.0/24 exist on Switch A, with the next hop being Switch B and Switch C, respectively. These two static routes back up each other as follows:

- The static route with Switch B as the next hop has a higher priority and is the master route. If this route is available, Switch A forwards packets to 30.1.1.0/24 through Switch B.
- The static route with Switch C as the next hop acts as the backup route.
- Configure static routing-track-BFD collaboration to determine whether the master route is available in real time. If the master route is unavailable, BFD can quickly detect the route failure to make the backup route take effect, and Switch A forwards packets to 30.1.1.0/24 through Switch C and Switch B.

Similarly, Switch B is the default gateway of the hosts in segment 30.1.1.0/24. Two static routes to 20.1.1.0/24 exist on Switch B, with the next hop being Switch A and Switch C, respectively. These two static routes back up each other as follows:

- The static route with Switch A as the next hop has a higher priority and is the master route. If this route is available, Switch B forwards packets to 20.1.1.0/24 through Switch A.
- The static route with Switch C as the next hop acts as the backup route.
- Configure static routing-track-BFD collaboration to determine whether the master route is available in real time. If the master route is unavailable, BFD can quickly detect the route failure to make the backup route take effect, and Switch B forwards packets to 20.1.1.0/24 through Switch C and Switch A.

Figure 60 Network diagram

Configuration procedure

1. Create VLANs, and assign corresponding ports to the VLANs. Configure the IP address of each VLAN interface as shown in [Figure 60](#). (Details not shown.)
2. Configure Switch A:
Configure a static route to 30.1.1.0/24, with the address of the next hop as 10.2.1.2 and the default priority 60. This static route is associated with track entry 1.

```

<SwitchA> system-view
[SwitchA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
# Configure a static route to 30.1.1.0/24, with the address of the next hop as 10.3.1.3 and the
priority 80.
[SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
# Configure the source address of BFD echo packets as 10.10.10.10.
[SwitchA] bfd echo-source-ip 10.10.10.10
# Configure track entry 1, and associate it with the BFD session. Check whether Switch A can be
interoperated with the next hop of static route (Switch B).
[SwitchA] track 1 bfd echo interface vlan-interface 2 remote ip 10.2.1.2 local ip
10.2.1.1

```

3. Configure Switch B:

```

# Configure a static route to 20.1.1.0/24, with the address of the next hop as 10.2.1.1 and the
default priority 60. This static route is associated with track entry 1.
<SwitchB> system-view
[SwitchB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
# Configure a static route to 20.1.1.0/24, with the address of the next hop as 10.4.1.3 and the
priority 80.
[SwitchB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
# Configure the source address of BFD echo packets as 1.1.1.1.
[SwitchB] bfd echo-source-ip 1.1.1.1
# Configure track entry 1 that is associated with the BFD session to check whether Switch B can
communicate with the next hop (Switch A) of the static route.
[SwitchB] track 1 bfd echo interface vlan-interface 2 remote ip 10.2.1.1 local ip
10.2.1.2

```

4. Configure Switch C:

```

# Configure a static route to 30.1.1.0/24, with the address of the next hop as 10.4.1.2.
<SwitchC> system-view
[SwitchC] ip route-static 30.1.1.0 24 10.4.1.2
# Configure a static route to 20.1.1.0/24, with the address of the next hop as 10.3.1.1.
[SwitchB] ip route-static 20.1.1.0 24 10.3.1.1

```

5. Verify the configuration:

```

# Display information about the track entry on Switch A.
[SwitchA] display track all
Track ID: 1
  Status: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Notification delay: Positive 0, Negative 0 (in seconds)
  Reference object:
    BFD Session:
      Packet type: Echo
      Interface   : Vlan-interface2
      Remote IP   : 10.2.1.2
      Local IP    : 10.2.1.1
# Display the routing table of Switch A.
[SwitchA] display ip routing-table

```

Routing Tables: Public

| Destination/Mask | Proto | Pre | Cost | NextHop | Interface |
|------------------|--------|-----|------|-----------|-----------|
| 10.2.1.0/24 | Direct | 0 | 0 | 10.2.1.1 | Vlan2 |
| 10.2.1.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 10.3.1.0/24 | Direct | 0 | 0 | 10.3.1.1 | Vlan3 |
| 10.3.1.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 20.1.1.0/24 | Direct | 0 | 0 | 20.1.1.1 | Vlan5 |
| 20.1.1.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 30.1.1.0/24 | Static | 60 | 0 | 10.2.1.2 | Vlan2 |
| 127.0.0.0/8 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 127.0.0.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |

The output shows the BFD detection result: the next hop 10.2.1.2 is reachable (the status of the track entry is Positive). The master static route takes effect. Switch A forwards packets to 30.1.1.0/24 through Switch B.

Remove the IP address of interface VLAN-interface 2 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] undo ip address
```

Display information about the track entry on Switch A.

```
[SwitchA] display track all

--- 30.1.1.1 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 1/1/2 ms
```

The output on Switch B is similar to that on Switch A. When the master route fails, the hosts in 30.1.1.0/24 can still communicate with the hosts in 20.1.1.0/24.

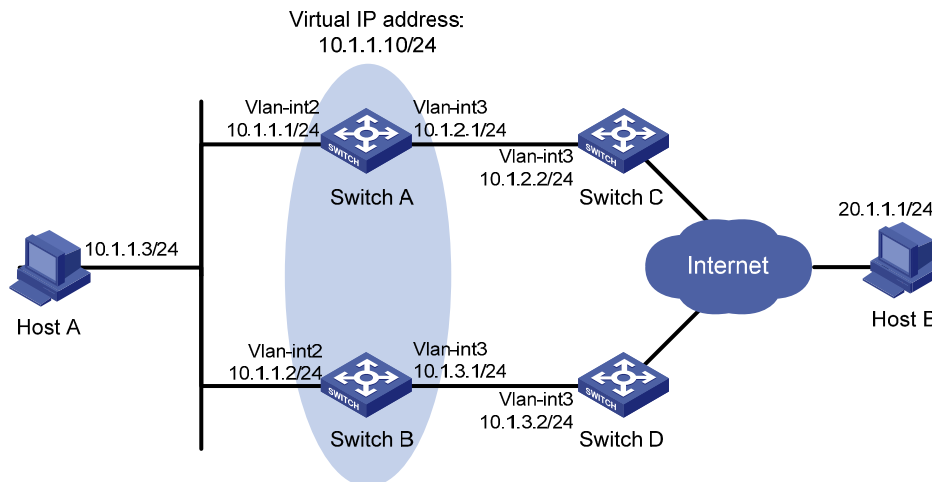

```
[SwitchB] ping -a 30.1.1.1 20.1.1.1
PING 20.1.1.1: 56 data bytes, press CTRL_C to break
  Reply from 20.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
  Reply from 20.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
  Reply from 20.1.1.1: bytes=56 Sequence=3 ttl=254 time=1 ms
  Reply from 20.1.1.1: bytes=56 Sequence=4 ttl=254 time=1 ms
  Reply from 20.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms
--- 20.1.1.1 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 1/1/2 ms
```

VRRP-track-interface management collaboration configuration example (the master monitors the uplink interface) (available only on the HP 5500 EI)

Network requirements

- As shown in [Figure 61](#), Host A needs to access Host B on the Internet. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1, whose virtual IP address is 10.1.1.10.
- When Switch A works properly, packets from Host A to Host B are forwarded through Switch A. When VRRP detects that a fault is on the uplink interface of Switch A through the interface management module, packets from Host A to Host B are forwarded through Switch B.

Figure 61 Network diagram

Configuration procedure

1. Create VLANs, and assign corresponding ports to the VLANs. Configure the IP address of each VLAN interface as shown in Figure 61. (Details not shown.)

2. Configure a track entry on Switch A:

```
# Configure track entry 1, and associate it with the physical status of the uplink interface  
Vlan-interface 3.
```

```
[SwitchA] track 1 interface vlan-interface 3
```

3. Configure VRRP on Switch A:

```
# Create VRRP group 1, and configure the virtual IP address 10.1.1.10 for the group.
```

```
[SwitchA] interface vlan-interface 2
```

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

```
# Set the priority of Switch A in VRRP group 1 to 110.
```

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

```
# Configure to monitor track entry 1, and specify the priority decrement as 30.
```

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 reduced 30
```

4. Configure VRRP on Switch B:

```
<SwitchB> system-view
```

```
[SwitchB] interface vlan-interface 2
```

```
# Create VRRP group 1, and configure the virtual IP address 10.1.1.10 for the group.
```

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

5. Verify the configuration:

After configuration, ping Host B on Host A, and you can see that Host B is reachable. Use the **display vrrp** command to view the configuration result.

```
# Display detailed information about VRRP group 1 on Switch A.
```

```
[SwitchA-Vlan-interface2] display vrrp verbose
```

```
IPv4 Standby Information:

Virtual IP    : 10.1.1.10
Master IP     : 10.1.1.2

```

VRRP Track Information:

Track Object : 1 State : Negative Pri Reduced : 30

After shutting down the uplink interface on Switch A, display detailed information about VRRP group 1 on Switch B.

```
[SwitchB-Vlan-interface2] display vrrp verbose
```

IPv4 Standby Information:

Run Mode : Standard

Run Method : Virtual MAC

Total number of virtual routers : 1

Interface Vlan-interface2

VRID : 1 Adver Timer : 1

Admin Status : Up State : Master

Config Pri : 100 Running Pri : 100

Preempt Mode : Yes Delay Time : 0

Auth Type : None

Virtual IP : 10.1.1.10

Virtual MAC : 0000-5e00-0101

Master IP : 10.1.1.2

The output shows that when the uplink interface on Switch A is shut down, the priority of Switch A decreases to 80. Switch A becomes the backup, and Switch B becomes the master. Packets from Host A to Host B are forwarded through Switch B.

Using ping, tracert, and system debugging

Use the ping, tracert, and system debugging utilities to test network connectivity and identify network problems.

Ping

The ping utility sends ICMP echo requests (ECHO-REQUEST) to the destination device. Upon receiving the requests, the destination device responds with ICMP echo replies (ECHO-REPLY) to the source device. The source device outputs statistics about the ping operation, including the number of packets sent, number of echo replies received, and the round-trip time. You can measure the network performance by analyzing these statistics.

Using a ping command to test network connectivity

| Task | Command | Remarks |
|--|--|---|
| Check whether a specified address in an IP network is reachable. | <ul style="list-style-type: none">For an IPv4 network:
ping [ip] [-a source-ip -c count -f -h ttl -i interface-type interface-number -m interval -n -p pad -q -r -s packet-size -t timeout -tos tos -v -vpn-instance vpn-instance-name] * hostFor an IPv6 network:
ping ipv6 [-a source-ipv6 -c count -m interval -s packet-size -t timeout -tos tos -vpn-instance vpn-instance-name] * host [-i interface-type interface-number] | Use one of the commands.
Available in any view.
Only the HP 5500 EI Switch Series supports the vpn-instance keyword. |

⚠ IMPORTANT:

When you configure the **ping** command for a low-speed network, HP recommends that you set a larger value for the timeout timer (indicated by the **-t** keyword in the command).

Ping example

Network requirements

Test the network connectivity between Device A and Device C in [Figure 1](#). If they can reach each other, get detailed information about routes from Device A to Device C.

Figure 1 Network diagram

Test procedure

Use the **ping** command on Device A to test connectivity to Device C.

```
<DeviceA> ping 1.1.2.2
PING 1.1.2.2: 56 data bytes, press CTRL_C to break
  Reply from 1.1.2.2: bytes=56 Sequence=1 ttl=254 time=205 ms
  Reply from 1.1.2.2: bytes=56 Sequence=2 ttl=254 time=1 ms
  Reply from 1.1.2.2: bytes=56 Sequence=3 ttl=254 time=1 ms
  Reply from 1.1.2.2: bytes=56 Sequence=4 ttl=254 time=1 ms
  Reply from 1.1.2.2: bytes=56 Sequence=5 ttl=254 time=1 ms

--- 1.1.2.2 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
round-trip min/avg/max = 1/41/205 ms
```

Get detailed information about routes from Device A to Device C.

```
<DeviceA> ping -r 1.1.2.2
PING 1.1.2.2: 56 data bytes, press CTRL_C to break
  Reply from 1.1.2.2: bytes=56 Sequence=1 ttl=254 time=53 ms
    Record Route:
      1.1.2.1
      1.1.2.2
      1.1.1.2
      1.1.1.1
  Reply from 1.1.2.2: bytes=56 Sequence=2 ttl=254 time=1 ms
    Record Route:
      1.1.2.1
      1.1.2.2
      1.1.1.2
      1.1.1.1
  Reply from 1.1.2.2: bytes=56 Sequence=3 ttl=254 time=1 ms
    Record Route:
      1.1.2.1
      1.1.2.2
      1.1.1.2
```

```

    1.1.1.1
Reply from 1.1.2.2: bytes=56 Sequence=4 ttl=254 time=1 ms
  Record Route:
    1.1.2.1
    1.1.2.2
    1.1.1.2
    1.1.1.1
Reply from 1.1.2.2: bytes=56 Sequence=5 ttl=254 time=1 ms
  Record Route:
    1.1.2.1
    1.1.2.2
    1.1.1.2
    1.1.1.1
--- 1.1.2.2 ping statistics ---
    5 packet(s) transmitted
    5 packet(s) received
    0.00% packet loss
round-trip min/avg/max = 1/11/53 ms

```

The test procedure with the **ping -r** command (see [Figure 1](#)) is as follows:

1. The source (Device A) sends an ICMP echo request with the RR option being empty to the destination (Device C).
2. The intermediate device (Device B) adds the IP address of its outbound interface (1.1.2.1) to the RR option of the ICMP echo request, and forwards the packet.
3. Upon receiving the request, the destination device copies the RR option in the request and adds the IP address of its outbound interface (1.1.2.2) to the RR option. Then the destination device sends an ICMP echo reply.
4. The intermediate device adds the IP address of its outbound interface (1.1.1.2) to the RR option in the ICMP echo reply, and then forwards the reply.
5. Upon receiving the reply, the source device adds the IP address of its inbound interface (1.1.1.1) to the RR option. Finally, you can get detailed information about routes from Device A to Device C: 1.1.1.1 <-> {1.1.1.2; 1.1.2.1} <-> 1.1.2.2.

Tracert

Tracert (also called "Traceroute") enables you to get the IP addresses of Layer 3 devices in the path to a specific destination. You can use tracert to test network connectivity and identify failed nodes.

Figure 2 Network diagram

Tracert uses received ICMP error messages to get the IP addresses of devices. As shown in [Figure 2](#), tracert works as follows:

1. The source device (Device A) sends a UDP packet with a TTL value of 1 to the destination device (Device D). The destination UDP port is not used by any application on the destination device.
2. The first hop (Device B, the first Layer 3 device that receives the packet) responds by sending a TTL-expired ICMP error message to the source, with its IP address encapsulated. In this way, the source device can get the address of the first Layer 3 device (1.1.1.2).
3. The source device sends a packet with a TTL value of 2 to the destination device.
4. The second hop (Device C) responds with a TTL-expired ICMP error message, which gives the source device the address of the second Layer 3 device (1.1.2.2).
5. The process continues until the packet sent by the source device reaches the ultimate destination device. Because no application uses the destination port specified in the packet, so the destination device responds with a port-unreachable ICMP message to the source device, with its IP address 1.1.3.2 encapsulated. This way, the source device gets the IP address of the destination device (1.1.3.2).
6. The source device thinks that the packet has reached the destination device after receiving the port-unreachable ICMP message, and the path to the destination device is 1.1.1.2 to 1.1.2.2 to 1.1.3.2.

Prerequisites

Before you use a tracert command, perform the tasks in this section.

For an IPv4 network:

- Enable sending of ICMP timeout packets on the intermediate devices (the devices between the source and destination devices). If the intermediate devices are HP devices, execute the **ip ttl-expires enable** command on the devices. For more information about this command, see *Layer 3—IP Services Command Reference*.
- Enable sending of ICMP destination unreachable packets on the destination device. If the destination device is an HP device, execute the **ip unreachable enable** command. For more information about this command, see *Layer 3—IP Services Command Reference*.

For an IPv6 network:

- Enable sending of ICMPv6 timeout packets on the intermediate devices (the devices between the source and destination devices). If the intermediate devices are HP devices, execute the **ipv6**

hoplimit-expires enable command on the devices. For more information about this command, see *Layer 3—IP Services Command Reference*.

- Enable sending of ICMPv6 destination unreachable packets on the destination device. If the destination device is an HP device, execute the **ipv6 unreachable enable** command. For more information about this command, see *Layer 3—IP Services Command Reference*.

Using a tracer command to identify failed or all nodes in a path

| Task | Command | Remarks |
|--|--|--|
| Display the routes from source to destination. | <ul style="list-style-type: none"> • For an IPv4 network:
 <code>tracer [-a source-ip -f first-ttl -m max-ttl -p port -q packet-number -tos tos -vpn-instance vpn-instance-name -w timeout] * host</code> • For an IPv6 network:
 <code>tracer ipv6 [-f first-ttl -m max-ttl -p port -q packet-number -tos tos -vpn-instance vpn-instance-name -w timeout] * host</code> | <p>Use one of the commands.</p> <p>Available in any view.</p> <p>Only the HP 5500 EI Switch Series supports the vpn-instance keyword.</p> |

System debugging

The device supports various debugging for the majority of protocols and features and provides debugging information to help users diagnose errors.

Debugging information control switches

The following two switches control the display of debugging information:

- **Protocol debugging switch**—Controls protocol-specific debugging information.
- **Screen output switch**—Controls whether to display the debugging information on a certain screen.

As shown in [Figure 3](#), assume that the device can provide debugging for the three modules 1, 2, and 3. The debugging information can be output on a terminal only when both the protocol debugging switch and the screen output switch are turned on.

Output of debugging information depends on the configurations of the information center and the debugging commands of each protocol and functional module. Debugging information is typically displayed on a terminal (including console or VTY) for display. You can also send debugging information to other destinations. For more information, see "[Configuring the information center](#)."

Figure 3 Relationship between the protocol and screen output switch

Debugging a feature module

Output of debugging commands is memory intensive. To guarantee system performance, enable debugging only for modules that are in an exceptional condition. When debugging is complete, use the **undo debugging all** command to disable all the debugging functions.

Configure the **debugging**, **terminal debugging**, and **terminal monitor** commands before you can display detailed debugging information on the terminal. For more information about the **terminal debugging** and **terminal monitor** commands, see *Network Management and Monitoring Command Reference*.

To debug a feature module and display the debugging information on a terminal:

| Step | Command | Remarks |
|--|--|---|
| 1. Enable the terminal monitoring of system information. | terminal monitor | Optional.
The terminal monitoring on the console is enabled by default and the terminal monitoring on the monitoring terminal is disabled by default.
Available in user view. |
| 2. Enable the terminal display of debugging information. | terminal debugging | Disabled by default.
Available in user view. |
| 3. Enable debugging for a specified module. | debugging <i>module-name</i> [<i>option</i>] | Disabled by default.
Available in user view. |
| 4. Display the enabled debugging functions. | display debugging [interface <i>interface-type interface-number</i>] [<i>module-name</i>] [{ begin exclude include } <i>regular-expression</i>] | Optional.
Available in any view. |

Ping and traceroute example

Network requirements

As shown in Figure 4, Device A failed to Telnet Device C. Determine whether Device A and Device C can reach each other. If they cannot reach each other, locate the failed nodes in the network.

Figure 4 Network diagram

Test procedure

1. Use the **ping** command to test connectivity between Device A and Device C.

```
<DeviceA> ping 1.1.2.2
PING 1.1.2.2: 56 data bytes, press CTRL_C to break
Request time out
Request time out
Request time out
Request time out
Request time out

--- 1.1.2.2 ping statistics ---
 5 packet(s) transmitted
 0 packet(s) received
100.00% packet loss
```

The output shows that Device A and Device C cannot reach each other.

2. Use the **tracert** command to identify failed nodes.

```
<DeviceA> system-view
[DeviceA] ip ttl-expires enable
[DeviceA] ip unreachable enable
[DeviceA] tracert 1.1.2.2
  traceroute to 1.1.2.2(1.1.2.2) 30 hops max, 40 bytes packet, press CTRL_C to break
 1  1.1.1.2  14 ms  10 ms  20 ms
 2  * * *
 3  * * *
 4  * * *
 5
<DeviceA>
```

The output shows that Device A and Device C cannot reach each other, Device A and Device B can reach each other, and an error has occurred on the connection between Device B and Device C.

3. Use the **debugging ip icmp** command on Device A and Device C to verify that they can send and receive the specific ICMP packets, or use the **display ip routing-table** command to verify the availability of active routes between Device A and Device C.

Configuring NTP

The term *Layer 3 Ethernet port* refers to route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

Overview

NTP is typically used in large networks to dynamically synchronize time among network devices. It guarantees higher clock accuracy than manual system clock setting. In a small network that does not require high clock accuracy, you can keep time synchronized among devices by changing their system clocks one by one.

NTP runs over UDP and uses UDP port 123.

NTP application

An administrator is unable to keep time synchronized among all devices within a network by changing the system clock on each station, because this is a huge work and does not guarantee clock precision. NTP, however, allows quick clock synchronization within the entire network and ensures high clock precision.

NTP is used when all devices within the network must keep consistent time. For example:

- In analyzing log and debugging information collected from different devices in network management, time must be used as a reference basis.
- All devices must use the same reference clock in a charging system.
- To implement certain functions, such as a scheduled restart of all devices within the network, all devices must keep consistent time.
- If multiple systems process a complex event in cooperation, these systems must use the same reference clock to ensure the correct execution sequence.
- For incremental backup between a backup server and clients, timekeeping must be synchronized between the backup server and all clients.

NTP advantages

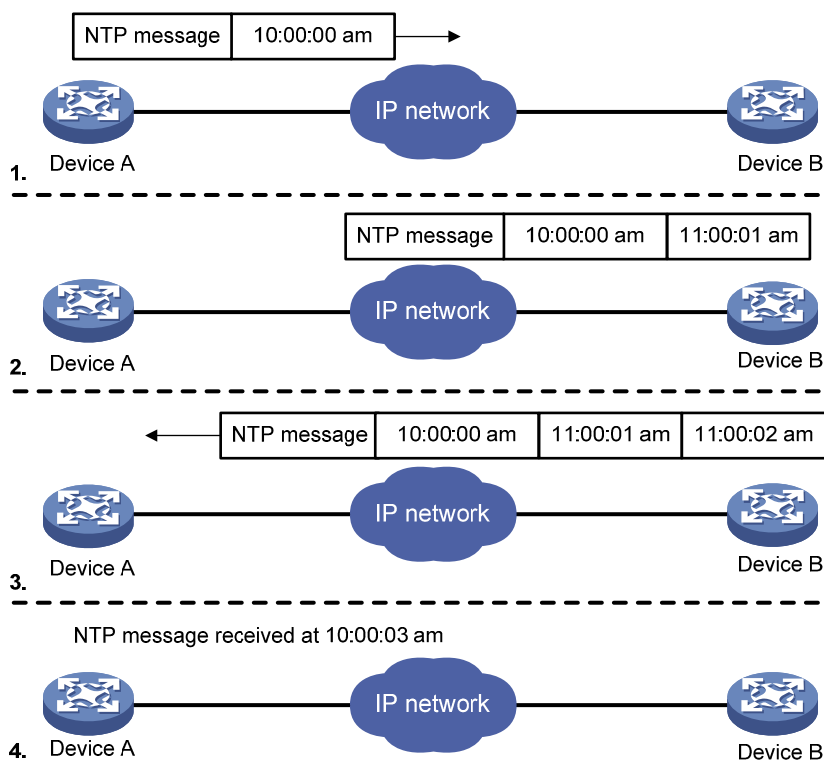

- NTP uses a stratum to describe clock accuracy. The stratum ranges from 1 to 16. Clock accuracy decreases as the stratum number increases. The stratum of a reference clock ranges from 1 to 15. A stratum 16 clock is in unsynchronized state.
- The local clock of this Switch Series cannot operate as a reference clock. It can serve as an NTP server only after it is synchronized.
- NTP supports access control and MD5 authentication.
- NTP can unicast, multicast, or broadcast protocol messages.

How NTP works

Figure 5 shows the basic workflow of NTP. Device A and Device B are connected over a network. They have their own independent system clocks, which need to be automatically synchronized through NTP. Assume that:

- Prior to system clock synchronization between Device A and Device B, the clock of Device A is set to 10:00:00 am while that of Device B is set to 11:00:00 am.
- Device B is used as the NTP time server, so Device A synchronizes to Device B.
- It takes 1 second for an NTP message to travel from one device to the other.

Figure 5 Basic workflow of NTP

The synchronization process is as follows:

- Device A sends Device B an NTP message, which is timestamped when it leaves Device A. The timestamp is 10:00:00 am (T1).
- When this NTP message arrives at Device B, it is timestamped by Device B. The timestamp is 11:00:01 am (T2).
- When the NTP message leaves Device B, Device B timestamps it. The timestamp is 11:00:02 am (T3).
- When Device A receives the NTP message, the local time of Device A is 10:00:03 am (T4).

Up to now, Device A can calculate the following parameters based on the timestamps:

- The roundtrip delay of NTP message: $\text{Delay} = (T4 - T1) - (T3 - T2) = 2 \text{ seconds}$.
- Time difference between Device A and Device B: $\text{Offset} = ((T2 - T1) + (T3 - T4)) / 2 = 1 \text{ hour}$.

Based on these parameters, Device A can synchronize its own clock to the clock of Device B.

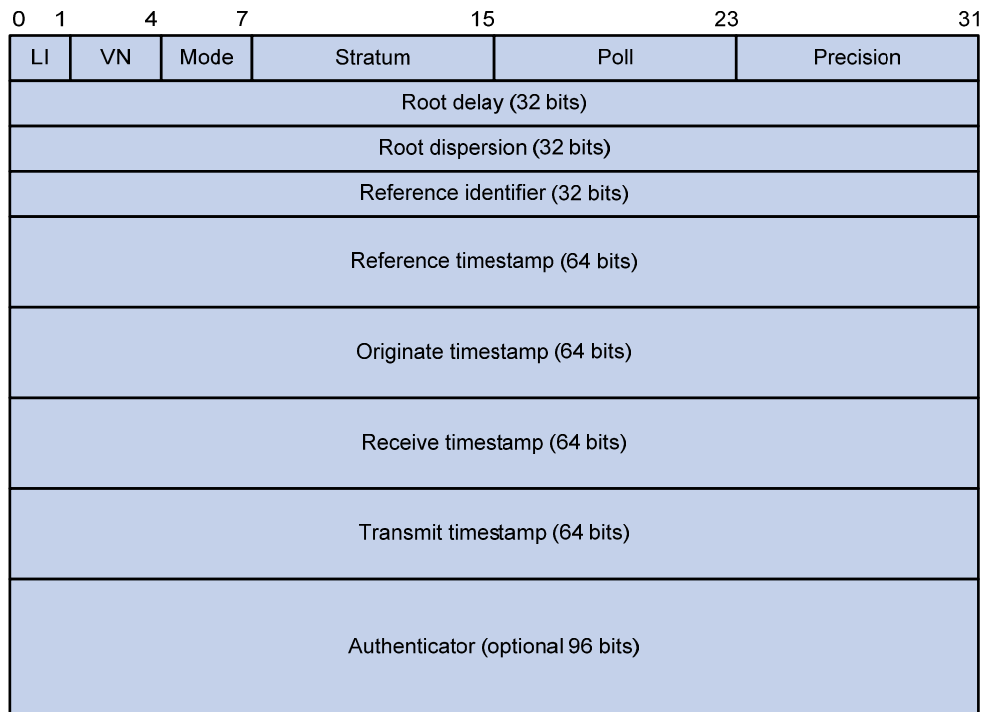

This is a rough description of how NTP works. For more information, see RFC 1305.

NTP message format

NTP uses two types of messages: clock synchronization and NTP control messages. All NTP messages mentioned in this document refer to NTP clock synchronization messages. NTP control messages are used in environments where network management is needed. Because NTP control messages are not essential for clock synchronization, they are not described in this document.

A clock synchronization message is encapsulated in a UDP message in the format shown in [Figure 6](#).

Figure 6 Clock synchronization message format

The main fields are described as follows:

- **LI (Leap Indicator)**—A 2-bit leap indicator. If set to 11, it warns of an alarm condition (clock unsynchronized). If set to any other value, it is not to be processed by NTP.
- **VN (Version Number)**—A 3-bit version number that indicates the version of NTP. The latest version is version 4.
- **Mode**—A 3-bit code that indicates the operation mode of NTP. This field can be set to these values:
 - **0**—Reserved
 - **1**—Symmetric active
 - **2**—Symmetric passive
 - **3**—Client
 - **4**—Server
 - **5**—Broadcast or multicast
 - **6**—NTP control message
 - **7**—Reserved for private use.

- **Stratum**—An 8-bit integer that indicates the stratum level of the local clock, with the value ranging from 1 to 16. Clock precision decreases from stratum 1 through stratum 16. A stratum 1 clock has the highest precision, and a stratum 16 clock is not synchronized.
- **Poll**—An 8-bit signed integer that indicates the maximum interval between successive messages, which is called the poll interval.
- **Precision**—An 8-bit signed integer that indicates the precision of the local clock.
- **Root Delay**—Roundtrip delay to the primary reference source.
- **Root Dispersion**—The maximum error of the local clock relative to the primary reference source.
- **Reference Identifier**—Identifier of the particular reference source.
- **Reference Timestamp**—The local time at which the local clock was last set or corrected.
- **Originate Timestamp**—The local time at which the request departed from the client for the service host.
- **Receive Timestamp**—The local time at which the request arrived at the service host.
- **Transmit Timestamp**—The local time at which the reply departed from the service host for the client.
- **Authenticator**—Authentication information.

Operation modes

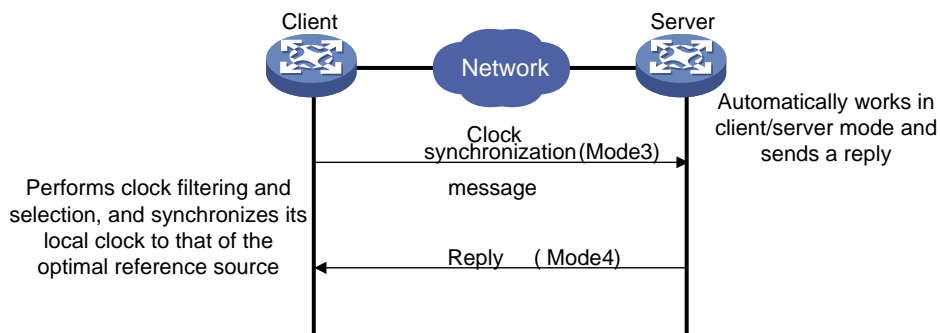

Devices that run NTP can implement clock synchronization in one of the following modes:

- Client/server mode
- Symmetric peers mode
- Broadcast mode
- Multicast mode

You can select operation modes of NTP as needed. If the IP address of the NTP server or peer is unknown and many devices in the network need to be synchronized, adopt the broadcast or multicast mode. In the client/server or symmetric peers mode, a device is synchronized from the specified server or peer, so clock reliability is enhanced.

Client/server mode

Figure 7 Client/server mode

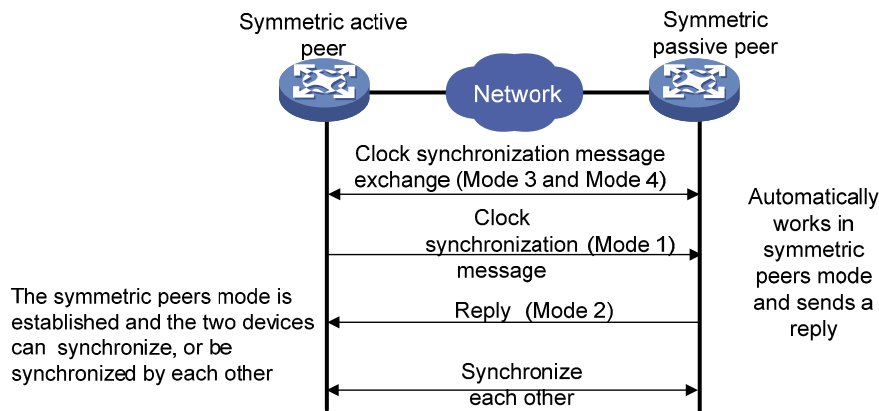

When operating in client/server mode, a client sends a clock synchronization message to servers with the Mode field in the message set to 3 (client mode). Upon receiving the message, the servers automatically operate in server mode and send a reply, with the Mode field in the messages set to 4 (server mode). Upon receiving the replies from the servers, the client performs clock filtering and selection and synchronizes to the optimal reference source.

In client/server mode, a client can synchronize to a server, but a server cannot synchronize to a client.

Symmetric peers mode

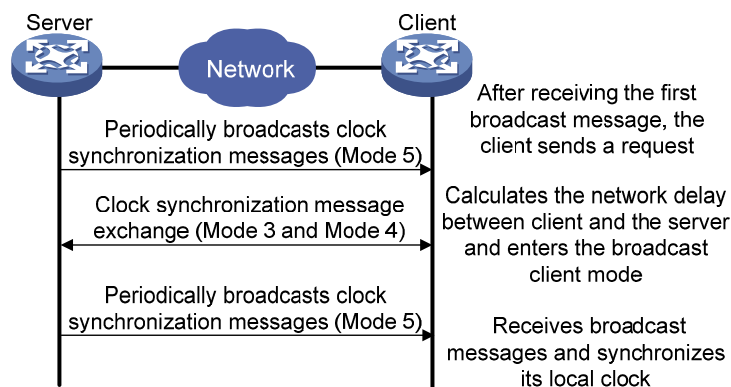

Figure 8 Symmetric peers mode

In symmetric peers mode, devices that operate in symmetric active mode and symmetric passive mode exchange NTP messages with the Mode field 3 (client mode) and 4 (server mode). Then the device that operates in symmetric active mode periodically sends clock synchronization messages, with the Mode field in the messages set to 1 (symmetric active). The device that receives the messages automatically enters symmetric passive mode and sends a reply, with the Mode field in the message set to 2 (symmetric passive). This exchange of messages establishes symmetric peers mode between the two devices, so the two devices can synchronize, or be synchronized by, each other. If the clocks of both devices have been synchronized, the device whose local clock has a lower stratum level synchronizes the other device.

Broadcast mode

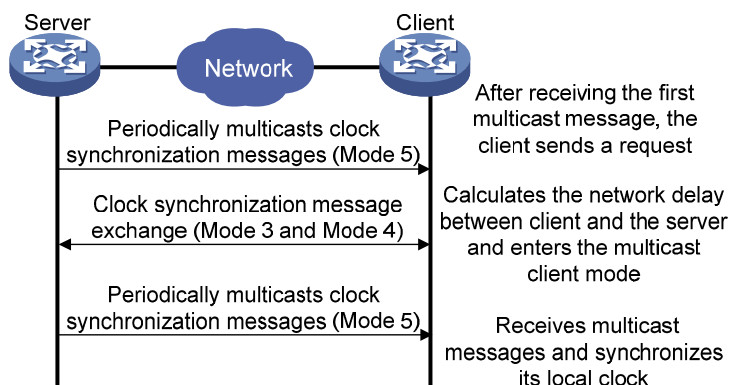

Figure 9 Broadcast mode

In broadcast mode, a server periodically sends clock synchronization messages to broadcast address 255.255.255.255, with the Mode field in the messages set to 5 (broadcast mode). Clients listen to the broadcast messages from servers. When a client receives the first broadcast message, the client and the server start to exchange messages with the Mode field set to 3 (client mode) and 4 (server mode), to calculate the network delay between client and the server. Then, the client enters broadcast client mode. The client continues listening to broadcast messages, and synchronizes its local clock based on the received broadcast messages.

Multicast mode

Figure 10 Multicast mode

In multicast mode, a server periodically sends clock synchronization messages to the user-configured multicast address, or, if no multicast address is configured, to the default NTP multicast address 224.0.1.1, with the Mode field in the messages set to 5 (multicast mode). Clients listen to the multicast messages from servers. When a client receives the first multicast message, the client and the server start to exchange messages with the Mode field set to 3 (client mode) and 4 (server mode), to calculate the network delay between client and server. Then, the client enters multicast client mode. It continues listening to multicast messages, and synchronizes its local clock based on the received multicast messages.

In symmetric peers mode, broadcast mode, and multicast mode, the client (or the symmetric active peer) and the server (the symmetric passive peer) can operate in the specified NTP operation mode only after they exchange NTP messages with the Mode field 3 (client mode) and the Mode field 4 (server mode). During this message exchange process, NTP clock synchronization can be implemented.

NTP configuration task list

| Task | Remarks |
|---|----------|
| Configuring NTP operation modes | Required |
| Configuring optional parameters | Optional |
| Configuring access-control rights | Optional |
| Configuring NTP authentication | Optional |

Configuring NTP operation modes

Devices can implement clock synchronization in one of the following modes:

- **Client/server mode**—Configure only clients.
- **Symmetric mode**—Configure only symmetric-active peers.
- **Broadcast mode**—Configure both clients and servers.
- **Multicast mode**—Configure both clients and servers.

Configuring the client/server mode

For devices operating in client/server mode, make configurations on the clients.

If you specify the source interface for NTP messages by specifying the source interface `source-interface` option, NTP uses the primary IP address of the specified interface as the source IP address of the NTP messages.

A device can act as a server to synchronize other devices only after it is synchronized. If a server has a stratum level higher than or equal to a client, the client will not synchronize to that server.

To specify an NTP server on the client:

| Step | Command | Remarks |
|--|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Specify an NTP server for the device. | ntp-service unicast-server
[vpn-instance <i>vpn-instance-name</i>]
{ <i>ip-address</i> <i>server-name</i> }
[authentication-keyid <i>keyid</i>
priority source-interface
<i>interface-type interface-number</i>
version <i>number</i>] * | By default, no NTP server is specified.

Only the HP 5500 EI supports the vpn-instance keyword.

In this command, the <i>ip-address</i> argument must be a unicast address, rather than a broadcast address, a multicast address or the IP address of the local clock.

You can configure multiple servers by repeating the command. The clients will select the optimal reference source. |

Configuring the symmetric peers mode

Follow these guidelines when you configure the NTP symmetric peers mode:

- For devices operating in symmetric mode, specify a symmetric-passive peer on a symmetric-active peer.
- Use any NTP configuration command in [Configuring NTP operation modes](#) to enable NTP. Otherwise, a symmetric-passive peer does not process NTP messages from a symmetric-active peer.
- Either the symmetric-active peer or the symmetric-passive peer must be in synchronized state. Otherwise, clock synchronization does not proceed.

To specify a symmetric-passive peer on the active peer:

| Step | Command | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |

| Step | Command | Remarks |
|---|--|---|
| 2. Specify a symmetric-passive peer for the device. | <pre> ntp-service unicast-peer [vpn-instance <i>vpn-instance-name</i>] { <i>ip-address</i> <i>peer-name</i> } [authentication-keyid <i>keyid</i> priority source-interface <i>interface-type interface-number</i> version <i>number</i>] *</pre> | <p>By default, no symmetric-passive peer is specified.</p> <p>Only the HP 5500 EI supports the vpn-instance keyword.</p> <p>The <i>ip-address</i> argument must be a unicast address, rather than a broadcast address, a multicast address, or the IP address of the local clock.</p> <p>After you specify the source interface for NTP messages by specifying the source interface <i>source-interface</i> option, the source IP address of the NTP messages is set as the primary IP address of the specified interface.</p> <p>You can configure multiple symmetric-passive peers by repeating this command.</p> |

Configuring the broadcast mode

The broadcast server periodically sends NTP broadcast messages to the broadcast address 255.255.255.255. After receiving the messages, the device operating in NTP broadcast client mode sends a reply and synchronizes to the server.

Configure the NTP broadcast mode on both the server and clients. The NTP broadcast mode can only be configured in a specific interface view because an interface needs to be specified on the broadcast server for sending NTP broadcast messages and on each broadcast client for receiving broadcast messages.

Configuring a broadcast client

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter Layer 3 Ethernet interface view or VLAN interface view. | interface <i>interface-type interface-number</i> | <p>This command enters the view of the interface for sending NTP broadcast messages.</p> <p>You can configure an Ethernet port as a Layer 3 Ethernet port only on the HP 5500 EI switch.</p> |
| 3. Configure the device to operate in NTP broadcast client mode. | ntp-service broadcast-client | N/A |

Configuring the broadcast server

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter Layer 3 Ethernet interface view or VLAN interface view. | interface <i>interface-type</i>
<i>interface-number</i> | This command enters the view of the interface for sending NTP broadcast messages.

You can configure an Ethernet port as a Layer 3 Ethernet port only on the HP 5500 EI switch. |
| 3. Configure the device to operate in NTP broadcast server mode. | ntp-service broadcast-server
[authentication-keyid <i>keyid</i>
version <i>number</i>] * | A broadcast server can synchronize broadcast clients only when its clock has been synchronized. |

Configuring the multicast mode

The multicast server periodically sends NTP multicast messages to multicast clients, which send replies after receiving the messages and synchronize their local clocks.

Configure the NTP multicast mode on both the server and clients. The NTP multicast mode must be configured in a specific interface view.

Configuring a multicast client

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter Layer 3 Ethernet interface view or VLAN interface view. | interface <i>interface-type</i>
<i>interface-number</i> | This command enters the view of the interface for sending NTP multicast messages.

You can configure an Ethernet port as a Layer 3 Ethernet port only on the HP 5500 EI switch. |
| 3. Configure the device to operate in NTP multicast client mode. | ntp-service multicast-client
[<i>ip-address</i>] | You can configure up to 1024 multicast clients, of which 128 can take effect at the same time. |

Configuring the multicast server

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter Layer 3 Ethernet interface view or VLAN interface view. | interface <i>interface-type</i>
<i>interface-number</i> | This command enters the view of the interface for sending NTP multicast messages.

You can configure an Ethernet port as a Layer 3 Ethernet port only on the HP 5500 EI switch. |

| Step | Command | Remarks |
|--|--|---|
| 3. Configure the device to operate in NTP multicast server mode. | ntp-service multicast-server
[<i>ip-address</i>]
[authentication-keyid <i>keyid</i> ttl <i>ttl-number</i> version <i>number</i>] * | A multicast server can synchronize broadcast clients only when its clock has been synchronized. |

Configuring optional parameters

This section explains how to configure the optional parameters of NTP.

