
Figure 120 Network diagram

Configuration procedure

1. Configure Switch A:

Configure IPv6 addresses for VLAN-interface 100 and VLAN-interface 200.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ipv6 address 10::1 32
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] ipv6 address 11::1 32
[SwitchA-Vlan-interface200] quit
```

Enable RIPng on VLAN-interface 100.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ripng 1 enable
[SwitchA-Vlan-interface100] quit
```

Configure three static routes—with next hop 11::2—and make sure that they are active.

```
[SwitchA] ipv6 route-static 20:: 32 11::2
[SwitchA] ipv6 route-static 30:: 32 11::2
[SwitchA] ipv6 route-static 40:: 32 11::2
```

Configure a routing policy.

```
[SwitchA] ip ipv6-prefix a index 10 permit 30:: 32
[SwitchA] route-policy static2ripng deny node 0
[SwitchA-route-policy] if-match ipv6 address prefix-list a
[SwitchA-route-policy] quit
[SwitchA] route-policy static2ripng permit node 10
[SwitchA-route-policy] quit
```

Enable RIPng and apply the routing policy to static route redistribution.

```
[SwitchA] ripng
[SwitchA-ripng-1] import-route static route-policy static2ripng
```

2. Configure Switch B:

Configure the IPv6 address for VLAN-interface 100.

```
[SwitchB] ipv6
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ipv6 address 10::2 32
```

Enable RIPng on VLAN-interface 100.

```
[SwitchB-Vlan-interface100] ripng 1 enable
[SwitchB-Vlan-interface100] quit
```

```

# Enable RIPng.
[SwitchB] ripng
# Display RIPng routing table information.
[SwitchB-ripng-1] display ripng 1 route
    Route Flags: A - Aging, S - Suppressed, G - Garbage-collect
    -----

Peer FE80::7D58:0:CA03:1 on Vlan-interface 100
Dest 10::/32,
    via FE80::7D58:0:CA03:1, cost 1, tag 0, A, 18 Sec
Dest 20::/32,
    via FE80::7D58:0:CA03:1, cost 1, tag 0, A, 8 Sec
Dest 40::/32,
    via FE80::7D58:0:CA03:1, cost 1, tag 0, A, 3 Sec

```

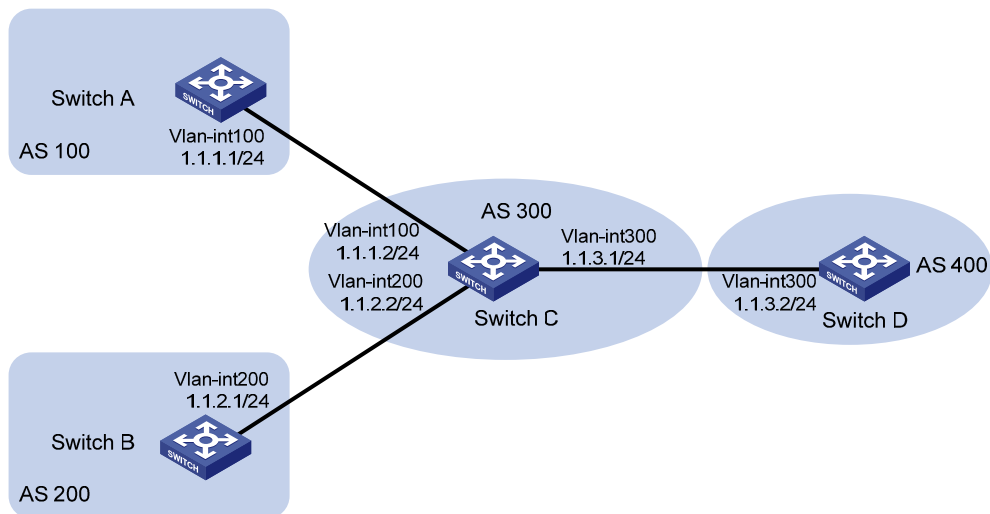

Applying a routing policy to filter received BGP routes

Network requirements

As shown in Figure 121, all the switches run BGP. Switch C establishes eBGP connections with other switches.

Configure a routing policy on Switch D to reject routes from AS 200.

Figure 121 Network diagram

Configuration procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure BGP:

```

# Configure Switch A.
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] peer 1.1.1.2 as-number 300

```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] peer 1.1.2.2 as-number 300
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 300
[SwitchC-bgp] router-id 3.3.3.3
[SwitchC-bgp] peer 1.1.1.1 as-number 100
[SwitchC-bgp] peer 1.1.2.1 as-number 200
[SwitchC-bgp] peer 1.1.3.2 as-number 400
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bgp 400
[SwitchD-bgp] router-id 4.4.4.4
[SwitchD-bgp] peer 1.1.3.1 as-number 300
[SwitchD-bgp] quit
```

On Switch A, inject routes 4.4.4.4/24, 5.5.5.5/24, and 6.6.6.6/24 to BGP.

```
[SwitchA-bgp] network 4.4.4.4 24
[SwitchA-bgp] network 5.5.5.5 24
[SwitchA-bgp] network 6.6.6.6 24
```

On Switch B, inject routes 7.7.7.7/24, 8.8.8.8/24, and 9.9.9.9/24 to BGP.

```
[SwitchB-bgp] network 7.7.7.7 24
[SwitchB-bgp] network 8.8.8.8 24
[SwitchB-bgp] network 9.9.9.9 24
```

Display the BGP routing table information of Switch D.

```
[SwitchD-bgp] display bgp routing-table
```

Total Number of Routes: 6

BGP Local router ID is 4.4.4.4

Status codes: * - valid, > - best, d - damped,

h - history, i - internal, s - suppressed, S - Stale

Origin : i - IGP, e - EGP, ? - incomplete

	Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>	4.4.4.0/24	1.1.3.1			0	300 100i
*>	5.5.5.0/24	1.1.3.1			0	300 100i
*>	6.6.6.0/24	1.1.3.1			0	300 100i
*>	7.7.7.0/24	1.1.3.1			0	300 200i
*>	8.8.8.0/24	1.1.3.1			0	300 200i
*>	9.9.9.0/24	1.1.3.1			0	300 200i

The output shows that Switch D has learned routes 4.4.4.0/24, 5.5.5.0/24, and 6.6.6.0/24 from AS 100 and 7.7.7.0/24, 8.8.8.0/24, and 9.9.9.0/24 from AS 200.

3. Configure Switch D to reject routes from AS 200:

```
# Configure AS_PATH list 1.
```

```

[SwitchD] ip as-path 1 permit .*200.*
# Create routing policy rt1 with node 1, and specify the match mode as deny to deny routes from AS 200.
[SwitchD] route-policy rt1 deny node 1
[SwitchD-route-policy] if-match as-path 1
[SwitchD-route-policy] quit
# Create routing policy rt1 with node 10, and specify the match mode as permit to permit routes from other ASs.
[SwitchD] route-policy rt1 permit node 10
[SwitchD-route-policy] quit
# On Switch D, specify routing policy rt1 to filter routes received from peer 1.1.3.1.
[SwitchD] bgp 400
[SwitchD-bgp] peer 1.1.3.1 route-policy rt1 import
# Display the BGP routing table information of Switch D.
[SwitchD-bgp] display bgp routing-table

```

Total Number of Routes: 3

BGP Local router ID is 4.4.4.4

Status codes: * - valid, > - best, d - damped,

h - history, i - internal, s - suppressed, S - Stale

Origin : i - IGP, e - EGP, ? - incomplete

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*> 4.4.4.0/24	1.1.3.1			0	300 100i
*> 5.5.5.0/24	1.1.3.1			0	300 100i
*> 6.6.6.0/24	1.1.3.1			0	300 100i

The output shows that Switch D has learned only routes 4.4.4.0/24, 5.5.5.0/24, and 6.6.6.0/24 from AS 100.

Troubleshooting routing policy configuration

IPv4 routing information filtering failure

Symptom

The routing protocol is running properly, but filtering routing information failed.

Analysis

At least one item of the IP prefix list must be configured as permit mode, and at least one node in the routing policy must be configured as permit mode.

Solution

1. Use the **display ip ip-prefix** command to display IP prefix list information.
2. Use the **display route-policy** command to display routing policy information.

IPv6 routing information filtering failure

Symptom

The routing protocol is running properly, but filtering routing information failed.

Analysis

At least one item of the IPv6 prefix list must be configured as permit mode, and at least one node of the routing policy must be configured as permit mode.

Solution

1. Use the **display ip ipv6-prefix** command to display IP prefix list information.
 2. Use the **display route-policy** command to display routing policy information.
-

Configuring policy-based routing

Hardware compatibility

The HP 5500 SI Switch Series does not support PBR.

Introduction to PBR

Policy-based routing (PBR) is a routing mechanism based on user-defined policies. Different from the traditional destination-based routing mechanism, PBR enables you to use a policy (based on the source address or other criteria) to route packets.

In general, PBR takes precedence over destination-based routing. PBR is applied to the packets matching the specified criteria, and other packets are forwarded through destination-based routing.

This Switch Series supports the following PBR implementation methods:

- Using a PBR policy

The PBR policy allows you to specify the next hop, priority, and default next hop to guide the forwarding of packets that match specific ACLs. Only IPv4 unicast PBR is supported.

You can modify ACL rules to implement flexible service control.

NOTE:

- If the configured next hop in the PBR policy does not exist, the matching packet is forwarded according to the routing table.
 - If a default next hop is configured in the PBR policy, destination-based routing takes precedence over PBR.
-

- Using a QoS policy

The QoS policy uses QoS traffic classification to define matching criteria, and uses the redirection action of traffic behavior to guide packet forwarding. This implementation method supports both IPv4 and IPv6 unicast PBR.

PBR modes

According to the objects to which the PBR applies, PBR involves local PBR and interface PBR.

- Local PBR applies to locally generated packets only, such as the ICMP packets generated by using the **ping** command.
- Interface PBR applies to packets forwarded through the interface only.

In most cases, interface PBR is implemented to meet the forwarding and security requirements.

NOTE:

The term "interface" in this chapter refers to Layer 3 interfaces, including VLAN interfaces and route mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

Concepts

Policy

A policy is used to route IP packets. A policy can consist of one or multiple nodes.

Node

A node is identified by a node number. The node with the smallest node number has the highest priority.

A policy node consists of **if-match** and **apply** clauses. An **if-match** clause specifies a match criterion on a node, and an **apply** clause specifies an action to be taken on packets.

The action to be taken on matched packets depends on the match mode, which can be **permit** or **deny**.

if-match clause

This Switch Series supports the **if-match acl** clause.

You can specify only one **if-match** clause of each type in a policy node.

apply clause

This Switch Series supports the following **apply** clauses: **apply ip-precedence**, **apply ip-address next-hop**, and **apply ip-address default next-hop**.

NOTE:

The **apply ip-address default next-hop** command takes effect only when no next hop is defined, or the defined next hop is invalid and the destination address does not match any route in the routing table.

Relationship between the match mode and clauses

If a packet...	Then...	
	In permit mode	In deny mode
Matches all the if-match clauses on a policy node	The apply clause is executed, and the packet will not go to the next policy node for a match.	The apply clause is not executed, the packets will not go to the next policy node for a match, and will be forwarded according to the routing table.

If a packet...	Then...	
	In permit mode	In deny mode
Fails to match an if-match clause on the policy node	The apply clause is not executed, and the packet will go to the next policy node for a match.	The apply clause is not executed, and the packet will go to the next policy node for a match.

The nodes of a policy are in an OR relationship. If a packet matches a node, it passes the policy; if the packet does not match any node of the policy, it fails to pass the policy and is forwarded according to the routing table.

QoS mode

The QoS policy uses QoS traffic classification to define matching criteria, and uses the redirection action of traffic behavior to guide packet forwarding in order to implement flexible routing.

PBR takes precedence over destination-based routing. If a packet meets the match criteria, PBR applies; otherwise, destination-based routing applies.

For more information about QoS policies, see *ACL and QoS Configuration Guide*.

Configuring PBR (using a PBR policy)

Defining a policy

Follow these guidelines when you define a policy:

- If an ACL match criterion is defined, packets are matched against the ACL rules, whereas the permit or deny action and the time range of the specified ACL are ignored. If the specified ACL does not exist, no packet is matched.
- You can configure two next hops by using the **apply ip-address next-hop** command twice (first case) or once (second case). After that, executing the **apply ip-address next-hop** command with a new next hop will replace the earlier configured next hop in the first case, or will replace the second next hop specified in the second case. To remove both next hops, execute the **apply ip-address next-hop** command again by specifying two next hops.
- If a policy has a node with no **if-match** clause configured, all packets can pass the policy node. However, an action is taken according to the match mode, and the packets will not go to the next policy node for a match.
- If a policy has a node with the **permit** match mode but no **apply** clause configured, all packets matching all the **if-match** clauses can pass the policy node. However, no action is taken, the packets will not go to the next policy node for a match, and will be forwarded according to the routing table.
- If a policy has a node with no **if-match** or **apply** clauses configured, all packets can pass the policy node. However, no action is taken; the packets will not go to the next policy node for a match, and will be forwarded according to the routing table.

To define a policy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Create a policy or policy node and enter PBR policy node view.	policy-based-route <i>policy-name</i> [deny permit] node <i>node-number</i>	N/A
3. Define an ACL match criterion.	if-match acl <i>acl-number</i>	Optional.
4. Set an IP precedence type/value.	apply ip-precedence { <i>type</i> <i>value</i> }	Optional.
5. Set next hops.	apply ip-address next-hop <i>ip-address</i> [direct] [track <i>track-entry-number</i>] [<i>ip-address</i> [direct] [track <i>track-entry-number</i>]]	Optional. You can specify two next hops at a time. <ul style="list-style-type: none"> For local PBR, both the two next hops take effect to implement load sharing. For interface PBR, the first next hop serves as the main next hop and the second one serves as the backup next hop.
6. Set default next hops.	apply ip-address default next-hop <i>ip-address</i> [track <i>track-entry-number</i>] [<i>ip-address</i> [track <i>track-entry-number</i>]]	Optional. You can specify two next hops at a time. <ul style="list-style-type: none"> For local PBR, both the two next hops take effect to implement load sharing. For interface PBR, the first next hop serves as the main next hop and the second one serves as the backup next hop.

Configuring local PBR

Only one policy can be referenced for local PBR.

To configure local PBR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure local PBR based on a policy.	ip local policy-based-route <i>policy-name</i>	Not configured by default.

NOTE:

If the specified policy does not exist, the local PBR configuration succeeds, but it takes effect only when the policy is created.

Configuring interface PBR

Only one policy can be referenced by an interface for interface PBR.

To configure interface PBR:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure interface PBR based on a policy.	ip policy-based-route <i>policy-name</i>	Not configured by default.

NOTE:

If the specified policy does not exist, the interface PBR configuration succeeds, but it takes effect only when the policy is created.

PBR and track

Associated with a Track object, PBR can sense topology changes faster. You can associate PBR with a track entry when configuring the outgoing interface, default outgoing interface, next hop, and default next hop to dynamically determine link reachability. The PBR configuration takes effect when the status of the associated Track object is **Positive** or **Invalid**.

For more information about track-PBR collaboration, see *High Availability Configuration Guide*.

Configuring PBR (using a QoS policy)

Before you configure PBR, complete the following tasks:

- Configure a QoS policy by configuring the match criteria and a redirection action for PBR.
- Apply the QoS policy by defining the occasion to which the PBR applies.

Configuring a QoS policy

To configure a QoS policy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator { and or }]	N/A
3. Configure the match criteria.	if-match <i>match-criteria</i>	N/A
4. Exit class view.	quit	N/A
5. Create a behavior and enter behavior view.	traffic behavior <i>behavior-name</i>	N/A
6. Configure a traffic redirection action.	redirect next-hop { <i>ipv4-add1</i> [<i>ipv4-add2</i>] <i>ipv6-add1</i> [<i>interface-type interface-number</i>] [<i>ipv6-add2</i> [<i>interface-type interface-number</i>]] } [fail-action { discard forward }]	Optional. The default option for the fail-action is forward .

Step	Command	Remarks
7. Exit behavior view.	quit	N/A
8. Create a policy and enter policy view.	qos policy <i>policy-name</i>	N/A
9. Associate the class with the traffic behavior in the QoS policy.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	N/A

Applying the QoS policy

When configuring PBR, you can apply a QoS policy to the following occasions:

- **Applied globally**—Affects the traffic sent or received on all ports.
- **Applied to an interface**—Affects the traffic sent or received on the interface.
- **Applied to a VLAN**—Affects the traffic sent or received on all ports in the VLAN.

NOTE:

A QoS policy used for PBR applies only to traffic received on all ports, on an interface, or on all ports in a VLAN.

To apply the QoS policy globally:

Step	Command
1. Enter system view.	system-view
2. Apply the QoS policy globally.	qos apply policy <i>policy-name</i> global inbound

To apply the QoS policy to an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> • Enter interface view: interface <i>interface-type</i> <i>interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use either approach. Settings in interface view take effect on the current interface; settings in port group view take effect on all ports in the port group.
3. Apply the policy to the interface or port group.	qos apply policy <i>policy-name</i> inbound	N/A

To apply the QoS policy to a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Apply the QoS policy to VLANs.	qos vlan-policy <i>policy-name</i> vlan <i>vlan-id-list</i> inbound	N/A

NOTE:

QoS policies cannot be applied to dynamic VLANs, for example, VLANs created by GVRP.

Displaying and maintaining PBR configuration

PBR configuration (using a PBR policy)

Task	Command	Remarks
Display the PBR routing information.	display ip policy-based-route [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the specified PBR routing information.	display ip policy-based-route setup { interface <i>interface-type interface-number</i> local <i>policy-name</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display PBR statistics.	display ip policy-based-route statistics { interface <i>interface-type interface-number</i> local } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the PBR policy information.	display policy-based-route [<i>policy-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear PBR statistics.	reset policy-based-route statistics [<i>policy-name</i>]	Available in user view

If a policy has a node with no **if-match** or **apply** clause configured, all packets can pass the policy. However, no action is taken and the packets will not go to the next policy node for a match. The statistics of PBR will be changed.

If a policy node has **if-match** clauses, but no **apply** clauses configured, packets will match against these **if-match** clauses. However, no **apply** clauses are applicable to the permitted packets, and the packets will not go to the next policy node for a match. The statistics of PBR will be changed.

If a policy node has no **if-match** clause, but **apply** clauses configured, all packets can pass the policy, and then are forwarded according to the **apply** clauses if the **permit** keyword is specified for the node, or are denied if the **deny** keyword is specified. The packets will not go to the next policy node for a match. The statistics of PBR will be changed.

If the match mode of a policy node is **deny**, no **apply** clause will be executed for the packets satisfying all the **if-match** clauses, and the packets will not go to the next policy node for a match. They will be forwarded according to the routing table instead. Neither debugging information nor statistics for the **deny** match mode can be displayed.

PBR configuration (using a QoS policy)

Task	Command	Remarks
Display user-defined QoS policy configuration information.	display qos policy user-defined [<i>policy-name</i>] [classifier <i>tcl-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display QoS policy configuration on the specified interface or on all interfaces.	display qos policy interface [<i>interface-type interface-number</i>] [inbound outbound] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display VLAN QoS policy information.	display qos vlan-policy { name <i>policy-name</i> vlan <i>vlan-id</i> } [slot <i>slot-number</i>] [inbound outbound] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display information about global QoS policies.	display qos policy global [slot <i>slot-number</i>] [inbound outbound] [[{ begin exclude include } <i>regular-expression</i>]]	Available in user view

PBR configuration examples

Configuring local PBR based on packet type

Network requirements

As shown in [Figure 122](#), configure PBR on Switch A, so that all TCP packets are forwarded to next hop 1.1.2.2 and other packets are forwarded according to the routing table.

Switch A is directly connected to Switch B and Switch C. Switch B and Switch C are unreachable to each other.

Figure 122 Network diagram

Configuration procedure

1. Configure Switch A:

Define ACL 3101 to match TCP packets.

```

<SwitchA> system-view
[SwitchA] acl number 3101
[SwitchA-acl-adv-3101] rule permit tcp
[SwitchA-acl-adv-3101] quit
  
```

Configure Node 5 of policy **aaa** to forward TCP packets to next hop 1.1.2.2.

```

[SwitchA] policy-based-route aaa permit node 5
[SwitchA-pbr-aaa-5] if-match acl 3101
[SwitchA-pbr-aaa-5] apply ip-address next-hop 1.1.2.2
[SwitchA-pbr-aaa-5] quit
  
```

Apply policy **aaa** to Switch A.

```

[SwitchA] ip local policy-based-route aaa
  
```

Configure the IP addresses of VLAN-interface 10 and VLAN-interface 20.

```

[SwitchA] interface vlan-interface 10
  
```

```
[SwitchA-Vlan-interface10] ip address 1.1.2.1 255.255.255.0
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 20
[SwitchA-Vlan-interface20] ip address 1.1.3.1 255.255.255.0
```

2. Configure Switch B:

Configure the IP address of VLAN-interface 10.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] ip address 1.1.2.2 255.255.255.0
[SwitchB-Vlan-interface10] quit
```

3. Configure Switch C:

Configure the IP address of VLAN-interface 20.

```
<SwitchC> system-view
[SwitchC] interface vlan-interface 20
[SwitchC-Vlan-interface20] ip address 1.1.3.2 255.255.255.0
[SwitchC-Vlan-interface20] quit
```

4. Verify the configuration:

Telnet to Switch B (1.1.2.2/24) from Switch A. The operation succeeds.

Telnet to Switch C (1.1.3.2/24) from Switch A. The operation fails.

```
<SwitchA> telnet 1.1.3.2
```

```
Trying 1.1.3.2 ...
```

```
Press CTRL+K to abort
```

```
Can't connect to the remote host!
```

Ping Switch C (1.1.3.2/24) from Switch A. The operation succeeds.

```
<SwitchA> ping 1.1.3.2
```

```
  PING 1.1.3.2: 56 data bytes, press CTRL_C to break
    Reply from 1.1.3.2: bytes=56 Sequence=1 ttl=255 time=2 ms
    Reply from 1.1.3.2: bytes=56 Sequence=2 ttl=255 time=1 ms
    Reply from 1.1.3.2: bytes=56 Sequence=3 ttl=255 time=1 ms
    Reply from 1.1.3.2: bytes=56 Sequence=4 ttl=255 time=1 ms
    Reply from 1.1.3.2: bytes=56 Sequence=5 ttl=255 time=1 ms
--- 1.1.3.2 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 1/1/2 ms
```

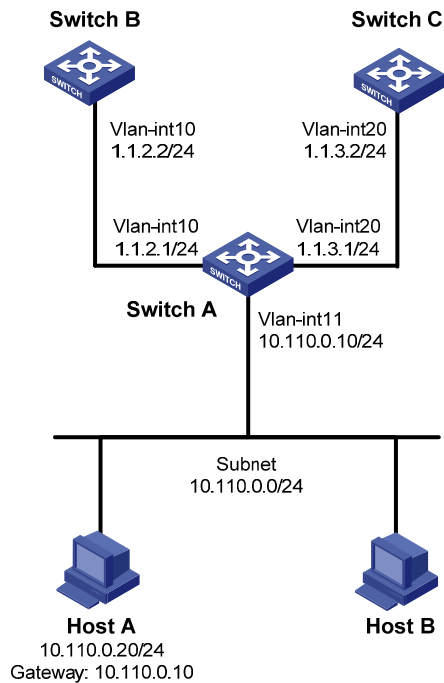

Telnet uses TCP, and ping uses ICMP. The preceding results show that all TCP packets of Switch A are forwarded to next hop 1.1.2.2, and other packets are forwarded via VLAN-interface 20. The PBR configuration is effective.

Configuring interface PBR based on packet type

Network requirements

As shown in [Figure 123](#), configure PBR on Switch A, so that TCP packets arriving on VLAN-interface 11 are forwarded to next hop 1.1.2.2 and other packets are forwarded according to the routing table.

Figure 123 Network diagram

Configuration procedure

In this example, static routes are configured to ensure the reachability among devices.