Specifying the source interface for NTP messages

If you specify the source interface for NTP messages, the device sets the source IP address of the NTP messages as the primary IP address of the specified interface when sending the NTP messages.

When the device responds to an NTP request received, the source IP address of the NTP response is always the IP address of the interface that received the NTP request.

Configuration guidelines

- The source interface for NTP unicast messages is the interface specified in the **ntp-service unicast-server** or **ntp-service unicast-peer** command.
- The source interface for NTP broadcast or multicast messages is the interface where you configure the **ntp-service broadcast-server** or **ntp-service multicast-server** command.
- If the specified source interface goes down, NTP uses the primary IP address of the outgoing interface as the source IP address.

Configuration procedure

To specify the source interface for NTP messages:

| Step | Command | Remarks |
|---|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Specify the source interface for NTP messages. | ntp-service source-interface
<i>interface-type interface-number</i> | By default, no source interface is specified for NTP messages, and the system uses the IP address of the interface determined by the matching route as the source IP address of NTP messages. |

Disabling an interface from receiving NTP messages

If NTP is enabled, NTP messages can be received from all interfaces by default. You can disable an interface from receiving NTP messages by using the following configuration.

| Step | Command | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |

| Step | Command | Remarks |
|--|---|--|
| 2. Enter Layer 3 Ethernet interface view or VLAN interface view. | interface <i>interface-type</i>
<i>interface-number</i> | You can configure an Ethernet port as a Layer 3 Ethernet port only on the HP 5500 EI switch. |
| 3. Disable the interface from receiving NTP messages. | ntp-service in-interface disable | By default, an interface is enabled to receive NTP messages. |

Configuring the allowed maximum number of dynamic sessions

A single device can have a maximum of 128 associations at the same time, including static associations and dynamic associations.

A static association refers to an association that a user has manually created by using an NTP command. A dynamic association is a temporary association created by the system during operation. A dynamic association is removed if the system fails to receive messages from it over a specific long time.

In client/server mode, for example, when you execute a command to synchronize the time to a server, the system creates a static association, and the server simply responds passively upon the receipt of a message, rather than creating an association (static or dynamic). In symmetric mode, static associations are created at the symmetric-active peer side, and dynamic associations are created at the symmetric-passive peer side. In broadcast or multicast mode, static associations are created at the server side, and dynamic associations are created at the client side.

To configure the allowed maximum number of dynamic sessions:

| Step | Command | Remarks |
|--|--|---------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the maximum number of dynamic sessions allowed to be established locally. | ntp-service max-dynamic-sessions
<i>number</i> | The default is 100. |

Configuring the DSCP value for NTP messages

| Step | Command | Remarks |
|---|---|----------------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the Differentiated Service Code Point (DSCP) value for NTP messages. | ntp-service dscp <i>dscp-value</i> | The default setting is 16. |

Configuring access-control rights

From the highest to lowest, the NTP service access-control rights are **peer**, **server**, **synchronization**, and **query**. If a device receives an NTP request, it performs an access-control right match and uses the first matched right. If no matched right is found, the device drops the NTP request.

- **query**—Control query permitted. This level of right permits the peer devices to perform control query to the NTP service on the local device, but it does not permit a peer device to synchronize to the local device. "Control query" refers to the query of some states of the NTP service, including alarm information, authentication status, and clock source information.
- **synchronization**—Server access only. This level of right permits a peer device to synchronize to the local device, but it does not permit the peer devices to perform control query.
- **server**—Server access and query permitted. This level of right permits the peer devices to perform synchronization and control query to the local device, but it does not permit the local device to synchronize to a peer device.
- **peer**—Full access. This level of right permits the peer devices to perform synchronization and control query to the local device, and it permits the local device to synchronize to a peer device.

The access-control right mechanism provides only a minimum level of security protection for a system running NTP. A more secure method is identity authentication.

Configuration prerequisites

Before you configure the NTP service access-control right to the local device, create and configure an ACL associated with the access-control right. For more information about ACLs, see *ACL and QoS Configuration Guide*.

Configuration procedure

To configure the NTP service access-control right to the local device:

| Step | Command | Remarks |
|---|--|------------------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the NTP service access-control right for a peer device to access the local device. | ntp-service access { peer query server synchronization }
acl-number | The default is peer . |

Configuring NTP authentication

Enable NTP authentication for a system running NTP in a network where there is a high security demand. NTP authentication enhances network security by using client-server key authentication, which prohibits a client from synchronizing with a device that fails authentication.

To configure NTP authentication, do the following:

- Enable NTP authentication
- Configure an authentication key
- Configure the key as a trusted key
- Associate the specified key with an NTP server or a symmetric peer

These tasks are required. If any task is omitted, NTP authentication cannot function.

Configuring NTP authentication in client/server mode

Follow these instructions to configure NTP authentication in client/server mode:

- A client can synchronize to the server only when you configure all the required tasks on both the client and server.
- On the client, if NTP authentication is not enabled or no key is specified to associate with the NTP server, the client is not authenticated. No matter whether NTP authentication is enabled or not on the server, the clock synchronization between the server and client can be performed.
- On the client, if NTP authentication is enabled and a key is specified to associate with the NTP server, but the key is not a trusted key, the client does not synchronize to the server no matter whether NTP authentication is enabled or not on the server.

Configuring NTP authentication for client

| Step | Command | Remarks |
|--|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enable NTP authentication. | ntp-service authentication enable | By default, NTP authentication is disabled. |
| 3. Configure an NTP authentication key. | ntp-service authentication-keyid
<i>keyid</i> authentication-mode md5
[cipher simple] <i>value</i> | By default, no NTP authentication key is configured.
Configure the same authentication key on the client and server. |
| 4. Configure the key as a trusted key. | ntp-service reliable
authentication-keyid <i>keyid</i> | By default, the authentication key is not configured as a trusted key. |
| 5. Associate the specified key with an NTP server. | <ul style="list-style-type: none"> • Client/server mode:
ntp-service unicast-server
{ <i>ip-address</i> <i>server-name</i> }
authentication-keyid <i>keyid</i> • Symmetric peers mode:
ntp-service unicast-peer
{ <i>ip-address</i> <i>peer-name</i> }
authentication-keyid <i>keyid</i> | You can associate a non-existing key with an NTP server. To make NTP authentication effective, you must configure the key as an authentication key and specify it as a trusted key after associating the key with the NTP server. |

Configuring NTP authentication for a server

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enable NTP authentication. | ntp-service authentication enable | By default, NTP authentication is disabled. |
| 3. Configure an NTP authentication key. | ntp-service authentication-keyid
<i>keyid</i> authentication-mode md5
[cipher simple] <i>value</i> | By default, no NTP authentication key is configured.
Configure the same authentication key on the client and server. |
| 4. Configure the key as a trusted key. | ntp-service reliable
authentication-keyid <i>keyid</i> | By default, the authentication key is not configured as a trusted key. |
| 5. Enter Layer 3 Ethernet port view or VLAN interface view. | interface <i>interface-type</i>
<i>interface-number</i> | You can configure an Ethernet port as a Layer 3 Ethernet port only on the HP 5500 EI switch. |

| Step | Command | Remarks |
|--|--|--|
| 6. Associate the specified key with an NTP server. | <ul style="list-style-type: none"> Broadcast server mode:
ntp-service broadcast-server authentication-keyid <i>keyid</i> Multicast server mode:
ntp-service multicast-server authentication-keyid <i>keyid</i> | You can associate a non-existing key with an NTP server. To enable NTP authentication, you must configure the key and specify it as a trusted key after associating the key with the NTP server. |

Displaying and maintaining NTP

| Task | Command | Remarks |
|---|---|-----------------------|
| Display information about NTP service status. | display ntp-service status [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display information about NTP sessions. | display ntp-service sessions [verbose] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the brief information about the NTP servers from the local device back to the primary reference source. | display ntp-service trace [{ begin exclude include } <i>regular-expression</i>] | Available in any view |

NTP configuration examples

This section provides configuration examples for NTP.

Configuring the client/server mode

Network requirements

As shown in Figure 11, configure Device A as a reference source, with the stratum level 2. Configure Device B to operate in client/server mode and use Device A as its NTP server.

Figure 11 Network diagram

Configuration procedure

- Set the IP address for each interface as shown in Figure 11. (Details not shown.)
- Configure Device B:

```
# Display the NTP status of Device B before clock synchronization.
```

```
<DeviceB> display ntp-service status
Clock status: unsynchronized
Clock stratum: 16
Reference clock ID: none
```

```

Nominal frequency: 64.0000 Hz
Actual frequency: 64.0000 Hz
Clock precision: 2^7
Clock offset: 0.0000 ms
Root delay: 0.00 ms
Root dispersion: 0.00 ms
Peer dispersion: 0.00 ms
Reference time: 00:00:00.000 UTC Jan 1 1900 (00000000.00000000)
# Specify Device A as the NTP server of Device B so Device B synchronizes to Device A.

```

```

<DeviceB> system-view
[DeviceB] ntp-service unicast-server 1.0.1.11
# Display the NTP status of Device B after clock synchronization.

```

```

[DeviceB] display ntp-service status
Clock status: synchronized
Clock stratum: 3
Reference clock ID: 1.0.1.11
Nominal frequency: 64.0000 Hz
Actual frequency: 64.0000 Hz
Clock precision: 2^7
Clock offset: 0.0000 ms
Root delay: 31.00 ms
Root dispersion: 1.05 ms
Peer dispersion: 7.81 ms
Reference time: 14:53:27.371 UTC Sep 19 2005 (C6D94F67.5EF9DB22)

```

The output shows that Device B has synchronized to Device A because it has a higher stratum than Device A.

```

# Display the NTP session information of Device B.

```

```

[DeviceB] display ntp-service sessions
      source      reference  stra reach poll now offset delay disper
*****
[12345] 1.0.1.11 127.127.1.0  2   63  64   3  -75.5  31.0 16.5
note: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured
Total associations : 1

```

The output shows that an association has been set up between Device B and Device A.

Configuring the NTP symmetric mode

Network requirements

- As shown in [Figure 12](#), configure Device A as a reference source, with the stratum level 2.
- Configure Device B to operate in client mode and use Device A as its NTP server.
- Configure Device C to operate in symmetric-active mode and use Device B as its symmetric-passive peer.

Figure 12 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure Device B:

Specify Device A as the NTP server of Device B.

```
<DeviceB> system-view
[DeviceB] ntp-service unicast-server 3.0.1.31
```

3. Display the NTP status of Device B after clock synchronization.

```
[DeviceB] display ntp-service status
Clock status: synchronized
Clock stratum: 3
Reference clock ID: 3.0.1.31
Nominal frequency: 100.0000 Hz
Actual frequency: 100.0000 Hz
Clock precision: 2^18
Clock offset: -21.1982 ms
Root delay: 15.00 ms
Root dispersion: 775.15 ms
Peer dispersion: 34.29 ms
Reference time: 15:22:47.083 UTC Sep 19 2005 (C6D95647.153F7CED)
```

The output shows that Device B has synchronized to Device A because it has a higher stratum than Device A.

4. Configure Device C (after Device B is synchronized to Device A):

Configure Device C as a symmetric peer after local synchronization.

```
[DeviceC] ntp-service unicast-peer 3.0.1.32
```

The output shows that Device B and Device C are configured as symmetric peers, with Device C in symmetric-active mode and Device B in symmetric-passive mode. Because the stratus level of Device C is 16 while that of Device B is 3, Device B synchronizes to Device C.

Display the NTP status of Device C after clock synchronization.

```
[DeviceC] display ntp-service status
Clock status: synchronized
Clock stratum: 4
Reference clock ID: 3.0.1.32
```

```

Nominal frequency: 100.0000 Hz
Actual frequency: 100.0000 Hz
Clock precision: 2^18
Clock offset: -21.1982 ms
Root delay: 15.00 ms
Root dispersion: 775.15 ms
Peer dispersion: 34.29 ms
Reference time: 15:22:47.083 UTC Sep 19 2005 (C6D95647.153F7CED)

```

The output shows that Device C has synchronized to Device B because it has a higher stratum than Device B.

Display the NTP session information of Device C.

```
[DeviceC] display ntp-service sessions
```

```

          source          reference      stra reach poll  now offset  delay disper
*****
[12345] 3.0.1.32          3.0.1.31          3    3    64    16   -6.4   4.8    1.0
note: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured
Total associations : 1

```

The output shows that an association has been set up between Device B and Device C.

Configuring NTP broadcast mode

Network requirements

- As shown in [Figure 13](#), configure Switch C as a reference source, with the stratum level 2.
- Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.
- Configure Switch A and Switch B to operate in broadcast client mode, and listen to broadcast messages through their VLAN-interface 2 respectively.

Figure 13 Network diagram

Configuration procedure

1. Set the IP address for each interface as shown in [Figure 13](#). (Details not shown.)
2. Configure Switch C:

Configure Switch C to operate in broadcast server mode and send broadcast messages through VLAN-interface 2.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ntp-service broadcast-server
```

3. Configure Switch A:

Configure Switch A to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ntp-service broadcast-client
```

4. Configure Switch B:

Configure Switch B to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ntp-service broadcast-client
```

Switch A and Switch B get synchronized upon receiving a broadcast message from Switch C.

Take Switch A as an example. Display the NTP status of Switch A after clock synchronization.

```
[SwitchA-Vlan-interface2] display ntp-service status
Clock status: synchronized
Clock stratum: 3
Reference clock ID: 3.0.1.31
Nominal frequency: 64.0000 Hz
Actual frequency: 64.0000 Hz
Clock precision: 2^7
Clock offset: 0.0000 ms
Root delay: 31.00 ms
Root dispersion: 8.31 ms
Peer dispersion: 34.30 ms
Reference time: 16:01:51.713 UTC Sep 19 2005 (C6D95F6F.B6872B02)
```

The output shows that Switch A has synchronized to Switch C because it has a higher stratum than Switch C.

Display the NTP session information of Switch A.

```
[SwitchA-Vlan-interface2] display ntp-service sessions
      source      reference      stra reach poll now offset delay disper
*****
[1234] 3.0.1.31 127.127.1.0 2 254 64 62 -16.0 32.0 16.6
note: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured
Total associations : 1
```

The output shows that an association has been set up between Switch A and Switch C.

Configuring NTP multicast mode

Network requirements

As shown in [Figure 14](#), configure Device C as a reference source, with the stratum level 2.

- Configure Device C to operate in multicast server mode and send multicast messages from VLAN-interface 2.
- Configure Device A and Device D to operate in multicast client mode and receive multicast messages through VLAN-interface 3 and VLAN-interface 2 respectively.

NOTE:

In this example, Switch B must be a Layer 3 switch that supports multicast routing.

Figure 14 Network diagram

Configuration procedure

1. Set the IP address for each interface as shown in Figure 14. (Details not shown.)
2. Configure Device C:

```
# Configure Device C to operate in multicast server mode and send multicast messages through VLAN-interface 2.
[DeviceC] interface vlan-interface 2
[DeviceC-Vlan-interface2] ntp-service multicast-server
```

3. Configure Device D:

```
# Configure Device D to operate in multicast client mode and receive multicast messages on VLAN-interface 2.
<DeviceD> system-view
[DeviceD] interface vlan-interface 2
[DeviceD-Vlan-interface2] ntp-service multicast-client
```

Because Device D and Device C are on the same subnet, Device D can receive the multicast messages from Device C without being enabled with the multicast functions and can synchronize to Device C.

Display the NTP status of Device D after clock synchronization.

```
[DeviceD-Vlan-interface2] display ntp-service status
Clock status: synchronized
Clock stratum: 3
Reference clock ID: 3.0.1.31
Nominal frequency: 64.0000 Hz
Actual frequency: 64.0000 Hz
Clock precision: 2^7
```

```

Clock offset: 0.0000 ms
Root delay: 31.00 ms
Root dispersion: 8.31 ms
Peer dispersion: 34.30 ms
Reference time: 16:01:51.713 UTC Sep 19 2005 (C6D95F6F.B6872B02)

```

The output shows that Device D has synchronized to Device C because it has a higher stratum than Device C.

Display the NTP session information of Device D.

```

[DeviceD-Vlan-interface2] display ntp-service sessions
      source      reference      stra reach poll now offset delay disper
*****
[1234] 3.0.1.31 127.127.1.0 2 254 64 62 -16.0 31.0 16.6
note: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured
Total associations : 1

```

The output shows that an association has been set up between Device D and Device C.

4. Configure Device B:

Because Device A and Device C are on different subnets, you must enable the multicast functions on Device B before Device A can receive multicast messages from Device C.

Enable IP multicast routing and IGMP. For more information about how to configure IGMP and PIM, see *IP Multicast Configuration Guide*.

```

<DeviceB> system-view
[DeviceB] multicast routing-enable
[DeviceB] interface vlan-interface 2
[DeviceB-Vlan-interface2] pim dm
[DeviceB-Vlan-interface2] quit
[DeviceB] vlan 3
[DeviceB-vlan3] port gigabitethernet 1/0/1
[DeviceB-vlan3] quit
[DeviceB] interface vlan-interface 3
[DeviceB-Vlan-interface3] igmp enable
[DeviceB-Vlan-interface3] igmp static-group 224.0.1.1
[DeviceB-Vlan-interface3] quit
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] igmp-snooping static-group 224.0.1.1 vlan 3

```

5. Configure Device A:

```

<DeviceA> system-view
[DeviceA] interface vlan-interface 3
# Configure Device A to operate in multicast client mode and receive multicast messages on
VLAN-interface 3.

```

```

[DeviceA-Vlan-interface3] ntp-service multicast-client

```

Display the NTP status of Device A after clock synchronization.

```

[DeviceA-Vlan-interface3] display ntp-service status
Clock status: synchronized
Clock stratum: 3
Reference clock ID: 3.0.1.31
Nominal frequency: 64.0000 Hz
Actual frequency: 64.0000 Hz

```

```

Clock precision: 2^7
Clock offset: 0.0000 ms
Root delay: 40.00 ms
Root dispersion: 10.83 ms
Peer dispersion: 34.30 ms
Reference time: 16:02:49.713 UTC Sep 19 2005 (C6D95F6F.B6872B02)

```

The output shows that Device A has synchronized to Device C because it has a higher stratum than Device C.

Display the NTP session information of Device A.

```

[DeviceA-Vlan-interface3] display ntp-service sessions
      source      reference      stra reach poll now offset delay disper
*****
[1234] 3.0.1.31 127.127.1.0 2 255 64 26 -16.0 40.0 16.6
note: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured
Total associations : 1

```

The output shows that an association has been set up between Device A and Device C.

Configuring NTP client/server mode with authentication

Network requirements

- As shown in [Figure 15](#), configure Device A as a reference source, with the stratum level 2.
- Configure Device B to operate in client mode and use Device A as its NTP server.
- Enable NTP authentication on both Device A and Device B.

Figure 15 Network diagram

Configuration procedure

1. Set the IP address for each interface as shown in [Figure 15](#). (Details not shown.)

2. Configure Device B:

```

<DeviceB> system-view
# Enable NTP authentication on Device B.
[DeviceB] ntp-service authentication enable
# Set an authentication key.
[DeviceB] ntp-service authentication-keyid 42 authentication-mode md5 aNiceKey
# Specify the key as a trusted key.
[DeviceB] ntp-service reliable authentication-keyid 42
# Specify Device A as the NTP server of Device B.
[DeviceB] ntp-service unicast-server 1.0.1.11 authentication-keyid 42

```

Before Device B can synchronize to Device A, enable NTP authentication for Device A.

3. Configure Device A:

```

# Enable NTP authentication.
[DeviceA] ntp-service authentication enable

```

```

# Set an authentication key.
[DeviceA] ntp-service authentication-keyid 42 authentication-mode md5 aNiceKey
# Specify the key as a trusted key.
[DeviceA] ntp-service reliable authentication-keyid 42
# Display the NTP status of Device B after clock synchronization.
[DeviceB] display ntp-service status
Clock status: synchronized
Clock stratum: 3
Reference clock ID: 1.0.1.11
Nominal frequency: 64.0000 Hz
Actual frequency: 64.0000 Hz
Clock precision: 2^7
Clock offset: 0.0000 ms
Root delay: 31.00 ms
Root dispersion: 1.05 ms
Peer dispersion: 7.81 ms
Reference time: 14:53:27.371 UTC Sep 19 2005 (C6D94F67.5EF9DB22)

```

The output shows that Device B has synchronized to Device A because it has a higher stratum than Device A.

```

# Display the NTP session information of Device B.
[DeviceB] display ntp-service sessions
      source      reference  stra reach poll now offset delay disper
*****
[12345] 1.0.1.11 127.127.1.0   2   63   64   3   -75.5  31.0 16.5
note: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured
Total associations : 1

```

The output shows that an association has been set up Device B and Device A.

Configuring NTP broadcast mode with authentication

Network requirements

- As shown in [Figure 16](#), configure Device C as a reference source, with the stratum level 3.
- Configure Device C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.
- Configure Device A and Device B to operate in broadcast client mode and receive broadcast messages through VLAN-interface 2.
- Enable NTP authentication on both Device B and Device C.

Figure 16 Network diagram

Configuration procedure

1. Set the IP address for each interface as shown in Figure 16. (Details not shown.)
2. Configure Device A:
Configure the Device A to operate in NTP broadcast client mode and receive NTP broadcast messages on VLAN-interface 2.

```
<DeviceA> system-view
[DeviceA] interface vlan-interface 2
[DeviceA-Vlan-interface2] ntp-service broadcast-client
```
3. Configure Device B:
Enable NTP authentication on Device B. Configure an NTP authentication key, with the key ID 88 and key value 123456, and specify the key as a trusted key.

```
<DeviceB> system-view
[DeviceB] ntp-service authentication enable
[DeviceB] ntp-service authentication-keyid 88 authentication-mode md5 123456
[DeviceB] ntp-service reliable authentication-keyid 88
```

Configure Device B to operate in broadcast client mode and receive NTP broadcast messages on VLAN-interface 2.

```
[DeviceB] interface vlan-interface 2
[DeviceB-Vlan-interface2] ntp-service broadcast-client
```
4. Configure Device C:
Configure Device C to operate in NTP broadcast server mode and use VLAN-interface 2 to send NTP broadcast packets.

```
[DeviceC] interface vlan-interface 2
[DeviceC-Vlan-interface2] ntp-service broadcast-server
[DeviceC-Vlan-interface2] quit
```

Display the NTP service status information on Device A.

```
[DeviceA-Vlan-interface2] display ntp-service status
Clock status: synchronized
Clock stratum: 4
Reference clock ID: 3.0.1.31
Nominal frequency: 64.0000 Hz
```

```

Actual frequency: 64.0000 Hz
Clock precision: 2^7
Clock offset: 0.0000 ms
Root delay: 31.00 ms
Root dispersion: 8.31 ms
Peer dispersion: 34.30 ms
Reference time: 16:01:51.713 UTC Sep 19 2005 (C6D95F6F.B6872B02)

```

The output shows that Device A has synchronized to Device C because it has a higher stratum than Device C.

Display the NTP session information of Device A.

```

[DeviceA-Vlan-interface2] display ntp-service sessions
      source      reference      stra reach poll now offset delay disper
*****
[1234] 3.0.1.31 127.127.1.0 3 254 64 62 -16.0 32.0 16.6
note: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured
Total associations : 1

```

The output shows that an association has been set up Device A and Device C.

.Display the NTP service status information on Device B.

```

[DeviceB-Vlan-interface2] display ntp-service status
Clock status: unsynchronized
Clock stratum: 16
Reference clock ID: none
Nominal frequency: 100.0000 Hz
Actual frequency: 100.0000 Hz
Clock precision: 2^18
Clock offset: 0.0000 ms
Root delay: 0.00 ms
Root dispersion: 0.00 ms
Peer dispersion: 0.00 ms
Reference time: 00:00:00.000 UTC Jan 1 1900(00000000.00000000)

```

The output shows that NTP authentication is enabled on Device B, but not enabled on Device C. Therefore, Device B cannot synchronize to Device C.

Enable NTP authentication Device C. Configure an NTP authentication key, with the key ID 88 and key value 123456, and specify the key as a trusted key.

```

[DeviceC] ntp-service authentication enable
[DeviceC] ntp-service authentication-keyid 88 authentication-mode md5 123456
[DeviceC] ntp-service reliable authentication-keyid 88

```

Specify Device C as an NTP broadcast server, and associate the key 88 with Device C.

```

[DeviceC] interface vlan-interface 2
[DeviceC-Vlan-interface2] ntp-service broadcast-server authentication-keyid 88

```

Display the NTP service status information on Device B.

```

[DeviceB-Vlan-interface2] display ntp-service status
Clock status: synchronized
Clock stratum: 4
Reference clock ID: 3.0.1.31
Nominal frequency: 64.0000 Hz
Actual frequency: 64.0000 Hz

```

```
Clock precision: 2^7
Clock offset: 0.0000 ms
Root delay: 31.00 ms
Root dispersion: 8.31 ms
Peer dispersion: 34.30 ms
Reference time: 16:01:51.713 UTC Sep 19 2005 (C6D95F6F.B6872B02)
```

The output shows that Device B has synchronized to Device C because it has a higher stratum than Device C.

Display the NTP session information of Device B.

```
[DeviceB-Vlan-interface2] display ntp-service sessions
      source      reference      stra reach poll now offset delay disper
*****
[1234] 3.0.1.31 127.127.1.0 3 254 64 62 -16.0 32.0 16.6
note: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured
Total associations : 1
```

The output shows that an association has been set up between Device B and Device C.

Display the NTP service status information on Device A.

```
[DeviceA-Vlan-interface2] display ntp-service status
Clock status: synchronized
Clock stratum: 4
Reference clock ID: 3.0.1.31
Nominal frequency: 64.0000 Hz
Actual frequency: 64.0000 Hz
Clock precision: 2^7
Clock offset: 0.0000 ms
Root delay: 31.00 ms
Root dispersion: 8.31 ms
Peer dispersion: 34.30 ms
Reference time: 16:01:51.713 UTC Sep 19 2005 (C6D95F6F.B6872B02)
```

The output shows that configuring NTP authentication on Device C does not affect Device A and Device A still synchronizes to Device C.

Configuring the information center

This chapter describes how to configure the information center.

Overview

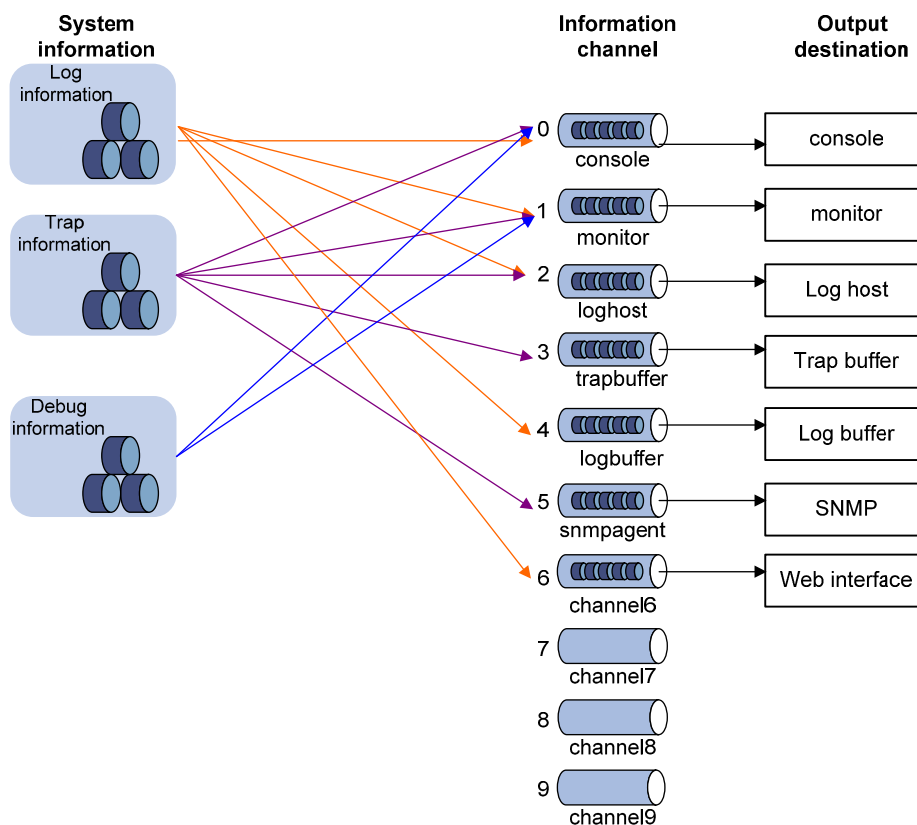

The information center classifies and manages system information so that network administrators and developers can monitor network performance and troubleshoot network problems.

The information center operates as follows:

- Receives system information including log, trap, and debugging information generated by each module.
- Outputs the information to different information channels, according to output rules.
- Outputs information to different destinations, based on information channel-to-destination associations.

Information center assigns log, trap, and debugging information to 10 information channels according to eight severity levels and then outputs the information to different destinations. The following describes the working process in detail.

Figure 17 Information center diagram (default)

By default, the information center is enabled. It affects system performance to some degree when it is processing large amounts of information. If the system resources are insufficient, disable the information center to save resources.

Classification of system information

The system information falls into the following types:

- Log information
- Trap information
- Debugging information

System information levels

The system information is classified into eight severity levels, from 0 through 7 in descending order. The device outputs the system information with a severity level that is higher than or equal to the specified level. For example, if you configure an output rule with a severity level of 6 (informational), information that has a severity level from 0 to 6 is output.

Table 1 Severity description

| Severity | Severity value | Description | Corresponding keyword in commands |
|---------------|----------------|-----------------------------------|-----------------------------------|
| Emergency | 0 | The system is unavailable. | emergencies |
| Alert | 1 | Action must be taken immediately. | alerts |
| Critical | 2 | Critical condition. | critical |
| Error | 3 | Error condition. | errors |
| Warning | 4 | Warning condition. | warnings |
| Notice | 5 | Normal but significant condition. | notifications |
| Informational | 6 | Informational messages. | informational |
| Debug | 7 | Debug messages. | debugging |

System information channels and output destinations

Table 2 shows the information channels and output destinations.

The system supports ten channels. By default, channels 0 through 6 are configured with channel names and output destinations, and they are associated with output destinations. You can change these default settings as needed. You can also configure channels 7, 8 and 9 associate them with specific output destinations to meet your needs.

Table 2 Information channels and output destinations

| Information channel number | Default channel name | Default output destination | Description |
|----------------------------|----------------------|----------------------------|---|
| 0 | console | Console | Receives log, trap and debugging information. |

| Information channel number | Default channel name | Default output destination | Description |
|----------------------------|----------------------|----------------------------|--|
| 1 | monitor | Monitor terminal | Receives log, trap and debugging information, facilitating remote maintenance. |
| 2 | loghost | Log host | Receives log, trap and debugging information and information will be stored in files for future retrieval. |
| 3 | trapbuffer | Trap buffer | Receives trap information, a buffer inside the device for recording information. |
| 4 | logbuffer | Log buffer | Receives log and debugging information, a buffer inside the device for recording information. |
| 5 | snmpagent | SNMP module | Receives trap information. |
| 6 | channel6 | Web interface | Receives log information. |
| 7 | channel7 | Not specified | Receives log, trap, and debugging information. |
| 8 | channel8 | Not specified | Receives log, trap, and debugging information. |
| 9 | channel9 | Not specified | Receives log, trap, and debugging information. |

Outputting system information by source module

The system is composed of a variety of protocol modules, and configuration modules. The system information is classified, filtered, and output according to source modules. You can use the **info-center source ?** command to view the supported information source modules.

Default output rules of system information

A default output rule specifies the system information source modules, information type, and severity levels for an output destination. [Table 3](#) shows the default output rules.

The following applies to all modules by default:

- All log information is allowed to be output to the Web interface. Log information that has a severity level of at least informational is allowed to be output to the log host. Log information that has a severity level of at least informational is allowed to be output to the console, monitor terminal, and log buffer. Log information is not allowed to be output to the trap buffer or the SNMP module.
- All trap information is allowed to be output to the console, monitor terminal, log host, Web interface. Trap information that has a severity level of at least informational is allowed to be output to the trap buffer and SNMP module. Trap information is not allowed to be output to the log buffer.
- All debugging information is allowed to be output to the console and monitor terminal. Debugging information is not allowed to be output to the log host, trap buffer, log buffer, the SNMP module, Web interface.

Table 3 Default output rules for different output destinations

| Output destination | Modules allowed | LOG | | TRAP | | DEBUG | |
|--------------------|-----------------------|------------------|---------------|------------------|---------------|------------------|----------|
| | | Enabled/disabled | Severity | Enabled/disabled | Severity | Enabled/disabled | Severity |
| Console | default (all modules) | Enabled | Informational | Enabled | Debug | Enabled | Debug |
| Monitor terminal | default (all modules) | Enabled | Informational | Enabled | Debug | Enabled | Debug |
| Log host | default (all modules) | Enabled | Informational | Enabled | Debug | Disabled | Debug |
| Trap buffer | default (all modules) | Disabled | Informational | Enabled | Informational | Disabled | Debug |
| Log buffer | default (all modules) | Enabled | Informational | Disabled | Debug | Disabled | Debug |
| SNMP module | default (all modules) | Disabled | Debug | Enabled | Informational | Disabled | Debug |
| Web interface | default (all modules) | Enabled | Debug | Enabled | Debug | Disabled | Debug |

System information format

The following shows the original format of system information, which might be different from what you see. The actual format depends on the log resolution tool you use.

Formats

The system information format depends on the output destinations, as shown in [Table 4](#).

Table 4 System information formats

| Output destination | Format | Example |
|---|---|--|
| Console, monitor terminal, logbuffer, trapbuffer, SNMP module | timestamp sysname
module/level/digest: content | %Jun 26 17:08:35:809 2011 Sysname
SHELL/4/LOGIN: VTY login from 1.1.1.1 |

| Output destination | Format | Example |
|--------------------|---|--|
| Log host | <ul style="list-style-type: none"> HP format:
<PRI>timestamp
Sysname %%vmodule/level
/digest: source content UNICOM format:
<PRI>timestamp Sysname
vmodule/level/serial_number: content | <ul style="list-style-type: none"> HP format:
<189>Oct 9 14:59:04 201
MyDevice %%10SHELL/5/SHELL_LOGIN():
VTY logged in from 192.168.1.21 UNICOM format: <ul style="list-style-type: none"> <186>Oct 13 16:48:08 2011 HP
10IFNET/2/210231a64jx073000020:
log_type=port;content=Vlan-interface 1
link status is DOWN. <186>Oct 13 16:48:08 2011 HP
10IFNET/2/210231a64jx073000020:
log_type=port;content=Line protocol on
the interface Vlan-interface1 is DOWN. |

NOTE:

The closing set of angle brackets (< >), the space, the forward slash (/), and the colon (:) are all required in the above format.

Following is a detailed explanation of the fields involved in system information:

PRI (priority)

The priority is calculated using the formula: $facility * 8 + level$, where:

- facility** is the facility name, ranging from local0 to local7 (16 to 23 in decimal integers) and defaults to local7. It can be configured with **info-center loghost**. It is used to identify different log sources on the log host, and to query and filter logs from specific log sources.
- level** ranges from 0 to 7. See [Table 1](#) for more information.

Note that the priority field is available only for information that is sent to the log host.

timestamp

Timestamp records the time when the system information was generated. The time stamp of the system information sent to the log host has a precision of seconds, and that to all the other destinations has a precision of milliseconds. The time stamp format of the system information sent to the log host is configured with the **info-center timestamp loghost** command, and that of the system information sent to the other destinations is configured with the **info-center timestamp** command.

Table 5 Description on the time stamp parameters

| Time stamp parameter | Description | Example |
|----------------------|---|--|
| boot | Time since system startup, in the format of xxxxxx.yyyyyy, where xxxxxx represents the higher 32 bits, and yyyyyy represents the lower 32 bits.
System information that is sent to all destinations except the log host supports this parameter. | %0.109391473 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.
0.109391473 is a time stamp in the boot format. |
| date | Current date and time of the system, in the format of Mmm dd hh:mm:ss:sss yyyy.
All system information supports this parameter. | %May 30 05:36:29:579 2011 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.
May 30 05:36:29:579 2011 is a time stamp in the date format. |
| iso | Time stamp format stipulated in ISO 8601
All system information supports this parameter. | <189>2011-05-30T06:42:44
Sysname %%10FTPD/5/FTPD_LOGIN(): User ftp (192.168.1.23) has logged in successfully.
2011-05-30T06:42:44 is a time stamp in the iso format. |
| none | No time stamp is included.
All system information supports this parameter. | % Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.
No time stamp is included. |
| no-year-date | Current date and time of the system, with year information excluded.
Only the system information that is sent to the log host supports this parameter. | <189>May 30 06:44:22
Sysname %%10FTPD/5/FTPD_LOGIN(): User ftp (192.168.1.23) has logged in successfully.
May 30 06:44:22 is a time stamp in the no-year-date format. |

Sysname (host name or host IP address)

- If the system information that is sent to a log host is in the UNICOM format, and the **info-center loghost source** command is configured, or **vpn-instance vpn-instance-name** is provided in the **info-center loghost** command, the field is displayed as the IP address of the device that generates the system information.
- If the system information is sent to other destinations, or is sent to a log host in the HP format, the field is displayed as the system name of the device that generates the system information. You can use the **sysname** command to modify the system name. For more information, see *Fundamentals Command Reference*.

%% (vendor ID)

This field indicates that the information is generated by an HP device. It is displayed only when the system information is sent to a log host in the format of HP.

vv

This field is a version identifier of syslog, with a value of 10. It is displayed only when the output destination is log host.

module

The module field represents the name of the module that generates system information. You can enter the **info-center source ?** command in system view to view the module list.

level (severity)

System information is divided into eight levels based on its severity, from 0 to 7. See [Table 1](#) for definitions and descriptions of these severity levels. The levels of system information generated by modules are predefined by developers, and you cannot change the system information levels. However, with the **info-center source** command, you can configure to output information of the specified level and not to output information lower than the specified level.

digest

The digest field is a string of up to 32 characters, outlining the system information.

For system information destined to the log host:

- If the character string ends with (l), the information is log information.
- If the character string ends with (t), the information is trap information.
- If the character string ends with (d), the information is debugging information.

For system information destined to other destinations:

- If the time stamp starts with a percent sign (%), the information is log information.
- If the time stamp starts with a pound sign (#), the information is trap information.
- If the time stamp starts with an asterisk (*), the information is debugging information.

serial number

This field indicates the serial number of the device that generates the system information. It is displayed only when the system information is sent to a log host in the UNICOM format.

source

This field indicates the source of the information. It is optional and is displayed only when the system information is sent to a log host in the HP format. This field takes one of the following values:

- IRF member ID
- IP address of the log sender

content

This field provides the content of the system information.

Information center configuration task list

| Task | Remarks |
|---|----------|
| Outputting system information to the console | Optional |
| Outputting system information to the monitor terminal | Optional |
| Outputting system information to a log host | Optional |

| Task | Remarks |
|---|----------|
| Outputting system information to the trap buffer | Optional |
| Outputting system information to the log buffer | Optional |
| Outputting system information to the SNMP module | Optional |
| Outputting system information to the Web interface | Optional |
| Saving security logs into the security log file | Optional |
| Configuring synchronous information output | Optional |
| Disabling an interface from generating link up/down logging information | Optional |

Outputting system information to the console

This section describes how to output system information to the console.

Configuring a system information output rule for the console

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable information center. | info-center enable | Optional.
Enabled by default. |
| 3. Name the channel with a specified channel number. | info-center channel <i>channel-number</i>
name <i>channel-name</i> | Optional.
See Table 2 for default channel names. |
| 4. Configure the channel through which system information can be output to the console. | info-center console channel
{ <i>channel-number</i> <i>channel-name</i> } | Optional.
By default, system information is output to the console through channel 0 (known as console). |
| 5. Configure an output rule for the console. | info-center source { <i>module-name</i> default } channel { <i>channel-number</i> <i>channel-name</i> } [debug { level <i>severity</i> state <i>state</i> } * log { level <i>severity</i> state <i>state</i> } * trap { level <i>severity</i> state <i>state</i> } *] * | Optional.
See " Default output rules of system information. " |
| 6. Configure the timestamp format. | info-center timestamp { debugging log trap } { boot date none } | Optional.
By default, the timestamp format for log, trap and debugging information is date . |

Enabling system information output to the console

To enable the display of system information on the console in user view:

| Step | Command | Remarks |
|---|---|--|
| 1. Enable system information output to the console. | terminal monitor | Optional.
The default setting is enabled. |
| 2. Enable the display of system information on the console. | <ul style="list-style-type: none"> Enable the display of debugging information on the console:
terminal debugging Enable the display of log information on the console:
terminal logging Enable the display of trap information on the console:
terminal trapping | Optional.
By default, the console only displays log and trap information. |

Outputting system information to the monitor terminal

Monitor terminals refer to terminals that log in to the switch through the VTY user interface.

Configuring a system information output rule for the monitor terminal

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enable information center. | info-center enable | Optional.
Enabled by default. |
| 3. Name the channel with a specified channel number. | info-center channel name <i>channel-number</i> <i>channel-name</i> | Optional.
See Table 2 for default channel names. |
| 4. Configure the channel through which system information can be output to a monitor terminal. | info-center monitor channel { <i>channel-number</i> <i>channel-name</i> } | Optional.
By default, system information is output to the monitor terminal through channel 1 (known as monitor). |
| 5. Configure a system information output rule for the monitor terminal. | info-center source { <i>module-name</i> default } channel { <i>channel-number</i> <i>channel-name</i> } [debug { level <i>severity</i> state <i>state</i> } * log { level <i>severity</i> state <i>state</i> } * trap { level <i>severity</i> state <i>state</i> } *] * | Optional.
See " Default output rules of system information. " |
| 6. Configure the timestamp format. | info-center timestamp { debugging log trap } { boot date none } | Optional.
By default, the time stamp format for log, trap and debugging information is date . |

Enabling system information output to the monitor terminal

| Step | Command | Remarks |
|---|--|--|
| 1. Enable the monitoring of system information on a monitor terminal. | terminal monitor | Enabled on the console and disabled on the monitor terminal by default. |
| 2. Enable the display of system information on the monitor terminal. | <ul style="list-style-type: none"> Enable the display of debugging information on a monitor terminal:
terminal debugging Enable the display of log information on a monitor terminal:
terminal logging Enable the display of trap information on a monitor terminal:
terminal trapping | <p>Optional.</p> <p>By default, the monitor terminal displays only the log and trap information.</p> |

Outputting system information to a log host

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enable information center. | info-center enable | Optional.
Enabled by default. |
| 3. Name the channel with a specified channel number. | info-center channel <i>channel-number</i>
name <i>channel-name</i> | Optional.
See Table 2 for default channel names. |
| 4. Configure a system information output rule for the log host. | info-center source { <i>module-name</i> default } channel { <i>channel-number</i> <i>channel-name</i> } [debug { level <i>severity</i> state <i>state</i> } * log { level <i>severity</i> state <i>state</i> } * trap { level <i>severity</i> state <i>state</i> } *] * | Optional.
See " Default output rules of system information. " |
| 5. Specify the source IP address for the log information. | info-center loghost source
<i>interface-type interface-number</i> | Optional.
By default, the source interface is determined by the matched route, and the primary IP address of this interface is the source IP address of the log information. |
| 6. Configure the format of the time stamp for system information output to the log host. | info-center timestamp loghost { date iso no-year-date none } | Optional.
date by default. |
| 7. Set the format of the system information sent to a log host to UNICOM. | info-center format unicom | Optional.
HP by default. |

| Step | Command | Remarks |
|--|---|---|
| 8. Specify a log host and configure the related output parameters. | info-center loghost [vpn-instance <i>vpn-instance-name</i>]
{ <i>host-ipv4-address</i> ipv6 <i>host-ipv6-address</i> } [port <i>port-number</i>] [dscp <i>dscp-value</i>]
[channel { <i>channel-number</i> <i>channel-name</i> }] facility <i>local-number</i>] * | By default, the system does not output information to a log host. If you specify to output system information to a log host, the system uses channel 2 (loghost) by default.

The value of the <i>port-number</i> argument should be the same as the value configured on the log host, otherwise, the log host cannot receive system information.

The vpn-instance keyword is available only on the HP 5500 EI switch series. |

Outputting system information to the trap buffer

The trap buffer only receives trap information, and discards log and debug information.

To output system information to the trap buffer:

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable information center. | info-center enable | Optional.
Enabled by default. |
| 3. Name the channel with a specified channel number. | info-center channel <i>channel-number</i>
name <i>channel-name</i> | Optional.
See Table 2 for default channel names. |
| 4. Configure the channel through which system information can be output to the trap buffer and specify the buffer size. | info-center trapbuffer [channel { <i>channel-number</i> <i>channel-name</i> }] size <i>buffersize</i>] * | Optional.
By default, system information is output to the trap buffer through channel 3 (known as trapbuffer) and the default buffer size is 256. |
| 5. Configure a system information output rule for the trap buffer. | info-center source { <i>module-name</i> default } channel { <i>channel-number</i> <i>channel-name</i> } [debug { level <i>severity</i> state <i>state</i> } *] log { level <i>severity</i> state <i>state</i> } * trap { level <i>severity</i> state <i>state</i> } *] * | Optional.
See " Default output rules of system information. " |
| 6. Configure the timestamp format. | info-center timestamp { debugging log trap } { boot date none } | Optional.
The time stamp format for log, trap and debugging information is date by default. |

Outputting system information to the log buffer

The log buffer only receives log information, and discards trap and debug information.

To output system information to the log buffer:

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable information center. | info-center enable | Optional.
Enabled by default. |
| 3. Name the channel with a specified channel number. | info-center channel <i>channel-number</i>
name <i>channel-name</i> | Optional.
See Table 2 for default channel names. |
| 4. Configure the channel through which system information can be output to the log buffer and specify the buffer size. | info-center logbuffer [channel { <i>channel-number</i> <i>channel-name</i> } size <i>buffersize</i>] * | Optional.
By default, system information is output to the log buffer through channel 4 (known as logbuffer) and the default buffer size is 512. |
| 5. Configure a system formation output rule for the log buffer. | info-center source { <i>module-name</i> default } channel { <i>channel-number</i> <i>channel-name</i> } [debug { level <i>severity</i> state <i>state</i> } * log { level <i>severity</i> state <i>state</i> } * trap { level <i>severity</i> state <i>state</i> } *] * | Optional.
See " Default output rules of system information. " |
| 6. Configure the timestamp format. | info-center timestamp { debugging log trap } { boot date none } | Optional.
The time stamp format for log, trap and debugging information is date by default. |

Outputting system information to the SNMP module

The SNMP module only receives trap information, and discards log and debug information.

To monitor the device running status, trap information is usually sent to the SNMP network management system (NMS). For this purpose, you must configure output of traps to the SNMP module, and set the trap sending parameters for the SNMP module. For more information about SNMP, see "[Configuring SNMP.](#)"

To output system information to the SNMP module:

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable information center. | info-center enable | Optional.
Enabled by default. |
| 3. Name the channel with a specified channel number. | info-center channel <i>channel-number</i>
name <i>channel-name</i> | Optional.
See Table 2 for default channel names. |
| 4. Configure the channel through which system information can be output to the SNMP module. | info-center snmp channel { <i>channel-number</i> <i>channel-name</i> } | Optional.
By default, system information is output to the SNMP module through channel 5 (known as snmpagent). |

| Step | Command | Remarks |
|--|---|---|
| 5. Configure a system formation output rule for the SNMP module. | info-center source { <i>module-name</i> default } channel { <i>channel-number</i> <i>channel-name</i> } [debug { level <i>severity</i> state <i>state</i> } * log { level <i>severity</i> state <i>state</i> } * trap { level <i>severity</i> state <i>state</i> } *] * | Optional.
See "Default output rules of system information." |
| 6. Configure the timestamp format. | info-center timestamp { debugging log trap } { boot date none } | Optional.
The time stamp format for log, trap and debugging information is date by default. |

Outputting system information to the Web interface

The Web interface only receives log information, and discards trap and debug information.

This feature allows you to control whether to output system information to the Web interface and, if so, which system information can be output to the Web interface. The Web interface provides search and sorting functions. You can view system information by clicking corresponding tabs after logging in to the device through the Web interface.

To output system information to the Web interface:

| Step | Command | Remarks |
|---|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enable information center. | info-center enable | Optional.
Enabled by default. |
| 3. Name the channel with a specified channel number. | info-center channel <i>channel-number</i>
name <i>channel-name</i> | Optional.
See Table 2 for default channel names. |
| 4. Configure the channel through which system information can be output to the Web interface. | info-center syslog channel
{ <i>channel-number</i> <i>channel-name</i> } | Optional.
By default, system information is output to the Web interface through channel 6. |
| 5. Configure a system formation output rule for the Web interface. | info-center source { <i>module-name</i> default } channel { <i>channel-number</i> <i>channel-name</i> } [debug { level <i>severity</i> state <i>state</i> } * log { level <i>severity</i> state <i>state</i> } * trap { level <i>severity</i> state <i>state</i> } *] * | Optional.
See "Default output rules of system information." |
| 6. Configure the format of the time stamp. | info-center timestamp { debugging log trap } { boot date none } | Optional.
The time stamp format for log, trap and debugging information is date by default. |

Saving security logs into the security log file

Security logs are very important for locating and troubleshooting network problems. Generally, security logs are output together with other logs. It is difficult to identify security logs among all logs.

To solve this problem, you can save security logs into a security log file without affecting the current log output rules.

The configuration of this feature and the management of the security log file are separate, and the security log file is managed by a privileged user. After logging in to the device, the administrator can enable the saving security logs into the security log file and configure related parameters. However, only the privileged user, known as the security log administrator, can perform operations on the security log file. The privileged user must pass AAA local authentication and log in to the device. No other users (including the system administrator) can perform operations on the security log file.

A security log administrator is a local user who is authorized by AAA to play the security log administrator role. You can authorize a security log administrator by executing the **authorization-attribute user-role security-audit** command in local user view.

The system administrator cannot view, copy, and rename the security log file. If they try, the system displays an "% Execution error" message. The system administrator can view, copy and rename other types of files.

For more information about local user and AAA local authentication, see *Security Configuration Guide*.

Saving security logs into the security log file

If this feature is enabled, the system first outputs security logs to the security log file buffer, and then saves the logs in the security log file buffer into the security log file at a specified interval (the security log administrator can also manually save security logs into the log file). After the logs are saved, the buffer is cleared immediately.

The size of the security log file is limited. When the maximum size is reached, the system deletes the oldest log and writes the new log into the security log file. To avoid security log loss, you can set an alarm threshold for the security log file usage. When the alarm threshold is reached, the system outputs a message to inform the administrator. The administrator can log in to the device as the security log administrator and back up the security log file to prevent the loss of important data.

By default, security logs are not saved into the security log file. The parameters, such as the saving interval, the maximum size, and the alarm threshold, have default settings. To modify these parameters, log in to the device as the system administrator, and then follow the steps in the following table to configure the related parameters:

To save security logs into the security log file:

| Step | Command | Remarks |
|---|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable the information center. | info-center enable | Optional.
Enabled by default. |
| 3. Enable the saving of the security logs into the security log file. | info-center security-logfile enable | Disabled by default. |
| 4. Set the frequency with which the system saves the security log file. | info-center security-logfile frequency freq-sec | Optional.
The default value is 600 seconds. |

| Step | Command | Remarks |
|--|--|--|
| 5. Set the maximum storage space reserved for the security log file. | info-center security-logfile size-quota <i>size</i> | Optional.
The default value is 1 MB. |
| 6. Set the alarm threshold of the security log file usage. | info-center security-logfile alarm-threshold <i>usage</i> | Optional.
80 by default. (That is, when the usage of the security log file reaches 80%, the system will inform the user.) |

Managing the security log file

After passing the AAA local authentication, the security log administrator can perform the following operations:

| Task | Command | Remarks |
|---|--|--|
| Display a summary of the security log file. | display security-logfile summary [{ begin exclude include } <i>regular-expression</i>] | Optional. |
| Change the directory where the security log file is saved. | info-center security-logfile switch-directory <i>dir-name</i> | Optional.
By default, the directory to save the security log file is the seclog directory in the root directory of the storage medium.
Available in user view. |
| Display contents of the security log file buffer. | display security-logfile buffer [{ begin exclude include } <i>regular-expression</i>] | Optional. |
| Save all the contents in the security log file buffer into the security log file. | security-logfile save | Optional.
By default, the system automatically saves the security log file at a frequency configured by the info-center security-logfile frequency command into a directory configured by the info-center security-logfile switch-directory command.
Available in user view. |

| Task | Command | Remarks |
|---|---|--|
| Perform these operations on the security log file. | <ul style="list-style-type: none"> • Display the contents of the specified file:
more <i>file-url</i> • Display information about all files and folders:
dir [/all] [<i>file-url</i>] • Create a folder under a specified directory on the storage medium:
mkdir <i>directory</i> • Change the current working directory:
cd { <i>directory</i> .. / } • Display the current path:
pwd • Move a specified file from a storage medium to the recycle bin:
delete [/unreserved] <i>file-url</i> • Remove a folder:
rmdir <i>directory</i> • Format a storage medium:
format <i>device</i> • Restore a file from the Recycle Bin:
undelete <i>file-url</i> | <p>Optional.</p> <p>Available in user view</p> <p>For more information about these commands, see <i>Fundamentals Command Reference</i>.</p> |
| Uploading the security log file to the SFTP server. | <ul style="list-style-type: none"> • Establish an SFTP connection in an IPv4 network:
sftp <i>server</i> [<i>port-number</i>] [vpn-instance <i>vpn-instance-name</i>] [identity-key { <i>dsa</i> <i>rsa</i> } prefer-ctos-cipher { <i>3des</i> <i>aes 128</i> <i>des</i> } prefer-ctos-hmac { <i>md5</i> <i>md5-96</i> <i>sha1</i> <i>sha1-96</i> } prefer-kex { <i>dh-group-exchange</i> <i>dh-group1</i> <i>dh-group14</i> } prefer-stoc-cipher { <i>3des</i> <i>aes 128</i> <i>des</i> } prefer-stoc-hmac { <i>md5</i> <i>md5-96</i> <i>sha1</i> <i>sha1-96</i> }] * • Establish an SFTP connection in an IPv6 network:
sftp <i>server</i> [<i>port-number</i>] [vpn-instance <i>vpn-instance-name</i>] [identity-key { <i>dsa</i> <i>rsa</i> } prefer-ctos-cipher { <i>3des</i> <i>aes 128</i> <i>des</i> } prefer-ctos-hmac { <i>md5</i> <i>md5-96</i> <i>sha1</i> <i>sha1-96</i> } prefer-kex { <i>dh-group-exchange</i> <i>dh-group1</i> <i>dh-group14</i> } prefer-stoc-cipher { <i>3des</i> <i>aes 128</i> <i>des</i> } prefer-stoc-hmac { <i>md5</i> <i>md5-96</i> <i>sha1</i> <i>sha1-96</i> }] * • Upload a file on the client to the remote SFTP server:
put <i>localfile</i> [<i>remotefile</i>] • Download a file from a remote SFTP server and save it:
get <i>remotefile</i> [<i>localfile</i>] • For all other operations supported by the device acting as an SFTP client, see <i>Security Configuration Guide</i>. | <p>Optional.</p> <p>The sftp commands are available in user view; the other commands are available in SFTP client view.</p> <p>For more information about these commands, see <i>Security Command Reference</i>.</p> <p>The vpn-instance keyword is available only on the HP 5500 EI switch.</p> |

Configuring synchronous information output

The output of system logs interrupts ongoing configuration operations, and you have to find the previously input commands before the logs. Synchronous information output can show the previous input after log output and a command prompt in command editing mode, or a [Y/N] string in interaction mode so you can continue your operation from where you were stopped.

To enable synchronous information output:

| Step | Command | Remarks |
|---|--------------------------------|---------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Enable synchronous information output. | info-center synchronous | Disabled by default |

If system information, such as log information, is output before you input any information under the current command line prompt, the system does not display the command line prompt.

If system information is output when you are inputting some interactive information (non Y/N confirmation information), the system displays your previous input in a new line but does not display the command line prompt.

Disabling an interface from generating link up/down logging information

By default, all interfaces generate link up or link down log information when the state changes. In some cases, you might want to disable specific interfaces from generating this information. For example:

- You are concerned only about the states of some interfaces. In this case, you can use this function to disable other interfaces from generating link up and link down log information.
- An interface is unstable and continuously outputs log information. In this case, you can disable the interface from generating link up and link down log information.

To disable an interface from generating link up/down logging information:

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter Layer 3 Ethernet interface view or Layer 2 Ethernet interface view or VLAN interface view. | interface <i>interface-type</i>
<i>interface-number</i> | You can configure an Ethernet interface as a Layer 3 Ethernet interface only on the HP 5500 EI switch. |
| 3. Disable the interface from generating link up or link down logging information. | undo enable log updown | By default, all interfaces generate link up and link down logging information when the state changes. |

Use the default setting in normal cases to avoid affecting interface status monitoring.

Displaying and maintaining information center

| Task | Command | Remarks |
|---|--|------------------------|
| Display the information about information channels. | display channel [<i>channel-number</i> <i>channel-name</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the information about each output destination. | display info-center [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the state of the log buffer and the log information recorded. | display logbuffer [reverse] [level <i>severity</i> size <i>buffersize</i> slot <i>slot-number</i>] * [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display a summary of the log buffer. | display logbuffer summary [level <i>severity</i> slot <i>slot-number</i>] * [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the state of the trap buffer and the trap information recorded. | display trapbuffer [reverse] [size <i>buffersize</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Reset the log buffer. | reset logbuffer | Available in user view |
| Reset the trap buffer. | reset trapbuffer | Available in user view |

Information center configuration examples

Outputting log information to a UNIX log host

Network requirements

Configure the device to send ARP and IP log information that has a severity level of at least informational to the UNIX log host at 1.2.0.1/16.

Figure 18 Network diagram

Configuration procedure

Before the configuration, make sure that the device and the log host can reach each other.

1. Configure the device:

```
# Enable the information center.
```

```
<Sysname> system-view
```

```
[Sysname] info-center enable
```

```
# Specify the host 1.2.0.1/16 as the log host. Use channel loghost to output log information (optional, loghost by default), and use local4 as the logging facility.
```

```
[Sysname] info-center loghost 1.2.0.1 channel loghost facility local4
```

```
# Disable the output of log, trap, and debugging information of all modules on channel loghost.
```

```
[Sysname] info-center source default channel loghost debug state off log state off
trap state off
```

To avoid outputting unnecessary information, disable the output of log, trap, and debugging information on the specified channel (**loghost** in this example) before you configure an output rule.

Configure an output rule to output to the log host ARP and IP log information that has a severity level of at least **informational**. (The source modules that are allowed to output information depend on the switch model.)

```
[Sysname] info-center source arp channel loghost log level informational state on
[Sysname] info-center source ip channel loghost log level informational state on
```

2. Configure the log host:

The following configurations were performed on SunOS 4.0 which has similar configurations to the UNIX operating systems implemented by other vendors.

- a. Log in to the log host as a root user.
- b. Create a subdirectory named **Device** in directory **/var/log/**, and then create file **info.log** in the **Device** directory to save logs from **Device**.

```
# mkdir /var/log/Device
# touch /var/log/Device/info.log
```

- c. Edit the file **/etc/syslog.conf** and add the following contents.

```
# Device configuration messages
local4.info    /var/log/Device/info.log
```

In this configuration, **local4** is the name of the logging facility that the log host uses to receive logs. **info** is the information level. The UNIX system records the log information that has a severity of at least **informational** to the file **/var/log/Device/info.log**.

NOTE:

Be aware of the following issues while editing the file **/etc/syslog.conf**:

- Comments must be on a separate line and must begin with a pound sign (#).
- No redundant spaces are allowed after the file name.
- The logging facility name and the information level specified in the **/etc/syslog.conf** file must be identical to those configured on the device using the **info-center loghost** and **info-center source** commands. Otherwise the log information might not be output properly to the log host.

- d. Display the process ID of **syslogd**, kill the **syslogd** process and then restart **syslogd** using the **-r** option to make the modified configuration take effect.

```
# ps -ae | grep syslogd
147
# kill -HUP 147
# syslogd -r &
```

Now, the system can record log information into the log file.

Outputting log information to a Linux log host

Network requirements

Configure the device to send log information that has a severity level of at least informational to the Linux log host at 1.2.0.1/16.

Figure 19 Network diagram

Configuration procedure

Before the configuration, make sure that the device and the PC can reach each other.

1. Configure the device:

Enable the information center.

```
<Sysname> system-view
[Sysname] info-center enable
```

Specify the host 1.2.0.1/16 as the log host. Use the channel **loghost** to output log information (optional, **loghost** by default), and use **local5** as the logging facility.

```
[Sysname] info-center loghost 1.2.0.1 channel loghost facility local5
```

Disable the output of log, trap, and debugging information of all modules on channel **loghost**.

```
[Sysname] info-center source default channel loghost debug state off log state off
trap state off
```

To avoid outputting unnecessary information, disable the output of log, trap, and debugging information on the specified channel (**loghost** in this example) before you configure an output rule.

Configure an output rule to output to the log host the log information that has a severity level of at least **informational**.

```
[Sysname] info-center source default channel loghost log level informational state
on
```

2. Configure the log host:

a. Log in to the log host as a root user.

b. Create a subdirectory named **Device** in directory **/var/log/**, and create file **info.log** in the **Device** directory to save logs of **Device**.

```
# mkdir /var/log/Device
# touch /var/log/Device/info.log
```

c. Edit the file **/etc/syslog.conf** and add the following contents.

```
# Device configuration messages
local5.info    /var/log/Device/info.log
```

In this configuration, **local5** is the name of the logging facility that the log host uses to receive logs. The information level is **info**. The Linux system records the log information that has a severity level of at least **informational** to the file **/var/log/Device/info.log**.

NOTE:

Be aware of the following issues while editing the file **/etc/syslog.conf**:

- Comments must be on a separate line and must begin with a pound sign (#).
 - No redundant spaces are allowed after the file name.
 - The logging facility name and the information level specified in the **/etc/syslog.conf** file must be identical to those configured on the device using the **info-center loghost** and **info-center source** commands. Otherwise the log information may not be output properly to the log host.
-

- d. Display the process ID of **syslogd**, kill the **syslogd** process, and restart **syslogd** using the **-r** option to make the modified configuration take effect.

```
# ps -ae | grep syslogd
147
# kill -9 147
# syslogd -r &
```

Make sure that the **syslogd** process is started with the **-r** option on the Linux log host.

Now, the system can record log information into the log file.

Outputting log information to the console

Network requirements

Configure the device to send ARP and IP log information that has a severity level of at least Informational to the console.

Figure 20 Network diagram

Configuration procedure

```
# Enable the information center.
```

```
<Sysname> system-view
[Sysname] info-center enable
```

```
# Use channel console to output log information to the console. (This step is optional because it is the default setting).
```

```
[Sysname] info-center console channel console
```

```
# Disable the output of log, trap, and debugging information of all modules on channel console.
```

```
[Sysname] info-center source default channel console debug state off log state off trap
state off
```

To avoid outputting unnecessary information, disable the output of log, trap, and debugging information of all modules on the specified channel (**console** in this example), and then configure the output rule as needed.

```
# Configure an output rule to output to the console ARP and IP log information that has a severity level of at least informational. (The source modules that are allowed to output information depend on the switch model.)
```

```
[Sysname] info-center source arp channel console log level informational state on
[Sysname] info-center source ip channel console log level informational state on
[Sysname] quit
```

```
# Enable the display of log information on a terminal. (Optional, this function is enabled by default.)
```

```
<Sysname> terminal monitor
Info: Current terminal monitor is on.
<Sysname> terminal logging
Info: Current terminal logging is on.
```

Now, if the ARP and IP modules generate log information, the information center automatically sends the log information to the console.

Saving security logs into the security log file

Network requirements

- Save security logs into the security log file **Flash:/securitylog/seclog.log** every one hour.
- Only the security log administrator can view the contents of the security log file. No other users cannot view, copy, or rename the security log file.

Figure 21 Network diagram

Configuration considerations

The configuration in this example includes two parts:

1. Log in to the device as the system administrator:
 - Enable saving the security logs into the security log file and set the saving interval to one hour.
 - Create a local user **seclog** with the password **123123123123**, and authorize this user as the security log administrator. That is, use the **authorization-attribute** command to set the user privilege level to 3 and specify the user role as security audit. In addition, specify the service types that the user can use by using **service-type**.
 - Set the authentication mode to **scheme** for the user logging in to the device, and make sure that only the local user that has passed the AAA local authentication can view and perform operations on the security log file.
2. Log in to the device as the security log administrator:
 - Set the directory for saving the security log file to **Flash:/securitylog/seclog.log**.
 - View the contents of the security log file to learn the security status of the device.

Configuration procedure

1. Configuration performed by the system administrator:

```
# Enable saving security logs into the security log file and set the saving interval to one hour.
<Sysname> system-view
```

```

[Sysname] info-center security-logfile enable
[Sysname] info-center security-logfile frequency 3600
# Create a local user seclog, and configure the password for the user as 123123123123.
[Sysname] local-user seclog
New local user added.
[Sysname-luser-seclog] password simple 123123123123
# Authorize the user to manage the security log file.
[Sysname-luser-seclog] authorization-attribute level 3 user-role security-audit
# Authorize the user to use SSH, Telnet, and terminal services.
[Sysname-luser-seclog] service-type ssh telnet terminal
[Sysname-luser-seclog] quit
# According to the network plan, the user logs in to the device through SSH or Telnet, so configure
the authentication mode of the VTY user interface as scheme.
[Sysname] display user-interface vty ?
    INTEGER<0-15> Specify one user terminal interface
The output shows that the device supports sixteen VTY user interfaces, which are numbered 0
through 15.
[Sysname] user-interface vty 0 15
[Sysname-ui-vty0-15] authentication-mode scheme
[Sysname-ui-vty0-15] quit

```

2. Configuration performed by the security log administrator:

```

# Log in to the device as user seclog.
C:/> telnet 1.1.1.1
*****
* Copyright (c) 2010-2012 Hewlett-Packard Development Company, L.P.          *
* Without the owner's prior written consent,                                *
* no decompiling or reverse-engineering shall be allowed.                  *
*****

```

Login authentication

```

Username:seclog
Password:
<Sysname>
# Display the summary of the security log file.
<Sysname> display security-logfile summary
  Security-log is enabled.
  Security-log file size quota: 1MB
  Security-log file directory: flash:/seclog
  Alarm-threshold: 80%
  Current usage: 0%
  Writing frequency: 1 hour 0 min 0 sec

```

The output shows that the directory for saving the security log file is **flash:/seclog**.

Change the directory where the security log file is saved to **Flash:/securitylog**.

```
<Sysname> mkdir securitylog
.
%Created dir flash:/securitylog.
<Sysname> info-center security-logfile switch-directory flash:/securitylog/
# Display the contents of the security log file buffer.
<Sysname> display security-logfile buffer
%@175 Nov  2 17:02:53:766 2011 Sysname SHELL/4/LOGOUT:
  Trap 1.3.6.1.4.1.25506.2.2.1.1.3.0.2: logout from Console
%@176 Nov  2 17:02:53:766 2011 Sysname SHELL/5/SHELL_LOGOUT:Console logged out from
aux0.
```

The content of other logs is not shown.

The preceding information indicates that there is still new content in the buffer that has not been saved into the security log file.

Manually save the contents of the security log file buffer into the security log file.

```
<Sysname> security-logfile save
Info: Save all the contents in the security log buffer into file
flash:/securitylog/seclog.log successfully.
```

Display the contents of the security log file.

```
<Sysname> more securitylog/seclog.log
%@157 Nov  2 16:12:01:750 2011 Sysname SHELL/4/LOGIN:
  Trap 1.3.6.1.4.1.25506.2.2.1.1.3.0.1: login from Console
%@158 Nov  2 16:12:01:750 2011 Sysname SHELL/5/SHELL_LOGIN:Console logged in from
aux0.
```

The content of other logs is not shown.

Configuring SNMP

This chapter provides an overview of the Simple Network Management Protocol (SNMP) and guides you through the configuration procedure.

Overview

SNMP is an Internet standard protocol widely used for a management station to access and operate the devices on a network, regardless of their vendors, physical characteristics and interconnect technologies.

SNMP enables network administrators to read and set the variables on managed devices for state monitoring, troubleshooting, statistics collection, and other management purposes.

SNMP framework

The SNMP framework comprises the following elements:

- **SNMP manager**—Works on an NMS to monitor and manage the SNMP-capable devices in the network.
- **SNMP agent**—Works on a managed device to receive and handle requests from the NMS, and send traps to the NMS when some events, such as an interface state change, occur.
- **Management Information Base (MIB)**—Specifies the variables (for example, interface status and CPU usage) maintained by the SNMP agent for the SNMP manager to read and set.

Figure 22 Relationship between an NMS, agent and MIB

MIB and view-based MIB access control

A MIB stores variables called "nodes" or "objects" in a tree hierarchy and identifies each node with a unique OID. An OID is a string of numbers that describes the path from the root node to a leaf node. For example, object B in Figure 23 is uniquely identified by the OID {1.2.1.1}.

Figure 23 MIB tree

A MIB view represents a set of MIB objects (or MIB object hierarchies) with certain access privilege and is identified by a view name. The MIB objects included in the MIB view are accessible while those excluded from the MIB view are inaccessible.

A MIB view can have multiple view records each identified by a *view-name oid-tree* pair.

You control access to the MIB by assigning MIB views to SNMP groups or communities.

SNMP operations

SNMP provides the following basic operations:

- **Get**—The NMS retrieves SNMP object nodes in an agent MIB.
- **Set**—The NMS modifies the value of an object node in an agent MIB.
- **Notifications**—Includes traps and informs. SNMP agent sends traps or informs to report events to the NMS. The difference between these two types of notification is that informs require acknowledgement but traps do not. The device supports only traps.

SNMP protocol versions

HP supports SNMPv1, SNMPv2c, and SNMPv3. An NMS and an SNMP agent must use the same SNMP version to communicate with each other.

- **SNMPv1**—Uses community names for authentication. To access an SNMP agent, an NMS must use the same community name as set on the SNMP agent. If the community name used by the NMS is different from that set on the agent, the NMS cannot establish an SNMP session to access the agent or receive traps from the agent.
- **SNMPv2c**—Uses community names for authentication. SNMPv2c is compatible with SNMPv1, but supports more operation modes, data types, and error codes.
- **SNMPv3**—Uses a user-based security model (USM) to secure SNMP communication. You can configure authentication and privacy mechanisms to authenticate and encrypt SNMP packets for integrity, authenticity, and confidentiality.

SNMP configuration task list

| Task | Remarks |
|---|----------|
| Configuring SNMP basic parameters | Required |
| Switching the NM-specific interface index | Optional |
| Configuring SNMP logging | Optional |
| Configuring SNMP traps | Optional |

Configuring SNMP basic parameters

SNMPv3 differs from SNMPv1 and SNMPv2c in many ways. Their configuration procedures are described in separate sections.

Configuring SNMPv3 basic parameters

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable the SNMP agent. | snmp-agent | Optional.
By default, the SNMP agent is disabled.

You can also enable the SNMP agent by using any command that begins with snmp-agent except the snmp-agent calculate-password and snmp-agent ifmib long-ifindex enable commands. |
| 3. Configure system information for the SNMP agent. | snmp-agent sys-info { contact <i>sys-contact</i> location <i>sys-location</i> version { all { v1 v2c v3 }* } } | Optional.
By default, the contact information is Hewlett-Packard Development Company, L.P. , the location information is null, and the protocol version is SNMPv3 . |
| 4. Configure the local engine ID. | snmp-agent local-engineid <i>engineid</i> | Optional.
The default local engine ID is the company ID plus the device ID.
After you change the local engine ID, the existing SNMPv3 users become invalid, and you must re-create the SNMPv3 users. |
| 5. Create or update a MIB view. | snmp-agent mib-view { excluded included } <i>view-name oid-tree</i> [mask <i>mask-value</i>] | Optional.
By default, the MIB view ViewDefault is predefined and its OID is 1.

Each <i>view-name oid-tree</i> pair represents a view record. If you specify the same record with different MIB subtree masks multiple times, the last configuration takes effect. Except the four subtrees in the default MIB view, you can create up to 16 unique MIB view records. |
| 6. Configure an SNMPv3 group. | snmp-agent group v3 <i>group-name</i> [authentication privacy] [read-view <i>read-view</i>] [write-view <i>write-view</i>] [notify-view <i>notify-view</i>] [acl <i>acl-number</i> acl ipv6 <i>ipv6-acl-number</i>] * | By default, no SNMP group exists. |
| 7. Convert a plaintext key to a ciphertext (encrypted) key. | snmp-agent calculate-password <i>plain-password</i> mode { 3desmd5 3dessha md5 sha } { local-engineid specified-engineid <i>engineid</i> } | Optional. |

| Step | Command | Remarks |
|--|---|---|
| 8. Add a user to the SNMPv3 group. | snmp-agent usm-user v3
<i>user-name group-name</i> [[cipher]
authentication-mode { md5 sha }
<i>auth-password</i> [privacy-mode
{ 3des aes128 des56 }
<i>priv-password</i>]] [acl <i>acl-number</i>
acl ipv6 <i>ipv6-acl-number</i>] * | N/A |
| 9. Configure the maximum SNMP packet size (in bytes) that the SNMP agent can handle. | snmp-agent packet max-size
<i>byte-count</i> | Optional.
By default, the SNMP agent can receive and send SNMP packets up to 1500 bytes. |
| 10. Configure the DSCP value for SNMP responses. | snmp-agent packet response dscp
<i>dscp-value</i> | Optional.
By default, the DSCP value for SNMP responses is 0. |

Configuring SNMPv1 or SNMPv2c basic parameters

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable the SNMP agent. | snmp-agent | Optional.
By default, the SNMP agent is disabled.
You can also enable the SNMP agent service by using any command that begins with snmp-agent except the snmp-agent calculate-password and snmp-agent ifmib long-ifindex enable commands. |
| 3. Configure system information for the SNMP agent. | snmp-agent sys-info { contact <i>sys-contact</i>
location <i>sys-location</i> version { all { v1 v2c v3 }* } } | By default, the contact information is Hewlett-Packard Development Company, L.P. , the location information is null, and the protocol version is SNMPv3 . |
| 4. Configure the local engine ID. | snmp-agent local-engineid <i>engineid</i> | Optional.
The default local engine ID is the company ID plus the device ID. |

| Step | Command | Remarks |
|--|---|--|
| 5. Create or update a MIB view. | snmp-agent mib-view { excluded included }
<i>view-name oid-tree</i> [mask mask-value] | Optional.
By default, the MIB view ViewDefault is predefined and its OID is 1.
Each <i>view-name oid-tree</i> pair represents a view record. If you specify the same record with different MIB subtree masks multiple times, the last configuration takes effect. Except the four subtrees in the default MIB view, you can create up to 16 unique MIB view records. |
| 6. Configure the SNMP access right. | <ul style="list-style-type: none"> • (Approach 1) Create an SNMP community:
snmp-agent community { read write }
<i>community-name</i> [mib-view view-name]
[acl acl-number acl ipv6 ipv6-acl-number] * • (Approach 2) Create an SNMP group, and add a user to the SNMP group: <ul style="list-style-type: none"> a. snmp-agent group { v1 v2c }
<i>group-name</i> [read-view read-view]
[write-view write-view] [notify-view notify-view] [acl acl-number acl ipv6 ipv6-acl-number] * b. snmp-agent usm-user { v1 v2c }
<i>user-name group-name</i> [acl acl-number acl ipv6 ipv6-acl-number] * | Use either approach.
By default, no SNMP group exists.
In approach 2, the username is equivalent to the community name in approach 1, and must be the same as the community name configured on the NMS. |
| 7. Configure the maximum size (in bytes) of SNMP packets for the SNMP agent. | snmp-agent packet max-size <i>byte-count</i> | Optional.
By default, the SNMP agent can receive and send the SNMP packets up to 1500 bytes. |
| 8. Configure the DSCP value for SNMP responses. | snmp-agent packet response dscp <i>dscp-value</i> | Optional.
By default, the DSCP value for SNMP responses is 0. |

Switching the NM-specific interface index format

A network management (NM)-specific ifindex identifies an interface and is provided by the SNMP managed device to the NMS. A network management-specific ifindex takes one of the following two formats:

- **16-bit NM-specific ifindex**—The system dynamically assigns 16-bit NM-specific ifindex values to uniquely identify its interfaces. The 16-bit NM-specific ifindex value starts from 1 and increments by 1.
- **32-bit NM-specific ifindex**—A 32-bit NM-specific ifindex value comprises an Offset, Interface Type, Slot ID, and Chassis ID, as shown in [Figure 24](#).

Figure 24 32-bit NM-specific ifindex

- **Offset**—This field is 16 bits long and distinguishes different interfaces of the same type on the same interface card.
- **Interface type**—This field is 7 bits long and contains the enumerated value specific to the interface type. It supports up to 128 different interface types and supports more than 80 interface types at present.
- **Slot ID**—This field is 5 bits long and contains the number of the physical slot that holds the interface.
- **Chassis ID**—This field is 4 bits long. For a distributed device in IRF mode, this field indicates the member ID of the device that provides the interface. For other types of devices, this field has no meanings and the value is 0.

Configuration guidelines

- Use the 32-bit NM-specific ifindex format if the NMS requires the format to get information such as the slot that contains a specific interface. If the network protocol operating on the NMS does not support 32-bit NM-specific ifindex values, make sure NM-specific ifindex values on the device are 16-bit. By default, the device adopts the 16-bit NM-specific ifindex format.
- An NM-specific ifindex format change invalidates the NM-specific ifindex dependent settings, and these settings cannot become valid until you switch the format back. To use these settings in the new format, you must re-configure them. For example, if an RMON alarm group or private alarm group has alarm variables in the format *OID/variable-name.NM-specific-ifindex*, you must reconfigure these variables after an NM-specific ifindex format change.

Configuration procedure

To switch the NM-specific ifindex format:

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Switch the format of an NM-specific ifindex from 16-bit to 32-bit. | snmp-agent ifmib long-ifindex enable | Optional.
By default, an NM-specific ifindex is in 16-bit format. |

| Step | Command | Remarks |
|------|--|--|
| 3. | Switch the format of an NM-specific ifindex from 32-bit to 16-bit.
undo snmp-agent ifmib long-ifindex enable | Optional.
By default, an NM-specific ifindex is in 16-bit format. |

Configuring SNMP logging

ⓘ IMPORTANT:

Disable SNMP logging in normal cases to prevent a large amount of SNMP logs from decreasing device performance.

The SNMP logging function logs Get requests, Set requests, and Set responses, but does not log Get responses.

- **Get operation**—The agent logs the IP address of the NMS, name of the accessed node, and node OID.
- **Set operation**—The agent logs the NMS' IP address, name of accessed node, node OID, and error code and index for the Set operation.

The SNMP module sends these logs to the information center as informational messages. You can configure the information center to output these messages to certain destinations, for example, the console and the log buffer. The total output size for the node field (MIB node name) and the value field (value of the MIB node) in each log entry is 1024 bytes. If this limit is exceeded, the information center truncates the data in the fields. For more information about the information center, see "[Configuring the information center](#)."

To configure SNMP logging:

| Step | Command | Remarks |
|------|---|---------------------------------------|
| 1. | Enter system view.
system-view | N/A |
| 2. | Enable SNMP logging.
snmp-agent log { all get-operation set-operation } | By default, SNMP logging is disabled. |

Configuring SNMP traps

The SNMP agent sends traps to inform the NMS of important events, such as a reboot.

Traps fall into generic traps and vendor-specific traps. Generic traps include **authentication**, **coldstart**, **linkdown**, **linkup** and **warmstart**. All other traps are vendor-defined.

SNMP traps generated by a module are sent to the information center. You can configure the information center to enable or disable outputting the traps from a module by severity and set output destinations. For more information about the information center, see "[Configuring the information center](#)."

Enabling SNMP traps

Enable SNMP traps only if necessary. SNMP traps are memory-intensive and may affect device performance.

To generate linkUp or linkDown traps when the link state of an interface changes, you must enable the linkUp or linkDown trap function globally by using the **snmp-agent trap enable [standard [linkdown | linkup] *]** command and on the interface by using the **enable snmp trap updown** command.

After you enable a trap function for a module, whether the module generates traps also depends on the configuration of the module. For more information, see the configuration guide for each module.

To enable traps:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable traps globally. | snmp-agent trap enable [arp rate-limit bgp configuration default-route flash ospf [process-id] [ifauthfail ifcfgerror ifrxbadpkt ifstatechange iftxretransmit lsdapproachoverflow lsdoverflow maxagelsa nbrstatechange originatelsa vifcfgerror virifauthfail virifrxbadpkt virifstatechange viriftxretransmit virnbrstatechange] * pim [candidatebsrwinelection electedbsrlostelection interfaceelection invalidjoinprune invalidregister neighborloss rpmappingchange] * standard [authentication coldstart linkdown linkup warmstart] * system vrrp [authfailure newmaster]] | By default, all traps are enabled.
The HP 5500 SI switches do not support the bgp , ospf , pim , or vrrp keyword. |
| 3. Enter Layer 2 Ethernet interface view, Layer 3 Ethernet interface view, or VLAN interface view. | interface interface-type interface-number | Only the HP 5500 EI switches support Layer 3 Ethernet port configuration. |
| 4. Enable link state traps. | enable snmp trap updown | By default, the link state traps are enabled. |

Configuring the SNMP agent to send traps to a host

The SNMP module buffers the traps received from a module in a trap queue. You can set the size of the queue, the duration that the queue holds a trap, and trap target (destination) hosts, typically the NMS.

To successfully send traps, you must also perform the following tasks:

- Complete the basic SNMP settings and verify that they are the same as on the NMS. If SNMPv1 or SNMPv2c is used, you must configure a community name. If SNMPv3 is used, you must configure an SNMPv3 user and MIB view.
- Make sure the device and the NMS can reach each other.

To configure the SNMP agent to send traps to a host:

| Step | Command | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |

| Step | Command | Remarks |
|---|--|---|
| 2. Configure a target host. | snmp-agent target-host trap address udp-domain { <i>ip-address</i> ipv6 <i>ipv6-address</i> } [udp-port <i>port-number</i>] [dscp <i>dscp-value</i>] [vpn-instance <i>vpn-instance-name</i>]
params securityname <i>security-string</i> [v1 v2c v3] [authentication privacy]] | If the trap destination is a host, the <i>ip-address</i> argument must be the IP address of the host.
Only the HP 5500 EI switches support the vpn-instance keyword. |
| 3. Configure the source address for traps. | snmp-agent trap source interface-type interface-number | Optional.
By default, SNMP chooses the IP address of an interface to be the source IP address of traps. |
| 4. Extend the standard linkUp/linkDown traps. | snmp-agent trap if-mib link extended | Optional.
By default, standard linkUp/linkDown traps are used.
Extended linkUp/linkDown traps add interface description and interface type to standard linkUp/linkDown traps. If the NMS does not support extended SNMP messages, use standard linkUp/linkDown traps. |
| 5. Configure the trap queue size. | snmp-agent trap queue-size <i>size</i> | Optional.
The default trap queue size is 100.
When the trap queue is full, the oldest traps are automatically deleted for new traps. |
| 6. Configure the trap holding time. | snmp-agent trap life <i>seconds</i> | Optional.
The default setting is 120 seconds.
A trap is deleted when its holding time expires. |

Displaying and maintaining SNMP

| Task | Command | Remarks |
|--|--|-----------------------|
| Display SNMP agent system information, including the contact, physical location, and SNMP version. | display snmp-agent sys-info [contact location version]* [[{ begin exclude include } <i>regular-expression</i>]] | Available in any view |
| Display SNMP agent statistics. | display snmp-agent statistics [[{ begin exclude include } <i>regular-expression</i>]] | Available in any view |
| Display the local engine ID. | display snmp-agent local-engineid [[{ begin exclude include } <i>regular-expression</i>]] | Available in any view |
| Display SNMP group information. | display snmp-agent group [<i>group-name</i>] [[{ begin exclude include } <i>regular-expression</i>]] | Available in any view |

| Task | Command | Remarks |
|--|---|-----------------------|
| Display basic information about the trap queue. | display snmp-agent trap queue [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the modules that can send traps and their trap status (enable or disable). | display snmp-agent trap-list [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display SNMPv3 user information. | display snmp-agent usm-user [engineid <i>engineid</i> username <i>user-name</i> group <i>group-name</i>] * [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display SNMPv1 or SNMPv2c community information. | display snmp-agent community [read write] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display MIB view information. | display snmp-agent mib-view [exclude include viewname <i>view-name</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |

SNMP configuration examples

This section gives examples of how to configure SNMPv1 or SNMPv2c, SNMPv3, and SNMP logging.

SNMPv1/SNMPv2c configuration example

Network requirements

As shown in [Figure 25](#), the NMS (1.1.1.2/24) uses SNMPv1 or SNMPv2c to manage the SNMP agent (1.1.1.1/24), and the agent automatically sends traps to report events to the NMS.

Figure 25 Network diagram

Configuration procedure

1. Configure the SNMP agent:

Configure the IP address of the agent, and make sure the agent and the NMS can reach each other. (Details not shown.)

Specify SNMPv1 and SNMPv2c, and create a read-only community **public** and a read and write community **private**.

```

<Agent> system-view
[Agent] snmp-agent sys-info version v1 v2c
[Agent] snmp-agent community read public
[Agent] snmp-agent community write private
  
```

Configure contact and physical location information for the agent.

```

[Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
[Agent] snmp-agent sys-info location telephone-closet,3rd-floor
  
```

```
# Enable SNMP traps, set the NMS at 1.1.1.2 as an SNMP trap destination, and use public as the
community name. (To make sure the NMS can receive traps, specify the same SNMP version in the
snmp-agent target-host command as is configured on the NMS.)
```

```
[Agent] snmp-agent trap enable
```

```
[Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params securityname
public v1
```

```
[Agent] quit
```

2. Configure the SNMP NMS:

```
# Configure the SNMP version for the NMS as v1 or v2c, create a read-only community and name
it public, and create a read and write community and name it private. For information about
configuring the NMS, see the NMS manual.
```

NOTE:

The SNMP settings on the agent and the NMS must match.

3. Verify the configuration:

```
# Try to get the count of sent traps from the agent. The attempt succeeds.
```

```
Send request to 1.1.1.1/161 ...
```

```
Protocol version: SNMPv1
```

SNMPv3 configuration example

Network requirements

As shown in [Figure 26](#), the NMS (1.1.1.2/24) uses SNMPv3 to monitor and manage the interface status of the agent (1.1.1.1/24), and the agent automatically sends traps to report events to the NMS.

The NMS and the agent perform authentication when they set up an SNMP session. The authentication algorithm is MD5 and the authentication key is **authkey**. The NMS and the agent also encrypt the SNMP packets between them by using the DES algorithm and the privacy key **prikey**.

Figure 26 Network diagram

Configuration procedure

1. Configure the agent:

Configure the IP address of the agent and make sure the agent and the NMS can reach each other. (Details not shown.)

Assign the NMS read and write access to the objects under the snmp node (OID 1.3.6.1.2.1.11), and deny its access to any other MIB object.

```
<Agent> system-view
[Agent] undo snmp-agent mib-view ViewDefault
[Agent] snmp-agent mib-view included test snmp
[Agent] snmp-agent group v3 managev3group read-view test write-view test
```

Set the username to **managev3user**, authentication algorithm to **MD5**, authentication key to **authkey**, encryption algorithm to **DES56**, and privacy key to **prikey**.

```
[Agent] snmp-agent usm-user v3 managev3user managev3group authentication-mode md5
authkey privacy-mode des56 prikey
```

Configure contact person and physical location information for the agent.

```
[Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
[Agent] snmp-agent sys-info location telephone-closet,3rd-floor
```

Enable traps, specify the NMS at 1.1.1.2 as a trap destination, and set the username to **managev3user** for the traps.

```
[Agent] snmp-agent trap enable
[Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params securityname
managev3user v3 privacy
```

2. Configure the SNMP NMS:

- Specify the SNMP version for the NMS as v3.
- Create two SNMP users: **managev3user** and **public**.
- Enable both authentication and privacy functions.
- Use MD5 for authentication and DES for encryption.
- Set the authentication key to **authkey** and the privacy key to **prikey**.
- Set the timeout time and maximum number of retries.

For information about configuring the NMS, see the NMS manual.

NOTE:

The SNMP settings on the agent and the NMS must match.

3. Verify the configuration:

Try to get the count of sent traps from the agent. The get attempt succeeds.

```
Send request to 1.1.1.1/161 ...
Protocol version: SNMPv3
Operation: Get
```

```

Request binding:
1: 1.3.6.1.2.1.11.29.0
Response binding:
1: Oid=snmpOutTraps.0 Syntax=CNTR32 Value=18
Get finished
# Try to get the device name from the agent. The get attempt fails because the NMS has no access
right to the node.
Send request to 1.1.1.1/161 ...
Protocol version: SNMPv3
Operation: Get
Request binding:
1: 1.3.6.1.2.1.1.5.0
Response binding:
1: Oid=sysName.0 Syntax=noSuchObject Value=NULL
Get finished
# Execute the shutdown or undo shutdown command on an idle interface on the agent. You can
see the interface state change traps on the NMS:
1.1.1.1/3374 V3 Trap = linkdown
SNMP Version = V3

Command = Trap

```

SNMP logging configuration example

Network requirements

Configure the SNMP agent (1.1.1.1/24) in [Figure 27](#) to log the SNMP operations performed by the NMS.

Figure 27 Network diagram

Configuration procedure

This example assumes you have configured all required SNMP settings for the NMS and the agent (see "[SNMPv1/SNMPv2c configuration example](#)" or "[SNMPv3 configuration example](#)").

Enable displaying log messages on the configuration terminal. (This function is enabled by default. Skip this step if you are using the default.)

```
<Agent> terminal monitor
<Agent> terminal logging
```

Enable the information center to output system information with severity level equal to or higher than informational to the console port.

```
<Agent> system-view
[Agent] info-center source snmp channel console log level informational
```

Enable logging GET and SET operations.

```
[Agent] snmp-agent log all
```

Verify the configuration:

Use the NMS to get a MIB variable from the agent. The following is a sample log message displayed on the configuration terminal:

```
%Jan 1 02:49:40:566 2011 Sysname SNMP/6/GET:
seqNO = <10> srcIP = <1.1.1.2> op = <get> node = <sysName(1.3.6.1.2.1.1.5.0)> value=<>
```

Use the NMS to set a MIB variable on the agent. The following is a sample log message displayed on the configuration terminal:

```
%Jan 1 02:59:42:576 2011 Sysname SNMP/6/SET:
seqNO = <11> srcIP = <1.1.1.2> op = <set> errorIndex = <0> errorStatus =<noError> node
= <sysName(1.3.6.1.2.1.1.5.0)> value = <Agent>
```

Table 6 SNMP log message field description

| Field | Description |
|-------------------------|--|
| Jan 1 02:49:40:566 2011 | Time when the SNMP log was generated. |
| seqNO | Serial number automatically assigned to the SNMP log, starting from 0. |
| srcIP | IP address of the NMS. |
| op | SNMP operation type (GET or SET). |
| node | MIB node name and OID of the node instance. |
| errorIndex | Error index, with 0 meaning no error. |
| errorStatus | Error status, with noError meaning no error. |
| value | Value set by the SET operation. This field is null for a GET operation.
If the value is a character string that has invisible characters or characters beyond the ASCII range 0 to 127, the string is displayed in hexadecimal format, for example, value = <81-43>[hex]. |

The information center can output system event messages to several destinations, including the terminal and the log buffer. In this example, SNMP log messages are output to the terminal. To configure other message destinations, see "[Configuring the information center.](#)"

Configuring RMON

This chapter describes how to configure RMON.

Overview

Remote Monitoring (RMON) is an enhancement to SNMP for remote device management and traffic monitoring. An RMON monitor, typically the RMON agent embedded in a network device, periodically or continuously collects traffic statistics for the network attached to a port, and when a statistic crosses a threshold, logs the crossing event and sends a trap to the management station.

RMON uses SNMP traps to notify NMSs of exceptional conditions. RMON SNMP traps report various events, including traffic events such as broadcast traffic threshold exceeded. In contrast, SNMP standard traps report device operating status changes such as link up, link down, and module failure.

RMON enables proactive monitoring and management of remote network devices and subnets. The managed device can automatically send a trap when a statistic crosses an alarm threshold, and the NMS does not need to constantly poll MIB variables and compare the results. As a result, network traffic is reduced.

Working mechanism

RMON monitors typically take one of the following forms:

- **Dedicated RMON probes.** NMSs can obtain management information from RMON probes directly and control network resources. In this approach, NMSs can obtain all RMON MIB information.
- **RMON agents embedded in network devices.** NMSs exchange data with RMON agents by using basic SNMP operations to gather network management information. Because this approach is resource intensive, most RMON agent implementations provide only four groups of MIB information: alarm, event, history, and statistics.

HP devices provide the embedded RMON agent function. You can configure your device to collect and report traffic statistics, error statistics, and performance statistics.

RMON groups

Among the RFC 2819 defined RMON groups, HP implements the statistics group, history group, event group, and alarm group supported by the public MIB. HP also implements a private alarm group, which enhances the standard alarm group.

Ethernet statistics group

The statistics group defines that the system collects traffic statistics on interfaces (only Ethernet interfaces are supported) and saves the statistics in the Ethernet statistics table (ethernetStatsTable). The interface traffic statistics include network collisions, CRC alignment errors, undersize/oversize packets, broadcasts, multicasts, bytes received, and packets received.

After you create a statistics entry for an interface, the statistics group starts to collect traffic statistics on the interface. The statistics in the Ethernet statistics table are cumulative sums.

History group

The history group defines that the system periodically collects traffic statistics on interfaces and saves the statistics in the history record table (ethernetHistoryTable). The statistics include bandwidth utilization, number of error packets, and total number of packets.

The history statistics table record traffic statistics collected for each sampling interval. The sampling interval is user-configurable.

Event group

The event group defines event indexes and controls the generation and notifications of the events triggered by the alarms defined in the alarm group and the private alarm group. The events can be handled in one of the following ways:

- **Log**—Logs event information (including event name and description) in the event log table of the RMON MIB, so the management device can get the logs through the SNMP Get operation.
- **Trap**—Sends a trap to notify an NMS of the event.
- **Log-Trap**—Logs event information in the event log table and sends a trap to the NMS.
- **None**—No action.

Alarm group

The RMON alarm group monitors alarm variables, such as the count of incoming packets (etherStatsPkts) on an interface. After you define an alarm entry, the system gets the value of the monitored alarm variable at the specified interval. If the value of the monitored variable is greater than or equal to the rising threshold, a rising event is triggered. If the value of the monitored variable is smaller than or equal to the falling threshold, a falling event is triggered. The event is then handled as defined in the event group.

If an alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event, as shown in [Figure 28](#).

Figure 28 Rising and falling alarm events

Private alarm group

The private alarm group calculates the values of alarm variables and compares the results with the defined threshold for a more comprehensive alarming function.

The system handles the private alarm entry (as defined by the user) in the following ways:

- Periodically samples the prialarm variables defined in the prialarm formula.
- Calculates the sampled values based on the prialarm formula.
- Compares the result with the defined threshold and generates an appropriate event if the threshold value is reached.

If a private alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event. If the count result of the private alarm group overpasses the same threshold multiple times, only the first one can cause an alarm event. In other words, the rising alarm and falling alarm are alternate.

Configuring the RMON statistics function

The RMON statistics function can be implemented by either the Ethernet statistics group or the history group, but the objects of the statistics are different, as follows:

- A statistics object of the Ethernet statistics group is a variable defined in the Ethernet statistics table, and the recorded content is a cumulative sum of the variable from the time the statistics entry is created to the current time. For more information, see "[Configuring the RMON Ethernet statistics function](#)."
- A statistics object of the history group is the variable defined in the history record table, and the recorded content is a cumulative sum of the variable in each period. For more information, see "[Configuring the RMON history statistics function](#)."

Configuring the RMON Ethernet statistics function

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter Layer 2 Ethernet interface view or Layer 3 Ethernet interface view. | interface <i>interface-type</i>
<i>interface-number</i> | You can configure an Ethernet port as a Layer 3 Ethernet port only on the HP 5500 EI switch. |
| 3. Create an entry in the RMON statistics table. | rmon statistics <i>entry-number</i> [owner <i>text</i>] | N/A |

You can create one statistics entry per interface and up to 100 statistics entries on the device. When the number of statistics entries exceeds 100, you cannot add new entries.

Configuring the RMON history statistics function

Follow these guidelines when you configure the RMON history statistics function:

- The *entry-number* for an RMON history control entry must be globally unique. If an entry number has been used on one interface, it cannot be used on another.

- You can configure multiple history control entries for one interface, but must make sure their entry numbers and sampling intervals are different.
- On the HP 5500 SI switch, up to 100 history entries can be created. On the HP 5500 EI switch, up to 1000 history entries can be created.
- You can successfully create a history control entry, even if the specified bucket size exceeds the history table size supported by the device. However, the effective bucket size will be the actual value supported by the device.

To configure the RMON history statistics function:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter Layer 2 Ethernet interface view or Layer 3 Ethernet interface view. | interface <i>interface-type</i>
<i>interface-number</i> | You can configure an Ethernet port as a Layer 3 Ethernet port only on the HP 5500 EI switch. |
| 3. Create an entry in the RMON history control table. | rmon history <i>entry-number</i> buckets
<i>number</i> interval <i>sampling-interval</i>
[owner <i>text</i>] | N/A |

Configuring the RMON alarm function

Follow these guidelines when you configure the RMON alarm function:

- To send traps to the NMS when an alarm is triggered, configure the SNMP agent as described in "Configuring SNMP" before configuring the RMON alarm function.
- If the alarm variable is a MIB variable defined in the history group or the Ethernet statistics group, make sure the RMON Ethernet statistics function or the RMON history statistics function is configured on the monitored Ethernet interface. Otherwise, even if you can create the alarm entry, no alarm event can be triggered.
- You cannot create a new event, alarm, or private alarm entry that has the same set of parameters as an existing entry. For parameters to be compared for duplication, see [Table 7](#).
- After the maximum number of entries is reached, no new entry can be created. For the table entry limits, see [Table 7](#).

To configure the RMON alarm function:

| Step | Command | Remarks |
|--|---|---------|
| 1. Enter system view. | system-view | N/A |
| 2. Create an event entry in the event table. | rmon event <i>entry-number</i> [description <i>string</i>] { log
log-trap <i>log-trapcommunity</i> none trap
<i>trap-community</i> } [owner <i>text</i>] | N/A |

| Step | Command | Remarks |
|---|---|---------------------------|
| 3. Create an entry in the alarm table or private alarm table. | <ul style="list-style-type: none"> Create an entry in the alarm table:
 rmon alarm <i>entry-number alarm-variable sampling-interval</i> { absolute delta }
 rising-threshold <i>threshold-value1 event-entry1</i>
 falling-threshold <i>threshold-value2 event-entry2</i>
 [owner text] Create an entry in the private alarm table:
 rmon prialarm <i>entry-number prialarm-formula prialarm-des sampling-interval</i> { absolute changeratio delta } rising-threshold <i>threshold-value1 event-entry1</i> falling-threshold <i>threshold-value2 event-entry2</i> entrytype { forever cycle <i>cycle-period</i> } [owner text] | Use at least one command. |

Table 7 RMON configuration restrictions

| Entry | Parameters to be compared | Maximum number of entries |
|----------|--|---------------------------|
| Event | Event description (description string), event type (log, trap, logtrap or none) and community name (<i>trap-community</i> or <i>log-trapcommunity</i>) | 60 |
| Alarm | Alarm variable (<i>alarm-variable</i>), sampling interval (<i>sampling-interval</i>), sampling type (absolute or delta), rising threshold (<i>threshold-value1</i>) and falling threshold (<i>threshold-value2</i>) | 60 |
| Prialarm | Alarm variable formula (<i>alarm-variable</i>), sampling interval (<i>sampling-interval</i>), sampling type (absolute, changeratio or delta), rising threshold (<i>threshold-value1</i>) and falling threshold (<i>threshold-value2</i>) | 50 |

Displaying and maintaining RMON

| Task | Command | Remarks |
|--|--|-----------------------|
| Display RMON statistics. | display rmon statistics [<i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the RMON history control entry and history sampling information. | display rmon history [<i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display RMON alarm configuration. | display rmon alarm [<i>entry-number</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display RMON private alarm configuration. | display rmon prialarm [<i>entry-number</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display RMON events configuration. | display rmon event [<i>entry-number</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display log information for event entries. | display rmon eventlog [<i>entry-number</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |

Ethernet statistics group configuration example

Network requirements

Configure the RMON statistics group on the RMON agent in [Figure 29](#) to gather cumulative traffic statistics for GigabitEthernet 1/0/1.

Figure 29 Network diagram

Configuration procedure

Configure the RMON statistics group on the RMON agent to gather statistics for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon statistics 1 owner user1
```

Display statistics collected by the RMON agent for GigabitEthernet 1/0/1.

```
<Sysname> display rmon statistics gigabitethernet 1/0/1
EtherStatsEntry 1 owned by user1-rmon is VALID.
  Interface : GigabitEthernet1/0/1<ifIndex.3>
  etherStatsOctets      : 21657      , etherStatsPkts      : 307
  etherStatsBroadcastPkts : 56      , etherStatsMulticastPkts : 34
  etherStatsUndersizePkts : 0      , etherStatsOversizePkts : 0
  etherStatsFragments   : 0      , etherStatsJabbers     : 0
  etherStatsCRCAlignErrors : 0      , etherStatsCollisions  : 0
  etherStatsDropEvents (insufficient resources): 0
  Packets received according to length:
  64      : 235      , 65-127 : 67      , 128-255 : 4
  256-511: 1      , 512-1023: 0      , 1024-1518: 0
```

On the configuration terminal, get the traffic statistics through SNMP. (Details not shown.)

History group configuration example

Network requirements

Configure the RMON history group on the RMON agent in [Figure 30](#) to gather periodical traffic statistics for GigabitEthernet 1/0/1 every one minute.

Figure 30 Network diagram

Configuration procedure

Configure the RMON history group on the RMON agent to gather traffic statistics every one minute for GigabitEthernet 1/0/1. Retain up to eight records for the interface in the history statistics table.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon history 1 buckets 8 interval 60 owner user1
```

Display the history data collected for GigabitEthernet 1/0/1.

```
[Sysname-GigabitEthernet1/0/1] display rmon history
HistoryControlEntry 2 owned by null is VALID
  Samples interface      : GigabitEthernet1/0/1<ifIndex.3>
  Sampling interval      : 10(sec) with 8 buckets max
  Sampled values of record 1 :
    dropevents           : 0           , octets           : 834
    packets              : 8           , broadcast packets : 1
    multicast packets    : 6           , CRC alignment errors : 0
    undersize packets    : 0           , oversize packets  : 0
    fragments            : 0           , jabbers           : 0

    multicast packets : 6      , CRC alignment errors : 0
    undersize packets : 0      , oversize packets  : 0
    fragments     : 0          , jabbers          : 0
    collisions    : 0          , utilization       : 0
Sampled values of record 8 :
    dropevents    : 0          , octets           : 1154
    packets       : 13         , broadcast packets : 1
    multicast packets : 6      , CRC alignment errors : 0
    undersize packets : 0      , oversize packets  : 0
    fragments     : 0          , jabbers          : 0
    collisions    : 0          , utilization       : 0

```

On the configuration terminal, get the traffic statistics through SNMP. (Details not shown.)

Alarm group configuration example

Network requirements

Configure the RMON alarm group on the RMON agent in [Figure 31](#) to send alarms in traps when the five-second incoming traffic statistic on GigabitEthernet 1/0/1 crosses the rising threshold or drops below the falling threshold.

Figure 31 Network diagram

Configuration procedure

Configure the SNMP agent with the same SNMP settings as the NMS at 1.1.1.2. This example uses SNMPv1, read community **public**, and write community **private**.

```
<Sysname> system-view
[Sysname] snmp-agent
[Sysname] snmp-agent community read public
[Sysname] snmp-agent community write private
[Sysname] snmp-agent sys-info version v1
[Sysname] snmp-agent trap enable
[Sysname] snmp-agent target-host trap address udp-domain 1.1.1.2 params securityname public
```

Configure the RMON statistics group to gather traffic statistics for GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon statistics 1 owner user1
[Sysname-GigabitEthernet1/0/1] quit
```

Create an RMON event entry and an RMON alarm entry so the RMON agent sends traps when the delta sampling value of node 1.3.6.1.2.1.16.1.1.1.4.1 exceeds 100 or drops below 50.

```
[Sysname] rmon event 1 trap public owner user1
[Sysname] rmon alarm 1 1.3.6.1.2.1.16.1.1.1.4.1 5 delta rising-threshold 100 1
falling-threshold 50 1
```

Display the RMON alarm entry configuration.

```
<Sysname> display rmon alarm 1
AlarmEntry 1 owned by null is Valid.
  Samples type          : delta
  Variable formula      : 1.3.6.1.2.1.16.1.1.1.4.1<etherStatsOctets.1>
  Sampling interval     : 5(sec)
  Rising threshold      : 100(linked with event 1)
  Falling threshold     : 50(linked with event 2)
  When startup enables  : risingOrFallingAlarm
  Latest value          : 0
```

Display statistics for GigabitEthernet 1/0/1.

```

Query alarm events on the NMS. (Details not shown.)

On the RMON agent, alarm event messages are displayed when events occur. The following is a sample output:

```
[Sysname]
#Jan 27 16:31:34:12 2011 Sysname RMON/2/ALARMFALL:Trap 1.3.6.1.2.1.16.0.2 Alarm table 1
monitors 1.3.6.1.2.1.16.1.1.1.4.1 with sample type 2,has sampled alarm value 0 less than(or
=) 50.
```

Configuring port mirroring

Both bridge mode (Layer 2) and route mode (Layer 3) Ethernet ports support port mirroring. The term *interface* in this chapter collectively refers to these two types of ports. You can use the **port link-mode** command to set an Ethernet port to operate in bridge or route mode (see *Layer 2—LAN Switching Configuration Guide*).

Only the HP 5500 EI switch series supports configuring port mirroring on Layer 3 Ethernet interfaces.

Introduction to port mirroring

Port mirroring is the process of copying the packets passing through a port to the monitor port connecting to a monitoring device for packet analysis.

Terminologies of port mirroring

Mirroring source

The mirroring source can be one or more monitored ports. Packets (called "mirrored packets") passing through them are copied to a port connecting to a monitoring device for packet analysis. Such a port is called a "source port" and the device where the port resides is called a "source device".

Mirroring destination

The mirroring destination is the destination port (also known as the monitor port) of mirrored packets and connects to the data monitoring device. The device where the monitor port resides is called the "destination device." The monitor port forwards mirrored packets to its connected monitoring device.

A monitor port may receive multiple duplicates of a packet in some cases because it can monitor multiple mirroring sources. For example, assume that Port 1 is monitoring bidirectional traffic on Port 2 and Port 3 on the same device. If a packet travels from Port 2 to Port 3, two duplicates of the packet will be received on Port 1.

Mirroring direction

The mirroring direction indicates that the inbound, outbound, or bidirectional traffic can be copied on a mirroring source.

- Inbound: Copies packets received on a mirroring source.
- Outbound: Copies packets sent out of a mirroring source.
- Bidirectional: Copies packets both received and sent on a mirroring source.

Mirroring group

Port mirroring is implemented through mirroring groups, which fall into local, remote source, and remote destination mirroring groups. For more information about the mirroring groups, see "[Port mirroring classification and implementation](#)."

Reflector port, egress port, and remote probe VLAN

The reflector port, remote probe VLAN, and egress port are used for Layer 2 remote port mirroring. The remote probe VLAN specially transmits mirrored packets to the destination device. Both the reflector port and egress port reside on a source device and send mirrored packets to the remote probe VLAN. The

egress port must belong to the remote probe VLAN while the reflector port may not. For more information about the source device, destination device, reflector port, egress port, and remote probe VLAN, see "Port mirroring classification and implementation."

NOTE:

The reflector port is used to enable local mirroring to support multiple monitor ports.

Port mirroring classification and implementation

According to the locations of the mirroring source and the mirroring destination, port mirroring falls into local port mirroring and remote port mirroring.

Local port mirroring

In local port mirroring, the mirroring source and the mirroring destination are on the same device. A mirroring group that contains the mirroring source and the mirroring destination on the device is called a "local mirroring group".

Figure 32 Local port mirroring implementation

As shown in [Figure 32](#), the source port GigabitEthernet 1/0/1 and monitor port GigabitEthernet 1/0/2 reside on the same device. Packets of GigabitEthernet 1/0/1 are copied to GigabitEthernet 1/0/2, which then forwards the packets to the data monitoring device for analysis.

Remote port mirroring

In remote port mirroring, the mirroring source and the mirroring destination reside on different devices and in different mirroring groups. The mirroring group that contains the mirroring source or the mirroring destination is called a "remote source/destination group". The devices between the source devices and destination device are intermediate devices.

Because the source and destination devices are on the same Layer 2 network, remote port mirroring is also referred to Layer 2 remote port mirroring.

Figure 33 Layer 2 remote port mirroring implementation

On the network shown in [Figure 33](#),

The source device does the following:

1. Copies the packets received on the source port GigabitEthernet 1/0/1 to the egress port GigabitEthernet 1/0/2.
2. Forwards the packets to the intermediate device, which then broadcasts the packets in the remote probe VLAN.
3. Transmits the packets to the destination device via the intermediate device.

Then, the destination device does the following:

4. Receives the mirrored packets.
5. Compares their VLAN IDs to the ID of the remote probe VLAN configured in the remote destination group.
6. If the VLAN IDs of these mirrored packets match the remote probe VLAN ID, the device forwards them to the data monitoring device through the monitor port GigabitEthernet 1/0/2.

Allow remote probe VLAN to pass through the intermediate devices to make sure the source device and the destination device can communicate at Layer 2 in the remote probe VLAN.

For a mirrored packet to successfully arrive at the remote destination device, make sure the VLAN ID of the mirrored packet is not removed or changed. Otherwise, the Layer 2 remote port mirroring configuration will fail.

To monitor both the received and sent packets of a port in a mirroring group, you must use the **mac-address mac-learning disable** command on the source, intermediate, and destination devices to disable MAC address learning of the remote probe VLAN. For more information about the **mac-address mac-learning disable** command, see *Layer 2—LAN Switch Command Reference*.

Configuring local port mirroring

Local port mirroring configuration task list

Configure a local mirroring group and then configure one or more source ports and a monitor port for the local mirroring group.

Complete these tasks to configure local port mirroring:

| Task | Remarks |
|---|----------|
| Creating a local mirroring group | Required |
| Configuring source ports for the local mirroring group | Required |
| Configuring the monitor port for the local mirroring group | Required |
| Using the remote probe VLAN to enable local mirroring to support multiple monitor ports | Optional |

Creating a local mirroring group

| Step | Command | Remarks |
|------------------------------------|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Create a local mirroring group. | mirroring-group <i>group-id</i> local | No local mirroring group exists by default. |

NOTE:

A local mirroring group takes effect only after you configure a monitor port and source ports for it.

Configuring source ports for the local mirroring group

If you use system view, you can use a list to configure multiple source ports for a mirroring group at one time. If you use interface view, you can assign only the current port to the group as a source port, so you must repeat the step for each additional port.

Configuration restrictions and guidelines

- A mirroring group can contain multiple source ports.
- A port can belong to only one mirroring group.

Configuring source ports in system view

| Step | Command | Remarks |
|----------------------------|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Configure source ports. | mirroring-group <i>group-id</i>
mirroring-port <i>mirroring-port-list</i>
{ both inbound outbound } | By default, no source port is configured for a local mirroring group. |

Configuring a source port in interface view

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 3. Configure the current port as a source port. | [mirroring-group <i>group-id</i>]
mirroring-port { both inbound outbound } | By default, a port does not serve as a source port for any local mirroring group. |

Configuring the monitor port for the local mirroring group

You can configure the monitor port for a mirroring group in system view, or assign the current port to a mirroring group as the monitor port in interface view. The two methods lead to the same result.

Configuration restrictions and guidelines

- A mirroring group contains only one monitor port.
- To make sure that the mirroring function works properly, do not assign the monitor port to a source VLAN, or enable the spanning tree feature on the monitor port.
- HP recommends you use a monitor port for port mirroring only. This is to make sure that the data monitoring device receives and analyzes only the mirrored traffic rather than a mix of mirrored traffic and normally forwarded traffic.
- You cannot configure the monitor port in a mirroring group as a port in a RRPP ring.

Configuring the monitor port in system view

| Step | Command | Remarks |
|--------------------------------|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the monitor port. | mirroring-group <i>group-id</i>
monitor-port <i>monitor-port-id</i> | By default, no monitor port is configured for a local mirroring group. |

Configuring the monitor port in interface view

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 3. Configure the current port as the monitor port. | [mirroring-group <i>group-id</i>]
monitor-port | By default, a port does not serve as the monitor port for any local mirroring group. |

Using the remote probe VLAN to enable local mirroring to support multiple monitor ports

In typical local port mirroring configuration, you can configure only one monitor port in a local mirroring group. As a result, you cannot monitor traffic of a local device on multiple data monitoring devices. To do that, you can take advantage of the remote probe VLAN used in Layer 2 remote mirroring.

In Layer 2 remote port mirroring, a remote probe VLAN is configured, and the mirrored packets are broadcast within the remote probe VLAN. By connecting multiple data monitoring devices to the member ports of the remote probe VLAN, you can monitor the traffic of the local device on multiple data monitoring devices.

Configure this feature in the following steps:

1. Configure a remote source mirroring group on the local device
2. Configure the monitored ports on the device as source ports of this mirroring group
3. Configure a remote probe VLAN for this mirroring group
4. Assign the ports connecting the data monitoring devices to the remote probe VLAN

In this way, when packets mirrored on the monitored ports are broadcast in the remote probe VLAN, they will be sent out of the ports connecting the data monitoring devices, and all the data monitoring devices can thus receive these mirrored packets.

Configuration restrictions and guidelines

- The reflector port of a remote source mirroring group must be an access port and belong to the default VLAN, VLAN 1.
- HP recommends that you configure an unused port as the reflector port of a remote source mirroring group and disable STP on it.
- A mirroring group can contain multiple source ports.
- To make sure that the port mirroring function works properly, do not assign a source port to the remote probe VLAN.
- If you have already configured a reflector port for a remote source mirroring group, you can no longer configure an egress port for it.
- A VLAN can serve as the remote probe VLAN for only one remote source mirroring group. HP recommends you use the remote probe VLAN for port mirroring exclusively. Do not create a VLAN interface for the VLAN or configure any other features for the VLAN.
- A remote probe VLAN must be a static VLAN. To remove the VLAN configured as a remote probe VLAN, you must first remove the remote probe VLAN with the **undo mirroring-group remote-probe vlan** command.
- If the remote probe VLAN of a remote mirroring group is removed, the remote mirroring group will become invalid.
- The link type of monitor ports configured for port mirroring must be access.

Configuration procedure

To configure local port mirroring with multiple monitor ports:

| Step | Command | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |

| Step | Command | Remarks |
|---|---|---|
| 2. Create a remote source mirroring group. | mirroring-group <i>group-id</i>
remote-source | By default, no mirroring group exists on a device. |
| 3. Configure source ports for the remote source mirroring group. | <ul style="list-style-type: none"> • (Approach 1) In system view:
mirroring-group <i>group-id</i>
mirroring-port <i>mirroring-port-list</i>
{ both inbound outbound } • (Approach 2) In interface view: <ul style="list-style-type: none"> a. interface <i>interface-type</i>
<i>interface-number</i> b. [mirroring-group <i>group-id</i>]
mirroring-port { both inbound outbound } c. quit | Use either approach.
By default, no source port is configured for a mirroring group. |
| 4. Configure the reflector port for the remote source mirroring group. | mirroring-group <i>group-id</i> reflector-port
<i>reflector-port</i> | By default, no reflector port is configured for a mirroring group. |
| 5. Create the remote probe VLAN and enter VLAN view. | vlan <i>vlan-id</i> | By default, no remote probe VLAN is configured for a mirroring group. |
| 6. Assign monitor ports to the remote probe VLAN. | port <i>interface-list</i> | By default, a newly-created VLAN does not have any member port. |
| 7. Return to system view. | quit | N/A |
| 8. Configure the remote probe VLAN for the remote source mirroring group. | mirroring-group <i>group-id</i>
remote-probe vlan <i>rprobe-vlan-id</i> | By default, no remote probe VLAN is configured for a mirroring group. |

Configuring Layer 2 remote port mirroring

Layer 2 remote port mirroring configuration task list

Configuring Layer 2 remote port mirroring is to configure remote mirroring groups. To do that, configure the remote source group on the source device and configure the cooperating remote destination group on the destination device. If an intermediate device exists, allow the remote probe VLAN to pass through the intermediate device.

NOTE:

HP recommends you not enable GARP VLAN Registration Protocol (GVRP). If GVRP is enabled, GVRP may register the remote probe VLAN to unexpected ports, resulting in undesired duplicates. For more information about GVRP, see *Layer 2—LAN Switching Configuration Guide*.

Configure the following on the source device:

- Source ports
- Remote probe VLAN
- The egress port

Then, configure the following on the destination device:

- Remote probe VLAN
- Monitor port

Complete these tasks to configure Layer 2 remote port mirroring:

| Task | Remarks | |
|--|--|----------|
| Configuring a remote source group | Creating a remote source group | Required |
| | Configuring source ports for the remote source group | Required |
| | Configuring the egress port for the remote source group | Required |
| | Configuring the remote probe VLAN for the remote source group | Required |
| Configuring a remote destination group | Creating a remote destination group | Required |
| | Configuring the monitor port for the remote destination group | Required |
| | Configuring the remote probe VLAN for the remote destination group | Required |
| | Assigning the monitor port to the remote probe VLAN | Required |

Configuring a remote source group (on the source device)

Creating a remote source group

| Step | Command | Remarks |
|----------------------------------|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Create a remote source group. | mirroring-group <i>group-id</i> remote-source | By default, no remote source group exists on a device. |

Configuring source ports for the remote source group

If you use system view, you can use a list to configure multiple source ports for a mirroring group at one time. If you use interface view, you can assign only the current port to the group as a source port, so you must repeat the step for each additional port.

1. Configuration restrictions and guidelines:
 - A mirroring group can contain multiple source ports.
 - A port can belong to only one mirroring group.

2. Configuration procedure:

To configure source ports for the remote source group in system view:

| Step | Command | Remarks |
|--|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Configure source ports for the remote source group. | mirroring-group <i>group-id</i>
mirroring-port <i>mirroring-port-list</i>
{ both inbound outbound } | By default, no source port is configured for a remote source group. |

To configure a source port for the remote source group in interface view:

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 3. Configure the current port as a source port. | [mirroring-group <i>group-id</i>]
mirroring-port { both inbound outbound } | By default, a port does not serve as a source port for any remote source group. |

Configuring the egress port for the remote source group

You can configure the egress port for a mirroring group in system view, or assign the current port to it as the egress port in interface view. The two configuration modes lead to the same result.

To make sure that the mirroring function works properly, disable these functions on the egress port: the spanning tree feature, 802.1X, IGMP snooping, static ARP, and MAC address learning.

To configure the egress port for the remote source group in system view:

| Step | Command | Remarks |
|---|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the egress port for the remote source group. | mirroring-group <i>group-id</i>
monitor-egress
<i>monitor-egress-port</i> | By default, no egress port is configured for a remote source group. |

To configure the egress port for the remote source group in interface view:

| Step | Command | Remarks |
|---|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 3. Configure the current port as the egress port. | mirroring-group <i>group-id</i>
monitor-egress | By default, a port does not serve as the egress port for any remote source group. |

NOTE:

- A mirroring group contains only one egress port.
- A source port of an existing mirroring group cannot be configured as an egress port.

Configuring the remote probe VLAN for the remote source group

Before configuring a remote probe VLAN, create a static VLAN that will serve as the remote probe VLAN for the remote source group.

1. Configuration restrictions and guidelines:
 - A VLAN can serve for only one mirroring group.
 - When a VLAN is configured as a remote probe VLAN, you must remove the remote probe VLAN configuration before deleting the VLAN.
 - When you remove the configuration of a remote probe VLAN, an active mirroring group becomes inactive.

- When a VLAN is configured as a remote probe VLAN, use the remote probe VLAN for port mirroring exclusively. Do not create a VLAN interface for the VLAN or configure any other features for the VLAN.
 - The remote mirroring groups on the source device and destination device must use the same remote probe VLAN.
2. Configuration procedure:
To configure the remote probe VLAN for the remote source group:

| Step | Command | Remarks |
|-------------------------------------|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the remote probe VLAN. | mirroring-group <i>group-id</i>
remote-probe vlan
<i>rprobe-vlan-id</i> | By default, no remote probe VLAN is configured for a remote source group. |

Configuring a remote destination group (on the destination device)

To configure a remote destination group, make the following configurations on the destination device:

Creating a remote destination group

| Step | Command | Remarks |
|---------------------------------------|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Create a remote destination group. | mirroring-group <i>group-id</i>
remote-destination | By default, no remote destination group exists on a device. |

Configuring the monitor port for the remote destination group

You can configure the monitor port for a mirroring group in system view, or assign the current port to a mirroring group as the monitor port in interface view. The two methods lead to the same result.

1. Configuration restrictions and guidelines:
- A mirroring group contains only one monitor port.
 - To make sure that the mirroring function works properly, do not enable the spanning tree feature on the monitor port.
 - HP recommends you use a monitor port only for port mirroring. This is to make sure that the data monitoring device receives and analyzes only the mirrored traffic rather than a mix of mirrored traffic and normally forwarded traffic.
 - You cannot configure the monitor port in a mirroring group as a port in a RRPP ring.
2. Configuration procedure:

To configure the monitor port for the remote destination group in system view:

| Step | Command | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |

| Step | Command | Remarks |
|--------------------------------|--|---|
| 2. Configure the monitor port. | mirroring-group <i>group-id</i>
monitor-port <i>monitor-port-id</i> | By default, no monitor port is configured for a remote destination group. |

To configure the monitor port for the remote destination group in interface view:

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 3. Configure the current port as the monitor port. | [mirroring-group <i>group-id</i>]
monitor-port | By default, a port does not serve as the monitor port for any remote destination group. |

Configuring the remote probe VLAN for the remote destination group

- Configuration restrictions and guidelines:
 - A VLAN can serve for only one mirroring group.
 - When a VLAN is configured as a remote probe VLAN, use the remote probe VLAN for port mirroring exclusively. Do not configure a VLAN interface for the VLAN or configure any other features for the VLAN.
 - When a VLAN is configured as a remote probe VLAN, you must remove the remote probe VLAN configuration before deleting the VLAN.
 - When you remove the configuration of a remote probe VLAN, an active mirroring group becomes inactive.
- Configuration procedure:

| Step | Command | Remarks |
|-------------------------------------|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the remote probe VLAN. | mirroring-group <i>group-id</i>
remote-probe vlan <i>rprobe-vlan-id</i> | By default, no remote probe VLAN is configured for a remote destination group. |

Assigning the monitor port to the remote probe VLAN

| Step | Command | Remarks |
|--|---|-------------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Enter the interface view of the monitor port. | interface <i>interface-type</i> <i>interface-number</i> | N/A |
| 3. Assign the port to the probe VLAN. | <ul style="list-style-type: none"> For an access port:
port access vlan <i>vlan-id</i> For a trunk port:
port trunk permit vlan <i>vlan-id</i> For a hybrid port:
port hybrid vlan <i>vlan-id</i> { tagged untagged } | Use one of the commands |

For more information about the **port access vlan**, **port trunk permit vlan**, and **port hybrid vlan** commands, see *Layer 2—LAN Switching Command Reference*.

Displaying and maintaining port mirroring

| Task | Command | Remarks |
|--|--|-----------------------|
| Display the configuration of mirroring groups. | display mirroring-group { <i>group-id</i> all local remote-destination remote-source } [{ begin exclude include } <i>regular-expression</i>] | Available in any view |

Port mirroring configuration examples

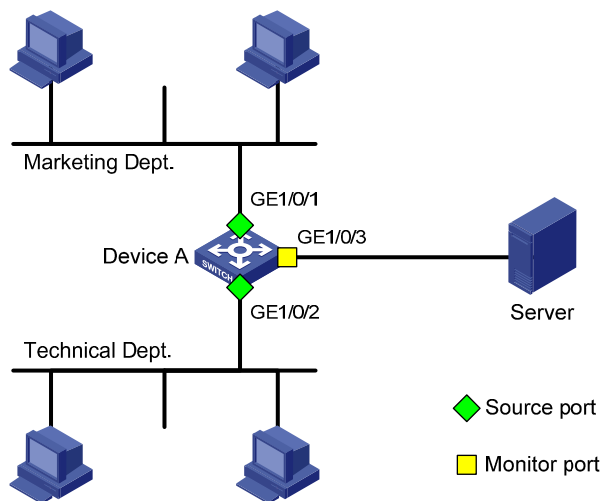

Local port mirroring configuration example

Network requirements

On the network shown in [Figure 34](#):

- Device A connects to the marketing department through GigabitEthernet 1/0/1 and to the technical department through GigabitEthernet 1/0/2. It connects to the server through GigabitEthernet 1/0/3.
- Configure local port mirroring in source port mode to enable the server to monitor the bidirectional traffic of the marketing department and the technical department.

Figure 34 Network diagram

Configuration procedure

1. Create a local mirroring group:

```
# Create local mirroring group 1.
```

```
<DeviceA> system-view
```

```
[DeviceA] mirroring-group 1 local
```

```
# Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as source ports and port GigabitEthernet 1/0/3 as the monitor port.
```

```
[DeviceA] mirroring-group 1 mirroring-port GigabitEthernet 1/0/1 GigabitEthernet
1/0/2 both
[DeviceA] mirroring-group 1 monitor-port GigabitEthernet 1/0/3
# Disable the spanning tree feature on the monitor port GigabitEthernet 1/0/3.
[DeviceA] interface GigabitEthernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] undo stp enable
[DeviceA-GigabitEthernet1/0/3] quit
```

2. Verify the configurations:

Display the configuration of all mirroring groups.