1. Configure Switch A:

Define ACL 3101 to match TCP packets.

```
<SwitchA> system-view
[SwitchA] acl number 3101
[SwitchA-acl-adv-3101] rule permit tcp
[SwitchA-acl-adv-3101] quit
```

Configure Node 5 of policy **aaa** to forward TCP packets to next hop 1.1.2.2.

```
[SwitchA] policy-based-route aaa permit node 5
[SwitchA-pbr-aaa-5] if-match acl 3101
[SwitchA-pbr-aaa-5] apply ip-address next-hop 1.1.2.2
[SwitchA-pbr-aaa-5] quit
```

Apply the policy **aaa** to VLAN-interface 11.

```
[SwitchA] interface vlan-interface 11
[SwitchA-Vlan-interface11] ip address 10.110.0.10 255.255.255.0
[SwitchA-Vlan-interface11] ip policy-based-route aaa
[SwitchA-Vlan-interface11] quit
```

Configure the IP addresses of VLAN-interface 10 and VLAN-interface 20.

```
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] ip address 1.1.2.1 255.255.255.0
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 20
[SwitchA-Vlan-interface20] ip address 1.1.3.1 255.255.255.0
```

2. Configure Switch B:

Configure a static route to subnet 10.110.0.0/24.

```

<SwitchB> system-view
[SwitchB] ip route-static 10.110.0.0 24 1.1.2.1
# Configure the IP address of VLAN-interface 10.
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] ip address 1.1.2.2 255.255.255.0
[SwitchB-Vlan-interface10] quit

```

3. Configure Switch C:

```

# Configure a static route to subnet 10.110.0.0/24.
<SwitchC> system-view
[SwitchC] ip route-static 10.110.0.0 24 1.1.3.1
# Configure the IP address of VLAN-interface 20.
[SwitchC] interface vlan-interface 20
[SwitchC-Vlan-interface20] ip address 1.1.3.2 255.255.255.0
[SwitchC-Vlan-interface20] quit

```

Verifying the configuration

Configure the IP address of Host A as 10.110.0.20/24, and the gateway as 10.110.0.10.

On Host A, Telnet to Switch B (1.1.2.2) that is directly connected to Switch A. The operation succeeds.

On Host A, Telnet to Switch C (1.1.3.2) that is directly connected to Switch A. The operation fails.

Ping Switch C from Host A. The operation succeeds.

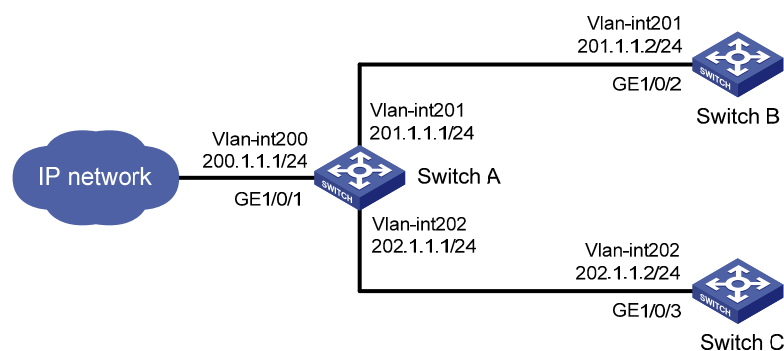

Telnet uses TCP, and ping uses ICMP. The preceding results show that all TCP packets arriving on VLAN-interface 11 of Switch A are forwarded to next hop 1.1.2.2, and other packets are forwarded via VLAN-interface 20. The PBR configuration is effective.

IPv4 PBR configuration example (using a QoS policy)

Network requirements

As shown in [Figure 124](#), redirect all packets received on GigabitEthernet 1/0/1 of Switch A to the next hop 202.1.1.2.

Figure 124 Network diagram

Configuration procedure

```

# Configure ACL 2000.
<SwitchA> system-view
[SwitchA] acl number 2000

```

```
[SwitchA-acl-basic-2000] rule 0 permit source any
[SwitchA-acl-basic-2000] quit

# Define a match criterion for class a to match ACL 2000.
[SwitchA] traffic classifier a
[SwitchA-classifier-a] if-match acl 2000
[SwitchA-classifier-a] quit

# Configure the action of redirecting traffic to the next hop 202.1.1.2 for behavior a.
[SwitchA] traffic behavior a
[SwitchA-behavior-a] redirect next-hop 202.1.1.2
[SwitchA-behavior-a] quit

# Associate class a with behavior a in QoS policy a.
[SwitchA] qos policy a
[SwitchA-qospolicy-a] classifier a behavior a
[SwitchA-qospolicy-a] quit

# Apply QoS policy a to the incoming traffic of GigabitEthernet 1/0/1.
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] qos apply policy a inbound
```

Verifying the configuration

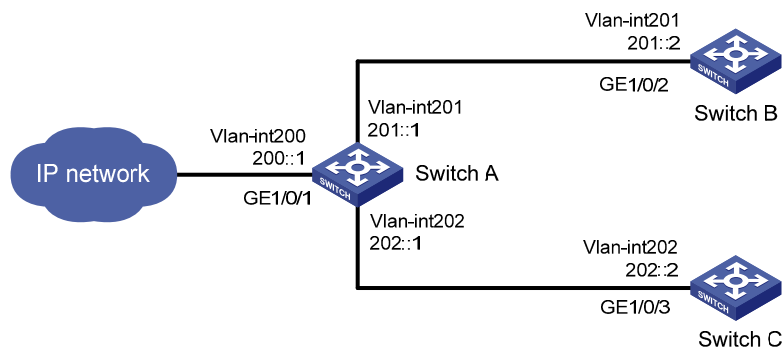

After completing the configuration, verify that when Switch A receives packets with destination IP address 201.1.1.2, it forwards the packets to Switch C instead of Switch B.

IPv6 PBR configuration example (using a QoS policy)

Network requirements

As shown in [Figure 125](#), redirect all packets received on GigabitEthernet 1/0/1 of Switch A to the next hop 202::2.

Figure 125 Network diagram

Configuration procedure

```
# Configure IPv6 ACL 2000.
<SwitchA> system-view
[SwitchA] acl ipv6 number 2000
[SwitchA-acl6-basic-2000] rule 0 permit source any
[SwitchA-acl6-basic-2000] quit

# Define a match criterion for class a to match IPv6 ACL 2000.
```

```
[SwitchA] traffic classifier a
[SwitchA-classifier-a] if-match acl ipv6 2000
[SwitchA-classifier-a] quit

# Configure the action of redirecting traffic to the next hop 202::2 for behavior a.
[SwitchA] traffic behavior a
[SwitchA-behavior-a] redirect next-hop 202::2
[SwitchA-behavior-a] quit

# Associate class a with behavior a in QoS policy a.
[SwitchA] qos policy a
[SwitchA-qospolicy-a] classifier a behavior a
[SwitchA-qospolicy-a] quit

# Apply QoS policy a to the incoming traffic of GigabitEthernet 1/0/1.
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] qos apply policy a inbound
```

Verifying th configuration

After completing the configuration, verify that when Switch A receives packets with destination IP address 201::2, it forwards the packets to Switch C instead of Switch B.

Configuring MCE

The term "router" in this document refers to both routers and Layer 3 switches.

The term "Layer 3 interface" in this chapter refers to route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

This chapter covers MCE related configuration. For information about routing protocols, see *Layer 3—IP Services Configuration Guide*. The MCE function is available only on the HP 5500 EI switch series.

MCE overview

MPLS L3VPN overview

MPLS L3VPN is a type of PE-based L3VPN technology for service provider VPN solutions. It uses BGP to advertise VPN routes and uses MPLS to forward VPN packets on service provider backbones.

MPLS L3VPN provides flexible networking modes, excellent scalability, and convenient support for MPLS QoS and MPLS TE.

The MPLS L3VPN model consists of the following types of devices:

- **Customer edge (CE) device**—A CE resides on a customer network and has one or more interfaces directly connected with service provider networks. It can be a router, a switch, or a host. It can neither "sense" the existence of any VPN nor does it need to support MPLS.
- **Provider edge (PE) device**—A PE resides on a service provider network and connects one or more CEs to the network. On an MPLS network, all VPN processing occurs on the PEs.
- **Provider (P) device**—A P device is a core device on a service provider network. It is not directly connected with any CE. It only needs to be equipped with basic MPLS forwarding capability.

Figure 126 Network diagram for MPLS L3VPN model

CEs and PEs mark the boundary between the service providers and the customers.

After a CE establishes adjacency with a directly connected PE, it advertises its VPN routes to the PE and learns remote VPN routes from the PE. A CE and a PE use BGP/IGP to exchange routing information. You can also configure static routes between them.

After a PE learns the VPN routing information of a CE, it uses BGP to exchange VPN routing information with other PEs. A PE maintains routing information about only VPNs that are directly connected, rather than all VPN routing information on the provider network.

A P router maintains only routes to PEs and does not deal with VPN routing information.

When VPN traffic travels over the MPLS backbone, the ingress PE functions as the ingress Label Switching Router (LSR), the egress PE functions as the egress LSR, and P routers function as the transit LSRs.

MPLS L3VPN concepts

Site

Sites are often mentioned in the VPN. A site has the following features:

- A site is a group of IP systems with IP connectivity that does not rely on any service provider network to implement.
- The classification of a site depends on the topology relationship of the devices, rather than the geographical positions, though the devices at a site are, in most cases, adjacent to each other geographically.
- The devices at a site can belong to multiple VPNs.
- A site is connected to a provider network through one or more CEs. A site can contain many CEs, but a CE can belong to only one site.

Sites connected to the same provider network can be classified into different sets by policies. Only the sites in the same set can access each other through the provider network. Such a set is called a VPN.

Address space overlapping

Each VPN independently manages the addresses it uses. The assembly of such addresses for a VPN is called an address space.

The address spaces of VPNs may overlap. For example, if both VPN 1 and VPN 2 use the addresses on network segment 10.110.10.0/24, address space overlapping occurs.

VPN instance

In MPLS VPN, routes of different VPNs are identified by VPN instance.

A PE creates and maintains a separate VPN instance for each VPN at a directly connected site. Each VPN instance contains the VPN membership and routing rules of the corresponding site. If a user at a site belongs to multiple VPNs at the same time, the VPN instance of the site contains information about all of the VPNs.

For independence and security of VPN data, each VPN instance on a PE maintains a relatively independent routing table and a separate label forwarding information base (LFIB). VPN instance information contains the following items: the LFIB, IP routing table, interfaces bound to the VPN instance, and administration information of the VPN instance. The administration information of the VPN instance includes the route distinguisher (RD), route filtering policy, and member interface list.

VPN-IPv4 address

Traditional BGP cannot process overlapping VPN routes. If, for example, both VPN 1 and VPN 2 use addresses on the segment 10.110.10.0/24 and each advertise a route to the segment, BGP selects only one of them, which results in the loss of the other route.

PEs use MP-BGP to advertise VPN routes and use VPN-IPv4 address family to solve the problem with traditional BGP.

A VPN-IPv4 address consists of 12 bytes. The first eight bytes represent the RD, followed by a four-byte IPv4 address prefix.

Figure 127 VPN-IPv4 address structure

When a PE receives an ordinary IPv4 route from a CE, it must advertise the VPN route to the peer PE. The uniqueness of a VPN route is implemented by adding an RD to the route.

A service provider can independently assign RDs if the assigned RDs are unique. A PE can advertise different routes to VPNs even if the VPNs are from different service providers and are using the same IPv4 address space.

Configure a distinct RD for each VPN instance on a PE, so that routes to the same CE use the same RD. The VPN-IPv4 address with an RD of 0 is a globally unique IPv4 address.

By prefixing a distinct RD to a specific IPv4 address prefix, you get a globally unique VPN IPv4 address prefix.

An RD can be related to an autonomous system (AS) number, in which case it is the combination of the AS number and a discretionary number; or it can be related to an IP address, in which case it is the combination of the IP address and a discretionary number.

An RD can be in one of the following formats distinguished by the Type field:

- When the value of the Type field is 0, the Administrator subfield occupies two bytes, the Assigned number subfield occupies four bytes, and the RD format is *16-bit AS number:32-bit user-defined number*. For example, 100:1.
- When the value of the Type field is 1, the Administrator subfield occupies four bytes, the Assigned number subfield occupies two bytes, and the RD format is *32-bit IPv4 address:16-bit user-defined number*. For example, 172.1.1.1:1.
- When the value of the Type field is 2, the Administrator subfield occupies four bytes, the Assigned number subfield occupies two bytes, and the RD format is *32-bit AS number:16-bit user-defined number*, where the minimum value of the AS number is 65536. For example, 65536:1.

To guarantee global uniqueness for an RD, do not set the Administrator subfield to any private AS number or private IP address.

Route target attributes

MPLS L3VPN uses the BGP extended community attributes called "route target" attributes to control the advertisement of VPN routing information.

A VPN instance on a PE supports the following types of route target attributes:

- **Export target attribute:** A local PE sets this type of route target attribute for VPN-IPv4 routes learned from directly connected sites before advertising them to other PEs.
- **Import target attribute:** A PE checks the export target attribute of VPN-IPv4 routes advertised by other PEs. If the export target attribute matches the import target attribute of the VPN instance, the PE adds the routes to the VPN routing table.

In other words, route target attributes define which sites can receive VPN-IPv4 routes, and from which sites that a PE can receive routes.

Similar to RDs, route target attributes can be of the following formats:

- *16-bit AS number:32-bit user-defined number.* For example, 100:1.
- *32-bit IPv4 address: 16-bit user-defined number.* For example, 172.1.1.1:1.
- *32-bit AS number: 16-bit user-defined number,* where the minimum value of the AS number is 65536. For example, 65536:1.

Multi-VPN-instance CE

Using tunnels, MPLS L3VPN implements private network data transmission over the public network. However, the traditional MPLS L3VPN architecture requires each VPN instance exclusively use a CE to connect with a PE, as shown in [Figure 126](#).

For better services and higher security, a private network is usually divided into multiple VPNs to isolate services. To meet these requirements, you can configure a CE for each VPN, which increases users' device expenses and maintenance costs. Or, you can configure multiple VPNs to use the same CE and the same routing table, which sacrifices data security.

Using the Multi-VPN-Instance CE (MCE) function of the switch, you can remove the contradiction of low cost and high security in multi-VPN networks. With MCE configured, a CE can bind each VPN in a network with a VLAN interface on the CE, and create and maintain a separate routing table (multi-VRF) for each VPN. This separates the forwarding paths of packets of different VPNs and, in conjunction with the PE, can correctly advertise the routes of each VPN to the peer PE, ensuring the normal transmission of VPN packets over the public network.

How MCE works

[Figure 128](#) shows how an MCE maintains the routing entries of multiple VPNs and how an MCE exchanges VPN routes with PEs.

Figure 128 Network diagram for the MCE function

On the left-side network, there are two VPN sites, both of which are connected to the MPLS backbone through the MCE device. VPN 1 and VPN 2 on the left-side network must establish a tunnel with VPN 1 and VPN 2 on the right-side network, respectively.

With MCE enabled, routing tables can be created for VPN 1 and VPN 2 individually, VLAN-interface 2 can be bound to VPN 1, and VLAN-interface 3 can be bound to VPN 2. When receiving a piece of routing information, MCE determines the source of the routing information according to the number of the interface receiving the information. It then maintains the corresponding routing table accordingly.

You must also bind the interfaces to the VPNs on PE 1 in the same way as those on the MCE device. The MCE device is connected to PE 1 through a trunk, which permits packets of VLAN 2 and VLAN 3 with VLAN tags carried. In this way, PE 1 can determine the VPN a received packet belongs to according to the VLAN tag of the packet and passes the packet to the corresponding tunnel.

Configuring routing on an MCE

Interface-to-VPN-instance binding enables MCEs and PEs to determine the sources of received packets and then forward the packets according to the routing information concerning the corresponding VPNs. MCE routing configuration includes:

- MCE-VPN site routing configuration
- MCE-PE routing configuration

Route exchange between an MCE and a VPN site

An MCE can adopt the following routing protocols to exchange VPN routes with a site:

- Static route
- RIP
- OSPF
- IS-IS
- IBGP
- EBGp

This section briefly introduces the cooperation of routing protocols and MCE.

Static routes

An MCE can communicate with a site through static routes. As static routes configured for traditional CEs take effect globally, address overlapping between multiple VPNs remains a problem until the emergence of MCE. MCE allows static-route-to-VPN-instance binding, which isolates the static routes of different VPNs.

RIP

The switch can bind RIP processes to VPN instances. With these bindings on the MCE, private network routes of different VPNs can be exchanged between MCE and sites through different RIP processes, isolating and securing VPN routes.

OSPF

The switch can bind OSPF processes to VPN instances and isolate the routes of different VPNs.

For an OSPF process bound to a VPN instance, the router ID of the public network configured in system view is invalid. You must specify the router ID when creating an OSPF process.

An OSPF process can be bound to only one VPN instance. However, a VPN instance can use multiple OSPF processes for private network route transmission. To make sure routes can be advertised properly, configure the same domain ID for all OSPF processes bound to the same VPN instance.

Routes redistributed from OSPF to BGP on the MCE have their OSPF attributes removed. To enable BGP to distinguish routes redistributed from different OSPF domains, you must enable the redistributed routes to carry the OSPF domain ID by configuring the **domain-id** command in OSPF view. The domain ID is added to BGP VPN routes as an extended community attribute.

In cases where a VPN has multiple MCE devices attached to it and when an MCE device advertises the routes learned from BGP within the VPN, the routes may be learned by other MCE devices, generating route loops. To prevent route loops, configure route tags for different VPN instances on each MCE. HP recommends that you assign the same route tag to the same VPN on all MCEs.

IS-IS

Similar to those in OSPF, IS-IS processes can be bound to VPN instances for private network routes to be exchanged between MCE and sites. An IS-IS process can be bound to only one VPN instance.

IBGP

To use IBGP to exchange private routes between an MCE and a site, configure IBGP peers for VPN instances on the MCE and redistribute IGP routing information from corresponding VPNs. If the MCE is connected with multiple sites in the same VPN, you can configure the MCE as a route reflector (RR) and configure the egress routers of the sites as clients, making the MCE reflect routing information between the sites. This eliminates the necessity for BGP connections between sites, reducing the number of BGP connections and simplifying network configuration.

EBGP

To use EBGP for exchanging routing information between an MCE and VPN sites, you must configure a BGP peer for each VPN instance on the MCE, and redistribute the IGP routes of each VPN instance on the VPN sites. You also can configure filtering policies to filter the received routes and the routes to be advertised.

Route exchange between an MCE and a PE

Routing information entries are bound to specific VPN instances on an MCE device, and packets of each VPN instance are forwarded between MCE and PE according to interface. As a result, VPN routing

information can be transmitted by performing relatively simple configurations between MCE and PE, such as importing the VPN routing entries on MCE devices to the routing table of the routing protocol running between MCE and PEs.

The following routing protocols can be used between MCE and PE devices for routing formation exchange:

- Static route
- RIP
- OSPF
- IS-IS
- IBGP
- EBGp

Configuring an MCE

Configuring VPN instances

Configuring VPN instances is required in all MCE networking schemes.

By configuring VPN instances on a PE, you isolate not only VPN routes from public network routes, but also routes of a VPN from those of another VPN. This feature allows VPN instances to be used in networking scenarios besides MCE.

Creating a VPN Instance

A VPN instance is associated with a site. It is a collection of the VPN membership and routing rules of its associated site. A VPN instance does not necessarily correspond to one VPN.

A VPN instance takes effect only after you configure an RD for it. Before configuring an RD for a VPN instance, you can configure no other parameters for the instance but a description.

You can configure a description for a VPN instance to record its related information, such as its relationship with a certain VPN.

To create and configure a VPN instance:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VPN instance and enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure an RD for the VPN instance.	route-distinguisher <i>route-distinguisher</i>	For easy management, set the same RD for the same VPN instance on the MCE and PE.
4. Configure a description for the VPN instance.	description <i>text</i>	Optional

Associating a VPN instance with an interface

In an MPLS L3VPN application, you must associate VPN instances with the interfaces connecting the PEs.

In a tunneling application, you must associate VPN instances with the tunnel interfaces connecting the peer MCE devices or CE devices.

You can add a management Ethernet interface on the switch to a VPN so that the IP address of the interface only participates in the route calculation of the specified VPN.

After creating and configuring a VPN instance, you associate the VPN instance with the interface for connecting different VPN sites.

To associate a VPN instance with an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Associate the current interface with the VPN instance.	ip binding vpn-instance <i>vpn-instance-name</i>	No VPN instance is associated with an interface by default.

NOTE:

The **ip binding vpn-instance** command clears the IP address of the interface on which it is configured. Be sure to reconfigure an IP address for the interface after configuring the command.

Configuring route-related attributes of a VPN instance

The control process of VPN route advertisement is as follows:

- When a VPN route learned from a site gets redistributed into BGP, BGP associates it with a route target extended community attribute list, which is usually the export target attribute of the VPN instance associated with the site.
- The VPN instance determines which routes it can accept and redistribute according to the **import-extcommunity** in the route target.
- The VPN instance determines how to change the route targets attributes for routes to be advertised according to the **export-extcommunity** in the route target.

! **IMPORTANT:**

- Only when BGP runs between the MCE and PE can the route target attribute be advertised to the PE along with the routing information. In other cases, configuring this attribute makes no sense.
- Before associating a routing policy with a VPN instance, you must first create the routing policy. Otherwise, the default routing policy is used.

To configure route related attributes of a VPN instance:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Enter IPv4 VPN view.	ipv4-family	Optional.
4. Associate the current VPN instance with one or more route targets.	vpn-target <i>vpn-target</i> <1-8> [both export-extcommunity import-extcommunity]	A single vpn-target command can configure up to eight route targets. You can configure up to 64 route targets for a VPN instance.

Step	Command	Remarks
5. Configure the maximum number of routes for the VPN instance.	routing-table limit <i>number</i> { <i>warn-threshold</i> simply-alert }	Optional. Not configured by default. Setting the maximum number of routes for a VPN instance to support is for preventing too many routes from being redistributed into the PE.
6. Apply an import routing policy to the current VPN instance.	import route-policy <i>route-policy</i>	Optional. By default, all routes permitted by the import target attribute can be redistributed into the VPN instance.
7. Apply an export routing policy to the current VPN instance.	export route-policy <i>route-policy</i>	Optional. By default, all VPN instance routes permitted by the export target attribute can be redistributed.

NOTE:

- Only when BGP runs between the MCE and PE can the route target attribute be advertised to the PE together with the routing information. In other cases, configuring this attribute makes no sense.
- You can configure route related attributes for IPv4 VPNs in both VPN instance view and IPv4 VPN view. Those configured in IPv4 VPN view take precedence.

Configuring routing on an MCE

MCE implements service isolation through route isolation. MCE routing configuration includes:

- MCE-VPN site routing configuration
- MCE-PE routing configuration

On the PE in an MCE network environment, disable routing loop detection to avoid route loss during route calculation and disable route redistribution between routing protocols to save system resources.

Configuration prerequisites

Before you configure routing on an MCE, complete the following tasks:

- On the MCE, configure VPN instances, and bind the VPN instances with the interfaces connected to the VPN sites and those connected to the PE.
- Configure the link layer and network layer protocols on related interfaces to ensure IP connectivity.

Configuring routing between MCE and VPN site

Configuring static routing between MCE and VPN site

An MCE can reach a VPN site through a static route. Static routing on a traditional CE is globally effective and thus does not support address overlapping among VPNs. An MCE supports binding a static route with a VPN instance, so that the static routes of different VPN instances can be isolated from each other.

To configure static routing between MCE and VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a static route for a VPN instance.	<ul style="list-style-type: none"> ip route-static <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } { <i>gateway-address</i> <i>interface-type interface-number</i> [<i>gateway-address</i>] vpn-instance <i>d-vpn-instance-name gateway-address</i> } [preference <i>preference-value</i>] [tag <i>tag-value</i>] [description <i>description-text</i>] ip route-static vpn-instance <i>s-vpn-instance-name</i> <1-6> <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } { <i>gateway-address</i> [public] <i>interface-type interface-number</i> [<i>gateway-address</i>] vpn-instance <i>d-vpn-instance-name gateway-address</i> } [preference <i>preference-value</i>] [tag <i>tag-value</i>] [description <i>description-text</i>] 	Use either command. Perform this configuration on the MCE. On a VPN site, configure a normal static route.
3. Configure the default precedence for static routes.	ip route-static default-preference <i>default-preference-value</i>	Optional. 60 by default.

Configuring RIP between MCE and VPN site

A RIP process belongs to the public network or a single VPN instance. If you create a RIP process without binding it to a VPN instance, the process belongs to the public network. By configuring RIP process-to-VPN instance bindings on a IPv6 MCE, you allow routes of different VPNs to be exchanged between the MCE and the sites through different RIP processes, ensuring the separation and security of VPN routes.