```
[DeviceA] display mirroring-group all
mirroring-group 1:
  type: local
  status: active
  mirroring port:
    GigabitEthernet1/0/1 both
    GigabitEthernet1/0/2 both
  monitor port: GigabitEthernet1/0/3
```

After the configurations are completed, you can monitor all the packets received and sent by the marketing department and the technical department on the server.

Local port mirroring with multiple monitor ports configuration example

Network requirements

As shown in [Figure 35](#), Dept. A, Dept. B, and Dept. C are connected to Device A through ports GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3, respectively. Configure port mirroring to enable all three data monitoring devices, Server A, Server B, and Server C, to monitor both the incoming and outgoing traffic of the three departments.

Figure 35 Network diagram

Configuration procedure

```
# Create remote source mirroring group 1.
<DeviceA> system-view
[DeviceA] mirroring-group 1 remote-source

# Configure GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 as source ports of remote source mirroring group 1.
[DeviceA] mirroring-group 1 mirroring-port gigabitethernet 1/0/1 to gigabitethernet 1/0/3 both

# Configure an unused port (GigabitEthernet 1/0/5 for example) of Device A as the reflector port of remote source mirroring group 1.
[DeviceA] mirroring-group 1 reflector-port GigabitEthernet 1/0/5

# Create VLAN 10 and assign the three ports (GigabitEthernet 1/0/11 through GigabitEthernet 1/0/13) connecting the three data monitoring devices to VLAN 10.
[DeviceA] vlan 10
[DeviceA-vlan10] port gigabitethernet 1/0/11 to gigabitethernet 1/0/13
[DeviceA-vlan10] quit

# Configure VLAN 10 as the remote probe VLAN of remote source mirroring group 1.
[DeviceA] mirroring-group 1 remote-probe vlan 10
```

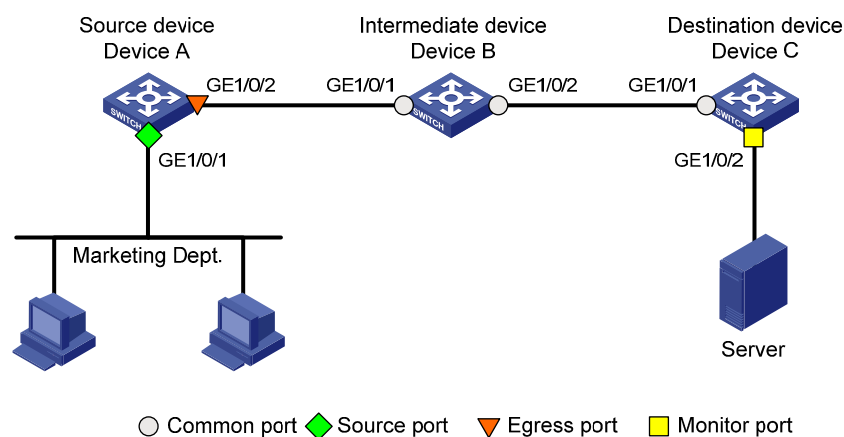

Layer 2 remote port mirroring configuration example

Network requirements

On the Layer 2 network shown in [Figure 36](#):

- Device A connects to the marketing department through GigabitEthernet 1/0/1 and connects to the trunk port GigabitEthernet 1/0/2 of Device B through the trunk port GigabitEthernet 1/0/1.
- Device C connects to the server through GigabitEthernet 1/0/2 and connects to the trunk port GigabitEthernet 1/0/1 of Device B through the trunk port GigabitEthernet 1/0/2.
- Configure Layer 2 remote port mirroring to enable the server to monitor the bidirectional traffic of the marketing department.

Figure 36 Network diagram

Configuration procedure

1. Configure Device A (the source device):

```

# Create a remote source group.
<DeviceA> system-view
[DeviceA] mirroring-group 1 remote-source
# Create VLAN 2 as the remote probe VLAN.
[DeviceA] vlan 2
# Disable MAC address learning for the remote probe VLAN.
[DeviceA-vlan2] mac-address mac-learning disable
[DeviceA-vlan2] quit
# Configure VLAN 2 as the remote probe VLAN of the mirroring group; configure GigabitEthernet
1/0/1 as a source port and GigabitEthernet 1/0/2 as the egress port in the mirroring group.
[DeviceA] mirroring-group 1 remote-probe vlan 2
[DeviceA] mirroring-group 1 mirroring-port GigabitEthernet 1/0/1 both
[DeviceA] mirroring-group 1 monitor-egress GigabitEthernet 1/0/2
# Configure output port GigabitEthernet 1/0/2 as a trunk port to permit the packets of VLAN 2 to
pass through, and disable the spanning tree feature on the port.
[DeviceA] interface GigabitEthernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] quit

```

2. Configure Device B (the intermediate device):

```

# Create VLAN 2 as the remote probe VLAN.
<DeviceB> system-view
[DeviceB] vlan 2
# Disable MAC address learning for the remote probe VLAN.
[DeviceB-vlan2] mac-address mac-learning disable
[DeviceB-vlan2] quit
# Configure GigabitEthernet 1/0/1 as a trunk port that permits the packets of VLAN 2 to pass
through.
[DeviceB] interface GigabitEthernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/1] quit
# Configure GigabitEthernet 1/0/2 as a trunk port that permits the packets of VLAN 2 to pass
through.
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface GigabitEthernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/2] quit

```

3. Configure Device C (the destination device):

```

# Configure GigabitEthernet 1/0/1 as a trunk port that permits the packets of VLAN 2 to pass
through.
<DeviceC> system-view
[DeviceC] interface GigabitEthernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] port link-type trunk

```

```

[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 2
[DeviceC-GigabitEthernet1/0/1] quit
# Create a remote destination group.

[DeviceC-GigabitEthernet1/0/2] quit

```

4. Verify the configurations.

After the configurations are completed, you can monitor all the packets received and sent by the marketing department on the server.

Configuring traffic mirroring

- Both bridge mode (Layer 2) and route mode (Layer 3) Ethernet ports support traffic mirroring. The term "interface" in this chapter collectively refers to these two types of ports. You can use the **port link-mode** command to set an Ethernet port to operate in bridge or route mode (see *Layer 2—LAN Switching Configuration Guide*).
- Only the HP 5500 EI switch series supports configuring traffic mirroring on Layer 3 Ethernet interfaces.

Introduction to traffic mirroring

Traffic mirroring copies the specified packets to the specified destination for packet analyzing and monitoring. It is implemented through QoS policies. In other words, you define traffic classes and configure match criteria to classify packets to be mirrored and then configure traffic behaviors to mirror packets that fit the match criteria to the specified destination. Traffic mirroring allows you to flexibly classify packets by defining match criteria and obtain accurate statistics.

You can configure the traffic to be mirrored to an interface, to a CPU, or to a VLAN.

- Mirroring traffic to an interface copies the matching packets to a destination interface.
- Mirroring traffic to a CPU copies the matching packets to a CPU.

For more information about QoS policies, traffic classes, and traffic behaviors, see *ACL and QoS Configuration Guide*.

Traffic mirroring configuration task list

| Task | Remarks |
|--|---|
| Configuring match criteria | Required |
| Configuring traffic mirroring of different types | Mirroring traffic to a port
Required |
| | Mirroring traffic to the CPU
Perform at least one configuration. |
| Configuring a QoS policy | Required |
| Applying a QoS policy | Apply a QoS policy to a port
Required |
| | Apply a QoS policy to a VLAN
Required |
| | Apply a QoS policy globally
Perform one of these configurations |
| | Apply a QoS policy to the control plane |

Configuring match criteria

| Step | Command | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |

| Step | Command | Remarks |
|---|--|--|
| 2. Create a class and enter class view. | traffic classifier <i>tcl-name</i> [operator { and or }] | By default, no traffic class exists. |
| 3. Configure match criteria. | if-match <i>match-criteria</i> | By default, no match criterion is configured in a traffic class. |

For more information about the **traffic classifier** and **if-match** commands, see *ACL and QoS Command Reference*.

Configuring traffic mirroring of different types

In a traffic behavior, you can configure only one type of traffic mirroring.

Mirroring traffic to a port

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Create a behavior and enter behavior view. | traffic behavior
<i>behavior-name</i> | By default, no traffic behavior exists.
For more information about the traffic behavior command, see <i>ACL and QoS Command Reference</i> . |
| 3. Specify the destination interface for traffic mirroring. | mirror-to interface
<i>interface-type</i>
<i>interface-number</i> | By default, traffic mirroring is not configured in a traffic behavior.
You can specify up to four destination interfaces by executing the mirror-to interface command repeatedly. |

Mirroring traffic to the CPU

| Step | Command | Remarks |
|---|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Create a behavior and enter behavior view. | traffic behavior
<i>behavior-name</i> | By default, no traffic behavior exists.
For more information about the traffic behavior command, see <i>ACL and QoS Command Reference</i> . |
| 3. Mirror traffic to the CPU. | mirror-to cpu | By default, no traffic mirroring is configured in a traffic behavior. |

NOTE:

The CPU refers to the CPU of the device where ports with traffic mirroring configured reside.

Configuring a QoS policy

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Create a policy and enter policy view. | qos policy <i>policy-name</i> | By default, no policy exists. |
| 3. Associate a class with a traffic behavior in the QoS policy. | classifier <i>tcl-name</i> behavior <i>behavior-name</i> | By default, no traffic behavior is associated with a class. |

For more information about the **qos policy** and **classifier behavior** commands, see *ACL and QoS Command Reference*.

Applying a QoS policy

For more information about applying a QoS policy, see *ACL and QoS Configuration Guide*.

Apply a QoS policy to a port

By applying a QoS policy to an interface, you can mirror the traffic in a specified direction on the interface. A policy can be applied to multiple interfaces, but in one direction (inbound or outbound) of an interface, only one policy can be applied.

To apply a QoS policy to a port:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter interface view or port group view. | <ul style="list-style-type: none"> Enter interface view:
interface <i>interface-type</i> <i>interface-number</i> Enter port group view:
port-group manual <i>port-group-name</i> | Use either command
Settings in interface view take effect on the current interface; settings in port group view take effect on all ports in the port group. |
| 3. Apply a policy to the interface, all ports in the port group, or the PVC. | qos apply policy <i>policy-name</i> { inbound outbound } | For more information about the qos apply policy command, see <i>ACL and QoS Command Reference</i> . |

Apply a QoS policy to a VLAN

You can apply a QoS policy to a VLAN to mirror the traffic in a specified direction on all ports in the VLAN.

To apply the QoS policy to a VLAN:

| Step | Command |
|----------------------------------|--|
| 1. Enter system view. | system-view |
| 2. Apply a QoS policy to a VLAN. | qos vlan-policy <i>policy-name</i> vlan <i>vlan-id-list</i> { inbound outbound } |

For more information about the **qos vlan-policy** command, see *ACL and QoS Command Reference*.

Apply a QoS policy globally

You can apply a QoS policy globally to mirror the traffic in a specified direction on all ports.

To apply a QoS policy globally:

| Step | Command |
|---------------------------------|---|
| 1. Enter system view. | system-view |
| 2. Apply a QoS policy globally. | qos apply policy <i>policy-name</i> global { inbound outbound } |

For more information about the **qos apply policy** command, see *ACL and QoS Command Reference*.

Apply a QoS policy to the control plane

You can apply a QoS policy to the control plane to mirror the traffic in the inbound direction of the control plane.

To apply a QoS policy to the control plane:

| Step | Command |
|---|---|
| 1. Enter system view. | system-view |
| 2. Enter control plane view. | control-plane slot <i>slot-number</i> |
| 3. Apply a QoS policy to the control plane. | qos apply policy <i>policy-name</i> inbound |

For more information about the **control-plane** and **qos apply policy** commands, see *ACL and QoS Command Reference*.

Displaying and maintaining traffic mirroring

| Task | Command | Remarks |
|--|---|-----------------------|
| Display user-defined traffic behavior configuration information. | display traffic behavior user-defined
[<i>behavior-name</i>] [[{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display user-defined QoS policy configuration information. | display qos policy user-defined [<i>policy-name</i>]
[classifier <i>tcl-name</i>] [[{ begin exclude include } <i>regular-expression</i>] | Available in any view |

For more information about the **display traffic behavior** and **display qos policy** commands, see *ACL and QoS Command Reference*.

Traffic mirroring configuration example

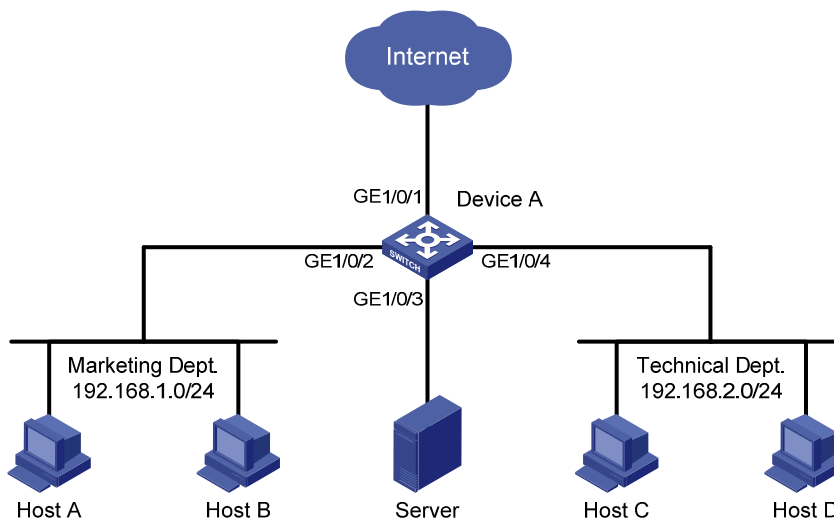

Traffic mirroring configuration example

Network requirements

As shown in Figure 37:

- Different departments of a company use IP addresses on different subnets. The marketing and technology departments use the IP addresses on subnets 192.168.1.0/24 and 192.168.2.0/24 respectively. The working hour of the company is from 8:00 to 18:00 on weekdays.
- Configure traffic mirroring so that the server can monitor the traffic that the technology department sends to access the Internet, and IP traffic that the technology department sends to the marketing department.

Figure 37 Network diagram

Configuration procedure

1. Monitor the traffic sent by the technology department to access the Internet:

Create ACL 3000 to allow packets from the technology department (on subnet 192.168.2.0/24) to access the Internet.

```
<DeviceA> system-view
[DeviceA] acl number 3000
[DeviceA-acl-adv-3000] rule permit tcp source 192.168.2.0 0.0.0.255 destination-port eq www
[DeviceA-acl-adv-3000] quit
```

Create traffic class **tech_c**, and configure the match criterion as ACL 3000.

```
[DeviceA] traffic classifier tech_c
[DeviceA-classifier-tech_c] if-match acl 3000
[DeviceA-classifier-tech_c] quit
```

Create traffic behavior **tech_b**, and configure the action of mirroring traffic to port GigabitEthernet 1/0/3.

```
[DeviceA] traffic behavior tech_b
[DeviceA-behavior-tech_b] mirror-to interface GigabitEthernet 1/0/3
```

```
[DeviceA-behavior-tech_b] quit
# Create QoS policy tech_p, and associate traffic class tech_c with traffic behavior tech_b in the
QoS policy.
[DeviceA] qos policy tech_p
[DeviceA-qospolicy-tech_p] classifier tech_c behavior tech_b
[DeviceA-qospolicy-tech_p] quit
# Apply QoS policy tech_p to the outgoing packets of GigabitEthernet 1/0/1.
[DeviceA] interface GigabitEthernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] qos apply policy tech_p outbound
[DeviceA-GigabitEthernet1/0/1] quit
```

2. Monitor the traffic that the technology department sends to the marketing department:

```
# Configure a time range named work to cover the time from 8: 00 to 18: 00 in working days.
[DeviceA] time-range work 8:0 to 18:0 working-day
# Create ACL 3001 to allow packets sent from the technology department (on subnet
192.168.2.0/24) to the marketing department (on subnet 192.168.1.0/24).
[DeviceA] acl number 3001
[DeviceA-acl-adv-3001] rule permit ip source 192.168.2.0 0.0.0.255 destination
192.168.1.0 0.0.0.255 time-range work
[DeviceA-acl-adv-3001] quit
# Create traffic class mkt_c, and configure the match criterion as ACL 3001.
[DeviceA] traffic classifier mkt_c
[DeviceA-classifier-mkt_c] if-match acl 3001
[DeviceA-classifier-mkt_c] quit
# Create traffic behavior mkt_b, and configure the action of mirroring traffic to port
GigabitEthernet 1/0/3.
[DeviceA] traffic behavior mkt_b
[DeviceA-behavior-mkt_b] mirror-to interface GigabitEthernet 1/0/3
[DeviceA-behavior-mkt_b] quit
# Create QoS policy mkt_p, and associate traffic class mkt_c with traffic behavior mkt_b in the
QoS policy.
[DeviceA] qos policy mkt_p
[DeviceA-qospolicy-mkt_p] classifier mkt_c behavior mkt_b
[DeviceA-qospolicy-mkt_p] quit
# Apply QoS policy mkt_p to the outgoing packets of GigabitEthernet 1/0/2.
[DeviceA] interface GigabitEthernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] qos apply policy mkt_p outbound
```

3. Verify the configurations.

After completing the configurations, through the server, you can monitor all traffic sent by the technology department to access the Internet and the IP traffic that the technology department sends to the marketing department during working hours.

Configuring NQA

Overview

Network Quality Analyzer (NQA) can perform various types of tests and collect network performance and service quality parameters such as delay jitter, time for establishing a TCP connection, time for establishing an FTP connection, and file transfer rate.

With the NQA test results, you can diagnose and locate network faults, be aware of network performance in time and take proper actions to correct any problems.

NQA features

Supporting multiple test types

Ping uses only the Internet Control Message Protocol (ICMP) to test the reachability of the destination host and the round-trip time. As an enhancement to ping, NQA supports more test types and functions.

NQA supports 11 test types: ICMP echo, DHCP, DNS, FTP, HTTP, UDP jitter, SNMP, TCP, UDP echo, voice, and DLSw.

NQA enables the client to send probe packets of different test types to detect the protocol availability and response time of the peer. Test results help you understand network performance.

Supporting the collaboration function

Collaboration is implemented by establishing reaction entries to monitor the detection results of NQA probes. If the number of consecutive probe failures reaches a limit, NQA informs the track module of the detection result, and the track module triggers other application modules to take predefined.

Figure 38 Implement collaboration

The collaboration comprises the following parts: the application modules, the track module, and the detection modules.

- A detection module monitors objects, such as the link status, and network performance, and informs the track module of detection results.
- Upon the detection results, the track module changes the status of the track entry and informs the associated application module. The track module works between the application modules and the detection modules. It hides the differences among detection modules from application modules.

- The application module takes actions when the tracked object changes its state.

The following describes how a static route is monitored through collaboration.

1. NQA monitors the reachability to 192.168.0.88.
2. When 192.168.0.88 becomes unreachable, NQA notifies the track module of the change.
3. The track module notifies the state change to the static routing module
4. The static routing module sets the static route as invalid.

For more information about collaboration and the track module, see *High Availability Configuration Guide*.

Supporting threshold monitoring

NQA supports threshold monitoring for performance parameters such as average delay jitter and packet round-trip time. The performance parameters to be monitored are monitored elements. NQA monitors threshold violations for a monitored element, and reacts to certain measurement conditions (for example, sending trap messages to the network management server). This helps network administrators understand the network service quality and network performance.

- Monitored elements

[Table 8](#) describes the monitored elements and the NQA test types in which the elements can be monitored.

Table 8 Monitored elements and NQA test types

| Monitored elements | Test type supported |
|---|--|
| Probe duration | Tests excluding UDP jitter test and voice test |
| Count of probe failures | Tests excluding UDP jitter test and voice test |
| Packet round-trip time | UDP jitter test and voice test |
| Count of discarded packets | UDP jitter test and voice test |
| One-way delay jitter (source-to-destination and destination-to-source) | UDP jitter test and voice test |
| One-way delay (source-to-destination and destination-to-source) | UDP jitter test and voice test |
| Calculated Planning Impairment Factor (ICPIF) (see " Configuring voice tests ") | Voice test |
| Mean Opinion Scores (MOS) (see " Configuring voice tests ") | Voice test |

- Threshold types

The following threshold types are supported:

- **average**—Monitors the average value of monitored data in a test. If the average value in a test exceeds the upper threshold or goes below the lower threshold, a threshold violation occurs. For example, you can monitor the average probe duration in a test.
- **accumulate**—Monitors total number of times the monitored data violates the threshold in a test. If the total number of times reaches or exceeds a specific value, a threshold violation occurs.
- **consecutive**—Monitors the number of consecutive times the monitored data violates the threshold since the test group starts. If the monitored data violates the threshold consecutively for a specific number of times, a threshold violation occurs.

The counting for the average or accumulate threshold type is performed per test, but the counting for the consecutive type is performed after the test group starts.

- Triggered actions

The following actions may be triggered:

- **none**—NQA only records events for terminal display; it does not send trap information to the network management server. NQA DNS tests do not support the action of sending trap messages. The action to be triggered in DNS tests can only be the default one, **none**.
- **trap-only**—NQA records events and sends trap messages to the network management server.

- Reaction entry

In a reaction entry, a monitored element, a threshold type, and the action to be triggered are configured to implement threshold monitoring.

The state of a reaction entry can be invalid, over-threshold, or below-threshold, using the following workflow:

- Before an NQA test group starts, the reaction entry is in the state of invalid.
- After each test or probe, threshold violations are counted according to the threshold type and range configured in the entry. If the threshold is violated consecutively or accumulatively for a specific number of times, the state of the entry is set to over-threshold; otherwise, the state of the entry is set to below-threshold.

If the action to be triggered is configured as **trap-only** for a reaction entry, when the state of the entry changes, a trap message is generated and sent to the network management server.

NQA concepts

Test group

An NQA test group specifies test parameters including the test type, destination address, and destination port. Each test group is uniquely identified by an administrator name and operation tag. You can configure and schedule multiple NQA test groups to test different objects.

Test and probe

After the NQA test group starts, tests are performed at a specific interval. During each test, a specific number of probe operations are performed. Both the test interval and the number of probe operations per test are configurable. But only one probe operation is performed during one voice test.

In different test types, probe operation has the following different meanings:

- During a TCP or DLSw test, one probe operation means setting up one connection.
- During a UDP jitter or a voice test, one probe operation means continuously sending a specific number of probe packets. The number of probe packets is configurable.
- During an FTP, HTTP, DHCP, or DNS test, one probe operation means uploading or downloading a file, obtaining a web page, obtaining an IP address through DHCP, or translating a domain name to an IP address.
- During an ICMP echo or UDP echo test, one probe operation means sending an ICMP echo request or a UDP packet.
- During an SNMP test, one probe operation means sending one SNMPv1 packet, one SNMPv2C packet, and one SNMPv3 packet.

NQA client and server

A device with NQA test groups configured is an NQA client, and the NQA client initiates NQA tests. An NQA server makes responses to probe packets destined to the specified destination address and port number.

Figure 39 Relationship between the NQA client and NQA server

Not all test types require the NQA server. Only the TCP, UDP echo, UDP jitter, or voice test requires both the NQA client and server, as shown in [Figure 39](#).

You can create multiple TCP or UDP listening services on the NQA server. Each listens to a specific destination address and port number. Make sure the destination IP address and port number for a listening service on the server are the same as those configured for the test group on the NQA client. Each listening service must be unique on the NQA server.

NQA probe operation procedure

An NQA probe operation involves the following steps:

1. The NQA client constructs probe packets for the specified type of NQA test, and sends them to the peer device.
2. Upon receiving the probe packets, the peer sends back responses with timestamps.
3. The NQA client computes the network performance and service quality parameters, such as the packet loss rate and round-trip time based on the received responses.

NQA configuration task list

| Task | Remarks |
|--|---|
| Configuring the NQA server | Required for TCP, UDP echo, UDP jitter, and voice tests |

To perform NQA tests successfully, perform the following configurations on the NQA client:

1. Enable the NQA client.
2. Create a test group and configure test parameters. The test parameters may vary with test types.
3. Configure a schedule for the NQA test group.

Complete these tasks to configure NQA client:

| Task | Remarks | |
|---|---|----------------------------|
| Enabling the NQA client | Required. | |
| Creating an NQA test group | Required. | |
| Configuring an NQA test group | Configuring ICMP echo tests | Required. |
| | Configuring DHCP tests | Use any of the approaches. |
| | Configuring DNS tests | |

| Task | Remarks |
|---|-----------|
| Configuring FTP tests | |
| Configuring HTTP tests | |
| Configuring UDP jitter tests | |
| Configuring SNMP tests | |
| Configuring TCP tests | |
| Configuring UDP echo tests | |
| Configuring voice tests | |
| Configuring DLSw tests | |
| Configuring the collaboration function | Optional. |
| Configuring threshold monitoring | Optional. |
| Configuring the NQA statistics collection function | Optional. |
| Configuring the history records saving function | Optional. |
| Configuring optional parameters for an NQA test group | Optional. |
| Configuring a schedule for an NQA test group | Required. |

Configuring the NQA server

To perform TCP, UDP echo, UDP jitter, or voice tests, configure the NQA server on the peer device. The NQA server responds to the probe packets sent from the NQA client by listening to the specified destination address and port number.

To configure the NQA server:

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable the NQA server. | nqa server enable | Disabled by default. |
| 3. Configure the listening service. | nqa server { tcp-connect udp-echo } ip-address port-number | The destination IP address and port number must be the same as those configured on the NQA client. A listening service must be unique on the NQA server. |
| 4. Configure the ToS value in the packets sent by the TCP or UDP listening service on the NQA server. | nqa server { tcp-connect udp-echo } tos tos | Optional.
By default, the ToS value is 0. |

Enabling the NQA client

Configurations on the NQA client take effect only when the NQA client is enabled.

To enable the NQA client:

| Step | Command | Remarks |
|---------------------------|-------------------------|----------------------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Enable the NQA client. | nqa agent enable | Optional.
Enabled by default. |

Creating an NQA test group

Create an NQA test group before you configure NQA tests.

To create an NQA test group:

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Create an NQA test group, and enter the NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | In the NQA test group view, you can specify the test type
You can use the nqa entry command to enter the test type view of an NQA test group with test type configured. |

Configuring an NQA test group

Configuring ICMP echo tests

ICMP echo tests of an NQA test group uses ICMP echo response information to test reachability of a destination host. An ICMP echo test has the same function as the **ping** command but provides more output information. In addition, you can specify the next hop for ICMP echo tests. ICMP echo tests are used to locate connectivity problems in a network.

NQA ICMP echo tests are not supported in IPv6 networks. To test the reachability of an IPv6 address, use the **ping ipv6** command. For more information about the command, see *Network Management and Monitoring Command Reference*.

To configure ICMP echo tests:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as ICMP echo, and enter test type view. | type icmp-echo | N/A |
| 4. Configure the destination address of ICMP echo requests. | destination ip <i>ip-address</i> | By default, no destination IP address is configured. |
| 5. Configure the size of the data field in each ICMP echo request. | data-size <i>size</i> | Optional.
100 bytes by default. |

| Step | Command | Remarks |
|---|---|--|
| 6. Configure the string to be filled in the data field of each ICMP echo request. | data-fill <i>string</i> | Optional.
By default, the string is the hexadecimal number 00010203040506070809. |
| 7. Apply ICMP echo tests to the specified VPN. | vpn-instance
<i>vpn-instance-name</i> | Optional.
By default, ICMP echo tests apply to the public network.
Only the HP 5500 EI Switch Series supports VPN instances. |
| 8. Configure the source interface for ICMP echo requests. | source interface
<i>interface-type</i>
<i>interface-number</i> | Optional.
By default, no source interface is configured for probe packets.
The requests take the IP address of the source interface as their source IP address when no source IP address is specified.
The specified source interface must be up; otherwise, no ICMP echo requests can be sent out. |
| 9. Configure the source IP address of ICMP echo requests. | source ip <i>ip-address</i> | Optional.
By default, no source IP address is configured.
If you configure both the source ip command and the source interface command, the source ip command takes effect.
The source IP address must be the IP address of a local interface. The local interface must be up; otherwise, no ICMP echo requests can be sent out. |
| 10. Configure the next hop IP address of ICMP echo requests. | next-hop <i>ip-address</i> | Optional.
By default, no next hop IP address is configured. |
| 11. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring DHCP tests

DHCP tests of an NQA test group are used to test if a DHCP server is on the network, and the time for the DHCP server to respond to a client request and assign an IP address to the client.

Before you start DHCP tests, configure the DHCP server. If the NQA (DHCP client) and the DHCP server are not in the same network segment, configure a DHCP relay. For the configuration of DHCP server and DHCP relay, see *Layer 3—IP Services Configuration Guide*.

The interface that performs DHCP tests does not change its IP address. A DHCP test only simulates address allocation in DHCP.

When a DHCP test completes, the NQA client sends a DHCP-RELEASE packet to release the obtained IP address.

To configuring DHCP tests:

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as DHCP, and enter test type view. | type dhcp | N/A |
| 4. Specify an interface to perform DHCP tests. | operation interface
<i>interface-type</i>
<i>interface-number</i> | By default, no interface is configured to perform DHCP tests.
The specified interface must be up; otherwise, no probe packets can be sent out. |
| 5. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring DNS tests

DNS tests of an NQA test group are used to test whether the NQA client can translate a domain name into an IP address through a DNS server and test the time required for resolution.

Before you start DNS tests, configure the mapping between a domain name and an IP address on a DNS server.

A DNS test simulates the domain name resolution. It does not save the mapping between the domain name and the IP address.

To configure DNS tests:

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i> <i>operation-tag</i> | N/A |
| 3. Configure the test type as DNS, and enter test type view. | type dns | N/A |
| 4. Specify the IP address of the DNS server as the destination address of DNS packets. | destination ip <i>ip-address</i> | By default, no destination IP address is configured. |
| 5. Configure the domain name that needs to be translated. | resolve-target <i>domain-name</i> | By default, no domain name is configured. |
| 6. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring FTP tests

FTP tests of an NQA test group are used to test the connection between the NQA client and an FTP server and the time required for the FTP client to transfer a file to or download a file from the FTP server.

Before you start FTP tests, configure the FTP server. For example, configure a username and password that are used to log in to the FTP server. For more information about FTP server configuration, see *Fundamentals Configuration Guide*.

Follow these guidelines when you configure FTP tests:

- When you execute the **put** command, the NQA client creates a file named *file-name* of fixed size on the FTP server. The *file-name* argument does not represent any file on the NQA client. When you execute the **get** command, the client does not save the files obtained from the FTP server.
- When you get a file that does not exist on the FTP server, FTP tests fail.
- When you perform an FTP test, use a small file and set a long NQA probe timeout time. A big file or short probe timeout time may result in probe timeout.

To configure FTP tests:

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as FTP, and enter test type view. | type ftp | N/A |
| 4. Specify the IP address of the FTP server as the destination address of FTP request packets. | destination ip <i>ip-address</i> | By default, no destination IP address is configured. |
| 5. Configure the source IP address of FTP request packets. | source ip <i>ip-address</i> | By default, no source IP address is specified.
The source IP address must be the IP address of a local interface. The local interface must be up; otherwise, no FTP requests can be sent out. |
| 6. Configure the operation type. | operation { get put } | Optional.
By default, the operation type for the FTP is get , which means obtaining files from the FTP server. |
| 7. Configure a login username. | username <i>name</i> | By default, no login username is configured. |
| 8. Configure a login password. | password [cipher simple] <i>password</i> | By default, no login password is configured. |
| 9. Specify a file to be transferred between the FTP server and the FTP client. | filename <i>file-name</i> | By default, no file is specified. |
| 10. Set the data transmission mode for FTP tests. | mode { active passive } | Optional.
active by default. |

| Step | Command | Remarks |
|------------------------------------|---|-----------|
| 11. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring HTTP tests

HTTP tests of an NQA test group are used to test the connection between the NQA client and an HTTP server, and the time required to obtain data from the HTTP server. HTTP tests enable you to detect the connectivity and performance of the HTTP server. The TCP port must be port 80 on the HTTP server for NQA HTTP tests.

Before you start HTTP tests, configure the HTTP server.

To configure HTTP tests:

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as HTTP, and enter test type view. | type http | N/A |
| 4. Configure the IP address of the HTTP server as the destination address of HTTP request packets. | destination ip <i>ip-address</i> | By default, no destination IP address is configured. |
| 5. Configure the source IP address of request packets. | source ip <i>ip-address</i> | Optional.
By default, no source IP address is specified.
The source IP address must be the IP address of a local interface. The local interface must be up; otherwise, no probe packets can be sent out. |
| 6. Configure the operation type. | operation { get post } | Optional.
By default, the operation type for the HTTP is get , which means obtaining data from the HTTP server. |
| 7. Configure the website that an HTTP test visits. | url <i>url</i> | N/A |
| 8. Configure the HTTP version used in HTTP tests. | http-version v1.0 | Optional.
By default, HTTP 1.0 is used. |
| 9. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring UDP jitter tests

! **IMPORTANT:**

Do not perform NQA UDP jitter tests on known ports, ports from 1 to 1023. Otherwise, UDP jitter tests might fail or the corresponding services of this port might be unavailable.

Real-time services such as voice and video have high requirements on delay jitters. UDP jitter tests of an NQA test group obtain uni/bi-directional delay jitters. The test results help you verify whether a network can carry real-time services.

A UDP jitter test performs the following procedure:

1. The source sends packets to the destination port at regular intervals.
2. The destination affixes a time stamp to each packet that it receives, and then sends the packet back to the source.
3. Upon receiving the response, the source calculates the delay jitter, which reflects network performance. Delay refers to the amount of time it takes a packet to be transmitted from source to destination or from destination to source. Delay jitter is the delay variation over time.

Configuration prerequisites

UDP jitter tests require cooperation between the NQA server and the NQA client. Before you start UDP jitter tests, configure UDP listening services on the NQA server. For more information about UDP listening service configuration, see "[Configuring the NQA server.](#)"

Configuration procedure

To configure UDP jitter tests:

| Step | Command | Remarks |
|--|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as UDP jitter, and enter test type view. | type udp-jitter | N/A |
| 4. Configure the destination address of UDP packets. | destination ip <i>ip-address</i> | By default, no destination IP address is configured.
The destination IP address must be the same as that of the listening service on the NQA server. |
| 5. Configure the destination port of UDP packets. | destination port
<i>port-number</i> | By default, no destination port number is configured.
The destination port must be the same as that of the listening service on the NQA server. |
| 6. Specify the source port number of UDP packets. | source port <i>port-number</i> | Optional.
By default, no source port number is specified. |
| 7. Configure the size of the data field in each UDP packet. | data-size <i>size</i> | Optional.
100 bytes by default. |
| 8. Configure the string to be filled in the data field of each probe packet. | data-fill <i>string</i> | Optional.
By default, the string is the hexadecimal number 00010203040506070809. |

| Step | Command | Remarks |
|---|---|--|
| 9. Configure the number of probe packets to be sent during each UDP jitter probe operation. | probe packet-number
<i>packet-number</i> | Optional.
10 by default. |
| 10. Configure the interval for sending probe packets during each UDP jitter probe operation. | probe packet-interval
<i>packet-interval</i> | Optional.
20 milliseconds by default. |
| 11. Configure the interval the NQA client must wait for a response from the server before it regards the response is timed out. | probe packet-timeout
<i>packet-timeout</i> | Optional.
3000 milliseconds by default. |
| 12. Configure the source IP address for UDP jitter packets. | source ip <i>ip-address</i> | Optional.
By default, no source IP address is specified.
The source IP address must be the IP address of a local interface. The local interface must be up; otherwise, no probe packets can be sent out. |
| 13. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

NOTE:

The **probe count** command specifies the number of probe operations during one UDP jitter test. The **probe packet-number** command specifies the number of probe packets sent in each UDP jitter probe operation.

Configuring SNMP tests

SNMP tests of an NQA test group are used to test the time the NQA client takes to send an SNMP packet to the SNMP agent and receive a response.

Before you start SNMP tests, enable the SNMP agent function on the device that serves as an SNMP agent. For more information about SNMP agent configuration, see "Configuring SNMP."

To configure SNMP tests:

| Step | Command | Remarks |
|---|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as SNMP, and enter test type view. | type snmp | N/A |
| 4. Configure the destination address of SNMP packets. | destination ip <i>ip-address</i> | By default, no destination IP address is configured. |

| Step | Command | Remarks |
|---|---|--|
| 5. Specify the source port of SNMP packets. | source port <i>port-number</i> | Optional.
By default, no source port number is specified. |
| 6. Configure the source IP address of SNMP packets. | source ip <i>ip-address</i> | Optional.
By default, no source IP address is specified.
The source IP address must be the IP address of a local interface. The local interface must be up; otherwise, no probe packets can be sent out. |
| 7. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring TCP tests

TCP tests of an NQA test group are used to test the TCP connection between the NQA client and a port on the NQA server and the time for setting up a connection. The test result helps you evaluate the availability and performance of the services provided by the port on the server.

TCP tests require cooperation between the NQA server and the NQA client. Before you start TCP tests, configure a TCP listening service on the NQA server. For more information about the TCP listening service configuration, see "[Configuring the NQA server.](#)"

To configure TCP tests:

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as TCP, and enter test type view. | type tcp | N/A |
| 4. Configure the destination address of TCP probe packets. | destination ip <i>ip-address</i> | By default, no destination IP address is configured.
The destination address must be the same as the IP address of the listening service configured on the NQA server. |
| 5. Configure the destination port of TCP probe packets. | destination port
<i>port-number</i> | By default, no destination port number is configured.
The destination port number must be the same as that of the listening service on the NQA server. |
| 6. Configure the source IP address of TCP probe packets. | source ip <i>ip-address</i> | Optional.
By default, no source IP address is specified.
The source IP address must be the IP address of a local interface. The local interface must be up; otherwise, no probe packets can be sent out. |
| 7. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring UDP echo tests

UDP echo tests of an NQA test group are used to test the connectivity and round-trip time of a UDP packet from the client to the specified UDP port on the NQA server.

UDP echo tests require cooperation between the NQA server and the NQA client. Before you start UDP echo tests, configure a UDP listening service on the NQA server. For more information about the UDP listening service configuration, see "[Configuring the NQA server.](#)"

To configure UDP echo tests:

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as UDP echo, and enter test type view. | type udp-echo | N/A |
| 4. Configure the destination address of UDP packets. | destination ip <i>ip-address</i> | By default, no destination IP address is configured.
The destination address must be the same as the IP address of the listening service configured on the NQA server. |
| 5. Configure the destination port of UDP packets. | destination port <i>port-number</i> | By default, no destination port number is configured.
The destination port number must be the same as that of the listening service on the NQA server. |
| 6. Configure the size of the data field in each UDP packet. | data-size <i>size</i> | Optional.
100 bytes by default. |
| 7. Configure the string to be filled in the data field of each UDP packet. | data-fill <i>string</i> | Optional.
By default, the string is the hexadecimal number 00010203040506070809. |
| 8. Specify the source port of UDP packets. | source port <i>port-number</i> | Optional.
By default, no source port number is specified. |
| 9. Configure the source IP address of UDP packets. | source ip <i>ip-address</i> | Optional.
By default, no source IP address is specified.
The source IP address must be that of an interface on the device and the interface must be up; otherwise, no probe packets can be sent out. |
| 10. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring voice tests

ⓘ **IMPORTANT:**

Do not perform voice tests on known ports, ports from 1 to 1023. Otherwise, the NQA test might fail or the corresponding services of these ports might be unavailable.

Voice tests of an NQA test group are used to test voice over IP (VoIP) network status, and collect VoIP network parameters so that users can adjust the network.

A voice test performs the following procedure:

1. The source (NQA client) sends voice packets of G.711 A-law, G.711 μ -law or G.729 A-law codec type at regular intervals to the destination (NQA server).
2. The destination affixes a time stamp to each voice packet that it receives and then sends it back to the source.
3. Upon receiving the packet, the source calculates results, such as the delay jitter and one-way delay based on the packet time stamps. The statistics reflect network performance.

Voice test result also includes the following parameters that reflect VoIP network performance:

- Calculated Planning Impairment Factor (ICPIF)—Measures impairment to voice quality in a VoIP network. It is decided by packet loss and delay. A higher value represents a lower service quality.
- Mean Opinion Scores (MOS)—A MOS value can be evaluated by using the ICPIF value, in the range of 1 to 5. A higher value represents a higher quality of a VoIP network.

The evaluation of voice quality depends on users' tolerance for voice quality, which should be taken into consideration. For users with higher tolerance for voice quality, use the **advantage-factor** command to configure the advantage factor. When the system calculates the ICPIF value, this advantage factor is subtracted to modify ICPIF and MOS values, so objective and subjective factors are both considered when you evaluate voice quality.

Configuration prerequisites

- Voice tests require cooperation between the NQA server and the NQA client. Before you start voice tests, configure a UDP listening service on the NQA server. For more information about UDP listening service configuration, see "[Configuring the NQA server.](#)"
- Only one probe operation is performed in one voice test.

Configuration procedure

To configure voice tests:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as voice, and enter test type view. | type voice | N/A |
| 4. Configure the destination address of voice probe packets. | destination ip <i>ip-address</i> | By default, no destination IP address is configured for a test operation.
The destination IP address must be the same as that of the listening service on the NQA server. |

| Step | Command | Remarks |
|--|---|--|
| 5. Configure the destination port of voice probe packets. | destination port <i>port-number</i> | By default, no destination port number is configured.
The destination port must be the same as that of the listening service on the NQA server. |
| 6. Configure the codec type. | codec-type { g711a g711u g729a } | Optional.
By default, the codec type is G.711 A-law. |
| 7. Configure the advantage factor for calculating MOS and ICPIF values. | advantage-factor <i>factor</i> | Optional.
By default, the advantage factor is 0. |
| 8. Specify the source IP address of probe packets. | source ip <i>ip-address</i> | Optional.
By default, no source IP address is specified.
The source IP address must be the IP address of a local interface. The local interface must be up; otherwise, no probe packets can be sent out. |
| 9. Specify the source port number of probe packets. | source port <i>port-number</i> | Optional.
By default, no source port number is specified. |
| 10. Configure the size of the data field in each probe packet. | data-size <i>size</i> | Optional.
By default, the probe packet size depends on the codec type. The default packet size is 172 bytes for G.711A-law and G.711 μ -law codec type, and 32 bytes for G.729 A-law codec type. |
| 11. Configure the string to be filled in the data field of each probe packet. | data-fill <i>string</i> | Optional.
By default, the string is the hexadecimal number 00010203040506070809. |
| 12. Configure the number of probe packets to be sent during each voice probe operation. | probe packet-number <i>packet-number</i> | Optional.
1000 by default. |
| 13. Configure the interval for sending probe packets during each voice probe operation. | probe packet-interval <i>packet-interval</i> | Optional.
20 milliseconds by default. |
| 14. Configure the interval the NQA client must wait for a response from the server before it regards the response times out. | probe packet-timeout <i>packet-timeout</i> | Optional.
5000 milliseconds by default. |
| 15. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring DLSw tests

DLSw tests of an NQA test group are used to test the response time of a DLSw device.

Before you start DLSw tests, enable the DLSw function on the peer device.

To configure DLSw tests:

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Configure the test type as DLSw, and enter test type view. | type dlsw | N/A |
| 4. Configure the destination address of probe packets. | destination ip <i>ip-address</i> | By default, no destination IP address is configured. |
| 5. Configure the source IP address of probe packets. | source ip <i>ip-address</i> | Optional.
By default, no source IP address is specified.
The source IP address must be the IP address of a local interface. The local interface must be up; otherwise, no probe packets can be sent out. |
| 6. Configure optional parameters. | See " Configuring optional parameters for an NQA test group " | Optional. |

Configuring the collaboration function

Collaboration is implemented by establishing reaction entries to monitor the detection results of a test group. If the number of consecutive probe failures reaches the threshold, the configured action is triggered.

To configure the collaboration function:

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Enter test type view of the test group. | type { dhcp dlsw dns ftp http icmp-echo snmp tcp udp-echo } | The collaboration function is not supported in UDP jitter and voice tests. |
| 4. Configure a reaction entry. | reaction <i>item-number</i>
checked-element probe-fail
threshold-type consecutive
<i>consecutive-occurrences</i>
action-type trigger-only | Not created by default.
You cannot modify the content of an existing reaction entry. |
| 5. Exit to system view. | quit | N/A |
| 6. Configure a track entry and associate it with the reaction entry of the NQA test group. | track <i>entry-number</i> nqa entry
<i>admin-name operation-tag</i>
reaction <i>item-number</i> | Not created by default. |

Configuring threshold monitoring

Configuration prerequisites

Before you configure threshold monitoring, complete the following tasks:

- Configure the destination address of the trap message by using the **snmp-agent target-host** command. For more information about the **snmp-agent target-host** command, see *Network Management and Monitoring Command Reference*.
- Create an NQA test group and configure the related parameters.

Configuration guidelines

Follow these guidelines when you configure threshold monitoring:

- NQA DNS tests do not support the action of sending trap messages. The action to be triggered in DNS tests can only be the default one, **none**.
- Only the **test-complete** keyword is supported for the **reaction trap** command in a voice test.

Configuration procedure

To configure threshold monitoring:

| Step | Command | Remarks |
|--|---|---------|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name operation-tag</i> | N/A |
| 3. Enter test type view of the test group. | type { dhcp dls w dns ftp http icmp-echo snmp tcp udp-echo udp-jitter voice } | N/A |

| Step | Command | Remarks |
|------------------------------------|--|---|
| 4. Configure threshold monitoring. | <ul style="list-style-type: none"> • Enable sending traps to the network management server under specified conditions:
reaction trap { probe-failure <i>consecutive-probe-failures</i> test-complete test-failure <i>cumulate-probe-failures</i> } • Configure a reaction entry for monitoring the probe duration of a test (not supported in UDP jitter and voice tests):
reaction <i>item-number</i> checked-element probe-duration threshold-type { accumulate <i>accumulate-occurrences</i> average consecutive <i>consecutive-occurrences</i> } threshold-value <i>upper-threshold lower-threshold</i> [action-type { none trap-only }] • Configure a reaction entry for monitoring the probe failure times (not supported in UDP jitter and voice tests):
reaction <i>item-number</i> checked-element probe-fail threshold-type { accumulate <i>accumulate-occurrences</i> consecutive <i>consecutive-occurrences</i> } [action-type { none trap-only }] • Configure a reaction entry for monitoring packet round-trip time (only supported in UDP jitter and voice tests):
reaction <i>item-number</i> checked-element rtt threshold-type { accumulate <i>accumulate-occurrences</i> average } threshold-value <i>upper-threshold lower-threshold</i> [action-type { none trap-only }] • Configure a reaction entry for monitoring the packet loss in each test (only supported in UDP jitter and voice tests):
reaction <i>item-number</i> checked-element packet-loss threshold-type accumulate <i>accumulate-occurrences</i> [action-type { none trap-only }] • Configure a reaction entry for monitoring one-way delay jitter (only supported in UDP jitter and voice tests):
reaction <i>item-number</i> checked-element { jitter-ds jitter-sd } threshold-type { accumulate <i>accumulate-occurrences</i> average } threshold-value <i>upper-threshold lower-threshold</i> [action-type { none trap-only }] • Configure a reaction entry for monitoring the one-way delay (only supported in UDP jitter and voice tests):
reaction <i>item-number</i> checked-element { owd-ds owd-sd } threshold-value <i>upper-threshold lower-threshold</i> • Configure a reaction entry for monitoring the ICPIF value (only supported in voice tests):
reaction <i>item-number</i> checked-element icpif threshold-value <i>upper-threshold lower-threshold</i> [action-type { none trap-only }] • Configure a reaction entry for monitoring the MOS value (only supported in voice tests):
reaction <i>item-number</i> checked-element mos threshold-value <i>upper-threshold lower-threshold</i> [action-type { none trap-only }] | <p>Configure to send traps.</p> <p>No traps are sent to the network management server by default.</p> |

Configuring the NQA statistics collection function

NQA groups tests completed in a time period for a test group, and calculates the test result statistics. The statistics form a statistics group. To view information about the statistics groups, use the **display nqa statistics** command. To set the interval for collecting statistics, use the **statistics interval** command.

When the number of statistics groups kept reaches the upper limit and a new statistics group is to be saved, the oldest statistics group is deleted. To set the maximum number of statistics groups that can be kept, use the **statistics max-group** command.

A statistics group is formed after the last test is completed within the specified interval. Statistics groups have an aging mechanism. A statistics group is deleted when its hold time expires. To set the hold time of statistics groups for a test group, use the **statistics hold-time** command.

Follow these guidelines when you configure the NQA statistics collection function:

- The NQA statistics collection function is not supported in DHCP tests.
- If you use the **frequency** command to set the frequency between two consecutive tests to 0, only one test is performed, and no statistics group information is collected.

To configure the NQA statistics collection function:

| Step | Command | Remarks |
|--|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name operation-tag</i> | N/A |
| 3. Enter test type view of the test group. | type { <i>dls</i> w <i>dns</i> <i>ftp</i> <i>http</i> <i>icmp-echo</i> <i>snmp</i> <i>tcp</i> <i>udp-echo</i> <i>udp-jitter</i> <i>voice</i> } | N/A |
| 4. Configure the interval for collecting the statistics of test results. | statistics interval <i>interval</i> | Optional.
60 minutes by default. |
| 5. Configure the maximum number of statistics groups that can be kept. | statistics max-group <i>number</i> | Optional.
2 by default.
To disable collecting NQA statistics, set the maximum number to 0. |
| 6. Configure the hold time of statistics groups. | statistics hold-time <i>hold-time</i> | Optional.
120 minutes by default. |

Configuring the history records saving function

The history records saving function enables the system to save the history records of NQA tests. To view the history records of a test group, use the **display nqa history** command.

The configuration task also allows you to configure the following elements:

- **Lifetime of the history records**—The records are removed when the lifetime is reached.
- **The maximum number of history records that can be saved in a test group**—If the number of history records in a test group exceeds the maximum number, the earliest history records are removed.

To configure the history records saving function of an NQA test group:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Enter NQA test type view. | type { dhcp dls w dns ftp
 http icmp-echo snmp
tcp udp-echo udp-jitter
voice } | N/A |
| 4. Enable the saving of the history records of the NQA test group. | history-record enable | By default, history records of the NQA test group are not saved. |
| 5. Set the lifetime of the history records in an NQA test group. | history-record keep-time
<i>keep-time</i> | Optional.
By default, the history records in the NQA test group are kept for 120 minutes. |
| 6. Configure the maximum number of history records that can be saved for a test group. | history-record number
<i>number</i> | Optional.
By default, the maximum number of records that can be saved for a test group is 50. |

Configuring optional parameters for an NQA test group

Optional parameters for an NQA test group are valid only for tests in this test group.

Unless otherwise specified, the following optional parameters are applicable to all test types.

To configure optional parameters for an NQA test group:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter NQA test group view. | nqa entry <i>admin-name</i>
<i>operation-tag</i> | N/A |
| 3. Enter test type view of a test group. | type { dhcp dls w dns
 ftp http icmp-echo
 snmp tcp udp-echo
 udp-jitter voice } | N/A |
| 4. Configure the description for a test group. | description <i>text</i> | Optional.
By default, no description is available for a test group. |

| Step | Command | Remarks |
|--|--|---|
| 5. Configure the interval between two consecutive tests for a test group. | frequency <i>interval</i> | Optional.
By default, the interval between two consecutive tests for a test group is 0 milliseconds. Only one test is performed.
If the last test is not completed when the interval specified by the frequency command is reached, a new test does not start. |
| 6. Configure the number of probe operations to be performed in one test. | probe count <i>times</i> | Optional.
By default, one probe operation is performed in one test.
Not available for voice tests, Only one probe operation can be performed in one voice test. |
| 7. Configure the NQA probe timeout time. | probe timeout <i>timeout</i> | Optional.
By default, the timeout time is 3000 milliseconds.
Not available for UDP jitter tests. |
| 8. Configure the maximum number of hops a probe packet traverses in the network. | ttl <i>value</i> | Optional.
20 by default.
Not available for DHCP tests. |
| 9. Configure the ToS field in an IP packet header in an NQA probe packet. | tos <i>value</i> | Optional.
0 by default. |
| 10. Enable the routing table bypass function. | route-option
bypass-route | Optional.
Disabled by default.
Not available for DHCP tests. |

Configuring a schedule for an NQA test group

You can configure a schedule for an NQA test group by setting the start time and test duration for a test group.

A test group performs tests between the scheduled start time and the end time (the start time plus test duration). If the scheduled start time is ahead of the system time, the test group starts testing immediately. If both the scheduled start and end time are behind the system time, no test will start. To view the current system time, use the **display clock** command.

Configuration prerequisites

Before you configure a schedule for an NQA test group, complete the following tasks:

- Configure test parameters required for the test type.
- Configure the NQA server for tests that require cooperation with the NQA server.

Configuration guidelines

Follow these guidelines when you schedule an NQA test group:

- After an NQA test group is scheduled, you cannot enter the test group view or test type view.
- System adjustment does not affect started or completed test groups. It only affects test groups that have not started.

Configuration procedure

To schedule an NQA test group:

| Step | Command | Remarks |
|--|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Configure a schedule for an NQA test group. | nqa schedule <i>admin-name operation-tag start-time</i> { <i>hh:mm:ss</i> [<i>yyyy/mm/dd</i>] now } lifetime { <i>lifetime</i> forever } | now specifies the test group starts testing immediately.
forever specifies that the tests do not stop unless you use the undo nqa schedule command. |
| 3. Configure the maximum number of tests that the NQA client can simultaneously perform. | nqa agent max-concurrent <i>number</i> | Optional.
By default, the maximum number of tests that the NQA client can simultaneously perform is 2. |

Displaying and maintaining NQA

| Task | Command | Remarks |
|--|--|-----------------------|
| Display history records of NQA test groups. | display nqa history [<i>admin-name operation-tag</i>] [{ begin exclude include } <i>regular-expression</i>] | |
| Display the current monitoring results of reaction entries. | display nqa reaction counters [<i>admin-name operation-tag</i> [<i>item-number</i>]] [{ begin exclude include } <i>regular-expression</i>] | |
| Display the results of the last NQA test. | display nqa result [<i>admin-name operation-tag</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display statistics of test results for the specified or all test groups. | display nqa statistics [<i>admin-name operation-tag</i>] [{ begin exclude include } <i>regular-expression</i>] | |
| Display NQA server status. | display nqa server status [{ begin exclude include } <i>regular-expression</i>] | |

NQA configuration examples

ICMP echo test configuration example

Network requirements

As shown in [Figure 40](#), configure NQA ICMP echo tests to test whether the NQA client (Device A) can send packets through a specific next hop to the specified destination (Device B) and test the round-trip time of the packets.

Figure 40 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

Create an ICMP echo test group, and specify 10.2.2.2 as the destination IP address for ICMP echo requests to be sent.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type icmp-echo
[DeviceA-nqa-admin-test-icmp-echo] destination ip 10.2.2.2
```

Configure 10.1.1.2 as the next hop IP address for ICMP echo requests. The ICMP echo requests are sent to Device C to Device B (the destination).

```
[DeviceA-nqa-admin-test-icmp-echo] next-hop 10.1.1.2
```

Configure the device to perform 10 probe operations per test, perform tests at an interval of 5000 milliseconds. Set the NQA probe timeout time as 500 milliseconds.

```
[DeviceA-nqa-admin-test-icmp-echo] probe count 10
[DeviceA-nqa-admin-test-icmp-echo] probe timeout 500
[DeviceA-nqa-admin-test-icmp-echo] frequency 5000
```

Enable the saving of history records and configure the maximum number of history records that can be saved for a test group.

```
[DeviceA-nqa-admin-test-icmp-echo] history-record enable
[DeviceA-nqa-admin-test-icmp-echo] history-record number 10
[DeviceA-nqa-admin-test-icmp-echo] quit
```

Start ICMP echo tests.

```
[DeviceA] nqa schedule admin test start-time now lifetime forever
```

Stop the ICMP echo tests after a period of time.

```
[DeviceA] undo nqa schedule admin test
```

Display the results of the last ICMP echo test.

```
[DeviceA] display nqa result admin test
NQA entry (admin admin, tag test) test results:
  Destination IP address: 10.2.2.2
  Send operation times: 10          Receive response times: 10
  Min/Max/Average round trip time: 2/5/3
  Square-Sum of round trip time: 96
  Last succeeded probe time: 2011-01-23 15:00:01.2

DHCP test configuration example

Network requirements

As shown in [Figure 41](#), configure NQA DHCP tests to test the time required for Device A to obtain an IP address from the DHCP server (Device B).

Figure 41 Network diagram

Configuration procedure

Create a DHCP test group, and specify interface VLAN-interface 2 to perform NQA DHCP tests.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type dhcp
[DeviceA-nqa-admin-test-dhcp] operation interface vlan-interface 2
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test-dhcp] history-record enable
[DeviceA-nqa-admin-test-dhcp] quit
```

Start DHCP tests.

```
[DeviceA] nqa schedule admin test start-time now lifetime forever
```

Stop DHCP tests after a period of time.

```
[DeviceA] undo nqa schedule admin test
```

Display the result of the last DHCP test.

```
[DeviceA] display nqa result admin test
NQA entry (admin admin, tag test) test results:
  Send operation times: 1          Receive response times: 1
  Min/Max/Average round trip time: 624/624/624
  Square-Sum of round trip time: 389376
  Last succeeded probe time: 2011-01-22 09:56:03.2
Extended results:
  Packet loss in test: 0%
  Failures due to timeout: 0
  Failures due to disconnect: 0
  Failures due to no connection: 0
  Failures due to sequence error: 0
  Failures due to internal error: 0
  Failures due to other errors: 0
  Packet(s) arrived late: 0
```

Display the history of DHCP tests.

```
[DeviceA] display nqa history admin test
NQA entry (admin admin, tag test) history record(s):
  Index      Response      Status          Time
  ---      -
  1          624           Succeeded       2011-01-22 09:56:03.2
```

DNS test configuration example

Network requirements

As shown in [Figure 42](#), configure NQA DNS tests to test whether Device A can translate the domain name **host.com** into an IP address through the DNS server and test the time required for resolution.

Figure 42 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

Create a DNS test group.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type dns
```

Specify the IP address of the DNS server 10.2.2.2 as the destination address for DNS tests, and specify the domain name that needs to be translated as **host.com**.

```
[DeviceA-nqa-admin-test-dns] destination ip 10.2.2.2
[DeviceA-nqa-admin-test-dns] resolve-target host.com
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test-dns] history-record enable
[DeviceA-nqa-admin-test-dns] quit
```

Start DNS tests.

```
[DeviceA] nqa schedule admin test start-time now lifetime forever
```

Stop the DNS tests after a period of time.

```
[DeviceA] undo nqa schedule admin test
```

Display the results of the last DNS test.

```
[DeviceA] display nqa result admin test
NQA entry (admin admin, tag test) test results:
  Destination IP address: 10.2.2.2
  Send operation times: 1                Receive response times: 1
  Min/Max/Average round trip time: 62/62/62
  Square-Sum of round trip time: 3844
  Last succeeded probe time: 2011-01-10 10:49:37.3
Extended results:
  Packet loss in test: 0%
  Failures due to timeout: 0
  Failures due to disconnect: 0
  Failures due to no connection: 0
  Failures due to sequence error: 0
  Failures due to internal error: 0
  Failures due to other errors: 0
```

```

Packet(s) arrived late: 0
# Display the history of DNS tests.
[DeviceA] display nqa history admin test
NQA entry (admin admin, tag test) history record(s):
  Index      Response      Status      Time
  1          62            Succeeded   2011-01-10 10:49:37.3

```

FTP test configuration example

Network requirements

As shown in [Figure 43](#), configure NQA FTP tests to test the connection with a specific FTP server and the time required for Device A to upload a file to the FTP server. The login username is **admin**, the login password is **systemtest**, and the file to be transferred to the FTP server is **config.txt**.

Figure 43 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

Create an FTP test group.

```

<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type ftp

```

Specify the IP address of the FTP server 10.2.2.2 as the destination IP address for FTP tests.

```

[DeviceA-nqa-admin-test-ftp] destination ip 10.2.2.2

```

Specify 10.1.1.1 as the source IP address for probe packets.

```

[DeviceA-nqa-admin-test-ftp] source ip 10.1.1.1

```

Set the FTP username to **admin**, and password to **systemtest**.

```

[DeviceA-nqa-admin-test-ftp] username admin
[DeviceA-nqa-admin-test-ftp] password systemtest

```

Configure the device to upload file **config.txt** to the FTP server for each probe operation.

```

[DeviceA-nqa-admin-test-ftp] operation put
[DeviceA-nqa-admin-test-ftp] filename config.txt

```

Enable the saving of history records.

```

[DeviceA-nqa-admin-test-ftp] history-record enable
[DeviceA-nqa-admin-test-ftp] quit

```

Start FTP tests.

```

[DeviceA] nqa schedule admin test start-time now lifetime forever

```

Stop the FTP tests after a period of time.

```

[DeviceA] undo nqa schedule admin test

```

Display the results of the last FTP test.

```
[DeviceA] display nqa result admin test
NQA entry (admin admin, tag test) test results:
  Destination IP address: 10.2.2.2
  Send operation times: 1          Receive response times: 1
  Min/Max/Average round trip time: 173/173/173
  Square-Sum of round trip time: 29929
  Last succeeded probe time: 2011-01-22 10:07:28.6
Extended results:
  Packet loss in test: 0%
  Failures due to timeout: 0
  Failures due to disconnect: 0
  Failures due to no connection: 0
  Failures due to sequence error: 0
  Failures due to internal error: 0
  Failures due to other errors: 0
  Packet(s) arrived late: 0
```

Display the history of FTP tests.

```
[DeviceA] display nqa history admin test
NQA entry (admin admin, tag test) history record(s):
  Index      Response      Status          Time
  ---      -
  1         173          Succeeded      2011-01-22 10:07:28.6
```

HTTP test configuration example

Network requirements

As shown in [Figure 44](#), configure NQA HTTP tests to test the connection with a specific HTTP server and the time required to obtain data from the HTTP server.

Figure 44 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

Create an HTTP test group.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type http
```

Specify the IP address of the HTTP server 10.2.2.2 as the destination IP address for HTTP tests.

```
[DeviceA-nqa-admin-test-http] destination ip 10.2.2.2
```

Configure the device to get data from the HTTP server for each HTTP probe operation. (get is the default HTTP operation type, and this step is optional.)

```
[DeviceA-nqa-admin-test-http] operation get
```

Configure HTTP tests to visit website **/index.htm**.

```

[DeviceA-nqa-admin-test-http] url /index.htm

# Configure the HTTP version 1.0 to be used in HTTP tests. (Version 1.0 is the default version, and this step
is optional.)
[DeviceA-nqa-admin-test-http] http-version v1.0

# Enable the saving of history records.
[DeviceA-nqa-admin-test-http] history-record enable
[DeviceA-nqa-admin-test-http] quit

# Start HTTP tests.
[DeviceA] nqa schedule admin test start-time now lifetime forever

# Stop HTTP tests after a period of time.
[DeviceA] undo nqa schedule admin test

# Display results of the last HTTP test.
[DeviceA] display nqa result admin test
  NQA entry (admin admin, tag test) test results:
    Destination IP address: 10.2.2.2
      Send operation times: 1          Receive response times: 1
      Min/Max/Average round trip time: 64/64/64
      Square-Sum of round trip time: 4096
      Last succeeded probe time: 2011-01-22 10:12:47.9
    Extended results:
      Packet loss in test: 0%
      Failures due to timeout: 0
      Failures due to disconnect: 0
      Failures due to no connection: 0
      Failures due to sequence error: 0
      Failures due to internal error: 0
      Failures due to other errors:
      Packet(s) arrived late: 0

# Display the history of HTTP tests.
[DeviceA] display nqa history admin test
  NQA entry (admin admin, tag test) history record(s):
    Index      Response      Status      Time
    1          64           Succeeded   2011-01-22 10:12:47.9

```

UDP jitter test configuration example

Network requirements

As shown in [Figure 45](#), configure NQA UDP jitter tests to test the delay jitter of packet transmission between Device A and Device B.

Figure 45 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

1. Configure Device B:

Enable the NQA server, and configure a listening service to listen to IP address 10.2.2.2 and UDP port 9000.

```
<DeviceB> system-view
[DeviceB] nqa server enable
[DeviceB] nqa server udp-echo 10.2.2.2 9000
```

2. Configure Device A:

Create a UDP jitter test group.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type udp-jitter
```

Configure UDP jitter packets to use 10.2.2.2 as the destination IP address and port 9000 as the destination port.

```
[DeviceA-nqa-admin-test-udp-jitter] destination ip 10.2.2.2
[DeviceA-nqa-admin-test-udp-jitter] destination port 9000
```

Configure the device to perform UDP jitter tests at an interval of 1000 milliseconds.

```
[DeviceA-nqa-admin-test-udp-jitter] frequency 1000
[DeviceA-nqa-admin-test-udp-jitter] quit
```

Start UDP jitter tests.

```
[DeviceA] nqa schedule admin test start-time now lifetime forever
```

Stop UDP jitter tests after a period of time.

```
[DeviceA] undo nqa schedule admin test
```

Display the result of the last UDP jitter test.

```
[DeviceA] display nqa result admin test
```

```
NQA entry (admin admin, tag test) test results:
```

```
Destination IP address: 10.2.2.2
```

```
Send operation times: 10
```

```
Receive response times: 10
```

```
Min/Max/Average round trip time: 15/32/17
```

```
Square-Sum of round trip time: 3235
```

NOTE:

The **display nqa history** command does not show the results of UDP jitter tests. To know the result of a UDP jitter test, use the **display nqa result** command to view the probe results of the latest NQA test, or use the **display nqa statistics** command to view the statistics of NQA tests.

SNMP test configuration example

Network requirements

As shown in [Figure 46](#), configure NQA SNMP tests to test the time it takes for Device A to send an SNMP query packet to the SNMP agent and receive a response packet.

Figure 46 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

1. Configure the SNMP agent (Device B):

Enable the SNMP agent service and set the SNMP version to **all**, the read community to **public**, and the write community to **private**.

```

<DeviceB> system-view
[DeviceB] snmp-agent sys-info version all
[DeviceB] snmp-agent community read public
[DeviceB] snmp-agent community write private

```

2. Configure Device A:

Create an SNMP test group, and configure SNMP packets to use 10.2.2.2 as their destination IP address.

```

<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type snmp
[DeviceA-nqa-admin-test-snmp] destination ip 10.2.2.2

```

Enable the saving of history records.

```

[DeviceA-nqa-admin-test-snmp] history-record enable

```

```

[DeviceA-nqa-admin-test-snmp] quit
# Start SNMP tests.
[DeviceA] nqa schedule admin test start-time now lifetime forever
# Stop the SNMP tests after a period of time.
[DeviceA] undo nqa schedule admin test
# Display the results of the last SNMP test.
[DeviceA] display nqa result admin test
  NQA entry (admin admin, tag test) test results:
    Destination IP address: 10.2.2.2
      Send operation times: 1                Receive response times: 1
      Min/Max/Average round trip time: 50/50/50
      Square-Sum of round trip time: 2500
      Last succeeded probe time: 2011-01-22 10:24:41.1
    Extended results:
      Packet loss in test: 0%
      Failures due to timeout: 0
      Failures due to disconnect: 0
      Failures due to no connection: 0
      Failures due to sequence error: 0
      Failures due to internal error: 0
      Failures due to other errors: 0
      Packet(s) arrived late: 0
# Display the history of SNMP tests.

```

TCP test configuration example

Network requirements

As shown in [Figure 47](#), configure NQA TCP tests to test the time for establishing a TCP connection between Device A and Device B.

Figure 47 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

1. Configure Device B:

```
# Enable the NQA server, and configure a listening service to listen to IP address 10.2.2.2 and TCP port 9000.
```

```
<DeviceB> system-view
[DeviceB] nqa server enable
```

```
[DeviceB] nqa server tcp-connect 10.2.2.2 9000
```

2. Configure Device A:

Create a TCP test group.

```
<DeviceA> system-view
```

```
[DeviceA] nqa entry admin test
```

```
[DeviceA-nqa-admin-test] type tcp
```

Configure TCP probe packets to use 10.2.2.2 as the destination IP address and port 9000 as the destination port.

```
[DeviceA-nqa-admin-test-tcp] destination ip 10.2.2.2
```

```
[DeviceA-nqa-admin-test-tcp] destination port 9000
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test-tcp] history-record enable
```

```
[DeviceA-nqa-admin-test-tcp] quit
```

Start TCP tests.

```
[DeviceA] nqa schedule admin test start-time now lifetime forever
```

Stop the TCP tests after a period of time.

```
[DeviceA] undo nqa schedule admin test
```

Display the results of the last TCP test.

```
[DeviceA] display nqa result admin test
```

```
NQA entry (admin admin, tag test) test results:
```

```

UDP echo test configuration example

Network requirements

As shown in [Figure 48](#), configure NQA UDP echo tests to test the round-trip time between Device A and Device B. The destination port number is 8000.

Figure 48 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

1. Configure Device B:

Enable the NQA server, and configure a listening service to listen to IP address 10.2.2.2 and UDP port 8000.

```
<DeviceB> system-view
[DeviceB] nqa server enable
[DeviceB] nqa server udp-echo 10.2.2.2 8000
```

2. Configure Device A:

Create a UDP echo test group.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type udp-echo
# Configure UDP packets to use 10.2.2.2 as the destination IP address and port 8000 as the destination port.
[DeviceA-nqa-admin-test-udp-echo] destination ip 10.2.2.2
[DeviceA-nqa-admin-test-udp-echo] destination port 8000
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test-udp-echo] history-record enable

Voice test configuration example

Network requirements

As shown in [Figure 49](#), configure NQA voice tests to test the delay jitter of voice packet transmission and voice quality between Device A and Device B.

Figure 49 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

1. Configure Device B:

Enable the NQA server, and configure a listening service to listen to IP address 10.2.2.2 and UDP port 9000.

```

<DeviceB> system-view
[DeviceB] nqa server enable
[DeviceB] nqa server udp-echo 10.2.2.2 9000

```

2. Configure Device A:

Create a voice test group.

```

<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type voice

```

Configure voice probe packets to use 10.2.2.2 as the destination IP address and port 9000 as the destination port.

```

[DeviceA-nqa-admin-test-voice] destination ip 10.2.2.2
[DeviceA-nqa-admin-test-voice] destination port 9000
[DeviceA-nqa-admin-test-voice] quit

```

Start voice tests.

```

[DeviceA] nqa schedule admin test start-time now lifetime forever

```

Stop the voice tests after a period of time.

```

[DeviceA] undo nqa schedule admin test

```

Display the result of the last voice test.

```

[DeviceA] display nqa result admin test
NQA entry (admin admin, tag test) test results:
  Destination IP address: 10.2.2.2

NOTE:

The **display nqa history** command cannot show you the results of voice tests. To know the result of a voice test, use the **display nqa result** command to view the probe results of the latest NQA test, or use the **display nqa statistics** command to view the statistics of NQA tests.

DLSw test configuration example

Network requirements

As shown in [Figure 50](#), configure NQA DLSw tests to test the response time of the DLSw device.

Figure 50 Network diagram

Configuration procedure

Before you make the configuration, make sure the devices can reach each other.

Create a DLSw test group, and configure DLSw probe packets to use 10.2.2.2 as the destination IP address.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test
[DeviceA-nqa-admin-test] type dlsw
[DeviceA-nqa-admin-test-dlsw] destination ip 10.2.2.2
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test-dlsw] history-record enable
[DeviceA-nqa-admin-test-dlsw] quit
```

Start DLSw tests.

```
[DeviceA] nqa schedule admin test start-time now lifetime forever
```

Stop the DLSw tests after a period of time.

```
[DeviceA] undo nqa schedule admin test
```

Display the result of the last DLSw test.

```
[DeviceA] display nqa result admin test
NQA entry (admin admin, tag test) test results:
  Destination IP address: 10.2.2.2
  Send operation times: 1          Receive response times: 1
  Min/Max/Average round trip time: 19/19/19
  Square-Sum of round trip time: 361
  Last succeeded probe time: 2011-01-22 10:40:27.7
Extended results:
  Packet loss in test: 0%
  Failures due to timeout: 0
  Failures due to disconnect: 0
  Failures due to no connection: 0
  Failures due to sequence error: 0
  Failures due to internal error: 0
  Failures due to other errors: 0
  Packet(s) arrived late: 0
```

Display the history of DLSw tests.

```
[DeviceA] display nqa history admin test
NQA entry (admin admin, tag test) history record(s):
  Index      Response      Status      Time
  ---      -
  1          19            Succeeded   2011-01-22 10:40:27.7
```

NQA collaboration configuration example

Network requirements

As shown in [Figure 51](#), configure a static route to Device C on Device A, with Device B as the next hop. Associate the static route, track entry, and NQA test group to verify whether static route is active in real time.

Figure 51 Network diagram

Configuration procedure

1. Assign each interface an IP address. (Details not shown.)
2. On Device A, configure a unicast static route and associate the static route with a track entry.
Configure a static route, whose destination address is 10.2.1.1, and associate the static route with track entry 1.

```
<DeviceA> system-view
[DeviceA] ip route-static 10.1.1.2 24 10.2.1.1 track 1
```
3. On Device A, create an NQA test group:
Create an NQA test group with the administrator name being **admin** and operation tag being **test**.

```
[DeviceA] nqa entry admin test
```

Configure the test type of the NQA test group as ICMP echo.

```
[DeviceA-nqa-admin-test] type icmp-echo
```

Configure ICMP echo requests to use 10.2.1.1 as their destination IP address.

```
[DeviceA-nqa-admin-test-icmp-echo] destination ip 10.2.1.1
```

Configure the device to perform tests at an interval of 100 milliseconds.

```
[DeviceA-nqa-admin-test-icmp-echo] frequency 100
```

Create reaction entry 1. If the number of consecutive probe failures reaches 5, collaboration with other modules is triggered.

```
[DeviceA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[DeviceA-nqa-admin-test-icmp-echo] quit
```

Configure the test start time and test duration for the test group.

```
[DeviceA] nqa schedule admin test start-time now lifetime forever
```
4. On Device A, create the track entry:
Create track entry 1, and associate it with reaction entry 1 of the NQA test group (admin-test).

```
[DeviceA] track 1 nqa entry admin test reaction 1
```

Verifying the configuration

On Device A, display information about all the track entries.

```
[DeviceA] display track all
Track ID: 1
  Status: Positive
  Notification delay: Positive 0, Negative 0 (in seconds)
  Reference object:
    NQA entry: admin test
    Reaction: 1
```

Display brief information about active routes in the routing table on Device A.

```
[DeviceA] display ip routing-table
Routing Tables: Public
          Destinations : 5          Routes : 5
```

| Destination/Mask | Proto | Pre | Cost | NextHop | Interface |
|------------------|--------|-----|------|-----------|-----------|
| 10.1.1.0/24 | Static | 60 | 0 | 10.2.1.1 | Vlan3 |
| 10.2.1.0/24 | Direct | 0 | 0 | 10.2.1.2 | Vlan3 |
| 10.2.1.2/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 127.0.0.0/8 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 127.0.0.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |

The output shows that the static route with the next hop 10.2.1.1 is active, and the status of the track entry is positive. The static route configuration works.

Remove the IP address of VLAN-interface 3 on Device B.

```
<DeviceB> system-view
[DeviceB] interface vlan-interface 3
[DeviceB-Vlan-interface3] undo ip address
```

On Device A, display information about all the track entries.

```
[DeviceA] display track all
Track ID: 1
  Status: Negative
  Notification delay: Positive 0, Negative 0 (in seconds)
  Reference object:
    NQA entry: admin test
    Reaction: 1
```

Display brief information about active routes in the routing table on Device A.

```
[DeviceA] display ip routing-table
Routing Tables: Public
          Destinations : 4          Routes : 4
```

| Destination/Mask | Proto | Pre | Cost | NextHop | Interface |
|------------------|--------|-----|------|-----------|-----------|
| 10.2.1.0/24 | Direct | 0 | 0 | 10.2.1.2 | Vlan3 |
| 10.2.1.2/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 127.0.0.0/8 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |
| 127.0.0.1/32 | Direct | 0 | 0 | 127.0.0.1 | InLoop0 |

The output shows that the next hop 10.2.1.1 of the static route is not reachable, and the status of the track entry is negative. The static route does not work.

Configuring sFlow

Both bridge mode (Layer 2) and route mode (Layer 3) Ethernet ports support sFlow. The term "interface" in this chapter collectively refers to these two types of ports. You can use the **port link-mode** command to set an Ethernet port to operate in bridge or route mode (see *Layer 2—LAN Switching Configuration Guide*).

sFlow overview

Introduction to sFlow

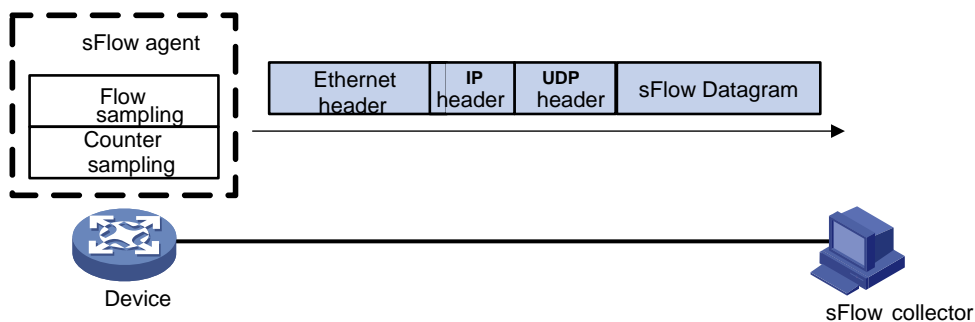

Sampled Flow (sFlow) is a traffic monitoring technology mainly used to collect and analyze traffic statistics.

As shown in [Figure 52](#), the sFlow system involves an sFlow agent embedded in a device and a remote sFlow collector. The sFlow agent collects traffic statistics and packet information from the sFlow-enabled interfaces and encapsulates them into sFlow packets. When the sFlow packet buffer is full, or the age time of sFlow packets is reached, (the age time is one second), the sFlow agent sends the packets to a specified sFlow collector. The sFlow collector analyzes the sFlow packets and displays the results.

sFlow has the following two sampling mechanisms:

- Flow sampling: Packet-based sampling, used to obtain packet content information.
- Counter sampling: Time-based sampling, used to obtain port traffic statistics.

Figure 52 sFlow system

As a traffic monitoring technology, sFlow has the following advantages:

- Supporting traffic monitoring on Gigabit and higher-speed networks.
- Providing good scalability to allow one sFlow collector to monitor multiple sFlow agents.
- Saving cost by embedding the sFlow agent in a device, instead of using a dedicated sFlow agent device.

NOTE:

Only the sFlow agent function is supported on the switch.

sFlow operation

sFlow operates in the following ways:

1. Before enabling the sFlow function, configure the sFlow agent and sFlow collector on the device.
2. With flow sampling enabled on an Ethernet interface, the sFlow agent samples packets and encapsulates them into sFlow packets. For the configuration, see "[Configuring flow sampling](#)."
3. With counter sampling enabled on an Ethernet interface, the sFlow agent periodically collects the statistics of the interface and encapsulates the statistics into sFlow packets. For the configuration, see "[Configuring flow sampling](#)."

Configuring sFlow

Before configuring sFlow, complete the following tasks:

- Configure the IP address, flow sampling, and counter sampling of the sFlow collector on the device.
- Configure the sFlow collector.

Configuring the sFlow agent and sFlow collector

The sFlow feature enables the remote sFlow collector to monitor the network and analyze sFlow packet statistics.

To configure the sFlow agent and sFlow collector:

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Specify the IP address for the sFlow agent. | sflow agent { ip <i>ip-address</i> ipv6 <i>ipv6-address</i> } | Optional
Not specified by default. The device periodically checks the existence of the sFlow agent address. If the sFlow agent has no IP address configured, the device automatically selects an interface IP address for the sFlow agent but does not save the selected IP address.
NOTE: <ul style="list-style-type: none">• HP recommends configuring an IP address manually for the sFlow agent.• Only one IP address can be specified for the sFlow agent on the device. |
| 3. Configure the sFlow collector. | sflow collector <i>collector-id</i> { { ip <i>ip-address</i> ipv6 <i>ipv6-address</i> } datagram-size <i>size</i> description <i>text</i> port <i>port-number</i> time-out <i>seconds</i> } * | By default, the device presets a number of sFlow collectors.
Use the display sflow command to display the parameters of the preset sFlow collectors. |
| 4. Specify the source IP address of sent sFlow packets. | sflow source { ip <i>ip-address</i> ipv6 <i>ipv6-address</i> } * | Optional
Not specified by default. |

Configuring flow sampling

| Step | Command | Remarks |
|---|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter Layer 2 Ethernet interface view/Layer 3 Ethernet interface view. | interface <i>interface-type</i>
<i>interface-number</i> | Only the HP 5500 EI switch series supports this command on Layer 3 Ethernet interfaces. |
| 3. Set the Flow sampling mode. | sflow sampling-mode
{ determine random } | Optional
random by default. |
| 4. Set the interval for flow sampling. | sflow sampling-rate <i>interval</i> | Not set by default. |
| 5. Set the maximum copied length of a sampled packet. | sflow flow max-header <i>length</i> | Optional
By default, up to 128 bytes of a sampled packet can be copied. You are recommended to use the default value. |
| 6. Specify the sFlow collector for flow sampling. | sflow flow collector
<i>collector-id</i> | No collector is specified for flow sampling by default. |

NOTE:

The switch does not support the flow sampling mode **determine**.

Configuring counter sampling

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter Layer 2 interface view/Layer 3 Ethernet interface view. | interface <i>interface-type</i>
<i>interface-number</i> | Only the HP 5500 EI switch series supports Layer 3 Ethernet interface view. |
| 3. Set the interval for counter sampling. | sflow counter interval <i>seconds</i> | Counter sampling is disabled by default. |
| 4. Specify the sFlow collector for counter sampling. | sflow counter collector
<i>collector-id</i> | No collector is specified for counter sampling by default. |

Displaying and maintaining sFlow

| Task | Command | Remarks |
|--|--|-----------------------|
| Display sFlow configuration information. | display sflow [slot <i>slot-number</i>] [
{ begin exclude include }
<i>regular-expression</i>] | Available in any view |

sFlow configuration example

Network requirements

As shown in [Figure 53](#), Host A is connected with the server through the device (sFlow agent).

Enable sFlow (including flow sampling and counter sampling) on GigabitEthernet 1/0/1 to monitor traffic on the port. The device sends sFlow packets through GigabitEthernet 1/0/3 to the sFlow collector, which analyzes the sFlow packets and displays results.

Figure 53 Network diagram

Configuration procedure

1. Configure the sFlow agent and sFlow collector:

Configure the IP address of vlan-interface 1 on Device as 3.3.3.1/16.

```
<Device> system-view
[Device] interface vlan-interface 1
[Device-Vlan-interface1] ip address 3.3.3.1 16
[Device-Vlan-interface1] quit
```

Specify the IP address for the sFlow agent.

```
[Device] sflow agent ip 3.3.3.1
```

Specify sFlow collector ID 2, IP address 3.3.3.2, the default port number, and description of **netserver** for the sFlow collector.

```
[Device] sflow collector 2 ip 3.3.3.2 description netserver
```

2. Configure counter sampling:

Set the counter sampling interval to 120 seconds.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] sflow counter interval 120
```

Specify sFlow collector 2 for counter sampling.

```
[Device-GigabitEthernet1/0/1] sflow counter collector 2
```

3. Configure flow sampling:

Set the Flow sampling mode and sampling interval.

```
[Device-GigabitEthernet1/0/1] sflow sampling-mode random
[Device-GigabitEthernet1/0/1] sflow sampling-rate 4000
```

Specify sFlow collector 2 for flow sampling.