To configure RIP between MCE and VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a RIP process for a VPN instance and enter RIP view.	rip [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	Perform this configuration on the MCE. On a VPN site, create a normal RIP process.
3. Enable RIP on the interface attached to the specified network.	network <i>network-address</i>	By default, RIP is disabled on an interface.
4. Redistribute remote site routes advertised by the PE.	import-route <i>protocol</i> [<i>process-id</i>] [allow-ibgp] [cost <i>cost</i>] route-policy <i>route-policy-name</i> tag <i>tag</i>] *	By default, no route is redistributed into RIP.
5. Configure the default cost value for the redistributed routes.	default cost <i>value</i>	Optional. 0 by default.

Configuring OSPF between MCE and VPN site

An OSPF process belongs to the public network or a single VPN instance. If you create an OSPF process without binding it to a VPN instance, the process belongs to the public network.

By configuring OSPF process-to-VPN instance bindings on a MCE, you allow routes of different VPNs to be exchanged between the MCE and the sites through different OSPF processes, ensuring the separation and security of VPN routes.

An OSPF process can belong to only one VPN instance, but one VPN instance can use multiple OSPF processes to advertise the VPN routes.

An OSPF process that is bound with a VPN instance does not use the public network router ID configured in system view. Therefore, you must configure a router ID when starting the OSPF process. All OSPF processes for the same VPN must be configured with the same OSPF domain ID to ensure correct route advertisement.

To configure OSPF between MCE and VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an OSPF process for a VPN instance and enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	Perform this configuration on the MCE. On a VPN site, create a normal OSPF process.
3. Configure the OSPF domain ID.	domain-id <i>domain-id</i> [secondary]	Optional. 0 by default. Perform this configuration on the MCE. On a VPN site, perform the common OSPF configuration.
4. Redistribute remote site routes advertised by the PE.	import-route <i>protocol</i> [<i>process-id</i> allow-ibgp] [cost <i>cost</i> type <i>type</i> tag <i>tag</i> route-policy <i>route-policy-name</i>] *	By default, no route of any other routing protocol is redistributed into OSPF.
5. Create an OSPF area and enter OSPF area view.	area <i>area-id</i>	By default, no OSPF area is created.
6. Enable OSPF on the interface attached to the specified network in the area.	network <i>ip-address</i> <i>wildcard-mask</i>	By default, an interface neither belongs to any area nor runs OSPF.

Configuring IS-IS between MCE and VPN site

An IS-IS process belongs to the public network or a single VPN instance. If you create an IS-IS process without binding it to a VPN instance, the process belongs to the public network.

By configuring IS-IS process-to-VPN instance bindings on a MCE, you allow routes of different VPNs to be exchanged between the MCE and the sites through different IS-IS processes, ensuring the separation and security of VPN routes.

To configure IS-IS between MCE and VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an IS-IS process for a VPN instance and enter IS-IS view.	isis [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	Perform this configuration on the MCE. On a VPN site, configure a normal IS-IS process.
3. Configure a network entity title.	network-entity <i>net</i>	Not configured by default.

Step	Command	Remarks
4. Redistribute remote site routes advertised by the PE.	import-route { <i>isis</i> [<i>process-id</i>] ospf [<i>process-id</i>] rip [<i>process-id</i>] bgp [allow-ibgp] direct static } [cost <i>cost</i> cost-type { external internal } [level-1 level-1-2 level-2] route-policy <i>route-policy-name</i> tag <i>tag</i>] *	Optional. By default, IS-IS does not redistribute routes of any other routing protocol. If you do not specify the route level in the command, the command will redistribute routes to the level-2 routing table by default.
5. Return to system view.	quit	N/A
6. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
7. Enable the IS-IS process on the interface.	isis enable [<i>process-id</i>]	Disabled by default.

Configuring EBGW between MCE and VPN site

To use EBGW for exchanging routing information between an MCE and VPN sites, you must configure a BGP peer for each VPN instance on the MCE, and redistribute the IGP routes of each VPN instance on the VPN sites.

If EBGW is used for route exchange, you also can configure filtering policies to filter the received routes and the routes to be advertised.

1. Configure the MCE:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter BGP-VPN instance view.	ipv4-family vpn-instance <i>vpn-instance-name</i>	N/A
4. Configure an EBGW peer.	peer { <i>group-name</i> <i>ip-address</i> } as-number <i>as-number</i>	N/A
5. Allow the local AS number to appear in the AS_PATH attribute of a received route, and set the maximum number of times that such case is allowed to appear.	peer { <i>group-name</i> <i>ip-address</i> } allow-as-loop [<i>number</i>]	Optional.
6. Redistribute remote site routes advertised by the PE.	import-route <i>protocol</i> [<i>process-id</i> all-processes] [med <i>med-value</i> route-policy <i>route-policy-name</i>] *	By default, no route redistribution is configured.
7. Configure a filtering policy to filter the routes to be advertised.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } export [direct isis <i>process-id</i> ospf <i>process-id</i> rip <i>process-id</i> static]	Optional. By default, BGP does not filter the routes to be advertised.
8. Configure a filtering policy to filter the received routes.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } import	Optional. By default, BGP does not filter the received routes.

BGP checks routing loops by examining AS numbers. When EBGP is used, the MCE advertises routing information carrying the local AS number to the site and then receives routing updates from the site. The routing updates carry the AS number of the MCE, so the MCE discards them to avoid routing loops. To enable the MCE to receive such routes, configure the MCE to allow routing loops.

Routes redistributed from OSPF to BGP on the MCE have their OSPF attributes removed. To enable BGP to distinguish routes redistributed from different OSPF domains, you must enable the redistributed routes to carry the OSPF domain ID by configuring the **domain-id** command in OSPF view. The domain ID is added to BGP VPN routes as an extended community attribute.

BGP runs in a BGP VPN instance in the same way as it runs in a normal network.

2. Configure a VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure the MCE as the EBGP peer.	peer { <i>group-name</i> <i>ip-address</i> } as-number <i>as-number</i>	N/A
4. Redistribute the IGP routes of the VPN.	import-route <i>protocol</i> [<i>process-id</i>] [med <i>med-value</i> route-policy <i>route-policy-name</i>] *	Optional. A VPN site must advertise the VPN network addresses it can reach to the connected MCE.

Configuring IBGP between MCE and VPN site

If IBGP is used for exchanging routing information between an MCE and VPN sites, you must configure a BGP peer for each VPN instance respectively, and redistribute the IGP routes of each VPN instance on the VPN sites.

1. Configure the MCE:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter BGP-VPN instance view.	ipv4-family vpn-instance <i>vpn-instance-name</i>	N/A
4. Configure an IBGP peer.	peer { <i>group-name</i> <i>ip-address</i> } as-number <i>as-number</i>	N/A
5. Configure the system to be the RR and specify the peer as the client of the RR.	peer { <i>group-name</i> <i>ip-address</i> } reflect-client	Optional. By default, no RR or RR client is configured.
6. Redistribute remote site routes advertised by the PE.	import-route <i>protocol</i> [<i>process-id</i>] all-processes] [med <i>med-value</i> route-policy <i>route-policy-name</i>] *	By default, no route redistribution is configured.
7. Configure a filtering policy to filter the routes to be advertised.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } export [direct isis <i>process-id</i> ospf <i>process-id</i> rip <i>process-id</i> static]	Optional. By default, BGP does not filter the routes to be advertised.

Step	Command	Remarks
8. Configure a filtering policy to filter the received routes.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } import	Optional. By default, BGP does not filter the received routes.

NOTE:

After you configure a VPN site as an IBGP peer of the MCE, the MCE does not advertise the BGP routes learned from the VPN site to other IBGP peers, including VPNv4 peers. Only when you configure the VPN site as a client of the RR (the MCE), does the MCE advertise routes learned from it to other IBGP peers.

2. Configure a VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Configure the MCE as the IBGP peer.	peer { <i>group-name</i> <i>ip-address</i> } as-number <i>as-number</i>	N/A
4. Redistribute the IGP routes of the VPN.	import-route <i>protocol</i> [<i>process-id</i>] [med <i>med-value</i> route-policy <i>route-policy-name</i>] *	Optional. A VPN site must advertise the VPN network addresses it can reach to the connected MCE.

Configuring routing between MCE and PE

MCE-PE routing configuration includes these tasks:

- Bind the MCE-PE interfaces to VPN instances
- Perform route configurations
- Redistribute VPN routes into the routing protocol running between the MCE and the PE.

Configuring static routing between MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Configure a static route for a VPN instance.	<ul style="list-style-type: none"> ip route-static <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } { <i>gateway-address</i> <i>interface-type interface-number</i> [<i>gateway-address</i>] vpn-instance <i>d-vpn-instance-name gateway-address</i> } [preference <i>preference-value</i>] [tag <i>tag-value</i>] [description <i>description-text</i>] ip route-static vpn-instance <i>s-vpn-instance-name</i><1-6> <i>dest-address</i> { <i>mask</i> <i>mask-length</i> } { <i>gateway-address</i> [public] <i>interface-type interface-number</i> [<i>gateway-address</i>] vpn-instance <i>d-vpn-instance-name gateway-address</i> } [preference <i>preference-value</i>] [tag <i>tag-value</i>] [description <i>description-text</i>] 	Use either command.
3. Configure the default precedence for static routes.	ip route-static default-preference <i>default-preference-value</i>	Optional. 60 by default.

Configuring RIP between MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a RIP process for a VPN instance and enter RIP view.	rip [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	N/A
3. Enable RIP on the interface attached to the specified network.	network <i>network-address</i>	By default, RIP is disabled on an interface.
4. Redistribute the VPN routes.	import-route <i>protocol</i> [<i>process-id</i>] [allow-ibgp] [cost <i>cost</i> route-policy <i>route-policy-name</i> tag <i>tag</i>] *	By default, no route of any other routing protocol is redistributed into RIP.
5. Configure the default cost value for the redistributed routes.	default cost <i>value</i>	Optional. 0 by default.

Configuring OSPF between MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an OSPF process for a VPN instance and enter OSPF view.	ospf [<i>process-id</i> router-id <i>router-id</i> vpn-instance <i>vpn-instance-name</i>] *	N/A

Step	Command	Remarks
3. Disable routing loop detection.	vpn-instance-capability simple	Disabled by default. You must disable routing loop detection for a VPN OSPF process on the MCE. Otherwise, the MCE cannot receive OSPF routes from the PE.
4. Configure the OSPF domain ID.	domain-id <i>domain-id</i> [secondary]	Optional. 0 by default.
5. Redistribute the VPN routes.	import-route <i>protocol</i> [<i>process-id</i> allow-ibgp] [cost <i>cost</i> type <i>type</i> tag <i>tag</i> route-policy <i>route-policy-name</i>] *	By default, no route of any other routing protocol is redistributed into OSPF.
6. Configure a filtering policy to filter advertised routes.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } export [<i>protocol</i> [<i>process-id</i>]]	Optional. By default, advertised routes are not filtered.
7. Configure the default parameters for redistributed routes (cost, route number, tag, and type).	default { cost <i>cost</i> limit <i>limit</i> tag <i>tag</i> type <i>type</i> } *	Optional. The default cost is 1, the default maximum number of routes redistributed per time is 1000, the default tag is 1, and default type of redistributed routes is Type-2.
8. Create an OSPF area and enter OSPF area view.	area <i>area-id</i>	By default, no OSPF area is created.
9. Enable OSPF on the interface attached to the specified network in the area.	network <i>ip-address</i> <i>wildcard-mask</i>	By default, an interface neither belongs to any area nor runs OSPF.

Configuring IS-IS between MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an IS-IS process for a VPN instance and enter IS-IS view.	isis [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure a network entity title.	network-entity <i>net</i>	Not configured by default.
4. Redistribute the VPN routes.	import-route { isis [<i>process-id</i>] ospf [<i>process-id</i>] rip [<i>process-id</i>] bgp [allow-ibgp] direct static } [cost <i>cost</i> cost-type { external internal }] [level-1 level-1-2 level-2] route-policy <i>route-policy-name</i> tag <i>tag</i>] *	Optional. By default, IS-IS does not redistribute routes of any other routing protocol. If you do not specify the route level in the command, the command will redistribute routes to the level-2 routing table by default.

Step	Command	Remarks
5. Configure a filtering policy to filter advertised routes.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> route-policy <i>route-policy-name</i> } export [isis <i>process-id</i> ospf <i>process-id</i> rip <i>process-id</i> bgp direct static]	Optional. By default, IS-IS does not filter advertised routes.
6. Return to system view.	quit	N/A
7. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
8. Enable the IS-IS process on the interface.	isis enable [<i>process-id</i>]	Disabled by default.

Configuring EBGP between MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter BGP-VPN instance view.	ipv4-family vpn-instance <i>vpn-instance-name</i>	N/A
4. Configure the PE as the EBGP peer.	peer { <i>group-name</i> <i>ip-address</i> } as-number <i>as-number</i>	N/A
5. Redistribute the VPN routes of the VPN site.	import-route <i>protocol</i> [<i>process-id</i> all-processes] [med <i>med-value</i> route-policy <i>route-policy-name</i>] *	By default, no route redistribution is configured.
6. Configure a filtering policy to filter the routes to be advertised.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } export [direct isis <i>process-id</i> ospf <i>process-id</i> rip <i>process-id</i> static]	Optional. By default, BGP does not filter the routes to be advertised.
7. Configure a filtering policy to filter the received routes.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } import	Optional. By default, BGP does not filter the received routes.

NOTE:

BGP runs within a VPN in the same way as it runs within a public network.

Configuring IBGP between MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter BGP-VPN instance view.	ipv4-family vpn-instance <i>vpn-instance-name</i>	N/A
4. Configure the PE as the IBGP peer.	peer { <i>group-name</i> <i>ip-address</i> } as-number <i>as-number</i>	N/A

Step	Command	Remarks
5. Redistribute the VPN routes of the VPN site.	import-route <i>protocol</i> [<i>process-id</i> all-processes] [med <i>med-value</i> route-policy <i>route-policy-name</i>] *	By default, no route redistribution is configured.
6. Configure the egress router of the site as a client of the route reflector.	peer { <i>group-name</i> <i>ip-address</i> } reflect-client	Optional. By default, no route reflector or client is configured.
7. Enable route reflection between clients.	reflect between-clients	Optional. Enabled by default. If the clients are fully meshed, you do not need to enable route reflection.
8. Specify a cluster ID for the route reflector.	reflector cluster-id <i>cluster-id</i>	Optional. By default, each RR in a cluster uses its own router ID as the cluster ID. If more than one RR exists in a cluster, use this command to configure the same cluster ID for all RRs in the cluster to avoid routing loops.
9. Configure a filtering policy to filter the routes to be advertised.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } export [direct isis <i>process-id</i> ospf <i>process-id</i> rip <i>process-id</i> static]	Optional. By default, BGP does not filter the routes to be advertised.
10. Configure a filtering policy to filter the received routes.	filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } import	Optional. By default, BGP does not filter the received routes.

Resetting BGP connections

When BGP configuration changes, you can use the soft reset function or reset BGP connections to make new configurations take effect. Soft reset requires that BGP peers have route refreshment capability (supporting Route-Refresh messages).

Step	Command	Remarks
1. Soft reset the BGP connections in a specified VPN instance.	refresh bgp vpn-instance <i>vpn-instance-name</i> { <i>ip-address</i> all external group <i>group-name</i> } { export import }	Available in user view
2. Reset BGP connections of a VPN instance.	reset bgp vpn-instance <i>vpn-instance-name</i> { <i>as-number</i> <i>ip-address</i> all external group <i>group-name</i> }	Available in user view

Displaying and maintaining MCE

Task	Command	Remarks
Display information about the routing table associated with a VPN instance.	display ip routing-table vpn-instance <i>vpn-instance-name</i> [verbose] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about a specific VPN instance or all VPN instances.	display ip vpn-instance [instance-name <i>vpn-instance-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the FIB of a VPN instance.	display fib vpn-instance <i>vpn-instance-name</i> [acl <i>acl-number</i> ip-prefix <i>ip-prefix-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the FIB of a VPN instance that matches the specified destination IP address.	display fib vpn-instance <i>vpn-instance-name</i> <i>ip-address</i> [<i>mask</i> <i>mask-length</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about a specific peer group or all BGP VPNv4 peer groups.	display bgp vpnv4 vpn-instance <i>vpn-instance-name</i> group [<i>group-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about BGP VPNv4 routes injected into a specific VPN instance or all VPN instances.	display bgp vpnv4 vpn-instance <i>vpn-instance-name</i> network [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display BGP VPNv4 AS path information.	display bgp vpnv4 vpn-instance <i>vpn-instance-name</i> paths [<i>as-regular-expression</i> { { begin exclude include } <i>regular-expression</i> }]	Available in any view
Display information about BGP VPNv4 peers.	display bgp vpnv4 vpn-instance <i>vpn-instance-name</i> peer [<i>group-name</i> log-info <i>ip-address</i> { log-info verbose } verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display the BGP VPNv4 routing information of a specific VPN instance.	<pre>display bgp vpnv4 vpn-instance vpn-instance-name routing-table [[network-address [{ mask mask-length } [longer-prefixes]] as-path-acl as-path-acl-number cidr community [aa:nn]&<1-13> [no-advertise no-export no-export-subconfed] * [whole-match] community-list { basic-community-list-number [whole-match] adv-community-list-number }&<1-16> dampened dampening parameter different-origin-as flap-info [network-address [{ mask mask-length } [longer-match]] as-path-acl as-path-acl-number] peer ip-address { advertised-routes received-routes } statistic] [{ begin exclude include } regular-expression] [flap-info] regular-expression as-regular-expression]</pre>	Available in any view
Clear the route flap dampening information of a VPN instance.	<pre>reset bgp vpn-instance vpn-instance-name dampening [network-address [mask mask-length]</pre>	Available in user view
Clear route flap history information about a BGP peer of a VPN instance.	<pre>reset bgp vpn-instance vpn-instance-name ip-address flap-info reset bgp vpn-instance vpn-instance-name flap-info [ip-address [mask mask-length] as-path-acl as-path-acl-number regexp as-path-regexp]</pre>	Available in user view

For commands to display information about a routing table, see *Layer 3—IP Routing Command Reference*.

MCE configuration examples

Using OSPF to advertise VPN routes to the PE

Network requirements

As shown in [Figure 129](#), the MCE device is connected to VPN 1 through VLAN-interface 10 and to VPN 2 through VLAN-interface 20. RIP runs in VPN 2.

Configure the MCE device to separate routes from different VPNs and advertise the VPN routes to PE 1 through OSPF.

Figure 129 Network diagram

Configuration procedure

Assume that the system name of the MCE device is MCE, the system names of the edge devices of VPN 1 and VPN 2 are VR1 and VR2, respectively, and the system name of PE 1 is PE1.

1. Configure the VPN instances on the MCE and PE 1:

On the MCE, configure VPN instances **vpn1** and **vpn2**, and specify an RD and route targets for each VPN instance.

```
<MCE> system-view
[MCE] ip vpn-instance vpn1
[MCE-vpn-instance-vpn1] route-distinguisher 10:1
[MCE-vpn-instance-vpn1] vpn-target 10:1
[MCE-vpn-instance-vpn1] quit
[MCE] ip vpn-instance vpn2
[MCE-vpn-instance-vpn2] route-distinguisher 20:1
[MCE-vpn-instance-vpn2] vpn-target 20:1
[MCE-vpn-instance-vpn2] quit
```

Create VLAN 10, add port GigabitEthernet 1/0/1 to VLAN 10, and create VLAN-interface 10.

```
[MCE] vlan 10
[MCE-vlan10] port gigabitethernet 1/0/1
[MCE-vlan10] quit
[MCE] interface vlan-interface 10
```

Bind VLAN-interface 10 with VPN instance **vpn1**, and configure an IP address for VLAN-interface 10.

```
[MCE-vlan-interface10] ip binding vpn-instance vpn1
```

```
[MCE-Vlan-interface10] ip address 10.214.10.3 24
# Configure VLAN 20, add port GigabitEthernet 1/0/2 to VLAN 20, bind VLAN-interface 20 with
VPN instance vpn2, and specify an IP address for VLAN-interface 20.
[MCE-Vlan-interface10] quit
[MCE] vlan 20
[MCE-vlan20] port gigabitethernet 1/0/2
[MCE-vlan20] quit
[MCE] interface vlan-interface 20
[MCE-Vlan-interface20] ip binding vpn-instance vpn2
[MCE-Vlan-interface20] ip address 10.214.20.3 24
[MCE-Vlan-interface20] quit
# On PE 1, configure VPN instances vpn1 and vpn2, specify an RD and route targets for each VPN
instance.
```

```
<PE1> system-view
[PE1] ip vpn-instance vpn1
[PE1-vpn-instance-vpn1] route-distinguisher 30:1
[PE1-vpn-instance-vpn1] vpn-target 10:1
[PE1-vpn-instance-vpn1] quit
[PE1] ip vpn-instance vpn2
[PE1-vpn-instance-vpn2] route-distinguisher 40:1
[PE1-vpn-instance-vpn2] vpn-target 20:1
[PE1-vpn-instance-vpn2] quit
```

2. Configure routing between the MCE and VPN sites:

The MCE is connected to VPN 1 directly, and no routing protocol is enabled in VPN 1. Therefore, you can configure static routes.

```
# On VR 1, assign IP address 10.214.10.2/24 to the interface connected to MCE and
192.168.0.1/24 to the interface connected to VPN 1. Add ports to VLANs correctly. (Details not
shown.)
```

```
# On VR 1, configure a default route with the next hop as 10.214.10.3.
```

```
<VR1> system-view
[VR1] ip route-static 0.0.0.0 0.0.0.0 10.214.10.3
```

```
# On the MCE, configure a static route to 192.168.0.0/24, specify the next hop as 10.214.10.2,
and bind the static route with VPN instance vpn1.
```

```
[MCE] ip route-static vpn-instance vpn1 192.168.0.0 24 10.214.10.2
```

```
# On the MCE, display the routing information maintained for VPN instance vpn1.
```

```
[MCE] display ip routing-table vpn-instance vpn1
Routing Tables: vpn1
          Destinations : 5          Routes : 5
Destination/Mask    Proto  Pre  Cost           NextHop           Interface
10.214.10.0/24      Direct  0    0           10.214.10.3       Vlan10
10.214.10.3/32      Direct  0    0           127.0.0.1         InLoop0
127.0.0.0/8         Direct  0    0           127.0.0.1         InLoop0
127.0.0.1/32       Direct  0    0           127.0.0.1         InLoop0
192.168.0.0/24     Static  60   0           10.214.10.2       Vlan10
```

The output shows that the MCE has a static route for VPN instance **vpn1**.

Run RIP in VPN 2. Create RIP process 20 and bind it with VPN instance **vpn2** on the MCE, so that the MCE can learn the routes of VPN 2 and add them to the routing table of the VPN instance **vpn2**.

```
[MCE] rip 20 vpn-instance vpn2
```

Advertise subnet 10.214.20.0.

```
[MCE-rip-20] network 10.214.20.0
```

```
[MCE-rip-20] quit
```

On VR 2, assign IP address 10.214.20.2/24 to the interface connected to MCE and 192.168.10.1/24 to the interface connected to VPN 2. (Details not shown.)

Configure RIP, and advertise subnets 192.168.10.0 and 10.214.20.0.

```
<VR2> system-view
```

```
[VR2] rip 20
```

```
[VR2-rip-20] network 192.168.10.0
```

```
[VR2-rip-20] network 10.214.20.0
```

On the MCE, display the routing information maintained for VPN instance **vpn2**.

```
[MCE] display ip routing-table vpn-instance vpn2
```

```
Routing Tables: vpn2
```

```
Destinations : 5          Routes : 5
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
10.214.20.0/24	Direct	0	0	10.214.20.3	Vlan20
10.214.20.3/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0
192.168.10.0/24	RIP	100	1	10.214.20.2	Vlan20

The output shows that the MCE has learned the private routes of VPN 2. The MCE maintains the routes of VPN 1 and those of VPN2 in two different routing tables. In this way, routes from different VPNs are separated.

3. Configure routing between MCE and PE 1:

The MCE uses port GigabitEthernet 1/0/3 to connect to PE's port GigabitEthernet 1/0/1. Configure the two ports as trunk ports, and configure them to permit packets carrying VLAN tags 30 and 40 to pass.

```
[MCE] interface gigabitethernet 1/0/3
```

```
[MCE-GigabitEthernet1/0/3] port link-type trunk
```

```
[MCE-GigabitEthernet1/0/3] port trunk permit vlan 30 40
```

```
[MCE-GigabitEthernet1/0/3] quit
```

Configure port GigabitEthernet1/0/1 on the PE.