```
[Device-GigabitEthernet1/0/1] sflow flow collector 2
```

```
# Display the sFlow configuration and operation information.
[Device-GigabitEthernet1/0/1] display sflow
sFlow Version: 5
sFlow Global Information:
Agent          IP:3.3.3.1
Collector Information:
ID   IP                               Port  Aging  Size  Description
1    3.3.3.2                             6343  0      1400  netserver
2    3.3.3.2                             6543  N/A    1400
3    3.3.3.2                             6343  0      1400
4    3.3.3.2                             6343  0      1400
5    3.3.3.2                             6343  0      1400
6    3.3.3.2                             6343  0      1400
7    3.3.3.2                             6343  0      1400
8    3.3.3.2                             6343  0      1400
9    3.3.3.2                             6343  0      1400
10   3.3.3.2                             6343  0      1400
sFlow Port Information:
Interface CID  Interval(s) FID  MaxHLen  Rate  Mode  Status
GigabitEthernet1/0/1  2    120    2    128    4000  Random  Active
```

The output shows that GigabitEthernet 1/0/1 enabled with sFlow is active, the counter sampling interval is 120 seconds, the Flow sampling interval is 4000, all of which indicate sFlow operates normally.

Troubleshooting sFlow configuration

Symptom

The remote sFlow collector cannot receive sFlow packets.

Analysis

- The sFlow collector has no IP address specified.
- No interface is enabled with sFlow to sample data.
- The IP address of the sFlow collector specified on the sFlow agent is different from that of the remote sFlow collector.
- No IP address is configured for the Layer 3 interface on the device, or the IP address is configured, but the UDP packets with the IP address being the source cannot reach the sFlow collector.
- The physical link between the device and the sFlow collector fails.

Solution

1. Check whether sFlow is correctly configured by displaying sFlow configuration with the **display sflow** command.
2. Check whether the correct IP address is configured for the device to communicate with the sFlow collector.
3. Check whether the physical link between the device and the sFlow collector is normal.

Configuring IPC

This chapter provides an overview of IPC and describes the IPC monitoring commands.

Overview

Inter-Process Communication (IPC) provides a reliable communication mechanism among processing units, typically CPUs. IPC is typically used on a distributed device or in an IRF fabric to provide reliable inter-card or inter-device transmission. This section describes the basic IPC concepts.

Node

An IPC node is an independent IPC-capable processing unit, typically, a CPU.

This series of devices are centralized devices that have only one CPU. The IRF fabrics formed by them have multiple CPUs, or IPC nodes.

Link

An IPC link is a connection between any two IPC nodes. Any two IPC nodes have one and only one IPC link for sending and receiving packets. All IPC nodes are fully meshed.

IPC links are created when the system is initialized. An IPC node, upon startup, sends handshake packets to other nodes. If the handshake succeeds, a connection is established.

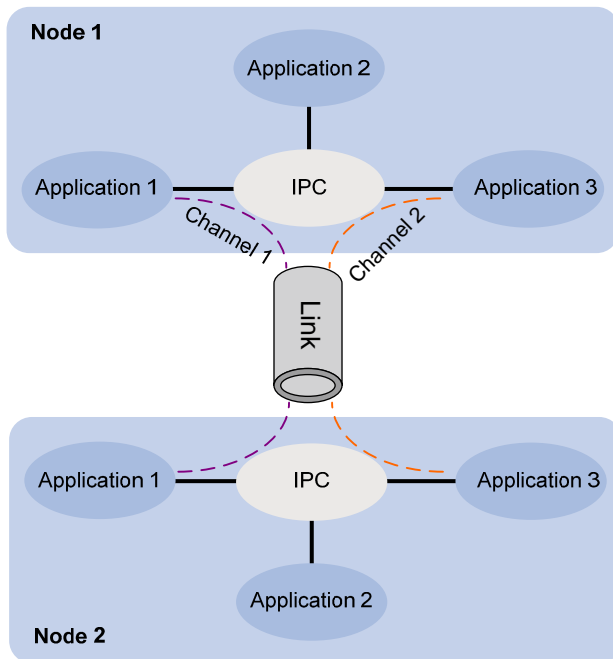

The system uses link status to identify the link connectivity between two nodes. An IPC node can have multiple links, and each link has its own status.

Channel

A channel is the communication interface between peer upper layer application modules that use different IPC nodes. Each node assigns a locally unique channel number to each upper layer application module for identification.

An upper layer application module sends data to an IPC module in a channel, and the IPC module sends the data to a peer node across a link, as shown in [Figure 54](#).

Figure 54 Relationship between a node, link and channel

Packet sending modes

IPC uses one of the following modes to send packets for upper layer application modules:

- **Unicast**—One node sends packets to another node.
- **Multicast**—One node sends packets to multiple nodes. This mode includes broadcast, a special multicast. To use multicast mode, an application module must create a multicast group that includes a set of nodes. Multicasts destined for this group are sent to all the nodes in the group. An application module can create multiple multicast groups. Creation and deletion of a multicast group or group member depend on the application module.
- **Mixcast**—Supports both unicast and multicast.

IPC assigns one queue for each mode. An upper layer application module automatically selects one mode as needed.

Enabling IPC performance statistics

The IPC performance statistics function provides the most recent 10-second, 1-minute, and 5-minute traffic input and output statistics for IPC nodes. If this function is disabled, the **display ipc performance** command displays the statistics collected before IPC performance statistics was disabled.

To enable IPC performance statistics:

| Task | Command | Remarks |
|---|--|---------------------------------------|
| Enable IPC performance statistics in user view. | ipc performance enable { node <i>node-id</i> self-node } [channel <i>channel-id</i>] | By default, the function is disabled. |

Displaying and maintaining IPC

| Task | Command | Remarks |
|---|--|------------------------|
| Display IPC node information. | display ipc node [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display channel information for a node. | display ipc channel { node <i>node-id</i> self-node } [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display queue information for a node. | display ipc queue { node <i>node-id</i> self-node } [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display multicast group information for a node. | display ipc multicast-group { node <i>node-id</i> self-node } [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display packet information for a node. | display ipc packet { node <i>node-id</i> self-node } [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display link status information for a node. | display ipc link { node <i>node-id</i> self-node } [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display IPC performance statistics of a node. | display ipc performance { node <i>node-id</i> self-node } [channel <i>channel-id</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Clear IPC performance statistics of a node. | reset ipc performance [node <i>node-id</i> self-node] [channel <i>channel-id</i>] | Available in user view |

Configuring PoE

Overview

Power over Ethernet (PoE) enables a power sourcing equipment (PSE) to supply power to powered devices (PDs) through Ethernet interfaces over twisted pair cables.

Advantages

- **Reliable**—Power is supplied in a centralized way so that it is very convenient to provide a backup power supply.
- **Easy to connect**—A network terminal requires no external power supply but only an Ethernet cable.
- **Standard**—In compliance with IEEE 802.3af, and a globally uniform power interface is adopted.
- **Promising**—It can be applied to IP telephones, wireless LAN access points (APs), portable chargers, card readers, web cameras, and data collectors.

PoE concepts

As shown in [Figure 55](#), a PoE system comprises PoE power, PSE, power interface (PI), and PD:

- **PoE power**—The whole PoE system is powered by the PoE power.
- **PSE**—A PSE supplies power for PDs. A PSE can examine the Ethernet cables connected to PoE interfaces, search for PDs, classify them, and supply power to them. When detecting that a PD is unplugged, the PSE stops supplying power to the PD. A PSE can be built-in (Endpoint) or external (Midspan). The switch uses built-in PSEs. To display the mapping between a PSE ID and the slot number of an interface card, execute the **display poe device** command.

The PSE ID is the *switch member ID* $\times 3 + 1$. For example, if the member ID of the device is 3, the PSE ID of the device is $3 \times 3 + 1 = 10$.

- **PI**—An Ethernet interface with the PoE capability is called PoE interface.
- **PD**—A PD accepts power from the PSE, including IP phones, wireless APs, chargers of portable devices, POS, and web cameras. The PD that is being powered by the PSE can be connected to another power supply unit for redundancy power backup.

Figure 55 PoE system diagram

Protocol specification

The protocol specification related to PoE is IEEE 802.3af.

PoE configuration task list

You can configure a PoE interface by using either of the following methods:

- At the command line interface (CLI).
- Through configuring the PoE profile and applying the PoE profile to the PoE interface.

To configure a single PoE interface, configure it at the CLI. To configure PoE interfaces in batches, use the PoE profile. For a PoE configuration parameter of a PoE interface, you can only select one mode (including modification and removal of a PoE interface).

Configuration guidelines

- Before configuring PoE, make sure the PoE power supply and PSE are operating normally. Otherwise, you cannot configure PoE or the configured PoE function does not take effect.
- Turning off the PoE power supply during the startup of the device might cause the PoE configuration in the PoE profile invalid.

Complete these tasks to configure PoE:

| Task | Remarks |
|---|---|
| Enabling PoE: | |
| Enabling PoE for a PoE interface | Required. |
| Detecting PDs: | |
| Enabling the PSE to detect nonstandard PDs | Optional. |
| Configuring a PD disconnection detection mode | Optional. |
| Configuring the PoE power: | |
| Configuring the maximum PoE interface power | Optional. |
| Configuring PoE power management: | |
| Configuring PoE interface power management | Optional. |
| Configuring the PoE monitoring function: | |
| Configuring PSE power monitoring | Optional. |
| Monitoring PD | Optional.
The device automatically monitors PDs when supplying power to them, so no configuration is required. |
| Configuring PoE interface through PoE profile: | |
| Configuring PoE profile | Optional. |
| Applying PoE profile | Optional. |
| Upgrading PSE processing software in service | Optional. |

Enabling PoE

Enabling PoE for a PoE interface

The system does not supply power to or reserve power for the PDs connected to a PoE interface if the PoE interface is not enabled with the PoE function.

You are allowed to enable PoE for a PoE interface if the PoE interface will not result in PoE power overload; otherwise, whether you can enable PoE for the PoE interface depends on whether the PoE interface is enabled with the PoE power management function. For more information about the PoE interface power management function, see "[Configuring PoE interface power management](#)".

- If the PoE interface is not enabled with the PoE power management function, you are not allowed to enable PoE for the PoE interface.
- If the PoE interface is enabled with the PoE power management function, you are allowed to enable PoE for the PoE interface (whether the PDs can be powered depends on other factors, for example, the power supply priority of the PoE interface).

The PSE supplies power over category 3/5 twisted pair cable for a PoE interface in the following modes:

- **Over signal wires**—The PSE uses data pairs (pins 1, 2 and 3, 6) to supply DC power to PDs.
- **Over spare wires**—The PSE uses spare pairs (pins 4, 5 and 7, 8) to supply DC power to PDs.

Configuration guidelines

- When the sum of the power consumption of all powered PoE interfaces on a PSE exceeds the maximum power of the PSE, the system considers the PSE overloaded (The maximum PSE power is decided by the user configuration).
- A PSE can supply power to a PD only when the selected power supply mode is supported by both the PSE and PD. If the PSE and PD support different power supply modes (for example, the PSE does not support power over spare wires, while the PD supports power over spare wires), you have to change the order of the lines in the twisted pair cable to supply power to the PD.
- The switch's PoE interfaces can supply power only over signal wires.

To enable PoE for a PoE interface:

| Step | Command | Remarks |
|---|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter PoE interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 3. Enable PoE for the PoE interface. | poe enable | By default, this function is disabled. |
| 4. Configure a description for the PD connected to the PoE interface. | poe pd-description <i>text</i> | Optional.
By default, no description for the PD connected to the PoE interface is available. |

Detecting PDs

Enabling the PSE to detect nonstandard PDs

There are standard PDs and nonstandard PDs. Usually, the PSE can detect only standard PDs and supply power to them. The PSE can detect nonstandard PDs and supply power to them only after the PSE is enabled to detect nonstandard PDs.

To enable the PSE to detect nonstandard PDs:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable the PSE to detect nonstandard PDs. | poe legacy enable pse <i>pse-id</i> | By default, the PSE can detect standard PDs rather than nonstandard PDs. |

Configuring a PD disconnection detection mode

To detect the PD connection with PSE, PoE provides two detection modes: AC detection and DC detection. The AC detection mode is energy saving relative to the DC detection mode.

To configure a PD disconnection detection mode:

| Step | Command | Remarks |
|---|-----------------------------------|---|
| 1. Enter system view. | system-view | N/A |
| 2. Configure a PD disconnection detection mode. | poe disconnect { ac dc } | Optional.
The default PD disconnection detection mode is AC detection. |

If you change the PD disconnection detection mode when the device is running, the connected PDs will be powered off. Therefore, be cautious to do so.

Configuring the PoE power

Configuring the maximum PoE interface power

The maximum PoE interface power is the maximum power that the PoE interface can provide to the connected PD. If the power required by the PD is larger than the maximum PoE interface power, the PoE interface will not supply power to the PD.

For HP 5500-48G-PoE+ EI Switch with 2 Interface Slots(JG240A), HP 5500-48G-PoE+ EI TAA Switch with 2 Interface Slots(JG253A), and HP 5500-48G-PoE+ SI Switch with 2 Interface Slots(JG239A), the total PoE power of ports numbered 1 through 24 is 370 W, and that of ports numbered 25 through 48 is 370 W.

To configure the maximum PSE power:

| Step | Command | Remarks |
|---|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter PoE interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 3. Configure the maximum power for the PoE interface. | poe max-power <i>max-power</i> | Optional.
By default, 30000 milliwatts is the maximum power for the PoE interface for PoE+ switches. |

Configuring PoE power management

PoE power management involves PSE power management and PoE interface power management.

Configuring PoE interface power management

The power supply priority of a PD depends on the priority of the PoE interface. The priority levels of PoE interfaces are critical, high and low in descending order. Power supply to a PD is subject to PoE interface power management policies.

All PSEs implement the same PoE interface power management policies. When a PSE supplies power to a PD, the following actions occur:

- If the PoE interface power management is not enabled, no power will be supplied to a new PD when the PSE power is overloaded.
- If the PoE interface power management priority policy is enabled, the PD with a lower priority is first powered off to guarantee the power supply to the PD with a higher priority when the PSE power is overloaded.

19 watts guard band is reserved for each PoE interface on the device to prevent a PD from being powered off because of a sudden increase of the PD power. When the remaining power of the PSE where the PoE interface resides is lower than 19 watts and no priority is configured for the PoE interface, the PSE does not supply power to the new PD; when the remaining power of the PSE where the PoE interface resides is lower than 19 watts, but priority is configured for the PoE interface, the interface with a higher priority can preempt the power of the interface with a lower priority to ensure the normal working of the higher priority interface.

If the sudden increase of the PD power results in PSE power overload, power supply to the PD on the PoE interface with a lower priority will be stopped to ensure the power supply to the PD with a higher priority.

If the guaranteed remaining PSE power (the maximum PSE power minus the power allocated to the critical PoE interface, regardless of whether PoE is enabled for the PoE interface) is lower than the maximum power of the PoE interface, you will fail to set the priority of the PoE interface to **critical**. Otherwise, you can succeed in setting the priority to **critical**, and this PoE interface will preempt the power of other PoE interfaces with a lower priority level. In the latter case, the PoE interfaces whose power is preempted will be powered off, but their configurations will remain unchanged. When you change the priority of a PoE interface from critical to a lower level, the PDs connecting to other PoE interfaces will have an opportunity of being powered.

Configuration prerequisites

Enable PoE for PoE interfaces.

Configuration procedure

To configure PoE interface power management:

| Step | Command | Remarks |
|--|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Configure PoE interface power management priority policy. | poe pd-policy priority | By default, this policy is not configured. |
| 3. Enter PoE interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |
| 4. Configure the power supply priority for a PoE interface. | poe priority { critical high low } | Optional.
By default, low is the power supply priority for the PSE. |

Configuring the PoE monitoring function

With the PoE monitoring function enabled, the system monitors the parameter values related to PoE power supply, PSE, PD, and device temperature in real time. When a specific value exceeds the limited range, the system automatically takes some measures to protect itself.

Configuring PSE power monitoring

When the PSE power exceeds or drops below the specified threshold, the system sends trap messages.

To configure a power alarm threshold for the PSE:

| Step | Command | Remarks |
|---|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Configure a power alarm threshold for the PSE. | poe utilization-threshold
<i>utilization-threshold-value</i> pse
<i>pse-id</i> | Optional.
The default setting is 80%. |

Monitoring PD

When a PSE starts or ends power supply to a PD, the system sends a trap message.

Configuring PoE interface through PoE profile

You can configure a PoE interface either at the CLI or by using a PoE profile and applying the PoE profile to the specified PoE interface(s).

To configure a single PoE interface, configure it at the CLI; to configure PoE interfaces in batches, use a PoE profile.

A PoE profile is a collection of configurations that contain multiple PoE features. On large-scale networks, you can apply a PoE profile to multiple PoE interfaces, and these interfaces have the same PoE features. If the PoE interface connecting to a PD changes to another one, apply the PoE profile applied on the

originally connected interface to the currently connected interface instead of reconfiguring the features defined in the PoE profile one by one, simplifying the PoE configurations.

The device supports multiple PoE profiles. You can define PoE configurations based on each PD, save the configurations for different PDs into different PoE profiles, and apply the PoE profiles to the access interfaces of PDs accordingly.

Configuration guidelines

- If a PoE profile is applied, it cannot be deleted or modified before you cancel its application.
- The **poe max-power** *max-power* and **poe priority** { **critical** | **high** | **low** } commands must be configured in only one way, that is, either at the CLI or by configuring PoE profile.
- A PoE parameter on a PoE interface must be configured, modified and deleted in only one way. If a parameter configured in a way (for example, at the CLI) is then configured in the other way (for example, through PoE profile), the latter configuration fails and the original one is still effective. To make the latter configuration effective, you must cancel the original one first.

Configuring PoE profile

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Create a PoE profile, and enter PoE profile view. | poe-profile <i>profile-name</i> [<i>index</i>] | N/A |
| 3. Enable PoE for the PoE interface. | poe enable | By default, this function is disabled. |
| 4. Configure the maximum power for the PoE interface. | poe max-power <i>max-power</i> | Optional.
By default, 30000 milliwatts is the maximum power for the PoE interface for PoE+ switches. |
| 5. Configure power supply priority for the PoE interface. | poe priority { critical high low } | Optional.
By default, low is the power supply priority for the PoE interface. |

Applying PoE profile

You can apply a PoE profile in either system view or interface view. If you perform application to a PoE interface in both views, the latter application takes effect. To apply a PoE profile to multiple PoE interfaces, the system view is more efficient.

To apply the PoE profile in system view:

| Step | Command |
|---|---|
| 1. Enter system view. | system-view |
| 2. Apply the PoE profile to one or multiple PoE interfaces. | apply poe-profile { index <i>index</i> name <i>profile-name</i> }
interface <i>interface-range</i> |

To apply the PoE profile in interface view:

| Step | Command |
|--|--|
| 1. Enter system view. | system-view |
| 2. Enter PoE interface view. | interface <i>interface-type interface-number</i> |
| 3. Apply the PoE profile to the current PoE interface. | apply poe-profile { index <i>index</i> name <i>profile-name</i> } |

A PoE profile can be applied to multiple PoE interfaces, while a PoE interface can be applied with only one PoE profile.

Upgrading PSE processing software in service

You can upgrade the PSE processing software in service in either of the following two modes:

- **refresh mode**—Enables you to update the PSE processing software without deleting it. Normally, you can upgrade the PSE processing software in the refresh mode through the command line.
- **full mode**—Deletes the PSE processing software and reloads it. If the PSE processing software is damaged (in this case, you can execute none of PoE commands successfully), you can upgrade the PSE processing software in full mode to restore the PSE function.

An in-service PSE processing software upgrade may be unexpectedly interrupted (for example, an error results in device reboot). If you fail to upgrade the PSE processing software in full mode after reboot, you can power off the device and restart it before upgrading it in full mode again. After upgrade, restart the device manually to make the new PSE processing software take effect.

Configuration guidelines

To upgrade the PSE processing software in service:

| Step | Command |
|--|---|
| 1. Enter system view. | system-view |
| 2. Upgrade the PSE processing software in service. | poe update { full refresh } <i>filename</i> pse <i>pse-id</i> |

Displaying and maintaining PoE

| Task | Command | Remarks |
|---|--|-----------------------|
| Display PSE information. | display poe device [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the power supplying state of the specified PoE interface. | display poe interface [<i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display power information for PoE interfaces. | display poe interface power [<i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display information about PSE. | display poe pse [<i>pse-id</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |

| Task | Command | Remarks |
|--|---|-----------------------|
| Display the power supply states of all PoE interfaces connected to the PSE. | display poe pse <i>pse-id</i> interface [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display power information for all PoE interfaces connected to the PSE. | display poe pse <i>pse-id</i> interface power [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the configurations and applications of the PoE profile. | display poe-profile [index <i>index</i> name <i>profile-name</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the configurations and applications of the PoE profile applied to the specified PoE interface. | display poe-profile interface <i>interface-type</i> <i>interface-number</i> [{ begin exclude include } <i>regular-expression</i>] | Available in any view |

PoE configuration example

Network requirements

As shown in [Figure 56](#), the device supplies power to PDs through its PoE interfaces:

- GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 are connected to IP telephones.
- GigabitEthernet 1/0/11 and GigabitEthernet 1/0/12 are connected to APs.
- The power supply priority of IP telephones is higher than that of the APs, for which the PSE supplies power to IP telephones first when the PSE power is overloaded.
- The maximum power of AP2 connected to GigabitEthernet 1/0/12 does not exceed 9000 milliwatts.

Figure 56 Network diagram

Configuration procedure

Enable PoE and specify the **critical** power supply priority on GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3.

```

<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] poe enable
[Sysname-GigabitEthernet1/0/1] poe priority critical
  
```

```
[Sysname-GigabitEthernet1/0/1] quit
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] poe enable
[Sysname-GigabitEthernet1/0/2] poe priority critical
[Sysname-GigabitEthernet1/0/2] quit
[Sysname] interface gigabitethernet 1/0/3
[Sysname-GigabitEthernet1/0/3] poe enable
[Sysname-GigabitEthernet1/0/3] poe priority critical
[Sysname-GigabitEthernet1/0/3] quit
```

Enable PoE on GigabitEthernet 1/0/11 and GigabitEthernet 1/0/12, and configure the maximum power of GigabitEthernet 1/0/12 as 9000 milliwatts.

```
[Sysname] interface gigabitethernet 1/0/11
[Sysname-GigabitEthernet1/0/11] poe enable
[Sysname-GigabitEthernet1/0/11] quit
[Sysname] interface gigabitethernet 1/0/12
[Sysname-GigabitEthernet1/0/12] poe enable
[Sysname-GigabitEthernet1/0/12] poe max-power 9000
```

After the configuration takes effect, the IP telephones and AP devices are powered and can work normally.

Troubleshooting PoE

Setting the priority of a PoE interface to critical fails

Analysis

- The guaranteed remaining power of the PSE is lower than the maximum power of the PoE interface.
- The priority of the PoE interface is already set.

Solution

- In the first case, you can solve the problem by increasing the maximum PSE power, or by reducing the maximum power of the PoE interface when the guaranteed remaining power of the PSE cannot be modified.
- In the second case, you should first remove the priority already configured.

Applying a PoE profile to a PoE interface fails

Analysis

- Some configurations in the PoE profile are already configured.
- Some configurations in the PoE profile do not meet the configuration requirements of the PoE interface.
- Another PoE profile is already applied to the PoE interface.

Solution

- In the first case, you can solve the problem by removing the original configurations of those configurations.
- In the second case, you need to modify some configurations in the PoE profile.

- In the third case, you need to remove the application of the undesired PoE profile to the PoE interface.

Configuring an AC input under-voltage threshold fails

Analysis

The AC input under-voltage threshold is greater than or equal to the AC input over-voltage threshold.

Solution

You can drop the AC input under-voltage threshold below the AC input over-voltage threshold.

Configuring cluster management

Overview

Cluster management is an effective way to manage large numbers of dispersed network switches in groups. Cluster management offers the following advantages:

- Saves public IP address resources. You do not have to assign one public IP address for every cluster member switch.
- Simplifies configuration and management tasks. By configuring a public IP address on one switch, you can configure and manage a group of switches without the trouble of logging in to each switch separately.
- Provides a useful topology discovery and display function for network monitoring and debugging.
- Allows simultaneous software upgrading and parameter configuration on multiple switches, free from topology and distance limitations.

Roles in a cluster

The switches in a cluster play different roles according to their different functions and status. You can specify the following three roles for the switches:

- **Management device (Administrator)**—A switch providing management interfaces for all switches in a cluster and the only switch configured with a public IP address. You can specify one and only one management switch for a cluster. Any configuration, management, and monitoring of the other switches in a cluster can only be implemented through the management switch. When a switch is specified as the management switch, it collects related information to discover and define candidate switches.
- **Member device (Member)**—A switch managed by the management switch in a cluster.
- **Candidate device (Candidate)**—A switch that does not yet belong to any cluster but can be added to a cluster. Different from a member switch, its topology information has been collected by the management switch but it has not been added to the cluster.

Figure 57 Network diagram

As shown in [Figure 57](#), the switch configured with a public IP address and performing the management function is the management switch, the other managed switches are member switches, and the switch that does not belong to any cluster but can be added to a cluster is a candidate switch. The management switch and the member switches form the cluster.

Figure 58 Role change in a cluster

As shown in [Figure 58](#), a switch in a cluster changes its role according to the following rules:

- A candidate switch becomes a management switch when you create a cluster on it. A management switch becomes a candidate switch only after the cluster is removed.
- A candidate switch becomes a member switch after being added to a cluster. A member switch becomes a candidate switch after it is removed from the cluster.

How a cluster works

Cluster management is implemented through HW Group Management Protocol version 2 (HGMPv2), which consists of the following three protocols:

- Neighbor Discovery Protocol (NDP)
- Neighbor Topology Discovery Protocol (NTDP)
- Cluster

A cluster configures and manages the switches in it through the above three protocols. Cluster management involves topology information collection and the establishment and maintenance of a cluster. Topology information collection and cluster maintenance are independent from each other; in fact, topology information collection starts before the cluster is created. The following workflow applies:

- All switches use NDP to collect the information of directly connected neighbors, including their software version, host name, MAC address and port number.
- The management switch uses NTDP to do the following:
 - Collect information about the switches within user-specified hops.
 - Collect the topology information of all switches.
 - Specifies the candidate switches of the cluster based on the collected information.
- The management switch adds or deletes a member switch and modifies cluster management configuration according to the candidate switch information collected through NTDP.

About NDP

NDP discovers information about directly connected neighbors, including the switch name, software version, and connecting port of the adjacent switches. NDP works in the following ways:

- A switch running NDP periodically sends NDP packets to its neighbors. An NDP packet carries NDP information (including the switch name, software version, and connecting port, etc.) and the holdtime, which is how long the receiving switches will keep the NDP information. At the same time, the switch also receives (but does not forward) NDP packets from its neighbors.
- A switch running NDP stores and maintains an NDP table. The switch creates an entry in the NDP table for each neighbor. If a new neighbor is found, meaning the switch receives an NDP packet sent by the neighbor for the first time, the switch adds an entry in the NDP table. If the NDP

information carried in the NDP packet is different from the stored information, the corresponding entry and holdtime in the NDP table are updated; otherwise, only the holdtime of the entry is updated. If an entry's holdtime expires (in other words, no NDP information from the neighbor is received to restart the hold time before it ages out), the entry is removed from the NDP table.

NDP runs on the data link layer, and supports different network layer protocols.

About NTDP

NTDP provides information required for cluster management; it collects topology information about the switches within the specified hop count. Based on the neighbor information stored in the neighbor table maintained by NDP, NTDP on the management switch advertises NTDP topology-collection requests to collect the NDP information of all the switches in a specific network range as well as the connection information of all its neighbors. The information collected will be used by the management switch or the network management software to implement required functions.

When a member switch detects a change on its neighbors through its NDP table, it informs the management switch through handshake packets. Then the management switch triggers its NTDP to collect specific topology information, so that its NTDP can discover topology changes promptly.

The management switch collects topology information periodically. You can also administratively launch a topology information collection. The process of topology information collection is as follows:

- The management switch periodically sends NTDP topology-collection request from the NTDP-enabled ports.
- Upon receiving the request, the switch sends NTDP topology-collection response to the management switch, copies this response packet on the NTDP-enabled port and sends it to the adjacent switch. Topology-collection response includes the basic information of the NDP-enabled switch and NDP information of all adjacent switches.
- The adjacent switch performs the same operation until the NTDP topology-collection request is sent to all the switches within specified hops.

To avoid concurrent responses to an NTDP topology-collection request causing congestion and deny of service on the management device, a delay mechanism was introduced. You configure the delay parameters for NTDP on the management device. As a result:

- Each device waits for a period of time before forwarding an NTDP topology-collection request on the first NTDP-enabled port.
- After the first NTDP-enabled port forwards the request, all other NTDP-enabled ports wait for a period of time and forward the NTDP topology-collection request.

Cluster management maintenance

1. Adding a candidate switch to a cluster

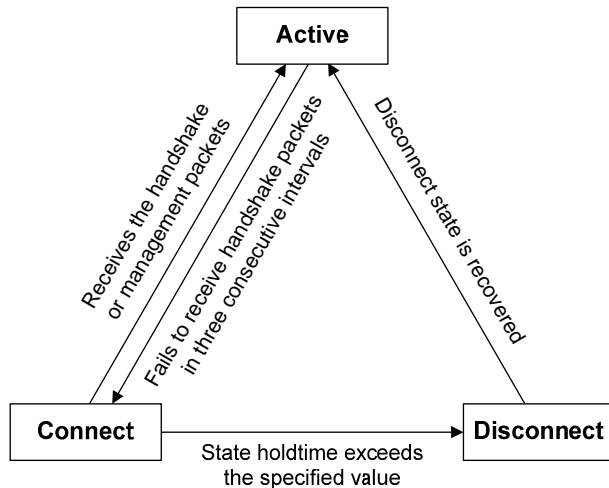

You should specify the management switch before creating a cluster. The management switch discovers and defines a candidate switch through NDP and NTDP protocols. The candidate switch can be automatically or manually added to the cluster.

After the candidate switch is added to the cluster, it can obtain the member number assigned by the management switch and the private IP address used for cluster management.

2. Communication within a cluster

In a cluster the management switch communicates with its member switches by sending handshake packets to maintain connection between them. The management/member switch state change is shown in [Figure 59](#).

Figure 59 Management/member switch state change

A cluster manages the state of its member devices as follows:

- After a cluster is created and a candidate switch is added to the cluster and becomes a member switch, the management switch saves the state information of the member switch and identifies it as Active. And the member switch also saves its state information and identifies itself as Active.
- After a cluster is created, its management switch and member switches begin to send handshake packets. Upon receiving the handshake packets from the other, the management switch or a member switch simply remains its state as Active, without sending a response.
- If the management switch does not receive the handshake packets from a member switch in an interval three times of the interval to send handshake packets, it changes the status of the member switch from Active to Connect. Likewise, if a member switch fails to receive the handshake packets from the management switch in an interval three times of the interval to send handshake packets, the status of itself will also be changed from Active to Connect.
- During information holdtime, if the management switch receives handshake or management packets from a member switch that is in Connect state, it changes the state of the member switch to Active. Otherwise, it considers the member switch to be disconnected, and changes the state of the member switch to Disconnect.
- During information holdtime, if a member switch in Connect state changes its state to Active if it receives handshake or management packets from the management switch; otherwise, it changes its state to Disconnect.
- If communication between the management switch and a member switch is recovered, the member switch which is in Disconnect state will be added to the cluster, and the state of the member switch locally and on the management switch will be changed to Active.
- Also, a member switch sends handshake packets to inform the management switch when there is a neighbor topology change.

Management VLAN

The management VLAN is a VLAN used for communication in a cluster; it limits the cluster management range. Through configuration of the management VLAN, the following functions can be implemented:

- Management packets (including NDP, NTDP and handshake packets) are restricted within the management VLAN. This isolates them from other packets, which enhances security.
- The management switch and the member switches communicate with each other through the management VLAN.

For a cluster to work normally, you must set the packets from the management VLAN to pass the ports connecting the management switch and the member/candidate switches (including the cascade ports). Therefore:

- If the packets from the management VLAN cannot pass a port, the switch connected with the port cannot be added to the cluster. Therefore, if the ports (including the cascade ports) connecting the management switch and the member/candidate switches prohibit the packets from the management VLAN, you can set the packets from the management VLAN to pass the ports on candidate switches with the management VLAN auto-negotiation function.
- Normally, only the packets with tags from the management VLAN can pass the ports. However, you can set packets without tags from the management VLAN to pass the ports if the default VLAN ID of the cascade ports and of the ports connecting the management switch and the member/candidate switches is the same as that of the management VLAN.

If a candidate switch is connected to a management switch through another candidate switch, the ports between the two candidate switches are cascade ports.

For more information about VLAN, see *Layer 2—LAN Switching Configuration Guide*.

Cluster management configuration task list

Before configuring a cluster, you need to determine the roles and functions the switches play. You also need to configure the related functions, preparing for the communication between switches within the cluster.

Configuration guidelines

- Disabling the NDP and NTDP functions on the management switch and member switches after a cluster is created will not cause the cluster to be dismissed, but will influence the normal operation of the cluster.
- In a cluster, if a member switch enabled with the 802.1X or MAC address authentication function has other member switches connected to it, you must enable HW Authentication Bypass Protocol (HABP) server on the switch. Otherwise, the management switch of the cluster cannot manage the switches connected with it. For more information about the HABP, see *Security Configuration Guide*.
- If the routing table of the management switch is full when a cluster is established, that is, entries with the destination address as a candidate switch cannot be added to the routing table, all candidate switches will be added to and removed from the cluster repeatedly.
- If the routing table of a candidate switch is full when the candidate switch is added to a cluster, that is, the entry with the destination address as the management switch cannot be added to the routing table, the candidate switch will be added to and removed from the cluster repeatedly.

Complete these tasks to configure cluster management functions:

| Task | Remarks |
|---|----------|
| Configuring the management switch: | |
| Enabling NDP globally and for specific ports | Optional |
| Configuring NDP parameters | Optional |
| Enabling NTDP globally and for specific ports | Optional |
| Configuring NTDP parameters | Optional |

| Task | Remarks |
|--|----------|
| Manually collecting topology information | Optional |
| Enabling the cluster function | Optional |
| Establishing a cluster | Required |
| Enabling management VLAN auto-negotiation | Required |
| Configuring communication between the management switch and the member switches within a cluster | Optional |
| Configuring cluster management protocol packets | Optional |
| Cluster member management | Optional |
| Configuring the member switches: | |
| Enabling NDP | Optional |
| Enabling NTDP | Optional |
| Manually collecting topology information | Optional |
| Enabling the cluster function | Optional |
| Deleting a member switch from a cluster | Optional |
| Configuring access between the management switch and its member switches | Optional |
| Adding a candidate switch to a cluster | Optional |
| Configuring advanced cluster management functions: | |
| Configuring topology management | Optional |
| Configuring interaction for a cluster | Optional |
| SNMP configuration synchronization function | Optional |
| Configuring web user accounts in batches | Optional |

Configuring the management switch

Perform the tasks in this section to configure the management switch for a cluster.

Enabling NDP globally and for specific ports

For NDP to work normally, you must enable NTDP both globally and on specific ports.

To enable NDP globally and for specific ports:

| Step | Command | Remarks |
|-------------------------|--------------------|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable NDP globally. | ndp enable | Optional.
By default, this function is enabled. |

| Step | Command | Remarks |
|-------------------------------------|--|---|
| 3. Enable the NDP feature on ports. | <ul style="list-style-type: none"> • In system view:
ndp enable
interface <i>interface-list</i> • In Ethernet interface view or Layer 2 aggregate interface view: <ul style="list-style-type: none"> a. interface <i>interface-type</i>
<i>interface-number</i> b. ndp enable | Use either command.
By default, NDP is enabled globally and also on all ports. |

HP recommends that you disable NDP on a port which connects with the switches that do not need to join the cluster. This prevents the management switch from adding and collecting topology information from switches which do not need to join the cluster.

Configuring NDP parameters

A port enabled with NDP periodically sends NDP packets to its neighbors. If no NDP information from the neighbor is received to reset the holdtime, the holdtime times out and the switch removes the corresponding entry from the NDP table.

The time for the receiving switch to hold NDP packets cannot be shorter than the interval for sending NDP packets. Otherwise, the NDP table may become instable.

To configure NDP parameters:

| Step | Command | Remarks |
|---|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the interval for sending NDP packets. | ndp timer hello <i>hello-time</i> | Optional.
The default interval is 60 seconds. |
| 3. Configure the period for the receiving switch to keep the NDP packets. | ndp timer aging <i>aging-time</i> | Optional.
The default setting is 180 seconds. |

Enabling NTDP globally and for specific ports

For NTDP to work normally, you must enable NTDP both globally and on specific ports.

To enable NTDP globally and for specific ports:

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable NTDP globally. | ntdp enable | Optional.
By default, NTDP is enabled globally. |
| 3. Enter Ethernet interface view or Layer 2 aggregate interface view. | interface <i>interface-type</i>
<i>interface-number</i> | N/A |

| Step | Command | Remarks |
|------------------------------|--------------------|--|
| 4. Enable NTDP for the port. | ntdp enable | Optional.
By default, NTDP is enabled on all ports. |

HP recommends that you disable NTDP on a port which connects with the switches that do not need to join the cluster. This prevents the management switch from adding and collecting topology information from switches which do not need to join the cluster.

Configuring NTDP parameters

By configuring the maximum hops for collecting topology information, you can get topology information of the switches in a specified range, thus avoiding unlimited topology collection.

After the interval for collecting topology information is configured, the switch collects the topology information at this interval.

To avoid network congestion caused by large amounts of topology responses received in short periods:

- Upon receiving an NTDP topology-collection request, a switch does not forward it immediately. Instead, it waits for a period of time and then forwards the NTDP topology-collection request on its first NTDP-enabled port.
- Except for its first port, each switch's NTDP-enabled ports wait for a period of time, and then forward the NTDP topology collection request after the previous port forwards it.

To configure NTDP parameters:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the maximum hops for topology collection. | ntdp hop <i>hop-value</i> | Optional.
The default setting is 3. |
| 3. Configure the interval for collecting topology information. | ntdp timer <i>interval</i> | Optional.
The default interval is 1 minute. |
| 4. Configure the delay to forward topology-collection request packets on the first port. | ntdp timer hop-delay <i>delay-time</i> | Optional.
The default setting is 200 ms. |
| 5. Configure the port delay to forward topology-collection request on other ports. | ntdp timer port-delay <i>delay-time</i> | Optional.
The default setting is 20 ms. |

The two delay values should be configured on the topology collecting switch. A topology-collection request sent by the topology collecting switch carries the two delay values, and a switch that receives the request forwards the request according to the delays.

Manually collecting topology information

The management switch collects topology information periodically after a cluster is created. In addition, you can manually start topology information collection on the management switch or NTDP-enabled

switch, thus managing and monitoring switches in real time, regardless of whether a cluster is created. To configure to manually collect topology information:

| Task | Command |
|--|---------------------|
| Manually collect topology information. | ntdp explore |

Enabling the cluster function

| Step | Command | Remarks |
|--|-----------------------|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enable the cluster function globally. | cluster enable | Optional.
By default, this function is enabled. |

Establishing a cluster

Before establishing a cluster, you need to specify the management VLAN, and you cannot modify the management VLAN after a device is added to the cluster.

In addition, you need to configure a private IP address pool for the devices to be added to the cluster on the device to be configured as the management device before establishing a cluster. Meanwhile, the IP addresses of the VLAN interfaces of the management device and member devices cannot be in the same network segment as that of the cluster address pool; otherwise, the cluster cannot work normally. When a candidate device is added to a cluster, the management device assigns it a private IP address for it to communicate with other devices in the cluster.

You can establish a cluster in two ways: manually and automatically. You can follow the prompts to establish a cluster automatically. The system cluster auto-establishment process will prompt you through the following steps:

1. Enter a name for the cluster you want to establish.
2. List all the candidate switches within your predefined hop count.
3. Start to automatically add them to the cluster.

You can press **Ctrl+C** anytime during the adding process to exit the cluster auto-establishment process. However, this will only stop adding new switches into the cluster, and switches already added into the cluster are not removed.

To establish a cluster manually or automatically:

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Specify the management VLAN. | management-vlan <i>vlan-id</i> | Optional.
By default, VLAN 1 is the management VLAN. |
| 3. Enter cluster view. | cluster | N/A |
| 4. Configure the private IP address range for member switches. | ip-pool <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } | By default, the private IP address range for member switches is not configured. |

| Step | Command | Remarks |
|-------------------------|---|---|
| 5. Establish a cluster. | <ul style="list-style-type: none"> Manually establish a cluster:
build <i>cluster-name</i> Automatically establish a cluster:
auto-build [recover] | <p>Use either approach.</p> <p>By default, the switch is not the management switch.</p> |

Handshake packets use UDP port 40000. For a cluster to be established successfully, make sure that the port is not in use before establishing it.

Enabling management VLAN auto-negotiation

The management VLAN limits the cluster management range. If the switch discovered by the management switch does not belong to the management VLAN, meaning the cascade ports and the ports connecting with the management switch do not allow the packets from the management VLAN to pass, and the new switch cannot be added to the cluster. Through the configuration of the management VLAN auto-negotiation function, the cascade ports and the ports directly connected to the management switch can be automatically added to the management VLAN.

Configuration guidelines

When the management VLAN auto-negotiation is enabled, the ports connecting member switches change as follows:

- If a port was an access port, after changing to a hybrid port, the port does not permit the packets of any other VLAN to pass through except the management VLAN, which passes as tagged.
- If a port was a trunk or a hybrid port, the link type change process does not affect the port type and the permitted VLANs. The only change is permit the packets of the management VLAN to pass through tagged only for a hybrid port.

Before enabling this function, check the link types of ports connecting member switches and the VLANs whose packets are permitted to pass through to avoid influence to your network due to link type change of ports.

To configure management VLAN auto-negotiation:

| Step | Command | Remarks |
|---|---|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter cluster view. | cluster | N/A |
| 3. Enable management VLAN auto-negotiation. | management-vlan synchronization
enable | By default, this function is disabled. |

Configuring communication between the management switch and the member switches within a cluster

In a cluster, the management switch and member switches communicate by sending handshake packets to maintain connection between them. You can configure interval of sending handshake packets and the holdtime of a switch on the management switch. This configuration applies to all member switches within the cluster. For a member switch in Connect state:

- If the management switch does not receive handshake packets from a member switch within the

holdtime, it changes the state of the member switch to Disconnect. When the communication is recovered, the member switch needs to be re-added to the cluster (this process is automatically performed).

- If the management switch receives handshake packets from the member switch within the holdtime, the state of the member switch remains Active and the holdtime is restarted.

To configure communication between the management switch and the member switches within a cluster:

| Step | Command | Remarks |
|--|----------------------------------|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter cluster view. | cluster | N/A |
| 3. Configure the handshake interval. | timer <i>interval</i> | Optional.
The default interval is 10 seconds. |
| 4. Configure the holdtime of a switch. | holdtime <i>hold-time</i> | Optional.
The default setting is 60 seconds. |

Configuring cluster management protocol packets

By default, the destination MAC address of cluster management protocol packets (including NDP, NTDP and HABP packets) is a multicast MAC address 0180-C200-000A, which IEEE reserved for later use. Since some switches cannot forward the multicast packets with the destination MAC address of 0180-C200-000A, so cluster management packets cannot traverse these switches. For a cluster to work normally in this case, you can modify the destination MAC address of a cluster management protocol packet without changing the current networking.

The management switch periodically sends MAC address negotiation broadcast packets to advertise the destination MAC address of the cluster management protocol packets.

When you configure the destination MAC address for cluster management protocol packets:

- If the interval for sending MAC address negotiation broadcast packets is 0, the system automatically sets it to 1 minute.
- If the interval for sending MAC address negotiation broadcast packets is not 0, the interval remains unchanged.

To configure the destination MAC address of the cluster management protocol packets:

| Step | Command | Remarks |
|------------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |
| 2. Enter cluster view. | cluster | N/A |

| Step | Command | Remarks |
|---|---|---|
| 3. Configure the destination MAC address for cluster management protocol packets. | cluster-mac <i>mac-address</i> | By default, the destination MAC address is 0180-C200-000A.
The following are the configurable MAC addresses: <ul style="list-style-type: none"> • 0180-C200-0000 • 0180-C200-000A • 0180-C200-0020 through 0180-C200-002F • 010F-E200-0002 |
| 4. Configure the interval for sending MAC address negotiation broadcast packets. | cluster-mac syn-interval <i>interval</i> | Optional.
The default interval is one minute. |

Cluster member management

You can manually add a candidate switch to a cluster, or remove a member switch from a cluster.

If a member switch needs to be rebooted for software upgrade or configuration update, you can remotely reboot it through the management switch.

Adding a member switch

| Step | Command |
|---|--|
| 1. Enter system view. | system-view |
| 2. Enter cluster view. | cluster |
| 3. Add a candidate switch to the cluster. | add-member [<i>member-number</i>] mac-address <i>mac-address</i> [password <i>password</i>] |

Removing a member switch

| Step | Command |
|---|--|
| 1. Enter system view. | system-view |
| 2. Enter cluster view. | cluster |
| 3. Remove a member switch from the cluster. | delete-member <i>member-number</i> [to-black-list] |

Rebooting a member switch

| Step | Command |
|--------------------------------------|---|
| 1. Enter system view. | system-view |
| 2. Enter cluster view. | cluster |
| 3. Reboot a specified member switch. | reboot member { <i>member-number</i> mac-address <i>mac-address</i> } [eraseflash] |

Configuring the member switches

Enabling NDP

See "Enabling NDP globally and for specific ports."

Enabling NTDP

See "Enabling NTDP globally and for specific ports."

Manually collecting topology information

See "Manually collecting topology information."

Enabling the cluster function

See "Enabling the cluster function."

Deleting a member switch from a cluster

| Step | Command |
|---|-----------------------------------|
| 1. Enter system view. | system-view |
| 2. Enter cluster view. | cluster |
| 3. Delete a member switch from the cluster. | undo administrator-address |

Configuring access between the management switch and its member switches

After having successfully configured NDP, NTDP and cluster, you can configure, manage and monitor the member switches through the management switch. You can manage member switches in a cluster through switching from the operation interface of the management switch to that of a member switch or configure the management switch by switching from the operation interface of a member switch to that of the management switch.

Configuration guidelines

Telnet connection is used in the switching between the management switch and a member switch. Note the following when switching between them:

- Authentication is required when you switch from a member switch to the management switch. The switching fails if authentication is not passed. If authentication is passed, your user level is allocated by the management switch according to the predefined level.
- When a candidate switch is added to a cluster and becomes a member switch, its super password with the level of 3 will be automatically synchronized to the management switch. Therefore, after a cluster is established, it is not recommended to modify the super password of any member

(including the management switch and member switches) of the cluster; otherwise, the switching may fail because of an authentication failure.

- If the member specified in this command does not exist, the system prompts error when you execute the command; if the switching succeeds, your user level on the management switch is retained.
- If the Telnet users on the switch to be logged in reach the maximum number, the switching fails.
- To prevent resource waste, avoid ring switching when configuring access between cluster members. For example, if you switch from the operation interface of the management switch to that of a member switch and then need to switch back to that of the management switch, use the **quit** command to end the switching, but not the **cluster switch-to administrator** command to switch to the operation interface of the management switch.

Configuration procedure

To configure access between member switches of a cluster:

| Step | Command |
|---|--|
| 1. Switch from the operation interface of the management switch to that of a member switch. | cluster switch-to { <i>member-number</i> mac-address <i>mac-address</i> sysname <i>member-sysname</i> } |
| 2. Switch from the operation interface of a member switch to that of the management switch. | cluster switch-to administrator |

Adding a candidate switch to a cluster

| Step | Command |
|---|---|
| 1. Enter system view. | system-view |
| 2. Enter cluster view. | cluster |
| 3. Add a candidate switch to the cluster. | administrator-address <i>mac-address</i> name <i>name</i> |

Configuring advanced cluster management functions

Configuring topology management

The concepts of blacklist and whitelist are used for topology management. An administrator can diagnose the network by comparing the current topology (namely, the information of a node and its neighbors in the cluster) and the standard topology.

- Topology management whitelist (standard topology): A whitelist is a list of topology information that has been confirmed by the administrator as correct. You can get the information of a node and its neighbors from the current topology. Based on the information, you can manage and maintain the whitelist by adding, deleting or modifying a node.
- Topology management blacklist: Switches in a blacklist are not allowed to join a cluster. A blacklist contains the MAC addresses of switches. If a blacklisted switch is connected to a network through

another switch not included in the blacklist, the MAC address and access port of the latter are also included in the blacklist. The candidate switches in a blacklist can be added to a cluster only if the administrator manually removes them from the list.

The whitelist and blacklist are mutually exclusive. A whitelist member cannot be a blacklist member, and the blacklist member cannot be a whitelist member. However, a topology node can belong to neither the whitelist nor the blacklist. Nodes of this type are usually newly added nodes, whose identities are to be confirmed by the administrator.

You can back up and restore the whitelist and blacklist in the following two ways:

- Backing them up on the FTP server shared by the cluster. You can manually restore the whitelist and blacklist from the FTP server.
- Backing them up in the Flash of the management switch. When the management switch restarts, the whitelist and blacklist will be automatically restored from the Flash. When a cluster is re-established, you can choose whether to restore the whitelist and blacklist from the Flash automatically, or you can manually restore them from the Flash of the management switch.

To configure cluster topology management:

| Step | Command | Remarks |
|---|---|-----------|
| 1. Enter system view. | system-view | N/A |
| 2. Enter cluster view. | cluster | N/A |
| 3. Add a switch to the blacklist. | black-list add-mac <i>mac-address</i> | Optional. |
| 4. Remove a switch from the blacklist. | black-list delete-mac { all <i>mac-address</i> } | Optional. |
| 5. Confirm the current topology and save it as the standard topology. | topology accept { all [save-to { ftp-server local-flash }] mac-address <i>mac-address</i> member-id <i>member-number</i> } | Optional. |
| 6. Save the standard topology to the FTP server or the local Flash. | topology save-to { ftp-server local-flash } | Optional. |
| 7. Restore the standard topology information. | topology restore-from { ftp-server local-flash } | Optional. |

Configuring interaction for a cluster

After establishing a cluster, you can configure FTP/TFTP server, NM host and log host for the cluster on the management switch.

- After you configure an FTP/TFTP server for a cluster, the members in the cluster access the FTP/TFTP server configured through the management switch. Execute the **ftp server-address** or **tftp server-address** command and specifying the private IP address of the management switch as the *server-address*. For more information about the **ftp** and **tftp** commands, see *Fundamentals Command Reference*.
- After you configure a log host for a cluster, all the log information of the members in the cluster will be output to the configured log host in the following way:
 - Member switches send their log information to the management switch.
 - The management switch converts the addresses of log information and sends them to the log host.

- After you configure an NM host for a cluster, the member switches in the cluster send their Trap messages to the shared SNMP NM host through the management switch.

If the port of an access NM switch (including FTP/TFTP server, NM host and log host) does not allow the packets from the management VLAN to pass, the NM switch cannot manage the switches in a cluster through the management switch. In this case, on the management switch, you need to configure the VLAN interface of the access NM switch (including FTP/TFTP server, NM host and log host) as the NM interface.

To isolate management protocol packets of a cluster from packets outside the cluster, HP recommends you configure the ports connected to the external networks as not allowing the management VLAN to pass through and configure the NM interface for the management switch.

To configure the interaction for a cluster:

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter cluster view. | cluster | N/A |
| 3. Configure the FTP server shared by the cluster. | ftp-server <i>ip-address</i> [user-name <i>username</i> password { simple cipher } <i>password</i>] | By default, no FTP server is configured for a cluster. |
| 4. Configure the TFTP server shared by the cluster. | tftp-server <i>ip-address</i> | By default, no TFTP server is configured for a cluster. |
| 5. Configure the log host shared by the member switches in the cluster. | logging-host <i>ip-address</i> | By default, no log host is configured for a cluster. |
| 6. Configure the SNMP NM host shared by the cluster. | snmp-host <i>ip-address</i> [community-string read <i>string1</i> write <i>string2</i>] | By default, no SNMP host is configured. |
| 7. Configure the NM interface of the management switch. | nm-interface vlan-interface <i>interface-name</i> | Optional. |

SNMP configuration synchronization function

Using the SNMP configuration synchronization function facilitates management of a cluster, with which you can perform SNMP-related configurations on the management switch and synchronize them to the member switches on the whitelist. This operation is equal to configuring multiple member switches at one time. It simplifies the configuration process.

To configure the SNMP configuration synchronization function:

| Step | Command | Remarks |
|---|--|---------|
| 1. Enter system view. | system-view | N/A |
| 2. Enter cluster view. | cluster | N/A |
| 3. Configure the SNMP community name shared by a cluster. | cluster-snmp-agent community { read write } <i>community-name</i> [mib-view <i>view-name</i>] | N/A |

| Step | Command | Remarks |
|--|--|---|
| 4. Configure the SNMPv3 group shared by a cluster. | cluster-snmp-agent group v3
<i>group-name</i> [authentication privacy] [read-view <i>read-view</i>] [write-view <i>write-view</i>] [notify-view <i>notify-view</i>] | N/A |
| 5. Create or update information of the MIB view shared by a cluster. | cluster-snmp-agent mib-view included <i>view-name oid-tree</i> | By default, the name of the MIB view shared by a cluster is ViewDefault and a cluster can access the ISO subtree. |
| 6. Add a user for the SNMPv3 group shared by a cluster. | cluster-snmp-agent usm-user v3
<i>user-name group-name</i>
[authentication-mode { md5 sha } <i>auth-password</i>] [privacy-mode des56 <i>priv-password</i>] | N/A |

The SNMP-related configurations are retained when a cluster is dismissed or the member switches are removed from the whitelist. For more information about SNMP, see "[Configuring SNMP](#)."

Configuring web user accounts in batches

Configuring web user accounts in batches enables you to do the following:

- Through the web interface, configure, on the management switch, the username and password used to log in to the cluster switches (including the management switch and member switches).
- Synchronize the configurations to the member switches in the whitelist.

This operation is equal to performing the configurations on the member switches. You need to enter your username and password when you log in to the cluster switches (including the management switch and member switches) through the web interface.

To configure web user accounts in batches:

| Step | Command |
|--|---|
| 1. Enter system view. | system-view |
| 2. Enter cluster view. | cluster |
| 3. Configure web user accounts in batches. | cluster-local-user <i>user-name password</i> { cipher simple } <i>password</i> |

If a cluster is dismissed or the member switches are removed from the whitelist, the configurations of web user accounts are still retained.

Displaying and maintaining cluster management

| Task | Command | Remarks |
|--|--|-----------------------|
| Display NDP configuration information. | display ndp [interface <i>interface-list</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |

| Task | Command | Remarks |
|---|---|------------------------|
| Display NTDP configuration information. | display ntdp [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the switch information collected through NTDP. | display ntdp device-list [verbose] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the detailed NTDP information of a specified switch. | display ntdp single-device mac-address <i>mac-address</i> [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display information of the cluster to which the current switch belongs. | display cluster [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the standard topology information. | display cluster base-topology [<i>mac-address mac-address</i> member-id <i>member-number</i>] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the current blacklist of the cluster. | display cluster black-list [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the information of candidate switches. | display cluster candidates [<i>mac-address mac-address</i> verbose] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the current topology information. | display cluster current-topology [<i>mac-address mac-address</i> [to-mac-address <i>mac-address</i>] member-id <i>member-number</i> [to-member-id <i>member-number</i>]] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display information about cluster members. | display cluster members [<i>member-number</i> verbose] [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Clear NDP statistics. | reset ndp statistics [interface <i>interface-list</i>] | Available in user view |

Cluster management configuration example

Network requirements

- Three switches form cluster **abc**, whose management VLAN is VLAN 10. In the cluster, Switch B serves as the management switch (Administrator), whose network management interface is VLAN-interface 2; Switch A and Switch C are the member switches (Member).
- All the switches in the cluster use the same FTP server and TFTP server on host 63.172.55.1/24, and use the same SNMP NMS and log services on host IP address: 69.172.55.4/24.
- Add the switch whose MAC address is 000f-e201-0013 to the blacklist.

Figure 60 Network diagram

Configuration procedure

1. Configure the member switch Switch A:

Enable NDP globally and for port GigabitEthernet 1/0/1.