```
[PE1] interface gigabitethernet 1/0/1
```

```
[PE1-GigabitEthernet1/0/1] port link-type trunk
```

```
[PE1-GigabitEthernet1/0/1] port trunk permit vlan 30 40
```

```
[PE1-GigabitEthernet1/0/1] quit
```

On the MCE, create VLAN 30 and VLAN-interface 30, bind the VLAN interface with VPN instance **vpn1**, and configure an IP address for the VLAN interface.

```
[MCE] vlan 30
```

```
[MCE-vlan30] quit
```

```
[MCE] interface vlan-interface 30
```

```
[MCE-Vlan-interface30] ip binding vpn-instance vpn1
[MCE-Vlan-interface30] ip address 30.1.1.1 24
[MCE-Vlan-interface30] quit
```

On the MCE, create VLAN 40 and VLAN-interface 40, bind the VLAN interface with VPN instance **vpn2**, and configure an IP address for the VLAN interface.

```
[MCE] vlan 40
[MCE-vlan40] quit
[MCE] interface vlan-interface 40
[MCE-Vlan-interface40] ip binding vpn-instance vpn2
[MCE-Vlan-interface40] ip address 40.1.1.1 24
[MCE-Vlan-interface40] quit
```

On PE 1, create VLAN 30 and VLAN-interface 30, bind the VLAN interface with VPN instance **vpn1**, and configure an IP address for the VLAN interface.

```
[PE1] vlan 30
[PE1-vlan30] quit
[PE1] interface vlan-interface 30
[PE1-Vlan-interface30] ip binding vpn-instance vpn1
[PE1-Vlan-interface30] ip address 30.1.1.2 24
[PE1-Vlan-interface30] quit
```

On PE 1, create VLAN 40 and VLAN-interface 40, bind the VLAN interface with VPN instance **vpn2**, and configure an IP address for the VLAN interface.

```
[PE1] vlan 40
[PE1-vlan40] quit
[PE1] interface vlan-interface 40
[PE1-Vlan-interface40] ip binding vpn-instance vpn2
[PE1-Vlan-interface40] ip address 40.1.1.2 24
[PE1-Vlan-interface40] quit
```

Configure the IP address of the interface Loopback0 as 101.101.10.1 for the MCE and as 100.100.10.1 for PE 1. Specify the loopback interface address as the router ID for the MCE and PE 1. (Details not shown.)

Enable OSPF process 10 on the MCE, bind the process to VPN instance **vpn1**, and set the domain ID to 10.

```
[MCE] ospf 10 router-id 101.101.10.1 vpn-instance vpn1
[MCE-ospf-10] vpn-instance-capability simple
[MCE-ospf-10] domain-id 10
```

On the MCE, advertise subnet 30.1.1.0 in area 0, and redistribute the static route of VPN 1.

```
[MCE-ospf-10] area 0
[MCE-ospf-10-area-0.0.0.0] network 30.1.1.0 0.0.0.255
[MCE-ospf-10-area-0.0.0.0] quit
[MCE-ospf-10] import-route static
```

On PE 1, start OSPF process 10, bind the process with VPN instance **vpn1**, set the domain ID to 10, and advertise subnet 30.1.1.0 in area 0.

```
[PE1] ospf 10 router-id 100.100.10.1 vpn-instance vpn1
[PE1-ospf-10] domain-id 10
[PE1-ospf-10] area 0
[PE1-ospf-10-area-0.0.0.0] network 30.1.1.0 0.0.0.255
[PE1-ospf-10-area-0.0.0.0] quit
```

```
[PE1-ospf-10] quit
```

On PE 1, display the routing table of VPN1.

```
[PE1] display ip routing-table vpn-instance vpn1
```

```
Routing Tables: vpn1
```

```
          Destinations : 5          Routes : 5
Destination/Mask    Proto  Pre  Cost           NextHop         Interface
30.1.1.0/24         Direct  0    0             30.1.1.2        Vlan30
30.1.1.2/32         Direct  0    0             127.0.0.1       InLoop0
127.0.0.0/8         Direct  0    0             127.0.0.1       InLoop0
127.0.0.1/32        Direct  0    0             127.0.0.1       InLoop0
192.168.0.0/24      O_ASE  150  1             30.1.1.1        Vlan30
```

The output shows that the static route of VPN 1 has been redistributed to the OSPF routing table of PE 1.

Take similar procedures to configure OSPF process 20 between MCE and PE 1 and redistribute VPN 2's routing information from RIP into the OSPF routing table of MCE. The following output shows that PE 1 has learned the private route of VPN 2 through OSPF.

```
<PE1> display ip routing-table vpn-instance vpn2
```

```
Routing Tables: vpn2
```

```
          Destinations : 5          Routes : 5
Destination/Mask    Proto  Pre  Cost           NextHop         Interface
40.1.1.0/24         Direct  0    0             40.1.1.2        Vlan40
40.1.1.2/32         Direct  0    0             127.0.0.1       InLoop0
127.0.0.0/8         Direct  0    0             127.0.0.1       InLoop0
127.0.0.1/32        Direct  0    0             127.0.0.1       InLoop0
192.168.10.0/24     O_ASE  150  1             40.1.1.1        Vlan40
```

Now, the routing information of the two VPNs has been redistributed into the routing tables on PE 1.

Using BGP to advertise VPN routes to the PE

Network requirements

As shown in [Figure 130](#), use an Ethernet switch as the MCE device. Advertise the VPN routes in site 1 and site 2 to PE 1, so that a VPN's sites across the MPLS backbone network can communicate with each other normally.

Use OSPF in both site 1 and site 2. Use EBGP between the MCE and PE 1.

Figure 130 Network diagram

Configuration procedure

1. Configure VPN instances:
Create VPN instances on the MCE and PE 1, and bind the VPN instances with VLAN interfaces. For the configuration procedure, see "[Using OSPF to advertise VPN routes to the PE.](#)"
2. Configure routing between the MCE and VPN sites:
Start an OSPF process on the devices in the two VPNs and advertise the subnets. (Details not shown.)
Configure OSPF on the MCE, and bind OSPF process 10 with VPN instance **vpn1** to learn the routes of VPN 1.

```
<MCE> system-view
[MCE] ospf router-id 10.214.10.3 10 vpn-instance vpn1
[MCE-ospf-10] area 0
[MCE-ospf-10-area-0.0.0.0] network 10.214.10.0 0.0.0.255
```

Display the routing table of VPN 1 on the MCE.

```
[MCE-ospf-10-area-0.0.0.0] display ip routing-table vpn-instance vpn1
```

Routing Tables: vpn1

Destinations : 5 Routes : 5

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
10.214.10.0/24	Direct	0	0	10.214.10.3	Vlan10
10.214.10.3/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0

```

127.0.0.1/32      Direct 0    0                127.0.0.1      InLoop0
192.168.0.0/24   OSPF   10    1                10.214.10.2    Vlan10

```

The output shows that the MCE has learned the private route of VPN 1 through OSPF process 10.

On MCE, bind OSPF process 20 with VPN instance **vpn2** to learn the routes of VPN 2. The configuration procedure is similar to that for OSPF process 10.

The following output shows that the MCE has learned the private route of VPN 2 through OSPF:

```
[MCE] display ip routing-table vpn-instance vpn2
```

```
Routing Tables: vpn2
```

```
Destinations : 5          Routes : 5
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
10.214.20.0/24	Direct	0	0	10.214.20.3	Vlan20
10.214.20.3/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0
192.168.0.0/24	OSPF	10	1	10.214.20.2	Vlan20

3. Configure routing between the MCE and PE 1:

Configure the connecting ports between the MCE and PE 1 as trunk ports. The configuration procedure is similar to that described in "[Using OSPF to advertise VPN routes to the PE.](#)" (Details not shown.)

Start BGP process 100 on the MCE, and enter the IPv4 address family view of VPN instance **vpn1**.

```
[MCE] bgp 100
```

```
[MCE-bgp] ipv4-family vpn-instance vpn1
```

Specify PE 1 as the EBGP peer of the MCE, and redistribute the routing information of OSPF process 10. (The IP address of PE 1's interface bound with VPN instance **vpn1** is 10.100.10.3, and the BGP process is 200.)

```
[MCE-bgp-vpn1] peer 30.1.1.2 as-number 200
```

```
[MCE-BGP-vpn1] import-route ospf 10
```

On PE 1, configure BGP process 200 and specify the MCE as its EBGP peer.

```
<PE1> system-view
```

```
[PE1] bgp 200
```

```
[PE1-bgp] ipv4-family vpn-instance vpn1
```

```
[PE1-bgp-vpn1] peer 30.1.1.1 as-number 100
```

```
[PE1-bgp-vpn1] quit
```

```
[PE1-bgp] quit
```

On PE 1, display the routing information of VPN instance **vpn1**.

```
[PE1] display ip routing-table vpn-instance vpn1
```

```
Routing Tables: vpn1
```

```
Destinations : 5          Routes : 5
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
30.1.1.0/24	Direct	0	0	30.1.1.2	Vlan30
30.1.1.2/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0

```

127.0.0.1/32      Direct 0    0          127.0.0.1      InLoop0
192.168.0.0/24   BGP     255  2          30.1.1.1       Vlan30

```

Perform similar configuration on the MCE and PE 1 for VPN 2. Redistribute the OSPF routes of VPN instance **vpn2** into the EBGp routing table. (Details not shown.)

The following output shows that PE 1 has learned the private route of VPN 2 through BGP:

```
[PE1] display ip routing-table vpn-instance vpn2
```

```
Routing Tables: vpn2
```

```
Destinations : 5      Routes : 5
```

Destination/Mask	Proto	Pre	Cost	NextHop	Interface
40.1.1.0/24	Direct	0	0	40.1.1.2	Vlan40
40.1.1.2/32	Direct	0	0	127.0.0.1	InLoop0
127.0.0.0/8	Direct	0	0	127.0.0.1	InLoop0
127.0.0.1/32	Direct	0	0	127.0.0.1	InLoop0
192.168.10.0/24	BGP	255	2	40.1.1.1	Vlan40

Now, the MCE has redistributed the OSPF routes of the two VPN instances into the EBGp routing tables of PE 1.

Configuring IPv6 MCE

The IPv6 MCE function is available only on the HP 5500 EI switch series.

Overview

In an IPv6 MPLS L3 VPN, an IPv6 MCE advertises IPv6 routing information between the VPN and the connected PE and forwards IPv6 packets. An IPv6 MCE operates in the same way as an IPv4 MCE. For more information, see "Configuring MCE."

Configuring an IPv6 MCE

Configuring VPN instances

By configuring VPN instances on a PE, you isolate not only VPN routes from public network routes, but also routes of a VPN from those of another VPN. This feature allows VPN instances to be used in network scenarios besides MPLS L3VPNs.

Creating a VPN instance

A VPN instance is associated with a site. It is a collection of the VPN membership and routing rules of its associated site. A VPN instance does not necessarily correspond to one VPN.

A VPN instance takes effect only after you configure an RD for it.

You can configure a description for a VPN instance to record its related information, such as its relationship with a certain VPN.

To create and configure a VPN instance:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VPN instance and enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure an RD for the VPN instance.	route-distinguisher <i>route-distinguisher</i>	N/A
4. Configure a description for the VPN instance.	description <i>text</i>	Optional.

Associating a VPN instance with an interface

After creating and configuring a VPN instance, you need to associate the VPN instance with the interface for connecting the CE. Any LDP-capable interface can be associated with a VPN instance.

To associate a VPN instance with an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Associate a VPN instance with the interface.	ip binding vpn-instance <i>vpn-instance-name</i>	No VPN instance is associated with an interface by default.

NOTE:

The **ip binding vpn-instance** command clears the IPv6 address of the interface on which it is configured. Be sure to re-configure an IPv6 address for the interface after configuring the command.

Configuring route related attributes for a VPN instance

The control process of VPN route advertisement is as follows:

- When a VPN route learned from a CE gets redistributed into BGP, BGP associates it with a route target extended community attribute list, which is usually the export target attribute of the VPN instance associated with the CE.
- The VPN instance determines which routes it can accept and redistribute according to the **import-extcommunity** in the route target.
- The VPN instance determines how to change the route targets attributes for routes to be advertised according to the **export-extcommunity** in the route target.

! IMPORTANT:

Create a routing policy before associating it with a VPN instance. Otherwise, the switch cannot filter the routes to be received and advertised.

To configure route related attributes for a VPN instance:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Enter IPv6 VPN view.	ipv6-family	Optional.
4. Configure route targets.	vpn-target <i>vpn-target</i> <1-8> [both export-extcommunity import-extcommunity]	A single vpn-target command can configure up to eight VPN targets. You can configure up to 64 VPN targets for a VPN instance.

Step	Command	Remarks
5. Set the maximum number of routes supported.	routing-table limit <i>number</i> { <i>warn-threshold</i> simply-alert }	Optional. Setting the maximum number of routes for a VPN instance to support is for preventing too many routes from being redistributed into the PE.
6. Apply an import routing policy.	import route-policy <i>route-policy</i>	Optional. By default, all routes matching the import target attribute are accepted.
7. Apply an export routing policy.	export route-policy <i>route-policy</i>	Optional. By default, routes to be advertised are not filtered.

NOTE:

- Route related attributes configured in VPN instance view are applicable to both IPv4 VPNs and IPv6 VPNs.
- You can configure route related attributes for IPv6 VPNs in both VPN instance view and IPv6 VPN view. Those configured in IPv6 VPN view take precedence.

Configuring routing on an IPv6 MCE

An IPv6 MCE implements service isolation through route isolation. IPv6 MCE routing configuration includes:

- IPv6 MCE-VPN site routing configuration
- IPv6 MCE-PE routing configuration

On the PE in an IPv6 MCE network environment, disable routing loop detection to avoid route loss during route calculation and disable route redistribution between routing protocols to save system resources.

Configuration prerequisites

Before you configure routing on an IPv6 MCE, complete the following tasks:

- On the IPv6 MCE, configure VPN instances, and bind the VPN instances with the interfaces connected to the VPN sites and those connected to the PE.
- Configure the link layer and network layer protocols on related interfaces to ensure IP connectivity.

Configuring routing between IPv6 MCE and VPN site

Configuring static routing between IPv6 MCE and VPN site

An IPv6 MCE can reach a VPN site through an IPv6 static route. IPv6 static routing on a traditional CE is globally effective and thus does not support address overlapping among VPNs. An IPv6 MCE supports

binding an IPv6 static route with an IPv6 VPN instance, so that the IPv6 static routes of different IPv6 VPN instances can be isolated from each other.

To configure IPv6 static routing between IPv6 MCE and VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure an IPv6 static route for an IPv6 VPN instance.	<ul style="list-style-type: none"> ipv6 route-static <i>ipv6-address prefix-length</i> { <i>interface-type interface-number</i> [<i>next-hop-address</i>] <i>next-hop-address</i> vpn-instance <i>d-vpn-instance-name nexthop-address</i> } [preference <i>preference-value</i>] ipv6 route-static vpn-instance <i>s-vpn-instance-name</i> <1-6> <i>ipv6-address prefix-length</i> { <i>interface-type interface-number</i> [<i>next-hop-address</i>] <i>next-hop-address</i> [public] vpn-instance <i>d-vpn-instance-name nexthop-address</i> } [preference <i>preference-value</i>] 	<p>Use either command.</p> <p>Perform this configuration on the IPv6 MCE. On a VPN site, configure normal IPv6 static routes.</p>

Configuring RIPng between IPv6 MCE and VPN site

A RIPng process belongs to the public network or a single IPv6 VPN instance. If you create a RIPng process without binding it to an IPv6 VPN instance, the process belongs to the public network. By configuring RIPng process-to-IPv6 VPN instance bindings on an IPv6 MCE, you allow routes of different VPNs to be exchanged between the IPv6 MCE and the sites through different RIPng processes, ensuring the separation and security of IPv6 VPN routes.

To configure RIPng between IPv6 MCE and VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a RIPng process for a VPN instance and enter RIPng view.	ripng [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	Perform this configuration on the IPv6 MCE. On a VPN site, configure normal RIPng.
3. Redistribute remote site routes advertised by the PE.	import-route <i>protocol</i> [<i>process-id</i>] [allow-ibgp] [cost <i>cost</i>] route-policy <i>route-policy-name</i>] *	By default, no route of any other routing protocol is redistributed into RIPng.
4. Configure the default cost value for the redistributed routes.	default cost <i>value</i>	Optional. 0 by default.
5. Return to system view.	quit	N/A
6. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
7. Enable RIPng on the interface.	ripng <i>process-id</i> enable	Disabled by default.

Configuring OSPFv3 between IPv6 MCE and VPN site

An OSPFv3 process belongs to the public network or a single IPv6 VPN instance. If you create an OSPFv3 process without binding it to an IPv6 VPN instance, the process belongs to the public network.

By configuring OSPFv3 process-to-IPv6 VPN instance bindings on an IPv6 MCE, you allow routes of different IPv6 VPNs to be exchanged between the IPv6 MCE and the sites through different OSPFv3 processes, ensuring the separation and security of IPv6 VPN routes.

To configure OSPFv3 between IPv6 MCE and VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an OSPFv3 process for a VPN instance and enter OSPFv3 view.	ospfv3 [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	Perform this configuration on the IPv6 MCE. On a VPN site, configure normal OSPFv3.
3. Set the router ID.	router-id <i>router-id</i>	N/A
4. Redistribute remote site routes advertised by the PE..	import-route <i>protocol</i> [<i>process-id</i> allow-ibgp] [cost <i>value</i> route-policy <i>route-policy-name</i> type <i>type</i>] *	By default, no route of any other routing protocol is redistributed into OSPFv3.
5. Return to system view.	quit	N/A
6. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
7. Enable OSPFv3 on the interface.	ospfv3 <i>process-id</i> area <i>area-id</i> [instance <i>instance-id</i>]	By default, OSPFv3 is disabled on an interface.

NOTE:

Deleting a VPN instance also deletes all related OSPFv3 processes at the same time.

Configuring IPv6 IS-IS between IPv6 MCE and VPN site

An IPv6 IS-IS process belongs to the public network or a single IPv6 VPN instance. If you create an IPv6 IS-IS process without binding it to an IPv6 VPN instance, the process belongs to the public network.

By configuring IPv6 IS-IS process-to-IPv6 VPN instance bindings on an IPv6 MCE, you allow routes of different IPv6 VPNs to be exchanged between the IPv6 MCE and the sites through different IPv6 IS-IS processes, ensuring the separation and security of IPv6 VPN routes.

To configure IPv6 IS-IS between IPv6 MCE and VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an IPv6 IS-IS process for a VPN instance and enter IS-IS view.	isis [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	Perform this configuration on the IPv6 MCE. On a VPN site, configure normal IPv6 IS-IS.
3. Configure a network entity title for the IS-IS process.	network-entity <i>net</i>	Not configured by default.

Step	Command	Remarks
4. Enable the IPv6 capacity for the IPv6 IS-IS process.	ipv6 enable	Disabled by default.
5. Redistribute remote site routes advertised by the PE.	ipv6 import-route <i>protocol</i> [<i>process-id</i>] [allow-ibgp] [cost cost [level-1 level-1-2 level-2] route-policy route-policy-name tag tag] *	Optional. By default, no routes from any other routing protocol are redistributed to IPv6 IS-IS. If you do not specify the route level in the command, redistributed routes are added to the level-2 routing table by default.
6. Return to system view.	quit	N/A
7. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
8. Enable the IPv6 IS-IS process on the interface.	isis ipv6 enable [<i>process-id</i>]	Disabled by default.

Configuring EBGp between IPv6 MCE and VPN site

To use EBGp for exchanging routing information between an IPv6 MCE and IPv6 VPN sites, you must configure a BGP peer for each IPv6 VPN instance on the IPv6 MCE, and redistribute the IGP routes of each VPN instance on the IPv6 VPN sites.

If EBGp is used for route exchange, you also can configure filtering policies to filter the received routes and the routes to be advertised.

1. Configure the IPv6 MCE:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 BGP-VPN instance view.	ipv6-family vpn-instance <i>vpn-instance-name</i>	N/A
4. Specify an IPv6 BGP peer in an AS.	peer <i>ipv6-address</i> as-number <i>as-number</i>	N/A
5. Redistribute remote site routes advertised by the PE.	import-route <i>protocol</i> [<i>process-id</i>] [med med-value route-policy route-policy-name] *	By default, No route redistribution is configured.
6. Configure a filtering policy to filter the routes to be advertised.	filter-policy { <i>acl6-number</i> ipv6-prefix <i>ip-prefix-name</i> } export [direct isisv6 process-id ripng process-id static]	Optional. By default, the IPv6 MCE does not filter the routes to be advertised.
7. Configure a filtering policy to filter the received routes.	filter-policy { <i>acl6-number</i> ipv6-prefix <i>ip-prefix-name</i> } import	Optional. By default, the IPv6 MCE does not filter the received routes.

NOTE:

After you configure an IPv6 BGP VPN instance, the IPv6 BGP route exchange for the IPv6 VPN instance is the same with the normal IPv6 BGP VPN route exchange.

2. Configure a VPN site:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Configure the IPv6 MCE as the EBGp peer.	peer <i>ipv6-address as-number as-number</i>	N/A
5. Redistribute the IGP routes of the VPN.	import-route <i>protocol [process-id [med med-value route-policy route-policy-name] *]</i>	Optional. By default, no route redistribution is configured. A VPN site must advertise the IPv6 VPN network addresses it can reach to the connected IPv6 MCE.

Configuring routing between IPv6 MCE and PE

IPv6 MCE-PE routing configuration includes these tasks:

- Bind the IPv6 MCE-PE interfaces to IPv6 VPN instances
- Perform routing configurations
- Redistribute IPv6 VPN routes into the routing protocol running between the IPv6 MCE and the PE.

Configuring IPv6 static routing between IPv6 MCE and PE

To configure IPv6 static routing between IPv6 MCE and PE:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure an IPv6 static route for an IPv6 VPN instance.	<ul style="list-style-type: none">• ipv6 route-static <i>ipv6-address prefix-length { interface-type interface-number [next-hop-address] next-hop-address vpn-instance d-vpn-instance-name nexthop-address } [preference preference-value]</i>• ipv6 route-static vpn-instance <i>s-vpn-instance-name&<1-6> ipv6-address prefix-length { interface-type interface-number [next-hop-address] nexthop-address [public] vpn-instance d-vpn-instance-name nexthop-address } [preference preference-value]</i>	User either command.

Configuring RIPng between IPv6 MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a RIPng process for an IPv6 VPN instance and enter RIPng view.	ripng [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	N/A
3. Redistribute the VPN routes.	import-route <i>protocol</i> [<i>process-id</i>] [allow-ibgp] [cost <i>cost</i> route-policy <i>route-policy-name</i>] *	By default, no route of any other routing protocol is redistributed into RIPng.
4. Configure the default cost value for the redistributed routes.	default cost <i>value</i>	Optional. 0 by default.
5. Return to system view.	quit	N/A
6. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
7. Enable the RIPng process on the interface.	ripng <i>process-id</i> enable	Disabled by default.

Configuring OSPFv3 between IPv6 MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an OSPFv3 process for an IPv6 VPN instance and enter OSPFv3 view.	ospfv3 [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	N/A
3. Set the router ID.	router-id <i>router-id</i>	N/A
4. Redistribute the VPN routes.	import-route <i>protocol</i> [<i>process-id</i> allow-ibgp] [cost <i>value</i> route-policy <i>route-policy-name</i> type <i>type</i>] *	By default, no route of any other routing protocol is redistributed into OSPFv3.
5. Configure a filtering policy to filter the redistributed routes.	filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> } export [bgp4+ direct isisv6 <i>process-id</i> ospfv3 <i>process-id</i> ripng <i>process-id</i> static]	Optional. By default, redistributed routes are not filtered.
6. Return to system view.	quit	N/A
7. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
8. Enable the OSPFv3 process on the interface.	ospfv3 <i>process-id</i> area <i>area-id</i> [instance <i>instance-id</i>]	Disabled by default.

Configuring IPv6 IS-IS between IPv6 MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an IS-IS process for an IPv6 VPN instance and enter IS-IS view.	isis [<i>process-id</i>] vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure a network entity title.	network-entity <i>net</i>	Not configured by default.
4. Enable the IPv6 capacity for the IS-IS process.	ipv6 enable	Disabled by default.
5. Redistribute the VPN routes.	ipv6 import-route <i>protocol</i> [<i>process-id</i>] [allow-ibgp] [cost <i>cost</i> [level-1 level-1-2 level-2] route-policy <i>route-policy-name</i> tag <i>tag</i>] *	Optional. By default, IS-IS does not redistribute routes of any other routing protocol. If you do not specify the route level in the command, the command will redistribute routes to the level-2 routing table by default.
6. Configure a filtering policy to filter the redistributed routes.	ipv6 filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> route-policy <i>route-policy-name</i> } export [<i>protocol</i> [<i>process-id</i>]]	Optional. By default, IPv6 IS-IS does not filter redistributed routes.
7. Return to system view.	quit	N/A
8. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
9. Enable IPv6 for the IS-IS process on the interface.	isis ipv6 enable [<i>process-id</i>]	Disabled by default.

Configuring EBGW between IPv6 MCE and PE

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 BGP-VPN instance view.	ipv6-family vpn-instance <i>vpn-instance-name</i>	N/A
4. Configure the PE as the EBGW peer.	peer <i>ipv6-address</i> as-number <i>as-number</i>	N/A
5. Redistribute the VPN routes.	import-route <i>protocol</i> [<i>process-id</i> [med <i>med-value</i> route-policy <i>route-policy-name</i>] *]	By default, No route redistribution is configured.
6. Configure a filtering policy to filter the routes to be advertised.	filter-policy { <i>acl6-number</i> ipv6-prefix <i>ip-prefix-name</i> } export [direct isisv6 <i>process-id</i> ripng <i>process-id</i> static]	Optional. By default, BGP does not filter the routes to be advertised.
7. Configure a filtering policy to filter the received routes.	filter-policy { <i>acl6-number</i> ipv6-prefix <i>ip-prefix-name</i> } import	Optional. By default, BGP does not filter the received routes.

NOTE:

IPv6 BGP runs within a VPN in the same way as it runs within a public network.

Resetting BGP connections

When BGP configuration changes, you can use the soft reset function or reset BGP connections to make new configurations take effect. Soft reset requires that BGP peers have route refreshment capability (supporting Route-Refresh messages).

Use the following commands to hard reset or soft reset BGP connections:

Step	Command	Remarks
1. Soft reset the IPv6 BGP connections in a VPN instance.	refresh bgp ipv6 vpn-instance <i>vpn-instance-name</i> { <i>ipv6-address</i> all external } { export import }	Available in user view
2. Hard reset the IPv6 BGP connections of a VPN instance.	reset bgp ipv6 vpn-instance <i>vpn-instance-name</i> { <i>as-number</i> <i>ipv6-address</i> all external }	Available in user view

Displaying information about IPv6 MCE

Task	Command	Remarks
Display information about a specific or all VPN instances.	display ip vpn-instance [<i>instance-name</i> <i>vpn-instance-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the IPv6 FIB of a VPN instance.	display ipv6 fib vpn-instance <i>vpn-instance-name</i> [acl6 <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display a VPN instance's FIB entries that match the specified destination IPv6 address.	display ipv6 fib vpn-instance <i>vpn-instance-name</i> <i>ipv6-address</i> [<i>prefix-length</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about BGP VPNv6 peers established between PEs.	display bgp vpnv6 all peer [<i>ipv4-address</i> verbose verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about IPv6 BGP peers established between the PE and CE in a VPN instance.	display bgp vpnv6 vpn-instance <i>vpn-instance-name</i> peer [<i>ipv6-address</i> verbose verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display all BGP VPNv6 routing information.	display bgp vpnv6 all routing-table [<i>network-address</i> <i>prefix-length</i> [longer-prefixes] peer <i>ip-address</i> { advertised-routes received-routes } [statistic] statistic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display the BGP VPNv6 routing information of a specified RD.	display bgp vpnv6 route-distinguisher <i>route-distinguisher</i> routing-table [<i>network-address prefix-length</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the BGP VPNv6 routing information of a VPN instance.	display bgp vpnv6 vpn-instance <i>vpn-instance-name</i> routing-table [<i>network-address prefix-length</i> [longer-prefixes] peer <i>ipv6-address</i> { advertised-routes received-routes }] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

For commands that display information about a routing table, see *Layer 3—IP Routing Command Reference*.

IPv6 MCE configuration examples

Using IPv6 ISIS to advertise VPN routes to the PE

Network requirements

As shown in [Figure 131](#), the IPv6 MCE device is connected to VPN 1 through VLAN-interface 10 and to VPN 2 through VLAN-interface 20. RIPng is used in VPN 2.

Configure the IPv6 MCE to separate routes from different VPNs and advertise VPN routes to PE 1 through OSPFv3.

Figure 131 Network diagram

Configuration procedure

Assume that the system name of the IPv6 MCE device is MCE, the system names of the edge devices of VPN 1 and VPN 2 are VR1 and VR2, respectively, and the system name of PE 1 is PE1.

1. Configure the VPN instances on the MCE and PE 1.

On the MCE, configure VPN instances **vpn1** and **vpn2**, and specify a RD and route targets for each VPN instance.