```
<SwitchA> system-view
[SwitchA] ndp enable
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] ndp enable
[SwitchA-GigabitEthernet1/0/1] quit
```

Enable NTPD globally and for port GigabitEthernet 1/0/1.

```
[SwitchA] ntpd enable
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] ntpd enable
[SwitchA-GigabitEthernet1/0/1] quit
```

Enable the cluster function.

```
[SwitchA] cluster enable
```

2. Configure the member switch Switch C:

As the configurations for the member switches are the same, the configuration procedure for Switch C is not shown here.

3. Configure the management switch Switch B:

Enable NDP globally and for ports GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

```
<SwitchB> system-view
[SwitchB] ndp enable
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ndp enable
[SwitchB-GigabitEthernet1/0/2] quit
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ndp enable
```

```

[SwitchB-GigabitEthernet1/0/3] quit
# Configure the period for the receiving switch to keep NDP packets as 200 seconds.
[SwitchB] ndp timer aging 200
# Configure the interval to send NDP packets as 70 seconds.
[SwitchB] ndp timer hello 70
# Enable NTDP globally and for ports GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.
[SwitchB] ntdp enable
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ntdp enable
[SwitchB-GigabitEthernet1/0/2] quit
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ntdp enable
[SwitchB-GigabitEthernet1/0/3] quit
# Configure the hop count to collect topology as 2.
[SwitchB] ntdp hop 2
# Configure the delay to forward topology-collection request packets on the first port as 150 ms.
[SwitchB] ntdp timer hop-delay 150
# Configure the delay to forward topology-collection request packets on the first port as 15 ms.
[SwitchB] ntdp timer port-delay 15

Configuring CWMP

Hardware compatibility

The CWMP feature is available only on the HP 5500 EI switches.

CWMP overview

CPE WAN Management Protocol (CWMP), also called "TR-069," is a DSL Forum technical specification for remote management of home network devices. It defines the general framework, message format, management method, and data model for managing and configuring home network devices.

CWMP is mainly applied to DSL access networks, which are hard to manage because end-user devices are dispersed and large in number. CWMP makes the management easier by using an auto-configuration server (ACS) to perform remote centralized management of customer premises equipment (CPE).

CWMP network framework

Figure 61 shows a basic CWMP network framework. The DHCP server, ACS, and DNS server can also be located on the same server.

Figure 61 CWMP network framework

The basic CWMP network elements include:

- **CPE**—Customer premises equipment, the managed device in the network.
- **ACS**—Auto-configuration server, the management device in the network. In this document, ACS refers to the server installed with the HP iMC BIMS system.
- **DNS server**—Domain name system server. An ACS and a CPE use URLs to identify and access each other. DNS is used to resolve the URLs.

- **DHCP server**—Dynamic Host Configuration Protocol (DHCP) server, which assigns IP addresses to CPEs, and uses the options filed in the DHCP packet to provide configuration parameters (such as URL) to the CPEs.

Basic CWMP functions

Automatic configuration file deployment

The network administrator can create different configuration files on the ACS for access switches according to their service functions to realize fast configuration. After a connection is established between the ACS and a CPE, the ACS determines the type of the CPE and delivers the corresponding configuration file to the CPE. In this way, CPEs of the same type obtain the same service configurations. The ACS divides CPEs by their switch models or serial IDs.

A configuration file delivered by the ACS can be either the startup configuration or the running configuration on the CPE.

- **Startup configuration**—The configuration file delivered by the ACS overwrites the default configuration file on the CPE. After the CPE reboots, it runs the new configuration file.
- **Running configuration**—The configuration file delivered by the ACS is written to the running configuration file on the CPE, and the new configurations take effect immediately. You need to save the new configurations to make them survive a switch reboot.

CPE system software image file and configuration file management

The network administrator can save important files such as the application file and configuration file of a CPE to an ACS. If the ACS finds that a file is updated, it notifies the CPE to download the file by sending a request. After the CPE receives the request, it automatically downloads the file from the specified file server according to the filename and downloading address provided in the ACS request. After the CPE downloads the file, it checks the file validity and then report the download result (success or failure) to the ACS.

CPEs can download the following types of files from the ACS: application file and configuration file.

To backup important data, a CPE can upload the current configuration file and log files to the specified server according to the requirement of an ACS.

CPE status and performance monitoring

An ACS can monitor the parameters of a CPE connected to it. Different CPEs have different performances and functionalities. Therefore the ACS must be able to identify each type of CPE and monitor the current configuration and configuration changes of each CPE. CWMP also allows the administrator to define monitor parameters and get the parameter values through an ACS, so as to get the CPE status and statistics.

The status and performance that can be monitored by an ACS include:

- Manufacture name (Manufacturer)
- ManufacturerOUI
- SerialNumber
- HardwareVersion
- SoftwareVersion
- DeviceStatus
- UpTime
- Configuration file (ConfigFile)

- ACS address (URL)
- ACS username (Username)
- ACS password (Password)
- PeriodicInformEnable
- PeriodicInformInterval
- PeriodicInformTime
- CPE address (ConnectionRequestURL)
- CPE username (ConnectionRequestUsername)
- CPE password (ConnectionRequestPassword)

CWMP mechanism

Auto-connection between the ACS and a CPE

When a CPE starts up for the first time, it automatically obtains an IP address from the DHCP server, which informs the CPE of the following information:

- The URL address of the ACS (assigned by the DHCP server through Option 43)
- Username and password for connecting the ACS (assigned by the DHCP server through Option 43)
- DNS server address (directly assigned)

After the CPE receives the above information, it has the IP address of the ACS resolved by the DNS server, and sends a connection request to the ACS. If the CPE passes the authentication with the acquired username and password, the connection between the ACS and the CPE is established.

If the current session is not finished but the connection between ACS and CPE is interrupted, the CPE automatically establishes a new connection with the ACS until the number of CPE auto-connection retries reaches the limit.

The CPE can send connection requests either periodically or at the specified time to the ACS. The ACS can initiate a connection request to the CPE at any time, and can establish a connection with the CPE after passing CPE authentication.

Configuration parameter deployment

When a CPE logs in to an ACS, the ACS can automatically apply some configurations to the CPE for it to perform auto configuration. [Table 9](#) lists the auto-configuration parameters supported by the switch.

Table 9 Auto-configuration parameters and their functions

| Auto-configuration parameters | Function |
|---------------------------------|--|
| Configuration file (ConfigFile) | Updates the local configuration file on the CPE. The ACS delivers a configuration file to the CPE in one of the following formats: file or current configuration. |
| ACS address (URL) | Updates the ACS address kept on the CPE. The parameter is used when there is an active and standby ACS switchover. |
| ACS username (Username) | Automatically synchronizes the username and password on the CPE when those on the ACS change. The parameters are also used to inform the CPE of the authentication information of the standby ACS server when there is an active and standby ACS switchover. |
| ACS password (Password) | |
| PeriodicInformEnable | Enables the sending of Inform messages. |

| Auto-configuration parameters | Function |
|---|--|
| PeriodicInformInterval | Configures the CPE to send an Inform message periodically. The parameter is used for querying updates and information backup regularly. |
| PeriodicInformTime | Configures the CPE to send an Inform message at a specified time. The parameter is used for querying updates and information backup at a specified time. |
| CPE username
(ConnectionRequestUsername) | Configures the CPE username and password for connection to the ACS. |
| CPE password
(ConnectionRequestPassword) | |

RPC methods

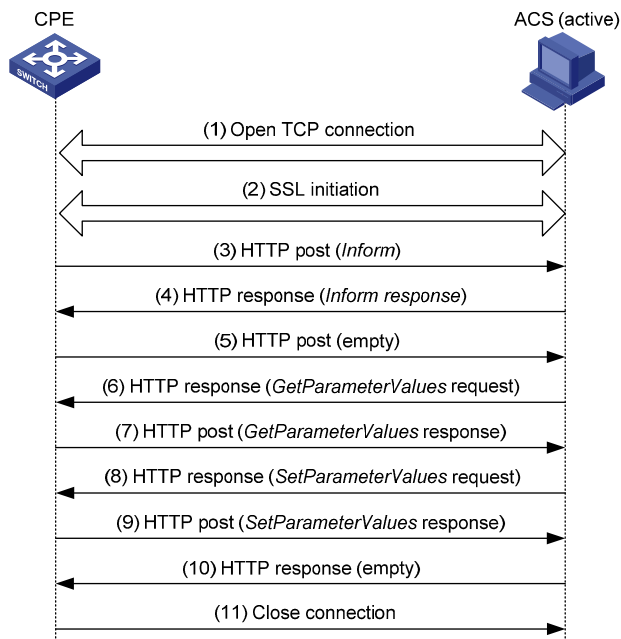

CWMP provides the following major remote procedure call (RPC) methods for an ACS to manage or monitor a CPE:

- **Get**—The ACS gets the value of one or more parameters from the CPE.
- **Set**—The ACS sets the value of one or more parameters on the CPE.
- **Inform**—The CPE sends an Inform message to an ACS whenever the CPE initiates a connection to the ACS, or the CPE's underlying configuration changes, or the CPE periodically sends its local information to the ACS.
- **Download**—The ACS requires a CPE to download a specific file from the specified URL, ensuring upgrading of CPE software and auto download of the vendor configuration file.
- **Upload**—The ACS requires a CPE to upload a specific file to the specified location.
- **Reboot**—The ACS remotely reboots the CPE when the CPE encounters a failure or completes a software upgrade.

How CWMP works

The following example illustrates how CWMP works. This example has two ACSs, main and backup in an area. The main ACS must restart for system upgrade. To ensure continuous CPE monitoring, the main ACS switch all CPEs in the area to the backup ACS.

Figure 62 Example of CWMP message interaction

The whole process is as follows:

1. Establish a TCP connection.
2. SSL initialization, and establish a security connection.
3. The CPE sends an Inform request message to initiate a CWMP connection. The Inform message carries the reason for sending this message in the Eventcode field. In this example, the reason is "6 CONNECTION REQUEST", indicating that the ACS requires the CPE to establish a connection.
4. If the CPE passes the authentication of the ACS, the ACS returns an Inform response, and the connection is established.
5. Receiving the Inform response, the CPE sends an empty message, if it has no other requests. The CPE does this in order to comply with the request/reply interaction model of HTTP, in which CWMP messages are conveyed.
6. The ACS queries the value of the ACS URL set on the CPE.
7. The CPE replies to the ACS with the obtained value of the ACS URL.
8. The ACS finds that its local URL value is the same as the value of the ACS URL on the CPE. Therefore, the ACS sends a Set request to the CPE to modify the ACS URL value of the CPE to the URL of the standby ACS.
9. The setting succeeds and the CPE sends a response.
10. The ACS sends an empty message to notify the CPE that it does not request for any other information from the CPE.
11. The CPE closes the connection.

After this, the CPE will initiate a connection to the standby ACS.

CWMP configuration tasks

Configuring the DHCP server

In a CWMP network, the DHCP server is mainly used to notify the ACS location and authentication information to the ACS. DHCP server configuration includes the following tasks:

- Configuring a DHCP address pool for allocating IP addresses to CPEs.
- Configuring the DNS server.
- Configuring the Option 43 field to notify the ACS information to CPEs.

The following describes how to configure the option 43 field:

You can configure ACS parameters for the CPE on the DHCP server through DHCP Option 43. When accessed by the CPE, the DHCP server sends the ACS parameters in DHCP Option 43 to the CPE. If the DHCP server is an HP switch that supports DHCP Option 43, you can configure the ACS parameters at the CLI with the command **option 43 hex 01 length URL username password**, where:

- *length* is a hexadecimal string that indicates the total length of the *URL username password* arguments. No space is allowed between the **01** keyword and the length value.
- *URL* is the ACS address.
- *username* is the ACS username.
- *password* is the ACS password.

When configuring the ACS URL, username and password, follow these guidelines:

- The three arguments take the hexadecimal format and the ACS URL and username must each end with a space (20 in hexadecimal format) for separation.
- The three arguments must be input in 2-digit, 4-digit, 6-digit, or 8-digit segments, each separated by a space.

For example, to set the ACS address to **http://169.254.76.31:7547/acs**, username to **1234**, and password to **5678**, you can configure as follows:

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] option 43 hex 0127 68747470 3A2F2F31 36392E32 35342E37 362E3331
3A373534 372F6163 73203132 33342035 3637 38
```

In the **option 43 hex** command:

- 27 indicates that the length of the subsequent hexadecimal strings is 39 characters.
- 68747470 3A2F2F31 36392E32 35342E37 362E3331 3A373534 372F6163 73 corresponds to the ACS address **http://169.254.76.31/acs**.
- 3132 3334 corresponds to the username **1234**.
- 35 3637 38 corresponds to the password **5678**.
- 20 is the end delimiter.

For more information about DHCP, DHCP Option 43, the **option** command, DHCP address pool configuration, and DNS server configuration, see *Layer 3—IP Services Configuration Guide*.

Configuring the DNS server

On the DNS server, you need to bind the URL address to the IP address of the ACS server to make sure that CPEs can obtain the IP address of the ACS through the DNS function.

Configuring the ACS server

An ACS performs auto-configuration of a CPE through remote management. For the primary configurable parameters, see "[Configuration parameter deployment](#)." For how to configure the ACS server, see the user manual came with your ACS server.

Configuring CPEs

You can set CWMP parameters at the CLI.

The switches operate as CPEs in a CWMP-enabled network, so the following describes only the configuration on CPEs.

Complete these tasks to configure CWMP:

| Task | Remarks |
|---|----------|
| Enabling CWMP | Required |
| Configuring the ACS server: | |
| Configuring the ACS URL | Required |
| Configuring the ACS username and password | Optional |
| Configuring CPE attributes: | |
| Configuring the CPE username and password | Optional |
| Configuring the CWMP connection interface | Optional |
| Configuring the CWMP connection interface | Optional |
| Configuring the maximum number of attempts made to retry a connection | Optional |
| Configuring the close-wait timer of the CPE | Optional |
| Configuring the CPE working mode | Optional |
| Specifying an SSL client policy for HTTPS connection to ACS | Optional |

Enabling CWMP

CWMP configurations can take effect only after you enable CWMP.

To enable CWMP:

| Step | Command | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |

| Step | Command | Remarks |
|-----------------|--------------------|---|
| 3. Enable CWMP. | cwmp enable | Optional.
By default, CWMP is enabled. |

Configuring the ACS attributes

ACS attributes include ACS URL, username and password. When the CPE initiates a connection to the ACS, the ACS URL, username and password are carried in the connection request. After the ACS receives the request, if the parameter values in the request are consistent with those configured locally, the authentication succeeds, and the connection is allowed to be established. If not, the authentication fails, and the connection is not allowed to be established.

Configuring the ACS URL

You can assign only one ACS to a CPE and the ACS URL you configured overwrites the old one, if any. To configure the ACS URL:

| Step | Command | Remarks |
|---------------------------|--------------------------------|---------------------------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |
| 3. Configure the ACS URL. | cwmp acs url <i>url</i> | By default, no ACS URL is configured. |

Configuring the ACS username and password

To pass ACS authentication, make sure that the configured username and password are the same as those configured for the CPE on the ACS.

To configure the ACS username and password:

| Step | Command | Remarks |
|--|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |
| 3. Configure the ACS username for connection to the ACS. | cwmp acs username <i>username</i> | By default, no ACS username is configured for connection to the ACS.

Optional. |
| 4. Configure the ACS password for connection to the ACS. | cwmp acs password [cipher simple] <i>password</i> | You can specify a username without a password that is used in the authentication. If so, the configuration on the ACS and that on the CPE must be the same.

By default, no ACS password is configured for connection to the ACS. |

Configuring CPE attributes

CPE attributes include CPE username and password, which are used by a CPE to authenticate an ACS. When an ACS initiates a connection to a CPE, the ACS sends a session request carrying the CPE URL, username, and password. When the switch (CPE) receives the request, it compares the CPE URL, username, and password with those configured locally. If they are the same, the ACS passes the authentication of the CPE, and the connection establishment proceeds. Otherwise, the authentication fails, and the connection establishment is terminated.

Configuring the CPE username and password

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |
| 3. Configure the CPE username for connection to the CPE. | cwmp cpe username <i>username</i> | By default, no CPE username is configured for connection to the CPE. |
| 4. Configure the CPE password for connection to the CPE. | cwmp cpe password [cipher simple] <i>password</i> | Optional.
You can specify a username without a password that is used in the authentication. If so, the configuration on the ACS and that on the CPE must be the same.
By default, no CPE password is configured for connection to the CPE. |

Configuring the CWMP connection interface

The CWMP connection interface is the interface that the CPE uses to communicate with the ACS. The CPE sends the IP address of this interface in the Inform messages and the ACS replies to this IP address for setting up a CWMP connection.

If the interface that connects the CPE to the ACS is the only Layer 3 interface that has an IP address on the device, you do not need to specify the CWMP connection interface. If multiple Layer 3 interfaces are configured, specify the CWMP connection interface to make sure that the IP address of the interface connects to the ACS is sent to the ACS for setting up CWMP connection.

To configure a CWMP connection interface:

| Step | Command | Remarks |
|--|--|--|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |
| 3. Set the interface that connects the CPE to the ACS. | cwmp cpe connect interface <i>interface-type interface-number</i> | By default, the interface for connecting the CPE to the ACS is not configured. |

Sending Inform messages

You must configure the Inform message sending parameter on the CPE to initiate a connection to the ACS.

To configure the CPE to periodically send Inform messages:

| Step | Command | Remarks |
|--|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |
| 3. Enable the periodical sending of Inform messages. | cwmp cpe inform interval enable | By default, this function is disabled. |
| 4. Configure the interval between sending the Inform messages. | cwmp cpe inform interval seconds | Optional.
By default, the CPE sends an Inform message every 600 seconds. |

To configure the CPE to send an Inform message at a specific time:

| Step | Command | Remarks |
|--|----------------------------------|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |
| 3. Configure the CPE to send an Inform message at a specific time. | cwmp cpe inform time time | By default, no time is set. The CPE is not configured to send an Inform message at a specific time. |

Configuring the maximum number of attempts made to retry a connection

If a CPE fails to establish a connection to an ACS, or the connection is interrupted during the session (the CPE does not receive a message indicating the normal close of the session), the CPE can automatically reinitiate a connection to the ACS.

To configure the maximum number of attempts that a CPE can make to retry a connection:

| Step | Command | Remarks |
|--|-------------------------------------|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |
| 3. Configure the maximum number of attempts that a CPE can make to retry a connection. | cwmp cpe connect retry times | Optional.
By default, a CPE regularly sends connection requests to the ACS until a connection is set up. |

Configuring the close-wait timer of the CPE

The close-wait timeout is used mainly in the following cases:

- During the establishment of a connection: If the CPE sends connection requests to the ACS, but the CPE does not receive a response within the configured close-wait timeout, the CPE will consider the connection failed.
- After a connection is established: If there is no packet interaction between the CPE and ACS within the configured close-wait timeout, the CPE will consider the connection invalid, and disconnect the connection.

To configure the close wait timer of a CPE:

| Step | Command | Remarks |
|---|--------------------------------------|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |
| 3. Configure the timeout value of the CPE close-wait timer. | cwmp cpe wait timeout seconds | Optional.
The default setting is 30 seconds. |

Configuring the CPE working mode

Configure the device to operate in one of the following CPE modes depending on its position in the network:

- **Gateway mode**—Enables the ACS to manage the device and any CPE attached to the device. Use this mode if the device is the egress to the WAN and has lower-level CPEs.
- **Device mode**—If no CPEs are attached to the device, configure the device to operate in device mode.

Disable CWMP before you change the CPE working mode.

To configure the working mode of the CPE:

| Step | Command | Remarks |
|---|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |
| 3. Configure the working mode of the CPE. | cwmp device-type { device gateway } | By default, the device operates in gateway mode. |

Specifying an SSL client policy for HTTPS connection to ACS

CWMP uses HTTP or HTTPS for data transmission. If the ACS uses HTTPS for secure access, its URL begins with **https://**. You must configure an SSL client policy for the CPE to authenticate the ACS for establishing an HTTPS connection. For more information about configuring SSL client policies, see *Security Configuration Guide*.

To specify an SSL client policy for the CPE to establish an HTTPS connection to the ACS:

| Step | Command | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | system-view | N/A |
| 2. Enter CWMP view. | cwmp | N/A |

| Step | Command | Remarks |
|----------------------------------|---|--|
| 3. Specify an SSL client policy. | ssl client-policy <i>policy-name</i> | By default, SSL client policy is disabled. |

Displaying and maintaining CWMP

| Task | Command | Remarks |
|-------------------------------------|--|-----------------------|
| Display CWMP configuration. | display cwmp configuration [{ begin exclude include } <i>regular-expression</i>] | Available in any view |
| Display the current status of CWMP. | display cwmp status [{ begin exclude include } <i>regular-expression</i>] | Available in any view |

CWMP configuration example

Configuration guidelines

Before configuring the ACS server, make sure that the HP iMC BIMS software is installed on the server. The BIMS functions and web interface might change along with software updates. If your web interface is different from that in this example, see the user manual came with your server.

Network requirements

A data center has two equipment rooms A and B. Both rooms require a great number of switches. There are ACS, DHCP, and DNS servers on the network. To improve deployment efficiency, use CWMP to deliver different configuration files to the switches in rooms A and B. In this example, each room has three switches.

Figure 63 Network diagram

Table 10 Switches deployed in two equipment rooms

| Equipment room | Switch | Serial ID |
|----------------|---------|---------------------|
| A | DeviceA | 210235AOLNH12000008 |
| | DeviceB | 210235AOLNH12000010 |
| | DeviceC | 210235AOLNH12000015 |
| B | DeviceD | 210235AOLNH12000017 |
| | DeviceE | 210235AOLNH12000020 |
| | DeviceF | 210235AOLNH12000022 |

The network administrator has created two configuration files **sys.a.cfg** and **sys_b.cfg** for the switches in the two rooms. The username and password for accessing the ACS server is **vicky** and **12345**. The URL address is <http://acs.database:9090/acs>.

Configuration procedure

1. Configure the ACS server:

ACS server configuration includes the following tasks:

- Setting the username and password for accessing the ACS server.
- Adding information about CPEs and divide CPEs into different groups.
- Binding configuration files to different CPE groups.

Other configurations on the ACS server keep their default value.

Set a username and password on the ACS server.

Click the **System Management** tab, and select **CPE Authentication Users** from the navigation tree to enter the CPE authentication user configuration page.

Figure 64 CPE Authentication User page

Configuration of the switches in room B is the same as that of the switches in room A except that you need to perform the following configuration:

- Create device class Device_B for switches in room B.
- Add switches in room B to the device class Device_B.
- Bind the configuration file corresponding to switches in room B to the device class Device_B.

2. Configure the DHCP server:

In this example, the DHCP server is an HP switch supporting the Option 43 function. If your DHCP server is not an HP switch supporting the Option 43 function, see the user manual came with your server.

Configure a DHCP address pool. Assign IP addresses to CPEs and the DNS server. In this example, the addresses are in the network segment 10.185.10.0/24.

Enable DHCP.

```
<DHCP_server> system-view
[DHCP_server] dhcp enable
```

Enable the DHCP server on VLAN-interface 1.

```
[DHCP_server] interface vlan-interface 1
[DHCP_server-Vlan-interface1] dhcp select server global-pool
[DHCP_server-Vlan-interface1] quit
```

Exclude IP addresses (addresses of the DNS server and ACS server).

```
[DHCP_server] dhcp server forbidden-ip 10.185.10.41
[DHCP_server] dhcp server forbidden-ip 10.185.10.60
```

Configure DHCP address pool 0 (subnet and DNS server address).

```
[DHCP_server] dhcp server ip-pool 0
[DHCP_server-dhcp-pool-0] network 10.185.10.0 mask 255.255.255.0
[DHCP_server-dhcp-pool-0] dns-list 10.185.10.60
```

Configure Option 43 to contain the ACS address, username, and password.

Convert the ACS address, username, and password to ASCII code. The ASCII code of the URL address is 68 74 74 70 3A 2F 2F 61 63 73 2E 64 61 74 61 62 61 73 65 3A 39 30 39 30 2F 61 63 73, that of the username Vicky is 76 69 63 6B 79, and that of the password 12345 is 31 32 33 34 35.

```
[DHCP_server-dhcp-pool-0] option 43 hex 0140 68747470 3A2F2F61 63732E64 61746162
6173653A 39303930 2F616373 20766963 6B792031 32333435
```

3. Configure the DNS server:

Configure the mappings between the domain name and IP address, that is, create the mapping between the addresses <http://acs.database:9090/acs> and <http://10.185.1.41:9090/acs>. For how to create a mapping between addresses, see the user manual came with your DNS server.

4. Connect CPEs to the network:

Connect the CPEs with network cables and power them on, the CPEs can automatically obtain configuration files from the ACS server.

5. Verify the configuration on the ACS server:

Click the **Resource** tab, select **Device Interaction Log** from the navigation tree to enter the page for querying device interaction records. You can view whether the deployment configuration of a switch is completed.

Configuring a stack (available only on the HP 5500 SI)

The stack management feature enables you to configure and monitor a group of connected switches by logging in to one switch in the stack, as shown in [Figure 75](#).

Figure 75 Network diagram for stack management

To set up a stack for a group of connected switches, you must log in to one switch to create the stack. This switch is the master switch for the stack, and you configure and monitor all other member switches on the master switch. The ports that connect the stack member switches are called stack ports.

Stack configuration task list

| Task | Remarks |
|---|----------|
| Configuring the master device of a stack | |
| Configuring a private IP address pool for the stack | Required |
| Configuring stack ports | Required |
| Creating a stack | Required |
| Configuring stack member switches | |
| Configuring the stack ports of a member device | Required |
| Logging in to the CLI of a member from the master | Optional |

Configuring the master device of a stack

Perform the tasks in this section to configure the master device. After you complete the stack configuration, the master automatically add member devices to the stack.

Always start configuring the master device with assigning a private IP address pool for the stack. You cannot perform this task after the switch is configured as the master device or a member device.

Configuring a private IP address pool for the stack

Make sure that the number of IP addresses in the address pool is equal to or greater than the number of devices to be added to the stack. If not, some devices cannot automatically join the stack for lack of private IP addresses.

To configure a private IP address pool for the stack:

| Step | Command | Remarks |
|---|---|---|
| 1. Enter system view. | system-view | N/A |
| 2. Configure a private IP address pool for the stack. | stack ip-pool <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } | By default, no IP address pool is configured for a stack. |

Configuring stack ports

Configure the ports that connect the master to member devices as stack ports.

To configure stack ports:

| Step | Command | Remarks |
|--|--|---------------------------------------|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the specified ports as stack ports. | stack stack-port <i>stack-port-num</i>
port <i>interface-list</i> | By default, no ports are stack ports. |

Creating a stack

After you execute the **stack role master** command, the device becomes the master device of a stack and automatically adds the devices connected to its stack ports to the stack.

To create a stack:

| Step | Command |
|-----------------------|--------------------------|
| 1. Enter system view. | system-view |
| 2. Create a stack. | stack role master |

After you configure a device as the master device of a stack, the prompt changes to <stack_0.Sysname>, where Sysname is the system name of the device.

Configuring the stack ports of a member device

To add a device to a stack, you must configure the ports that connect the device to other stack members as stack ports.

To configure stack ports:

| Step | Command | Remarks |
|--|--|---|
| 1. Enter system view. | system-view | N/A |
| 2. Configure the specified ports as stack ports. | stack stack-port stack-port-num
port interface-list | By default, a port is not a stack port. |

After a device joins a stack and becomes a member device of the stack, the prompt changes to <stack_n.Sysname>, where n is the stack number assigned by the master device, and Sysname is the system name of the device.

Logging in to the CLI of a member from the master

Perform this task on the master device in user view.

| Task | Command |
|--|----------------------------------|
| Log in to the CLI of a member device from the master device. | stack switch-to member-id |

The **stack switch-to** command does not change the user privilege level. To return to the master device, use the **quit** command.

Displaying and maintaining stack configuration

| Task | Command | Remarks |
|---|---|-----------------------|
| Display the stack configuration of stack members. | display stack [members] [
{ begin exclude include }
regular-expression] | Available in any view |

Stack configuration example

Network requirements

Switch A, Switch B, Switch C, and Switch D are connected with one another.

Create a stack, where Switch A is the master device, Switch B, Switch C, and Switch D are member devices. An administrator can log in to Switch B, Switch C and Switch D through Switch A to perform remote configurations.

Figure 76 Network diagram

Configuration procedure

1. Configure the master device:

Configure a private IP address pool for the stack on Switch A.

```
<SwitchA> system-view
```

```
[SwitchA] stack ip-pool 192.168.1.1 24
```

Configure port GigabitEthernet 1/0/1 as a stack port on Switch A.

```
[SwitchA] stack stack-port 1 port gigabitethernet 1/0/1
```

Configure switch A as the master device.

```
[SwitchA] stack role master
```

2. Configure the member devices:

On Switch B, configure local ports GigabitEthernet 1/0/2, GigabitEthernet 1/0/1, and GigabitEthernet 1/0/3 as stack ports.

```
<SwitchB> system-view
```

```
[SwitchB] stack stack-port 3 port gigabitethernet 1/0/1 gigabitethernet 1/0/2  
gigabitethernet 1/0/3
```

On Switch C, configure local port GigabitEthernet 1/0/1 as a stack port.

```
<SwitchC> system-view
```

```
[SwitchC] stack stack-port 1 port gigabitethernet 1/0/1
```

On Switch D, configure local port GigabitEthernet 1/0/1 as a stack port.

```
<SwitchD> system-view
```

```
[SwitchD] stack stack-port 1 port gigabitethernet 1/0/1
```

3. Verify the configuration:

Display information about stack members on Switch A.

```
<stack_0.SwitchA> display stack members
```

```
Number      : 0
```

```
Role        : Master
```

```
Sysname     : stack_0. SwitchA
```

```
Switch type: HP 5500-24G SI Switch with 2 Interface Slots
```

```
MAC address: 000f-e200-1000
```

```
Number      : 1
```

```
Role        : Slave
```

```
Sysname     : stack_1. SwitchB
```