```
<MCE> system-view
[MCE] ip vpn-instance vpn1
[MCE-vpn-instance-vpn1] route-distinguisher 10:1
[MCE-vpn-instance-vpn1] vpn-target 10:1
[MCE-vpn-instance-vpn1] quit
[MCE] ip vpn-instance vpn2
[MCE-vpn-instance-vpn2] route-distinguisher 20:1
[MCE-vpn-instance-vpn2] vpn-target 20:1
[MCE-vpn-instance-vpn2] quit
```

Create VLAN 10, add port GigabitEthernet 1/0/1 to VLAN 10, and create VLAN-interface 10.

```
[MCE] vlan 10
[MCE-vlan10] port gigabitethernet 1/0/1
```

```
[MCE-vlan10] quit
```

Bind VLAN-interface 10 with VPN instance **vpn1**, and configure an IPv6 address for the VLAN interface.

```
[MCE] interface vlan-interface 10
[MCE-Vlan-interface10] ip binding vpn-instance vpn1
[MCE-Vlan-interface10] ipv6 address 2001:1::1 64
[MCE-Vlan-interface10] quit
```

Configure VLAN 20, add port GigabitEthernet 1/0/2 to VLAN 20, bind VLAN-interface 20 with VPN instance **vpn2**, and assign an IPv6 address to VLAN-interface 20.

```
[MCE] vlan 20
[MCE-vlan20] port gigabitethernet 1/0/2
[MCE-vlan20] quit
[MCE] interface vlan-interface 20
[MCE-Vlan-interface20] ip binding vpn-instance vpn2
[MCE-Vlan-interface20] ipv6 address 2002:1::1 64
[MCE-Vlan-interface20] quit
```

On PE 1, configure VPN instances **vpn1** and **vpn2**, and specify an RD and route targets for each VPN instance.

```
<PE1> system-view
[PE1] ip vpn-instance vpn1
[PE1-vpn-instance-vpn1] route-distinguisher 30:1
[PE1-vpn-instance-vpn1] vpn-target 10:1
[PE1-vpn-instance-vpn1] quit
[PE1] ip vpn-instance vpn2
[PE1-vpn-instance-vpn2] route-distinguisher 40:1
[PE1-vpn-instance-vpn2] vpn-target 20:1
[PE1-vpn-instance-vpn2] quit
```

2. Configure routing between the MCE and VPN sites.

The MCE is connected with VPN 1 directly, and no routing protocol is enabled in VPN 1. Therefore, you can configure IPv6 static routes.

On VR 1, assign IP address 2001:1::2/64 to the interface connected to the MCE and 2012:1::2/64 to the interface connected to VPN 1. Add ports to VLANs. (Details not shown.)

On VR 1, configure a default route, specifying the next hop as 2001:1::1.

```
<VR1> system-view
[VR1] ipv6 route-static :: 0 2001:1::1
```

On the MCE, configure an IPv6 static route to 2012:1::/64, specify the next hop as 2001:1::2, and bind the static route with VPN instance **vpn1**.

```
[MCE] ipv6 route-static vpn-instance vpn1 2012:1:: 64 vpn-instance vpn1 2001:1::2
```

Run RIPng in VPN 2. Configure RIPng process 20 for VPN instance **vpn2** on the MCE, so that the MCE can learn the routes of VPN 2 and add them to the routing table of VPN instance **vpn2**.

Configure RIPng process 20, binding it with VPN instance **vpn2**.

```
[MCE] ripng 20 vpn-instance vpn2
```

Advertise subnet 2002:1::/64 through RIPng.

```
[MCE] interface vlan-interface 20
[MCE-Vlan-interface20] ripng 20 enable
[MCE-Vlan-interface20] quit
```

On VR 2, assign IPv6 address 2002:1::2/64 to the interface connected to the MCE and 2012::2/64 to the interface connected to VPN 2. (Details not shown.)

Configure RIPng, and advertise subnets 2012::/64 and 2002:1::/64.

```
<VR2> system-view
[VR2] ripng 20
[VR2-ripng-20] quit
[VR2] interface vlan-interface 20
[VR2-Vlan-interface20] ripng 20 enable
[VR2-Vlan-interface20] quit
[VR2] interface vlan-interface 21
[VR2-Vlan-interface21] ripng 20 enable
[VR2-Vlan-interface21] quit
```

On MCE, display the routing tables of VPN instances **vpn1** and **vpn2**.

```
[MCE] display ipv6 routing-table vpn-instance vpn1
```

```
Routing Table : vpn1
Destinations : 5          Routes : 5
```

```
Destination: ::1/128          Protocol : Direct
NextHop      : ::1           Preference: 0
Interface   : InLoop0       Cost      : 0
```

```
Destination: 2001:1::/64     Protocol : Direct
NextHop      : 2001:1::1     Preference: 0
Interface   : Vlan10        Cost      : 0
```

```
Destination: 2001:1::1/128   Protocol : Direct
NextHop      : ::1           Preference: 0
Interface   : InLoop0       Cost      : 0
```

```
Destination: 2012:1::/64     Protocol : Static
NextHop      : 2001:1::2     Preference: 60
Interface   : Vlan10        Cost      : 0
```

```
Destination: FE80::/10       Protocol : Direct
NextHop      : ::            Preference: 0
Interface   : NULL0         Cost      : 0
```

```
[MCE] display ipv6 routing-table vpn-instance vpn2
```

```
Routing Table : vpn2
Destinations : 5          Routes : 5
```

```
Destination: ::1/128          Protocol : Direct
NextHop      : ::1           Preference: 0
Interface   : InLoop0       Cost      : 0
```

```

Destination: 2002:1::/64                                Protocol : Direct
NextHop      : 2002:1::1                                Preference: 0
Interface    : Vlan20                                    Cost      : 0

```

```

Destination: 2002:1::1/128                              Protocol : Direct
NextHop      : ::1                                       Preference: 0
Interface    : InLoop0                                    Cost      : 0
Destination: 2012::/64                                  Protocol : RIPng
NextHop      : FE80::20F:E2FF:FE3E:9CA2                 Preference: 100
Interface    : Vlan20                                    Cost      : 1

```

```

Destination: FE80::/10                                   Protocol : Direct
NextHop      : ::                                         Preference: 0
Interface    : NULL0                                     Cost      : 0

```

The output shows that the MCE has learned the private route of VPN 2. The MCE maintains the routes of VPN 1 and VPN 2 in two different routing tables. In this way, routes from different VPNs are separated.

3. Configure routing between the MCE and PE 1.

On the MCE, configure the port connected to PE 1 as a trunk port, and configure it to permit packets of VLAN 30 and VLAN 40 to pass with VLAN tags.

```

[MCE] interface gigabitethernet 1/0/3
[MCE-GigabitEthernet1/0/3] port link-type trunk
[MCE-GigabitEthernet1/0/3] port trunk permit vlan 30 40
[MCE-GigabitEthernet1/0/3] quit

```

On PE 1, configure the port connected to MCE as a trunk port, and configure it to permit packets of VLAN 30 and VLAN 40 to pass with VLAN tags.

```

[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] port link-type trunk
[PE1-GigabitEthernet1/0/1] port trunk permit vlan 30 40
[PE1-GigabitEthernet1/0/1] quit

```

On the MCE, create VLAN 30 and VLAN-interface 30, bind VLAN-interface 30 with VPN instance **vpn1** and configure an IPv6 address for the VLAN-interface 30.

```

[MCE] vlan 30
[MCE-vlan30] quit
[MCE] interface vlan-interface 30
[MCE-Vlan-interface30] ip binding vpn-instance vpn1
[MCE-Vlan-interface30] ipv6 address 30::1 64
[MCE-Vlan-interface30] quit

```

On the MCE, create VLAN 40 and VLAN-interface 40, bind VLAN-interface 40 with VPN instance **vpn2** and configure an IPv6 address for the VLAN-interface 40.

```

[MCE] vlan 40
[MCE-vlan40] quit
[MCE] interface vlan-interface 40
[MCE-Vlan-interface40] ip binding vpn-instance vpn2

```

```
[MCE-Vlan-interface40] ipv6 address 40::1 64
[MCE-Vlan-interface40] quit
```

On PE 1, create VLAN 30 and VLAN-interface 30, bind VLAN-interface 30 with VPN instance **vpn1** and configure an IPv6 address for the VLAN-interface 30.

```
[PE1] vlan 30
[PE1-vlan30] quit
[PE1] interface vlan-interface 30
[PE1-Vlan-interface30] ip binding vpn-instance vpn1
[PE1-Vlan-interface30] ipv6 address 30::2 64
[PE1-Vlan-interface30] quit
```

On PE 1, create VLAN 40 and VLAN-interface 40, bind VLAN-interface 40 with VPN instance **vpn2** and configure an IPv6 address for the VLAN-interface 40.

```
[PE1] vlan 40
[PE1-vlan40] quit
[PE1] interface vlan-interface 40
[PE1-Vlan-interface40] ip binding vpn-instance vpn2
[PE1-Vlan-interface40] ipv6 address 40::2 64
[PE1-Vlan-interface40] quit
```

Configure the IP address of the interface Loopback0 as 101.101.10.1 for the MCE and as 100.100.10.1 for PE 1. Specify the loopback interface address as the router ID for the MCE and PE 1. (Details not shown.)

Enable OSPFv3 process 10 on the MCE, bind the process to VPN instance **vpn1**, and redistribute the IPv6 static route of VPN 1.

```
[MCE] ospfv3 10 vpn-instance vpn1
[MCE-ospf-10] router-id 101.101.10.1
[MCE-ospf-10] import-route static
[MCE-ospf-10] quit
```

Enable OSPFv3 on VLAN-interface 30.

```
[MCE] interface vlan-interface 30
[MCE-Vlan-interface30] ospfv3 10 area 0.0.0.0
[MCE-Vlan-interface30] quit
```

On PE 1, enable OSPFv3 process 10 and bind the process to VPN instance **vpn1**.

```
[PE1] ospfv3 10 vpn-instance vpn1
[PE1-ospf-10] router-id 100.100.10.1
[PE1-ospf-10] quit
```

Enable OSPFv3 on VLAN-interface 30.

```
[PE1] interface vlan-interface 30
[PE1-Vlan-interface30] ospfv3 10 area 0.0.0.0
[PE1-Vlan-interface30] quit
```

On PE 1, display the routing table of VPN 1.

```
[PE1] display ipv6 routing-table vpn-instance vpn1
Routing Table : vpn1
                Destinations : 5                Routes : 5
```

```
Destination: ::1/128
```

```
Protocol : Direct
```

```

NextHop      : ::1                      Preference: 0
Interface    : InLoop0                  Cost       : 0

Destination: 30::/64                    Protocol   : Direct
NextHop      : 30::2                      Preference: 0
Interface    : Vlan30                    Cost       : 0

Destination: 30::2/128                   Protocol   : Direct
NextHop      : ::1                        Preference: 0
Interface    : InLoop0                    Cost       : 0

Destination: 2012:1::/64                  Protocol   : OSPFv3
NextHop      : FE80::202:FF:FE02:2        Preference: 150
Interface    : Vlan30                      Cost       : 1

Destination: FE80::/10                    Protocol   : Direct
NextHop      : ::                          Preference: 0
Interface    : NULL0                       Cost       : 0

```

The output shows that PE 1 has learned the private route of VPN 1 through OSPFv3.

Take similar procedures to configure OSPFv3 process 20 between the MCE and PE 1 and redistribute VPN 2's routes from RIPng process 20 into the OSPFv3 routing table of the MCE. The following output shows that PE 1 has learned the private route of VPN 2 through OSPFv3.

```

[PE1] display ipv6 routing-table vpn-instance vpn2
Routing Table : vpn2
                Destinations : 5          Routes : 5

```

```

Destination: ::1/128                      Protocol   : Direct
NextHop      : ::1                          Preference: 0
Interface    : InLoop0                       Cost       : 0

Destination: 40::/64                       Protocol   : Direct
NextHop      : 40::2                          Preference: 0
Interface    : Vlan40                         Cost       : 0

Destination: 40::2/128                     Protocol   : Direct
NextHop      : ::1                            Preference: 0
Interface    : InLoop0                         Cost       : 0

Destination: 2012::/64                      Protocol   : OSPFv3
NextHop      : FE80::200:FF:FE0F:5           Preference: 150
Interface    : Vlan40                          Cost       : 1

Destination: FE80::/10                      Protocol   : Direct
NextHop      : ::                            Preference: 0
Interface    : NULL0                           Cost       : 0

```

Now, the routing information of the two VPNs has been added into the routing tables on PE 1.

Multicast overview

Introduction to multicast

As a technique that coexists with unicast and broadcast, the multicast technique effectively addresses the issue of point-to-multipoint data transmission. By enabling high-efficiency point-to-multipoint data transmission over a network, multicast greatly saves network bandwidth and reduces network load.

By using multicast technology, a network operator can easily provide new value-added services, such as live webcasting, web TV, distance learning, telemedicine, web radio, real time video conferencing, and other bandwidth-critical and time-critical information services.

The term "router " in this document refers to both routers and Layer 3 switches.

Unless otherwise stated, the term "multicast" in this document refers to IP multicast.

Information transmission techniques

The information transmission techniques include unicast, broadcast, and multicast.

Unicast

In unicast transmission, the information source must send a separate copy of information to each host that needs the information.

Figure 1 Unicast transmission

In [Figure 1](#), assume that Host B, Host D and Host E need the information. A separate transmission channel must be established from the information source to each of these hosts.

In unicast transmission, the traffic transmitted over the network is proportional to the number of hosts that need the information. If a large number of hosts need the information, the information source must send a separate copy of the same information to each of these hosts. Sending many copies can place a tremendous pressure on the information source and the network bandwidth.

Unicast is not suitable for batch transmission of information.

Broadcast

In broadcast transmission, the information source sends information to all hosts on the subnet, even if some hosts do not need the information.

Figure 2 Broadcast transmission

In Figure 2, assume that only Host B, Host D, and Host E need the information. If the information is broadcast to the subnet, Host A and Host C also receive it. In addition to information security issues, broadcasting to hosts that do not need the information also causes traffic flooding on the same subnet.

Broadcast is disadvantageous in transmitting data to specific hosts. Moreover, broadcast transmission is a significant waste of network resources.

Multicast

Unicast and broadcast techniques cannot provide point-to-multipoint data transmissions with the minimum network consumption.

Multicast transmission can solve this problem. When some hosts on the network need multicast information, the information sender, or multicast source, sends only one copy of the information. Multicast distribution trees are built through multicast routing protocols, and the packets are replicated only on nodes where the trees branch.

Figure 3 Multicast transmission

The multicast source sends only one copy of the information to a multicast group. Host B, Host D and Host E, which are receivers of the information, must join the multicast group. The routers on the network duplicate and forward the information based on the distribution of the group members. Finally, the information is correctly delivered to Host B, Host D, and Host E.

To summarize, multicast has the following advantages:

- **Advantages over unicast**—Because multicast traffic flows to the farthest-possible node from the source before it is replicated and distributed, an increase in the number of hosts does not increase the load of the source or remarkably add to the usage of network resources.
- **Advantages over broadcast**—Because multicast data is sent only to the receivers that need it, multicast uses network bandwidth reasonably and enhances network security. In addition, data broadcast is confined to the same subnet, but multicast is not.

Multicast features

- A multicast group is a multicast receiver set identified by an IP multicast address. Hosts join a multicast group to become members of the multicast group before they can receive the multicast data addressed to that multicast group. Typically, a multicast source does not need to join a multicast group.
- An information sender is called a "multicast source". A multicast source can send data to multiple multicast groups at the same time, and multiple multicast sources can send data to the same multicast group at the same time.
- All hosts that have joined a multicast group become members of the multicast group. The group memberships are dynamic. Hosts can join or leave multicast groups at any time. Multicast groups are not subject to geographic restrictions.
- Routers or Layer 3 switches that support Layer 3 multicast are called "multicast routers" or "Layer 3 multicast devices". In addition to providing the multicast routing function, a multicast router can also manage multicast group memberships on stub subnets with attached group members. A multicast router itself can be a multicast group member.

For a better understanding of the multicast concept, you can compare multicast transmission to the transmission of TV programs.

Table 1 Comparing TV transmission and multicast transmission

TV transmission	Multicast transmission
A TV station transmits a TV program through a channel.	A multicast source sends multicast data to a multicast group.
A user tunes the TV set to the channel.	A receiver joins the multicast group.
The user starts to watch the TV program transmitted by the TV station via the channel.	The receiver starts to receive the multicast data that the source is sending to the multicast group.
The user turns off the TV set or tunes to another channel.	The receiver leaves the multicast group or joins another group.

Common notations in multicast

The following notations are commonly used in multicast transmission:

- **(*, G)**—Indicates a rendezvous point tree (RPT), or a multicast packet that any multicast source sends to multicast group G. Here, the asterisk represents any multicast source, and "G" represents a specific multicast group.
- **(S, G)**—Indicates a shortest path tree (SPT), or a multicast packet that multicast source S sends to multicast group G. Here, "S" represents a specific multicast source, and "G" represents a specific multicast group.

For more information about the concepts RPT and SPT, see "[Configuring PIM \(available only on the HP 5500 EI\)](#)" and "[Configuring IPv6 PIM \(available only on the HP 5500 EI\)](#)."

Multicast advantages and applications

Multicast advantages

Advantages of the multicast technique include the following:

- **Enhanced efficiency**—Reduces the processor load of information source servers and network devices.
- **Optimal performance**—Reduces redundant traffic.
- **Distributed application**—Enables point-to-multipoint applications at the price of minimum network resources.

Multicast applications

The scenarios in which the multicast technique can be effectively applied are:

- Multimedia and streaming applications, such as web TV, web radio, and real time video/audio conferencing
- Communication for training and cooperative operations, such as distance learning and telemedicine
- Data warehouse and financial applications (stock quotes)
- Any other point-to-multipoint application for data distribution

Multicast models

Based on how the receivers treat the multicast sources, the multicast models include any-source multicast (ASM), source-filtered multicast (SFM), and source-specific multicast (SSM).

ASM model

In the ASM model, any sender can send information to a multicast group as a multicast source, and receivers can join a multicast group (identified by a group address) and obtain multicast information addressed to that multicast group. In this model, receivers do not know the positions of the multicast sources in advance. However, they can join or leave the multicast group at any time.

SFM model

The SFM model is derived from the ASM model. To a sender, the two models appear to have the same multicast membership architecture.

The SFM model functionally extends the ASM model. The upper-layer software checks the source address of received multicast packets and permits or denies multicast traffic from specific sources. Therefore, receivers can receive the multicast data from only part of the multicast sources. To a receiver, multicast sources are not all valid; they are filtered.

SSM model

Users might be interested in the multicast data from only certain multicast sources. The SSM model provides a transmission service that enables users to specify the multicast sources that they are interested in at the client side.

The main difference between the SSM model and the ASM model is that in the SSM model, receivers have already determined the locations of the multicast sources by some other means. In addition, the SSM model uses a multicast address range that is different from that of the ASM/SFM model, and dedicated multicast forwarding paths are established between receivers and the specified multicast sources.

Multicast architecture

IP multicast addresses the following questions:

- Where should the multicast source transmit information to? (multicast addressing)
- What receivers exist on the network? (host registration)
- Where is the multicast source that will provide data to the receivers? (multicast source discovery)
- How should information be transmitted to the receivers? (multicast routing)

IP multicast is an end-to-end service. The multicast architecture involves the following parts:

- **Addressing mechanism**—A multicast source sends information to a group of receivers through a multicast address.
- **Host registration**—Receiver hosts can join and leave multicast groups dynamically. This mechanism is the basis for management of group memberships.
- **Multicast routing**—A multicast distribution tree (namely, a forwarding path tree for multicast data on the network) is constructed for delivering multicast data from a multicast source to receivers.
- **Multicast applications**—A software system that supports multicast applications, such as video conferencing, must be installed on multicast sources and receiver hosts. The TCP/IP stack must support reception and transmission of multicast data.

Multicast addresses

Network-layer multicast addresses (multicast IP addresses) enables communication between multicast sources and multicast group members. In addition, a technique must be available to map multicast IP addresses to link-layer multicast MAC addresses.

IP multicast addresses

- IPv4 multicast addresses
Internet Assigned Numbers Authority (IANA) assigned the Class D address space (224.0.0.0 to 239.255.255.255) to IPv4 multicast.

Table 2 Class D IP address blocks and description

Address block	Description
224.0.0.0 to 224.0.0.255	Reserved permanent group addresses. The IP address 224.0.0.0 is reserved. Other IP addresses can be used by routing protocols and for topology searching, protocol maintenance, and so on. Table 3 lists common permanent group addresses. A packet destined for an address in this block will not be forwarded beyond the local subnet regardless of the Time to Live (TTL) value in the IP header.
224.0.1.0 to 238.255.255.255	Globally scoped group addresses. This block includes the following types of designated group addresses: <ul style="list-style-type: none">• 232.0.0.0/8—SSM group addresses, and• 233.0.0.0/8—Glop group addresses.
239.0.0.0 to 239.255.255.255	Administratively scoped multicast addresses. These addresses are considered locally unique rather than globally unique, and can be reused in domains administered by different organizations without causing conflicts. For more information, see RFC 2365.

NOTE:

"Glop" is a mechanism for assigning multicast addresses between different autonomous systems (ASs). By filling an AS number into the middle two bytes of 233.0.0.0, you get 255 multicast addresses for that AS. For more information, see RFC 2770.

Table 3 Some reserved multicast addresses

Address	Description
224.0.0.1	All systems on this subnet, including hosts and routers
224.0.0.2	All multicast routers on this subnet
224.0.0.3	Unassigned
224.0.0.4	Distance Vector Multicast Routing Protocol (DVMRP) routers
224.0.0.5	Open Shortest Path First (OSPF) routers
224.0.0.6	OSPF designated routers and backup designated routers
224.0.0.7	Shared Tree (ST) routers
224.0.0.8	ST hosts
224.0.0.9	Routing Information Protocol version 2 (RIPv2) routers
224.0.0.11	Mobile agents

Address	Description
224.0.0.12	Dynamic Host Configuration Protocol (DHCP) server/relay agent
224.0.0.13	All Protocol Independent Multicast (PIM) routers
224.0.0.14	Resource Reservation Protocol (RSVP) encapsulation
224.0.0.15	All Core-Based Tree (CBT) routers
224.0.0.16	Designated Subnetwork Bandwidth Management (SBM)
224.0.0.17	All SBMs
224.0.0.18	Virtual Router Redundancy Protocol (VRRP)

- IPv6 multicast addresses

Figure 4 IPv6 multicast format

The following describes the fields of an IPv6 multicast address:

- **0xFF**—The most significant eight bits are 11111111, which indicates that this address is an IPv6 multicast address.
- **Flags**—The Flags field contains four bits.

Figure 5 Flags field format

Table 4 Flags field description

Bit	Description
0	Reserved, set to 0
R	<ul style="list-style-type: none"> • When set to 0, it indicates that this address is an IPv6 multicast address without an embedded RP address • When set to 1, it indicates that this address is an IPv6 multicast address with an embedded RP address (the P and T bits must also be set to 1)
P	<ul style="list-style-type: none"> • When set to 0, it indicates that this address is an IPv6 multicast address not based on a unicast prefix • When set to 1, it indicates that this address is an IPv6 multicast address based on a unicast prefix (the T bit must also be set to 1)
T	<ul style="list-style-type: none"> • When set to 0, it indicates that this address is an IPv6 multicast address permanently-assigned by IANA • When set to 1, it indicates that this address is a transient, or dynamically assigned IPv6 multicast address

- **Scope**—The Scope field contains four bits, which indicate the scope of the IPv6 internetwork for which the multicast traffic is intended.

Table 5 Values of the Scope field

Value	Meaning
0, F	Reserved
1	Interface-local scope
2	Link-local scope
3	Subnet-local scope
4	Admin-local scope
5	Site-local scope
6, 7, 9 through D	Unassigned
8	Organization-local scope
E	Global scope

- **Group ID**—The Group ID field contains 112 bits. It uniquely identifies an IPv6 multicast group in the scope that the Scope field defines.

Ethernet multicast MAC addresses

A multicast MAC address identifies a group of receivers at the data link layer.

- IPv4 multicast MAC addresses

As defined by IANA, the most significant 24 bits of an IPv4 multicast MAC address are 0x01005E. Bit 25 is 0, and the other 23 bits are the least significant 23 bits of a multicast IPv4 address.

Figure 6 IPv4-to-MAC address mapping

The most significant four bits of a multicast IPv4 address are 1110, which indicates that this address is a multicast address. Only 23 bits of the remaining 28 bits are mapped to a MAC address, so five bits of the multicast IPv4 address are lost. As a result, 32 multicast IPv4 addresses map to the same IPv4 multicast MAC address. Therefore, in Layer 2 multicast forwarding, a switch might receive some multicast data destined for other IPv4 multicast groups. The upper layer must filter such redundant data.

- IPv6 multicast MAC addresses

The most significant 16 bits of an IPv6 multicast MAC address are 0x3333. The least significant 32 bits are the least significant 32 bits of a multicast IPv6 address.

Figure 7 An example of IPv6-to-MAC address mapping

Multicast protocols

Generally, Layer 3 multicast refers to IP multicast working at the network layer. The corresponding multicast protocols are Layer 3 multicast protocols, which include IGMP, MLD, PIM, IPv6 PIM, MSDP, MBGP, and IPv6 MBGP. Layer 2 multicast refers to IP multicast working at the data link layer. The corresponding multicast protocols are Layer 2 multicast protocols, which include IGMP snooping, MLD snooping, PIM snooping, IPv6 PIM snooping, multicast VLAN, and IPv6 multicast VLAN.

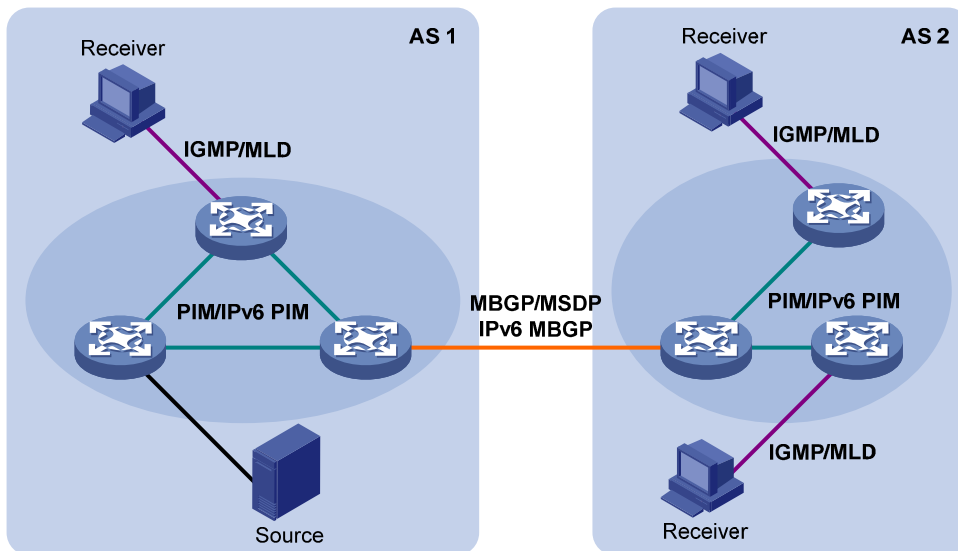

IGMP snooping, PIM snooping, multicast VLAN, IGMP, PIM, MSDP, and MBGP are for IPv4, and MLD snooping, IPv6 PIM snooping, IPv6 multicast VLAN, MLD, IPv6 PIM, and IPv6 MBGP are for IPv6.

This section provides only general descriptions about applications and functions of the Layer 2 and Layer 3 multicast protocols in a network. For more information about these protocols, see the related chapters.

Layer 3 multicast protocols

Layer 3 multicast protocols include multicast group management protocols and multicast routing protocols.

Figure 8 Positions of Layer 3 multicast protocols

- Multicast group management protocols
Typically, the Internet Group Management Protocol (IGMP) or Multicast Listener Discovery Protocol (MLD) is used between hosts and Layer 3 multicast devices that directly connect to the hosts. These

protocols define the mechanism of establishing and maintaining group memberships between hosts and Layer 3 multicast devices.

- Multicast routing protocols

A multicast routing protocol runs on Layer 3 multicast devices to establish and maintain multicast routes and forward multicast packets correctly and efficiently. Multicast routes constitute loop-free data transmission paths from a data source to multiple receivers, namely, a multicast distribution tree.

In the ASM model, multicast routes include intra-domain routes and inter-domain routes.

- An intra-domain multicast routing protocol discovers multicast sources and builds multicast distribution trees within an AS to deliver multicast data to receivers. Among a variety of mature intra-domain multicast routing protocols, Protocol Independent Multicast (PIM) is most widely used. Based on the forwarding mechanism, PIM has dense mode (often referred to as "PIM-DM"), and sparse mode (often referred to as "PIM-SM").
- An inter-domain multicast routing protocol is used for delivery of multicast information between two ASs. So far, mature solutions include Multicast Source Discovery Protocol (MSDP) and Multicast Border Gateway Protocol (MBGP). MSDP propagates multicast source information among different ASs. MBGP is an extension of the Multiprotocol Border Gateway Protocol (MP-BGP) for exchanging multicast routing information among different ASs.

For the SSM model, multicast routes are not divided into intra-domain routes and inter-domain routes. Because receivers know the position of the multicast source, channels established through PIM-SM are sufficient for the transport of multicast information.

Layer 2 multicast protocols

Layer 2 multicast protocols include IGMP snooping, MLD snooping, PIM snooping, IPv6 PIM snooping, multicast VLAN, and IPv6 multicast VLAN.

Figure 9 Positions of Layer 2 multicast protocols

- IGMP snooping and MLD snooping

IGMP snooping and MLD snooping are multicast constraining mechanisms that run on Layer 2 devices. They manage and control multicast groups by monitoring and analyzing IGMP or MLD messages exchanged between the hosts and Layer 3 multicast devices, effectively controlling the flooding of multicast data in a Layer 2 network.

- PIM snooping and IPv6 PIM snooping
PIM snooping and IPv6 PIM snooping run on Layer 2 devices. They determine which ports are interested in multicast data by analyzing the received IPv6 PIM messages, and add the ports to a multicast forwarding entry to make sure that multicast data can be forwarded to only the ports that are interested in the data.
- Multicast VLAN and IPv6 multicast VLAN
In the traditional multicast-on-demand mode, when users in different VLANs on a Layer 2 device need multicast information, the upstream Layer 3 device must forward a separate copy of the multicast data to each VLAN of the Layer 2 device. When the multicast VLAN or IPv6 multicast VLAN feature is enabled on the Layer 2 device, the Layer 3 multicast device sends only one copy of multicast to the multicast VLAN or IPv6 multicast VLAN on the Layer 2 device. This approach avoids waste of network bandwidth and extra burden on the Layer 3 device.

Multicast packet forwarding mechanism

In a multicast model, a multicast source sends information to the host group identified by the multicast group address in the destination address field of IP multicast packets. To deliver multicast packets to receivers located at different positions of the network, multicast routers on the forwarding paths usually need to forward multicast packets that an incoming interface receives to multiple outgoing interfaces. Compared with a unicast model, a multicast model is more complex in the following aspects:

- To ensure multicast packet transmission in the network, unicast routing tables or multicast routing tables (for example, the MBGP routing table) specially provided for multicast must be used as guidance for multicast forwarding.
- To process the same multicast information from different peers received on different interfaces of the same device, every multicast packet undergoes a reverse path forwarding (RPF) check on the incoming interface. The result of the RPF check determines whether the packet will be forwarded or discarded. The RPF check mechanism is the basis for most multicast routing protocols to implement multicast forwarding.

For more information about the RPF mechanism, see "[Configuring multicast routing and forwarding \(available only on the HP 5500 EI\)](#)" and "[Configuring IPv6 multicast routing and forwarding \(available only on the HP 5500 EI\)](#)."

Multicast support for VPNs

Multicast support for VPNs refers to multicast applied in virtual private networks (VPNs).

NOTE:

- Multicast support for VPNs is not available in IPv6 networks.
 - Multicast supporting for VPNs is not available for the HP 5500 SI switches.
-

Introduction to VPN instances

VPNs must be isolated from one another and from the public network. As shown in [Figure 10](#), VPN A and VPN B separately access the public network through PE devices.

Figure 10 VPN networking diagram

- The provider (P) device belongs to the public network. The customer edge (CE) devices belong to their respective VPNs. Each CE device serves its own VPN and maintains only one set of forwarding mechanisms.
- The provider edge (PE) devices connect to the public network and the VPNs at the same time. Each PE device must strictly distinguish the information for different networks, and maintain a separate forwarding mechanism for each network. On a PE device, a set of software and hardware that serve the same network forms an instance. Multiple instances can exist on the same PE device, and an instance can reside on different PE devices. On a PE device, the instance for the public network is called the public network instance, and those for VPNs are called VPN instances.

Multicast application in VPNs

A PE device that supports multicast for VPNs does the following operations:

- Maintains an independent set of independent multicast forwarding mechanisms for each VPN, including the multicast protocols, PIM neighbor information, and multicast routing table. In a VPN the device forwards multicast data based on the forwarding table or routing table for that VPN.
- Implements the isolation between different VPNs.
- Implements information exchange and data conversion between the public network and VPN instances.

As shown in [Figure 10](#), when a multicast source in VPN A sends a multicast stream to a multicast group, only the receivers that belong to both the multicast group and VPN A can receive the multicast stream. The multicast data is multicast both in VPN A and in the public network.

Configuring IGMP snooping

Overview

Internet Group Management Protocol (IGMP) snooping is a multicast constraining mechanism that runs on Layer 2 devices to manage and control multicast groups.

By analyzing received IGMP messages, a Layer 2 device that runs IGMP snooping establishes mappings between ports and multicast MAC addresses, and forwards multicast data based on these mappings.

As shown in [Figure 11](#), when IGMP snooping does not run on the Layer 2 switch, multicast packets are flooded to all devices at Layer 2. When IGMP snooping runs on the Layer 2 switch, multicast packets for known multicast groups are multicast to the receivers, rather than flooded to all hosts at Layer 2.

Figure 11 Before and after IGMP snooping is enabled on the Layer 2 device

IGMP snooping enables the Layer 2 switch to forward multicast data to only the receivers that require the data at Layer 2. It has the following advantages:

- Reducing Layer 2 broadcast packets, thus saving network bandwidth
- Enhancing the security of multicast traffic
- Facilitating the implementation of per-host accounting

Basic concepts in IGMP snooping

IGMP snooping related ports

As shown in [Figure 12](#), Router A connects to the multicast source, IGMP snooping runs on Switch A and Switch B, and Host A and Host C are receiver hosts (namely, members of a multicast group).

Figure 12 IGMP snooping related ports

Ports involved in IGMP snooping, as shown in [Figure 12](#), are described as follows:

- Router port**—A router port is a port on an Ethernet switch that leads the switch toward a Layer 3 multicast device (designated router or IGMP querier). In the figure, GigabitEthernet 1/0/1 of Switch A and GigabitEthernet 1/0/1 of Switch B are router ports. The switch registers all its local router ports in its router port list.

In this document, a router port is a port on a switch that leads the switch toward a Layer 3 multicast device. It is not a port on an ordinary router.

- Member port**—A member port is a port on an Ethernet switch that leads the switch toward multicast group members. In the figure, GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 of Switch A and GigabitEthernet 1/0/2 of Switch B are member ports. The switch registers all the member ports on the local device in its IGMP snooping forwarding table.

Unless otherwise specified, router ports and member ports in this document include both static and dynamic router ports and member ports.

NOTE:

An IGMP-snooping-enabled switch deems that all its ports on which IGMP general queries with the source IP address other than 0.0.0.0 or that receive PIM hello messages are received are dynamic router ports. For more information about PIM hello messages, see "[Configuring PIM \(available only on the HP 5500 EI\)](#)"

Aging timers for dynamic ports in IGMP snooping and related messages and actions

Timer	Description	Message before expiry	Action after expiry
Dynamic router port aging timer	For each dynamic router port, the switch sets an aging timer. When the timer expires, the dynamic router port ages out.	IGMP general query of which the source address is not 0.0.0.0 or PIM hello	The switch removes this port from its router port list.

Timer	Description	Message before expiry	Action after expiry
Dynamic member port aging timer	When a port dynamically joins a multicast group, the switch starts an aging timer for the port. When the timer expires, the dynamic member port ages out.	IGMP membership report	The switch removes this port from the IGMP snooping forwarding table.

NOTE:

In IGMP snooping, only dynamic ports age out. Static ports never age out.

How IGMP snooping works

In this section, the involved ports are dynamic ports. For information about how to configure and remove static ports, see "[Configuring static ports.](#)"

A switch that runs IGMP snooping performs different actions when it receives different IGMP messages.

When receiving a general query

The IGMP querier periodically sends IGMP general queries to all hosts and routers (224.0.0.1) on the local subnet to determine whether any active multicast group members exist on the subnet.

After receiving an IGMP general query, the switch forwards it to all ports in the VLAN (except the port that received the query). The switch also performs the following judgment:

- If the port that received the query is a dynamic router port in the router port list of the switch, the switch restarts the aging timer for the port.
- If the port is not in its router port list, the switch adds it into its router port list as a dynamic router port and starts an aging timer for the port.

When receiving a membership report

A host sends an IGMP report to the IGMP querier in the following circumstances:

- If the host has been a member of a multicast group, after receiving an IGMP query, the host responds to the query with an IGMP report.
- When the host wants to join a multicast group, it sends an IGMP report to the IGMP querier, specifying the multicast group to join.

After receiving an IGMP report, the switch forwards it through all the router ports in the VLAN, resolves the address of the reported multicast group. The switch also performs the following judgment:

- If no forwarding entry matches the group address, the switch creates a forwarding entry for the group, adds the port that received the IGMP report as a dynamic member port to the forwarding entry, and starts an aging timer for the port.
- If a forwarding entry matches the group address, but the port that received the IGMP report is not in the forwarding entry for the group, the switch adds the port as a dynamic member port to the forwarding entry, and starts an aging timer for the port.
- If a forwarding entry matches the group address and the port that received the IGMP report is in the forwarding entry for the group, the switch restarts the aging timer for the port.

A switch does not forward an IGMP report through a non-router port. The reason is that if the switch forwards a report message through a member port, all the attached hosts that are monitoring the

reported multicast address suppress their own reports after receiving this report according to the IGMP report suppression mechanism. This prevents the switch from confirming whether the reported multicast group still has active members attached to that port. For more information about the IGMP report suppression mechanism, see "[Configuring IGMP \(available only on the HP 5500 E1\)](#)"

When receiving a leave message

When an IGMPv1 host leaves a multicast group, the host does not send an IGMP leave message, and the switch cannot know immediately that the host has left the multicast group. However, because the host stops sending IGMP reports as soon as it leaves the multicast group, the switch removes the port that connects to the host from the forwarding entry for the multicast group when the aging timer for the port expires.

When an IGMPv2 or IGMPv3 host leaves a multicast group, the host sends an IGMP leave message to the multicast router.

When the switch receives an IGMP leave message on a dynamic member port, the switch first checks whether a forwarding entry matches the group address in the message, and, if a match is found, whether the forwarding entry for the group contains the dynamic member port.

- If no forwarding entry matches the group address, or if the forwarding entry does not contain the port, the switch directly discards the IGMP leave message.
- If a forwarding entry matches the group address and the forwarding entry contains the port, the switch forwards the leave message to all router ports in the VLAN. Because the switch does not know whether any other hosts attached to the port are still listening to that group address, the switch does not immediately remove the port from the forwarding entry for that group. Instead, it restarts the aging timer for the port.

After receiving the IGMP leave message, the IGMP querier resolves the multicast group address in the message and sends an IGMP group-specific query to the multicast group through the port that received the leave message. After receiving the IGMP group-specific query, the switch forwards it through all its router ports in the VLAN and all member ports of the multicast group. The switch also performs the following judgment for the port that received the IGMP leave message:

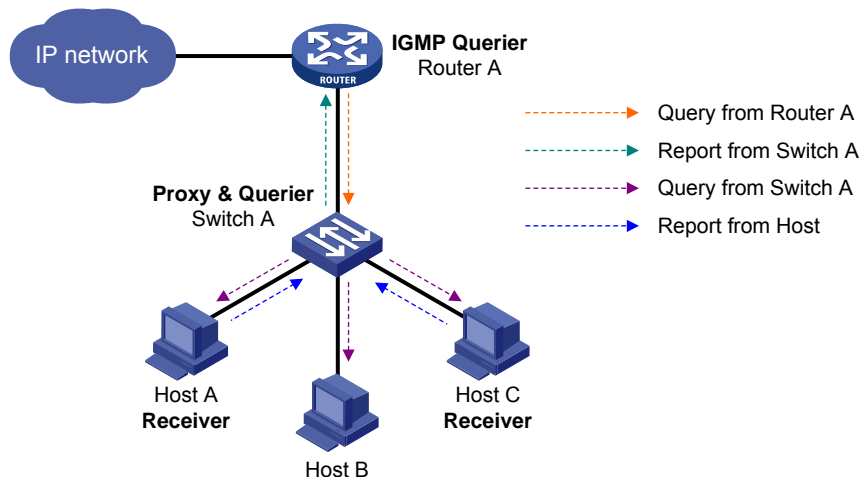

- If the port (assuming that it is a dynamic member port) receives an IGMP report in response to the group-specific query before its aging timer expires, it indicates that some host attached to the port is receiving or expecting to receive multicast data for the multicast group. The switch restarts the aging timer for the port.
- If the port receives no IGMP report in response to the group-specific query before its aging timer expires, it indicates that no hosts attached to the port are still listening to that group address. The switch removes the port from the forwarding entry for the multicast group when the aging timer expires.

IGMP snooping proxying

You can configure the IGMP snooping proxying function on an edge device to reduce the number of IGMP reports and leave messages sent to its upstream device. The device configured with IGMP snooping proxying is called an IGMP snooping proxy. It is a host from the perspective of its upstream device.

Even though an IGMP snooping proxy is a host from the perspective of its upstream device, the IGMP membership report suppression mechanism for hosts does not take effect on it. For more information about the IGMP report suppression mechanism for hosts, see "[Configuring IGMP \(available only on the HP 5500 E1\)](#)."

Figure 13 Network diagram

As shown in Figure 13, Switch A works as an IGMP snooping proxy. As a host from the perspective of the querier Router A, Switch A represents its attached hosts to send membership reports and leave messages to Router A.

Table 6 IGMP message processing on an IGMP snooping proxy

IGMP message	Actions
General query	When receiving an IGMP general query, the proxy forwards it to all ports but the receiving port. In addition, the proxy generates a report according to the group memberships it maintains and sends the report out of all router ports.
Group-specific query	In response to the IGMP group-specific query for a certain multicast group, the proxy sends the report to the group out of all router ports if the forwarding entry for the group still contains a member port.
Report	<p>After receiving a report for a multicast group, the proxy looks up the multicast forwarding table for the forwarding entry for the multicast group.</p> <ul style="list-style-type: none"> • If a forwarding entry matches the multicast group and contains the receiving port as a dynamic member port, the proxy restarts the aging timer for the port. • If a forwarding entry matches the multicast group but does not contain the receiving port, the proxy adds the port to the forwarding entry as a dynamic member port and starts an aging timer for the port. • If no forwarding entry matches the multicast group, the proxy creates a forwarding entry for the multicast group, adds the receiving port to the forwarding entry as a dynamic member port, and starts an aging timer for the port.
Leave	In response to an IGMP leave message for a multicast group, the proxy sends a group-specific query out of the receiving port. After making sure that no member port is contained in the forwarding entry for the multicast group, the proxy sends a leave message to the group out of all router ports.

Protocols and standards

RFC 4541, *Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches*

IGMP snooping configuration task list

Task	Remarks	
Configuring basic IGMP snooping functions	Enabling IGMP snooping	Required
	Specifying the version of IGMP snooping	Optional
	Configuring static multicast MAC address entries	Optional
Configuring IGMP snooping port functions	Setting aging timers for dynamic ports	Optional
	Configuring static ports	Optional
	Configuring a port as a simulated member host	Optional
	Enabling fast-leave processing	Optional
Configuring IGMP snooping querier	Disabling a port from becoming a dynamic router port	Optional
	Enabling IGMP snooping querier	Optional
	Configuring parameters for IGMP queries and responses	Optional
	Configuring the source IP addresses for IGMP queries	Optional
Configuring IGMP snooping proxying	Enabling IGMP snooping proxying	Optional
	Configuring a source IP address for the IGMP messages sent by the proxy	Optional
Configuring an IGMP snooping policy	Configuring a multicast group filter	Optional
	Configuring multicast source port filtering	Optional
	Enabling dropping unknown multicast data	Optional
	Configuring IGMP report suppression	Optional
	Setting the maximum number of multicast groups that a port can join	Optional
	Setting the 802.1p precedence for IGMP messages	Optional
	Enabling multicast group replacement	Optional
	Configuring a multicast user control policy	Optional
	Enabling the IGMP snooping host tracking function	Optional
Setting the DSCP value for IGMP messages	Optional	

For the configuration tasks in this section:

- In IGMP snooping view, configurations that you make are effective in all VLANs. In VLAN view, configurations that you make are effective on only the ports that belong to the current VLAN. For a given VLAN, a configuration that you make in IGMP snooping view is effective only if you do not make the same configuration in VLAN view.

- In IGMP snooping view, configurations that you make are effective on all ports. In Layer 2 Ethernet interface view or Layer 2 aggregate interface view, configurations that you make are effective only on the current port. In port group view, configurations that you make are effective on all ports in the current port group. For a given port, a configuration that you make in IGMP snooping view is effective only if you do not make the same configuration in Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.
- For IGMP snooping, configurations that you make on a Layer 2 aggregate interface do not interfere with configurations that you make on its member ports, nor do they participate in aggregation calculations. Configurations that you make on a member port of an aggregate group do not take effect until it leaves the aggregate group.

Configuring basic IGMP snooping functions

Before you configure basic IGMP snooping functions, complete the following tasks:

- Configure the corresponding VLANs.
- Determine the version of IGMP snooping.

Enabling IGMP snooping

Configuration guidelines

- You must enable IGMP snooping globally before you enable it in a VLAN.
- After you enable IGMP snooping in a VLAN, do not enable IGMP or PIM on the corresponding VLAN interface.
- When you enable IGMP snooping in a specified VLAN, IGMP snooping works only on the ports in this VLAN.

Configuration procedure

To enable IGMP snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IGMP snooping globally and enter IGMP-snooping view.	igmp-snooping	Disabled by default
3. Return to system view.	quit	N/A
4. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
5. Enable IGMP snooping in the VLAN.	igmp-snooping enable	Disabled by default

Specifying the version of IGMP snooping

Configuration guidelines

Different versions of IGMP snooping can process different versions of IGMP messages:

- IGMPv2 snooping can process IGMPv1 and IGMPv2 messages, but cannot process IGMPv3 messages, which will be flooded in the VLAN.
- IGMPv3 snooping can process IGMPv1, IGMPv2 and IGMPv3 messages.

If you change IGMPv3 snooping to IGMPv2 snooping, the system clears all IGMP snooping forwarding entries that are dynamically added, and also does the following:

- Keeps static IGMPv3 snooping forwarding entries (*, G).
- Clears static IGMPv3 snooping forwarding entries (S, G), which will be restored when IGMP snooping is switched back to IGMPv3 snooping.

For more information about static joins, see "[Configuring static ports.](#)"

Configuration procedure

To specify the version of IGMP snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Specify the version of IGMP snooping.	igmp-snooping version <i>version-number</i>	Version 2 by default

Configuring static multicast MAC address entries

Configuration guidelines

In Layer-2 multicast, a Layer 2 multicast protocol (such as, IGMP snooping) can dynamically add multicast MAC address entries. Or, you can manually configure multicast MAC address entries.

In system view, the configuration is effective for the specified ports. In interface view or port group view, the configuration is effective only on the current port or the ports in the current port group.

Any legal multicast MAC address except 0100-5Exx-xxxx (where x represents a hexadecimal number from 0 to F) can be manually added to the multicast MAC address table. Multicast MAC addresses are the MAC addresses whose the least significant bit of the most significant octet is 1.

Configuration procedure

To configure a static multicast MAC address entry in system view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a static multicast MAC address entry.	mac-address multicast <i>mac-address interface interface-list</i> vlan <i>vlan-id</i>	No static multicast MAC address entries exist by default.

To configure static multicast MAC address entries in interface view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Configure a static multicast MAC address entry.	mac-address multicast <i>mac-address</i> vlan <i>vlan-id</i>	No static multicast MAC address entries exist by default.

Configuring IGMP snooping port functions

Configuration prerequisites

Before you configure IGMP snooping port functions, complete the following tasks:

- Enable IGMP snooping in the VLAN.
- Configure the corresponding port groups.
- Determine the aging time of dynamic router ports.
- Determine the aging time of dynamic member ports.
- Determine the multicast group and multicast source addresses.

Setting aging timers for dynamic ports

If a switch receives no IGMP general queries or PIM hello messages on a dynamic router port when the aging timer of the port expires, the switch removes the port from the router port list.

If the switch receives no IGMP reports for a multicast group on a dynamic member port when the aging timer of the port expires, the switch removes the port from the multicast forwarding entry for that multicast group.

If the memberships of multicast groups change frequently, you can set a relatively small value for the aging timer of the dynamic member ports. If the memberships of multicast groups change rarely, you can set a relatively large value.

Configuring aging timers for dynamic ports globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Set the aging timer for dynamic router ports.	router-aging-time <i>interval</i>	105 seconds by default
4. Set the aging timer for dynamic member ports.	host-aging-time <i>interval</i>	260 seconds by default

Configuring aging timers for dynamic ports in a VLAN

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Set the aging timer for dynamic router ports.	igmp-snooping router-aging-time <i>interval</i>	105 seconds by default
4. Set the aging timer for dynamic member ports.	igmp-snooping host-aging-time <i>interval</i>	260 seconds by default

Configuring static ports

Configuration guidelines

If all hosts attached to a port are interested in the multicast data addressed to a particular multicast group or the multicast data that a particular multicast source sends to a particular group, you can configure the port as a static member port for the specified multicast group or the specified multicast source and group.

You can also configure a port as a static router port, through which the switch can forward all the multicast traffic that it received.

A static member port does not respond to queries from the IGMP querier; when you configure a port as a static member port or cancel this configuration on the port, the port does not send an unsolicited IGMP report or an IGMP leave message.

Static member ports and static router ports never age out. To remove such a port, use the corresponding **undo** command.

Configuration procedure

To configure static ports:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Configure the port as a static member port.	igmp-snooping static-group <i>group-address</i> [source-ip <i>source-address</i>] vlan <i>vlan-id</i>	No static member ports exist by default.
4. Configure the port as a static router port.	igmp-snooping static-router-port vlan <i>vlan-id</i>	No static router ports exist by default.

Configuring a port as a simulated member host

Configuration guidelines

Generally, a host that runs IGMP can respond to IGMP queries that the IGMP querier sends. If a host fails to respond, the multicast router might deem that no member of this multicast group exists on the network segment, and removes the corresponding forwarding path.

To avoid this situation, you can configure the port as a simulated member host for a multicast group. A simulated host is equivalent to an independent host. For example, when a simulated member host receives an IGMP query, it gives a response separately. Therefore, the switch can continue receiving multicast data.

A simulated host acts like a real host in the following ways:

- When a port is configured as a simulated member host, the switch sends an unsolicited IGMP report through the port, and can respond to IGMP general queries with IGMP reports through the port.
- When the simulated joining function is disabled on a port, the switch sends an IGMP leave message through the port.

Unlike a static member port, a port that you configure as a simulated member host ages out like a dynamic member port.

Configuration procedure

To configure a port as a simulated member host:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none">• Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i>• Enter port group view: port-group manual <i>port-group-name</i>	Use either command.
3. Configure a port as a simulated member host.	igmp-snooping host-join <i>group-address</i> [source-ip <i>source-address</i>] vlan <i>vlan-id</i>	Not configured by default.

Enabling fast-leave processing

Configuration guidelines

The fast-leave processing feature enables the switch to process IGMP leave messages quickly. With the fast-leave processing feature enabled, when the switch receives an IGMP leave message on a port, it immediately removes that port from the forwarding entry for the multicast group specified in the message. Then, when the switch receives IGMP group-specific queries for that multicast group, it does not forward them to that port.

On a port that has only one host attached, you can enable fast-leave processing to save bandwidth and resources. However, on a port that has multiple hosts attached, you should not enable fast-leave

processing if you have enabled dropping unknown multicast data globally or for the port. Otherwise, if a host on the port leaves a multicast group, the other hosts attached to the port in the same multicast group cannot receive the multicast data for the group.

Configuration procedure

To enable fast-leave processing globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Enable fast-leave processing.	fast-leave [vlan vlan-list]	Disabled by default

To enable fast-leave processing for a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface interface-type interface-number Enter port group view: port-group manual port-group-name 	Use either command.
3. Enable fast-leave processing.	igmp-snooping fast-leave [vlan vlan-list]	Disabled by default.

Disabling a port from becoming a dynamic router port

The following problems might exist in a multicast access network:

- After receiving an IGMP general query or a PIM hello message from a connected host, a router port becomes a dynamic router port. Before its timer expires, this dynamic router port receives all multicast packets within the VLAN where the port belongs, and forwards them to the host, affecting normal multicast reception of the host.
- In addition, the IGMP general query or PIM hello message that the host sends affects the multicast routing protocol state on Layer 3 devices, such as the IGMP querier or DR election, and might further cause network interruption.

To solve these problems, disable that router port from becoming a dynamic router port after the port receives an IGMP general query or a PIM hello message, so as to improve network security and control over multicast users.

To disable a port from becoming a dynamic router port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Disable the ports from becoming dynamic router port.	igmp-snooping router-port-deny [vlan <i>vlan-list</i>]	By default, a port can become a dynamic router port.

NOTE:

This configuration does not affect the static router port configuration.

Configuring IGMP snooping querier

Configuration prerequisites

Before you configure IGMP snooping querier, complete the following tasks:

- Enable IGMP snooping in the VLAN.
- Determine the IGMP general query interval.
- Determine the IGMP last-member query interval.
- Determine the maximum response delay for IGMP general queries.
- Determine the source address of IGMP general queries.
- Determine the source address of IGMP group-specific queries.

Enabling IGMP snooping querier

In an IP multicast network that runs IGMP, a multicast router or Layer 3 multicast switch sends IGMP queries, so that all Layer 3 multicast devices can establish and maintain multicast forwarding entries, in order to forward multicast traffic correctly at the network layer. This router or Layer 3 switch is called the "IGMP querier". For more information about IGMP querier, see "[Configuring IGMP \(available only on the HP 5500 EI\)](#)."

However, a Layer 2 multicast switch does not support IGMP, and therefore cannot send general queries by default. When you enable IGMP snooping querier on a Layer 2 switch in a VLAN where multicast traffic is switched only at Layer 2 and no multicast routers are present, the Layer 2 switch sends IGMP queries, so that multicast forwarding entries can be established and maintained at the data link layer.

To enable IGMP snooping querier:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A

Step	Command	Remarks
3. Enable IGMP snooping querier.	igmp-snooping querier	Disabled by default

! **IMPORTANT:**

In a multicast network that runs IGMP, you do not need to configure an IGMP snooping querier because it may affect IGMP querier elections by sending IGMP general queries with a low source IP address.

Configuring parameters for IGMP queries and responses

Configuration guidelines

You can modify the IGMP general query interval based on actual condition of the network.

A multicast listening host starts a timer for each multicast group that it has joined when it receives an IGMP query (general query or group-specific query). This timer is initialized to a random value in the range of 0 to the maximum response delay advertised in the IGMP query message. When the timer value decreases to 0, the host sends an IGMP report to the multicast group.

To speed up the response of hosts to IGMP queries and avoid simultaneous timer expirations causing IGMP report traffic bursts, you must properly set the maximum response delay.

- The maximum response delay for IGMP general queries is set by the **max-response-time** command.
- The maximum response delay for IGMP group-specific queries equals the IGMP last-member query interval.

In the configuration, make sure that the IGMP general query interval is larger than the maximum response delay for IGMP general queries. Otherwise, multicast group members might be deleted by mistake.

Configuration procedure

To configure the global parameters for IGMP queries and responses:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Set the maximum response delay for IGMP general queries.	max-response-time <i>interval</i>	10 seconds by default
4. Set the IGMP last-member query interval.	last-member-query-interval <i>interval</i>	1 second by default

To configure the parameters for IGMP queries and responses in a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Set the interval for sending IGMP general queries.	igmp-snooping query-interval <i>interval</i>	60 seconds by default

Step	Command	Remarks
4.	Set the maximum response delay for IGMP general queries.	igmp-snooping max-response-time <i>interval</i> 10 seconds by default
5.	Set the IGMP last-member query interval.	igmp-snooping last-member-query-interval <i>interval</i> 1 second by default

Configuring the source IP addresses for IGMP queries

After the switch receives an IGMP query whose source IP address is 0.0.0.0 on a port, it does not enlist that port as a dynamic router port. This might prevent multicast forwarding entries from being correctly created at the data link layer and eventually cause multicast traffic forwarding to fail. To avoid this problem, when a Layer 2 switch acts as the IGMP snooping querier, HP recommends you to configure a non-all-zero IP address as the source IP address of IGMP queries.

ⓘ IMPORTANT:

The source address of IGMP query messages might affect the IGMP querier election within the segment

To configure the source IP addresses for IGMP queries:

Step	Command	Remarks
1.	Enter system view.	system-view N/A
2.	Enter VLAN view.	vlan <i>vlan-id</i> N/A
3.	Configure the source address of IGMP general queries.	igmp-snooping general-query source-ip { <i>ip-address</i> current-interface } 0.0.0.0 by default
4.	Configure the source IP address of IGMP group-specific queries.	igmp-snooping special-query source-ip { <i>ip-address</i> current-interface } 0.0.0.0 by default

Configuring IGMP snooping proxying

Configuration prerequisites

Before you configure IGMP snooping proxying in a VLAN, complete the following tasks:

- Enable IGMP snooping in the VLAN.
- Determine the source IP address for the IGMP reports sent by the proxy.
- Determine the source IP address for the IGMP leave messages sent by the proxy.

Enabling IGMP snooping proxying

The IGMP snooping proxying function works on a per-VLAN basis. After you enable the function in a VLAN, the device works as the IGMP snooping proxy for the downstream hosts and upstream router in the VLAN.

To enable IGMP snooping proxying in a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Enable IGMP snooping proxying in the VLAN.	igmp-snooping proxying enable	Disabled by default

Configuring a source IP address for the IGMP messages sent by the proxy

You can set the source IP addresses in the IGMP reports and leave messages that the IGMP snooping proxy sends on behalf of its attached hosts.

To configure the source IP addresses for the IGMP messages that the IGMP snooping proxy sends on behalf of its attached hosts in a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Configure a source IP address for the IGMP reports that the proxy sends.	igmp-snooping report source-ip { <i>ip-address</i> current-interface }	The default is 0.0.0.0.
4. Configure a source IP address for the IGMP leave messages that the proxy sends.	igmp-snooping leave source-ip { <i>ip-address</i> current-interface }	The default is 0.0.0.0.

Configuring an IGMP snooping policy

Configuration prerequisites

Before you configure an IGMP snooping policy, complete the following tasks:

- Enable IGMP snooping in the VLAN.
- Determine the ACL rule for multicast group filtering.
- Determine the maximum number of multicast groups that a port can join.
- Determine the 802.1p precedence for IGMP messages.

Configuring a multicast group filter

On an IGMP snooping-enabled switch, you can configure a multicast group filter to limit multicast programs available to users.

Configuration guidelines

In an application, when a user requests a multicast program, the user's host initiates an IGMP report. After receiving this report message, the switch resolves the multicast group address in the report and looks up the ACL. If a match is found to permit the port that received the report to join the multicast group,

the switch creates an IGMP snooping forwarding entry for the multicast group and adds the port to the forwarding entry. Otherwise, the switch drops this report message, in which case, the multicast data for the multicast group is not sent to this port, and the user cannot retrieve the program.

When you configure a multicast group filter in a multicast VLAN, be sure to configure the filter in the sub-VLANs of the multicast VLAN. Otherwise, the configuration does not take effect.

In IGMPv3, when a host is enabled to join multiple multicast groups, the multicast group filter cannot correctly filter multicast groups because the host that runs IGMPv3 sends multiple multicast groups that it wants to join in one membership report.

Configuration procedure

To configure a multicast group filter globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Configure a multicast group filter.	group-policy <i>acl-number</i> [vlan <i>vlan-list</i>]	By default, no group filter is globally configured. That is, the hosts in a VLAN can join any valid multicast group.

To configure a multicast group filter for a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Configure a multicast group filter.	igmp-snooping group-policy <i>acl-number</i> [vlan <i>vlan-list</i>]	By default, no group filter is configured on the current port. That is, the hosts on this port can join any valid multicast group.

Configuring multicast source port filtering

When the multicast source port filtering feature is enabled on a port, the port can connect to only multicast receivers rather than to multicast sources, because the port blocks all multicast data packets but it permits multicast protocol packets to pass.

If this feature is disabled on a port, the port can connect to both multicast sources and multicast receivers.

Configuring multicast source port filtering globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Enable multicast source port filtering.	source-deny port <i>interface-list</i>	Disabled by default

Configuring multicast source port filtering on a port

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable multicast source port filtering.	igmp-snooping source-deny	Disabled by default.

Enabling dropping unknown multicast data

Configuration guidelines

Unknown multicast data refers to multicast data for which no entries exist in the IGMP snooping forwarding table. When the switch receives such multicast traffic, one of the following occurs:

- When the function of dropping unknown multicast data is disabled, the switch floods unknown multicast data in the VLAN that the unknown multicast data belongs to, causing network bandwidth waste and low forwarding efficiency.
- When the function of dropping unknown multicast data is enabled, the switch forwards unknown multicast data to its router ports instead of flooding it in the VLAN. If no router ports exist, the switch drops the unknown multicast data.

Configuration procedure

To enable dropping unknown multicast data in a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Enable dropping unknown multicast data.	igmp-snooping drop-unknown	Disabled by default

Configuring IGMP report suppression

When a Layer 2 switch receives an IGMP report from a multicast group member, the switch forwards the message to the Layer 3 device that directly connects to the Layer 2 switch. When multiple members of a multicast group are attached to the Layer 2 switch, the Layer 3 device might receive duplicate IGMP reports for the multicast group from these members.

With the IGMP report suppression function enabled, within each query interval, the Layer 2 switch forwards only the first IGMP report for the multicast group to the Layer 3 device. It does not forward the subsequent IGMP reports for the same multicast group. This helps reduce the number of packets being transmitted over the network.

! IMPORTANT:

On an IGMP snooping proxy, IGMP membership reports are suppressed if the entries for the corresponding groups exist in the forwarding table, no matter the suppression function is enabled or not.

To configure IGMP report suppression:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Enable IGMP report suppression.	report-aggregation	Enabled by default

Setting the maximum number of multicast groups that a port can join

To regulate multicast traffic on a port, configure the maximum number of multicast groups that the port can join.

When you configure this maximum number, if the number of multicast groups the port has joined exceeds the configured maximum value, the system deletes all the forwarding entries for the port from the IGMP snooping forwarding table, and the hosts on this port join multicast groups again until the number of multicast groups that the port joins reaches the maximum value. When the port joins a multicast group, if the port has been configured as a static member port, the system applies the configurations to the port again. If you have configured simulated joining on the port, the system establishes corresponding forwarding entry for the port after receiving a report from the simulated member host.

To set the maximum number of multicast groups that a port can join:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Set the maximum number of multicast groups that a port can join.	igmp-snooping group-limit <i>limit</i> [vlan <i>vlan-list</i>]	By default, the upper limit is 2000 for the HP 5500 EI switches, and 1000 for the HP 5500 SI switches.

Enabling multicast group replacement

Configuration guidelines

For various reasons, the number of multicast groups that the switch or a port joins might exceed the upper limit. In addition, in some specific applications, a multicast group that the switch newly joins must replace an existing multicast group automatically. A typical example is channel switching. To view a new channel, a user switches from the current multicast group to the new one.

To realize such requirements, you can enable the multicast group replacement function on the switch or on a certain port. When the number of multicast groups that the switch or on the port has joined reaches the limit, one of the following occurs:

- If the multicast group replacement feature is disabled, new IGMP reports are automatically discarded.
- If the multicast group replacement feature is enabled, the multicast group that the switch or a port newly joins automatically replaces an existing multicast group that has the lowest address.

In the configuration, be sure to configure the maximum number of multicast groups allowed on a port (see "[Setting the maximum number of multicast groups that a port can join](#)") before enabling multicast group replacement. Otherwise, the multicast group replacement functionality will not take effect.

Configuration procedure

To enable multicast group replacement globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Enable multicast group replacement.	overflow-replace [vlan <i>vlan-list</i>]	Disabled by default

To enable multicast group replacement for a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable multicast group replacement.	igmp-snooping overflow-replace [vlan <i>vlan-list</i>]	Disabled by default.

Setting the 802.1p precedence for IGMP messages

You can change the 802.1p precedence for IGMP messages so that they can be assigned higher forwarding priority when congestion occurs on their outgoing ports.

Setting the 802.1p precedence for IGMP messages globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Set the 802.1p precedence for IGMP messages.	dot1p-priority <i>priority-number</i>	The default 802.1p precedence for IGMP messages is 0.

Setting the 802.1p precedence for IGMP messages in a VLAN

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Set the 802.1p precedence for IGMP messages in the VLAN.	igmp-snooping dot1p-priority <i>priority-number</i>	The default 802.1p precedence for IGMP messages is 0.

Configuring a multicast user control policy

Configuration guidelines

Multicast user control policies are configured on access switches to allow only authorized users to receive requested multicast traffic flows. This helps restrict users from ordering certain multicast-on-demand programs.

In practice, a device first needs to perform authentication (802.1X authentication, for example) on connected hosts through a RADIUS server. Then, the device uses the configured multicast user control policy to perform multicast access control on authenticated users as follows:

- After receiving an IGMP report from a host, the access switch matches the multicast group address and multicast source address carried in the report with the configured policies. If a match is found,

the host is allowed to join the multicast group. Otherwise, the join report is dropped by the access switch.

- After receiving an IGMP leave message from a host, the access switch matches the multicast group and source addresses with the policies. If a match is found, the host is allowed to leave the group. Otherwise, the leave message is dropped by the access switch.

A multicast user control policy is functionally similar to a multicast group filter. A difference is that a control policy can control both multicast joining and leaving of users based on authentication and authorization, but a multicast group filter is configured on a port to control only multicast joining but not leaving of users without authentication or authorization.

Configuration procedure

To configure a multicast user control policy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a user profile and enter its view.	user-profile <i>profile-name</i>	N/A
3. Configure a multicast user control policy.	igmp-snooping access-policy <i>acl-number</i>	No policy is configured by default. That is, a host can join or leave a valid multicast group at any time.
4. Return to system view.	quit	N/A
5. Enable the created user profile.	user-profile <i>profile-name</i> enable	Disabled by default.

For more information about the **user-profile** and **user-profile enable** commands, see *Security Command Reference*.

Enabling the IGMP snooping host tracking function

With the IGMP snooping host tracking function, the switch can record the information of the member hosts that are receiving multicast traffic, including the host IP address, running duration, and timeout time. You can monitor and manage the member hosts according to the recorded information.

Enabling the IGMP snooping host tracking function globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Enable the IGMP snooping host tracking function globally.	host-tracking	Disabled by default

Enabling the IGMP snooping host tracking function in a VLAN

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Enable the IGMP snooping host tracking function in the VLAN.	igmp-snooping host-tracking	Disabled by default

Setting the DSCP value for IGMP messages

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IGMP-snooping view.	igmp-snooping	N/A
3. Set the DSCP value for IGMP messages	dscp <i>dscp-value</i>	By default, the DSCP value in IGMP messages is 48.

NOTE:

This configuration applies to only the IGMP messages that the local switch generates rather than those forwarded ones.

Displaying and maintaining IGMP snooping

Task	Command	Remarks
Display IGMP snooping group information.	display igmp-snooping group [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the hosts tracked by IGMP snooping.	display igmp-snooping host vlan <i>vlan-id group group-address</i> [source <i>source-address</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display static multicast MAC address entries.	display mac-address [<i>mac-address</i> [vlan <i>vlan-id</i>] [multicast] [vlan <i>vlan-id</i>] [count]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display statistics for the IGMP messages learned by IGMP snooping.	display igmp-snooping statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Remove all the dynamic group entries of a specified IGMP snooping group or all IGMP snooping groups.	reset igmp-snooping group { <i>group-address</i> all } [vlan <i>vlan-id</i>]	Available in user view
Clear statistics for the IGMP messages learned by IGMP snooping.	reset igmp-snooping statistics	Available in user view

NOTE:

- The **reset igmp-snooping group** command works only on an IGMP snooping-enabled VLAN, but not in a VLAN with IGMP enabled on its VLAN interface.
 - The **reset igmp-snooping group** command cannot remove the static group entries of IGMP snooping groups.
-

IGMP snooping configuration examples

Group policy and simulated joining configuration example

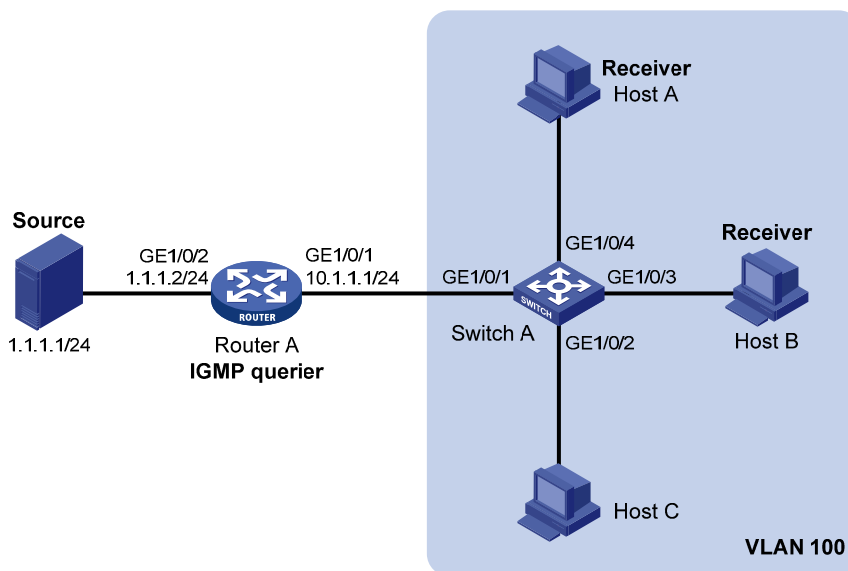

Network requirements

As shown in [Figure 14](#), IGMPv2 runs on Router A, IGMPv2 snooping runs on Switch A, and Router A acts as the IGMP querier on the subnet.

The receivers, Host A and Host B, can receive multicast traffic addressed to multicast group 224.1.1.1 only.

Multicast data for group 224.1.1.1 can be forwarded through GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 of Switch A even if Host A and Host B accidentally, temporarily stop receiving multicast data, and that Switch A drops unknown multicast data and does not broadcast the data to the VLAN where Switch A resides.

Figure 14 Network diagram

Configuration procedure

1. Configure IP addresses:
Configure an IP address and subnet mask for each interface as per [Figure 14](#). (Details not shown.)
2. Configure Router A:
Enable IP multicast routing, enable PIM-DM on each interface, and enable IGMP on GigabitEthernet 1/0/1.

```
<RouterA> system-view  
[RouterA] multicast routing-enable
```

```
[RouterA] interface gigabitethernet 1/0/1
[RouterA-GigabitEthernet1/0/1] igmp enable
[RouterA-GigabitEthernet1/0/1] pim dm
[RouterA-GigabitEthernet1/0/1] quit
[RouterA] interface gigabitethernet 1/0/2
[RouterA-GigabitEthernet1/0/2] pim dm
[RouterA-GigabitEthernet1/0/2] quit
```

3. Configure Switch A:

Enable IGMP snooping globally.

```
<SwitchA> system-view
[SwitchA] igmp-snooping
[SwitchA-igmp-snooping] quit
```

Create VLAN 100, assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to this VLAN, and enable IGMP snooping and the function of dropping unknown multicast traffic in the VLAN.

```
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[SwitchA-vlan100] igmp-snooping enable
[SwitchA-vlan100] igmp-snooping drop-unknown
[SwitchA-vlan100] quit
```

Configure a multicast group filter so that the hosts in VLAN 100 can join only the multicast group 224.1.1.1.

```
[SwitchA] acl number 2001
[SwitchA-acl-basic-2001] rule permit source 224.1.1.1 0
[SwitchA-acl-basic-2001] quit
[SwitchA] igmp-snooping
[SwitchA-igmp-snooping] group-policy 2001 vlan 100
[SwitchA-igmp-snooping] quit
```

Configure GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 as simulated hosts for multicast group 224.1.1.1.

```
[SwitchA] interface gigabitethernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] igmp-snooping host-join 224.1.1.1 vlan 100
[SwitchA-GigabitEthernet1/0/3] quit
[SwitchA] interface gigabitethernet 1/0/4
[SwitchA-GigabitEthernet1/0/4] igmp-snooping host-join 224.1.1.1 vlan 100
[SwitchA-GigabitEthernet1/0/4] quit
```

4. Verify the configuration:

Display detailed IGMP snooping groups information in VLAN 100 on Switch A.

```
[SwitchA] display igmp-snooping group vlan 100 verbose
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
```

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port

Subvlan flags: R-Real VLAN, C-Copy VLAN

Vlan(id):100.

Total 1 IP Group(s).

Total 1 IP Source(s).

```

Total 1 MAC Group(s).
Router port(s):total 1 port.
    GE1/0/1                (D) ( 00:01:30 )
IP group(s):the following ip group(s) match to one mac group.
  IP group address:224.1.1.1
  (0.0.0.0, 224.1.1.1):
    Attribute:    Host Port
  Host port(s):total 2 port.
    GE1/0/3      (D) ( 00:03:23 )
    GE1/0/4      (D) ( 00:04:10 )
MAC group(s):
  MAC group address:0100-5e01-0101
  Host port(s):total 2 port.
    GE1/0/3
    GE1/0/4

```

The output shows that GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 of Switch A has joined multicast group 224.1.1.1.

Static port configuration example

Network requirements

As shown in [Figure 15](#), IGMPv2 runs on Router A, and IGMPv2 snooping runs on Switch A, Switch B, and Switch C. Router A acts as the IGMP querier.

Host A and host C are permanent receivers of multicast group 224.1.1.1. GigabitEthernet 1/0/3 and GigabitEthernet 1/0/5 on Switch C are required to be configured as static member ports for multicast group 224.1.1.1 to enhance the reliability of multicast traffic transmission.

Suppose STP runs on the network. To avoid data loops, the forwarding path from Switch A to Switch C is blocked under normal conditions, and multicast traffic flows to the receivers attached to Switch C only along the path of Switch A—Switch B—Switch C.

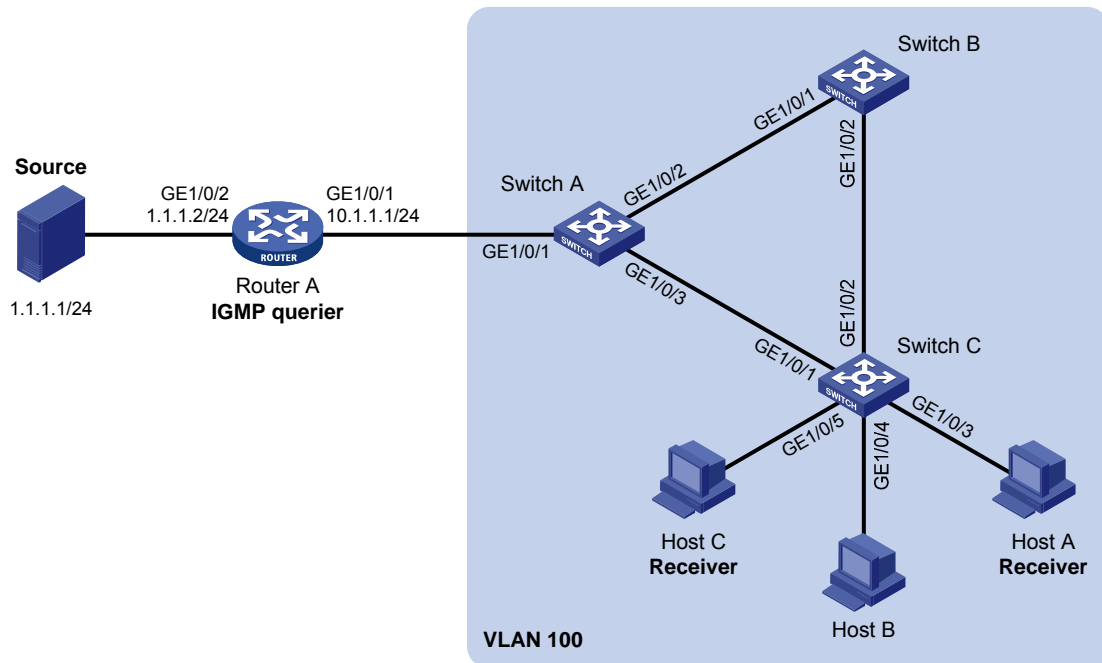

Configure GigabitEthernet 1/0/3 on Switch A as a static router port, so that multicast traffic can flow to the receivers nearly uninterrupted along the path of Switch A—Switch C in the case that the path of Switch A—Switch B—Switch C gets blocked.

For more information about the Spanning Tree Protocol (STP), see *Layer 2—LAN Switching Configuration Guide*.

NOTE:

If no static router port is configured, when the path of Switch A—Switch B—Switch C gets blocked, at least one IGMP query-response cycle must be completed before the multicast data can flow to the receivers along the new path of Switch A—Switch C. Namely multicast delivery will be interrupted during this process.

Figure 15 Network diagram

Configuration procedure

1. Configure IP addresses:

Configure an IP address and subnet mask for each interface as per Figure 15. (Details not shown.)

2. Configure Router A:

Enable IP multicast routing, enable PIM-DM on each interface, and enable IGMP on GigabitEthernet 1/0/1.

```
<RouterA> system-view
[RouterA] multicast routing-enable
[RouterA] interface gigabitethernet 1/0/1
[RouterA-GigabitEthernet1/0/1] igmp enable
[RouterA-GigabitEthernet1/0/1] pim dm
[RouterA-GigabitEthernet1/0/1] quit
[RouterA] interface gigabitethernet 1/0/2
[RouterA-GigabitEthernet1/0/2] pim dm
[RouterA-GigabitEthernet1/0/2] quit
```

3. Configure Switch A:

Enable IGMP snooping globally.

```
<SwitchA> system-view
[SwitchA] igmp-snooping
[SwitchA-igmp-snooping] quit
```

Create VLAN 100, assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to this VLAN, and enable IGMP snooping in the VLAN.

```
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/3
[SwitchA-vlan100] igmp-snooping enable
[SwitchA-vlan100] quit
```

```
# Configure GigabitEthernet 1/0/3 to be a static router port.
```

```
[SwitchA] interface gigabitethernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] igmp-snooping static-router-port vlan 100
[SwitchA-GigabitEthernet1/0/3] quit
```

4. Configure Switch B:

```
# Enable IGMP snooping globally.
```

```
<SwitchB> system-view
[SwitchB] igmp-snooping
[SwitchB-igmp-snooping] quit
```

```
# Create VLAN 100, assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to this VLAN,
and enable IGMP snooping in the VLAN.
```

```
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/1 gigabitethernet 1/0/2
[SwitchB-vlan100] igmp-snooping enable
[SwitchB-vlan100] quit
```

5. Configure Switch C:

```
# Enable IGMP snooping globally.
```

```
<SwitchC> system-view
[SwitchC] igmp-snooping
[SwitchC-igmp-snooping] quit
```

```
# Create VLAN 100, assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 to this VLAN,
and enable IGMP snooping in the VLAN.
```

```
[SwitchC] vlan 100
[SwitchC-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/5
[SwitchC-vlan100] igmp-snooping enable
[SwitchC-vlan100] quit
```

```
# Configure GigabitEthernet 1/0/3 and GigabitEthernet 1/0/5 as static member ports for
multicast group 224.1.1.1.
```

```
[SwitchC] interface GigabitEthernet 1/0/3
[SwitchC-GigabitEthernet1/0/3] igmp-snooping static-group 224.1.1.1 vlan 100
[SwitchC-GigabitEthernet1/0/3] quit
[SwitchC] interface GigabitEthernet 1/0/5
[SwitchC-GigabitEthernet1/0/5] igmp-snooping static-group 224.1.1.1 vlan 100
[SwitchC-GigabitEthernet1/0/5] quit
```

6. Verify the configuration:

```
# Display detailed IGMP snooping group information in VLAN 100 on Switch A.
```

```
[SwitchA] display igmp-snooping group vlan 100 verbose
```

```
Total 1 IP Group(s).
```

```
Total 1 IP Source(s).
```

```
Total 1 MAC Group(s).
```

```
Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
```

```
Subvlan flags: R-Real VLAN, C-Copy VLAN
```

```
Vlan(id):100.
```

```
Total 1 IP Group(s).
```

```
Total 1 IP Source(s).
```

```
Total 1 MAC Group(s).
```

```

Router port(s):total 2 port.
    GE1/0/1                (D) ( 00:01:30 )
    GE1/0/3                (S)
IP group(s):the following ip group(s) match to one mac group.
IP group address:224.1.1.1
(0.0.0.0, 224.1.1.1):
Attribute:    Host Port
Host port(s):total 1 port.
    GE1/0/2                (D) ( 00:03:23 )
MAC group(s):
MAC group address:0100-5e01-0101
Host port(s):total 1 port.
    GE1/0/2

```

The output shows that GigabitEthernet 1/0/3 of Switch A has become a static router port.

Display detailed IGMP snooping group information in VLAN 100 on Switch C.

```
[SwitchC] display igmp-snooping group vlan 100 verbose
```

```

Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).

```

```

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
Subvlan flags: R-Real VLAN, C-Copy VLAN

```

```
Vlan(id):100.
```

```

Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
Router port(s):total 1 port.
    GE1/0/2                (D) ( 00:01:23 )
IP group(s):the following ip group(s) match to one mac group.
IP group address:224.1.1.1
(0.0.0.0, 224.1.1.1):
Attribute:    Host Port
Host port(s):total 2 port.
    GE1/0/3                (S)
    GE1/0/5                (S)
MAC group(s):
MAC group address:0100-5e01-0101
Host port(s):total 2 port.
    GE1/0/3
    GE1/0/5

```

The output shows that GigabitEthernet 1/0/3 and GigabitEthernet 1/0/5 on Switch C have become static member ports for multicast group 224.1.1.1.

IGMP snooping querier configuration example

Network requirements

As shown in [Figure 16](#), in a Layer 2-only network environment, two multicast sources Source 1 and Source 2 send multicast data to multicast groups 224.1.1.1 and 225.1.1.1 respectively, Host A and Host C

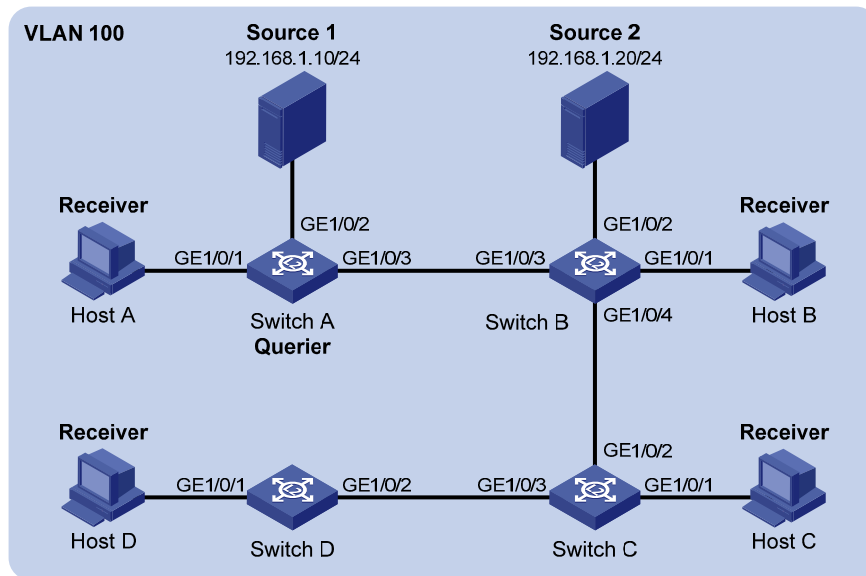

are receivers of multicast group 224.1.1.1, and Host B and Host D are receivers of multicast group 225.1.1.1.

All the receivers run IGMPv2, and all the switches run IGMPv2 snooping. Switch A, which is close to the multicast sources, is chosen as the IGMP snooping querier.

To prevent flooding of unknown multicast traffic within the VLAN, be sure to configure all the switches to drop unknown multicast data packets.

Because a switch does not enlist a port that has heard an IGMP query with a source IP address of 0.0.0.0 (default) as a dynamic router port, configure a non-all-zero IP address as the source IP address of IGMP queries to ensure normal creation of Layer 2 multicast forwarding entries.

Figure 16 Network diagram

Configuration procedure

1. Configure switch A:

Enable IGMP snooping globally.

```
<SwitchA> system-view
[SwitchA] igmp-snooping
[SwitchA-igmp-snooping] quit
```

Create VLAN 100 and assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to the VLAN.

```
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/3
```

Enable IGMP snooping and the function of dropping unknown multicast traffic in VLAN 100.

```
[SwitchA-vlan100] igmp-snooping enable
[SwitchA-vlan100] igmp-snooping drop-unknown
```

Enable the IGMP snooping querier function in VLAN 100

```
[SwitchA-vlan100] igmp-snooping querier
```

Set the source IP address of IGMP general queries and group-specific queries to 192.168.1.1 in VLAN 100.

```
[SwitchA-vlan100] igmp-snooping general-query source-ip 192.168.1.1
[SwitchA-vlan100] quit
```

2. Configure Switch B:

Enable IGMP snooping globally.

```
<SwitchB> system-view
[SwitchB] igmp-snooping
[SwitchB-igmp-snooping] quit
```

Create VLAN 100, and assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to the VLAN.

```
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/4
```

Enable IGMP snooping and the function of dropping unknown multicast traffic in VLAN 100.

```
[SwitchB-vlan100] igmp-snooping enable
[SwitchB-vlan100] igmp-snooping drop-unknown
[SwitchB-vlan100] quit
```

Configurations on Switch C and Switch D are similar to the configuration on Switch B.

3. Verify the configuration:

After the IGMP snooping querier starts to work, all the switches but the querier can receive IGMP general queries. By using the **display igmp-snooping statistics** command, you can view the statistics information about the IGMP messages received. For example:

Display IGMP message statistics on Switch B.

```
[SwitchB] display igmp-snooping statistics
Received IGMP general queries:3.
Received IGMPv1 reports:0.
Received IGMPv2 reports:12.
Received IGMP leaves:0.
Received IGMPv2 specific queries:0.
Sent IGMPv2 specific queries:0.
Received IGMPv3 reports:0.
Received IGMPv3 reports with right and wrong records:0.
Received IGMPv3 specific queries:0.
Received IGMPv3 specific sg queries:0.
Sent IGMPv3 specific queries:0.
Sent IGMPv3 specific sg queries:0.
Received error IGMP messages:0.
```

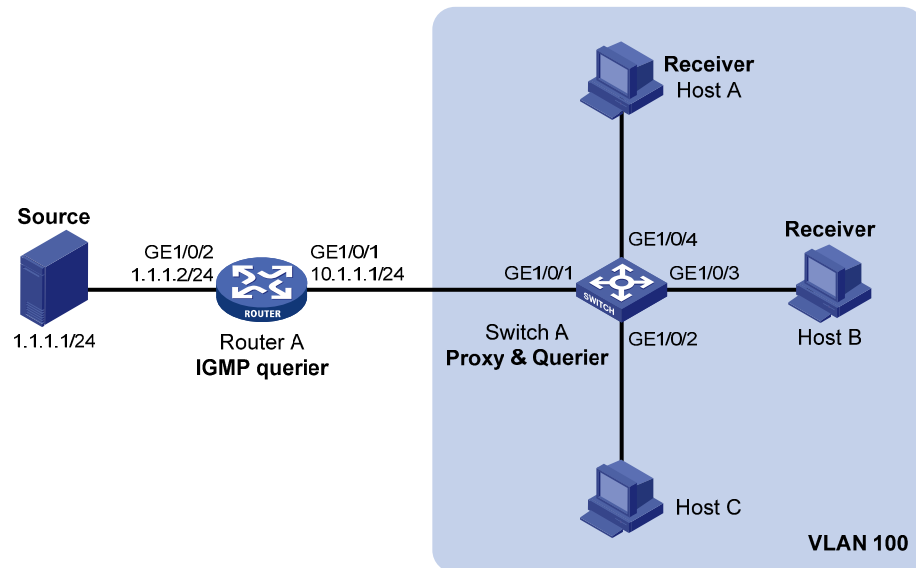

IGMP snooping proxying configuration example

Network requirements

As shown in [Figure 17](#), Router A runs IGMPv2 and Switch A runs IGMPv2 snooping. Router A acts as the IGMP querier.

Configure IGMP snooping proxying on Switch A, enabling the switch to forward IGMP reports and leave messages on behalf of attached hosts and to respond to IGMP queries from Router A and forward the queries to the hosts on behalf of Router A.

Figure 17 Network diagram

Configuration procedure

1. Configure IP addresses for interfaces:
Configure an IP address and subnet mask for each interface as per Figure 17. (Details not shown.)
2. Configure Router A:
Enable IP multicast routing, enable PIM-DM on each interface, and enable IGMP on GigabitEthernet 1/0/1.

```
<RouterA> system-view
[RouterA] multicast routing-enable
[RouterA] interface gigabitethernet 1/0/1
[RouterA-GigabitEthernet1/0/1] igmp enable
[RouterA-GigabitEthernet1/0/1] pim dm
[RouterA-GigabitEthernet1/0/1] quit
[RouterA] interface gigabitethernet 1/0/2
[RouterA-GigabitEthernet1/0/2] pim dm
[RouterA-GigabitEthernet1/0/2] quit
```
3. Configure Switch A:
Enable IGMP snooping globally.

```
<SwitchA> system-view
[SwitchA] igmp-snooping
[SwitchA-igmp-snooping] quit
```

Create VLAN 100, assign ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to this VLAN, and enable IGMP snooping and IGMP snooping proxying in the VLAN.

```
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[SwitchA-vlan100] igmp-snooping enable
[SwitchA-vlan100] igmp-snooping proxying enable
[SwitchA-vlan100] quit
```
4. Verify the configuration:

After the configuration is completed, Host A and Host B send IGMP join messages for group 224.1.1.1. Receiving the messages, Switch A sends a join message for the group out of port GigabitEthernet 1/0/1 (a router port) to Router A.

Use the **display igmp-snooping group** command and the **display igmp group** command to display information about IGMP snooping groups and IGMP multicast groups. For example:

Display information about IGMP snooping groups on Switch A.

```
[SwitchA] display igmp-snooping group
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
Subvlan flags: R-Real VLAN, C-Copy VLAN
Vlan(id):100.
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
Router port(s):total 1 port.
    GE1/0/1                (D) ( 00:01:23 )
IP group(s):the following ip group(s) match to one mac group.
IP group address:224.1.1.1
(0.0.0.0, 224.1.1.1):
Host port(s):total 2 port.
    GE1/0/3                (D)
    GE1/0/4                (D)
MAC group(s):
MAC group address:0100-5e01-0101
Host port(s):total 2 port.
    GE1/0/3
    GE1/0/4
```

Display information about IGMP multicast groups on Router A.

```
[RouterA] display igmp group
Total 1 IGMP Group(s).
Interface group report information of VPN-Instance: public net
GigabitEthernet1/0/1(10.1.1.1):
Total 1 IGMP Group reported
Group Address      Last Reporter      Uptime      Expires
224.1.1.1          0.0.0.0            00:00:06    00:02:04
```

When Host A leaves the multicast group, it sends an IGMP leave message to Switch A. Receiving the message, Switch A removes port GigabitEthernet 1/0/4 from the member port list of the forwarding entry for the group; however, it does not remove the group or forward the leave message to Router A because Host B is still in the group. Use the **display igmp-snooping group** command to display information about IGMP snooping groups. For example:

Display information about IGMP snooping groups on Switch A.

```
[SwitchA] display igmp-snooping group
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
```

```

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
Subvlan flags: R-Real VLAN, C-Copy VLAN
Vlan(id):100.
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
Router port(s):total 1 port.
    GE1/0/1                (D) ( 00:01:23 )
IP group(s):the following ip group(s) match to one mac group.
IP group address:224.1.1.1
(0.0.0.0, 224.1.1.1):
Host port(s):total 1 port.
    GE1/0/3                (D)
MAC group(s):
MAC group address:0100-5e01-0101
Host port(s):total 1 port.
    GE1/0/3

```

Multicast source and user control policy configuration example

Network requirements

As shown in [Figure 18](#), Switch A is a Layer-3 switch. Switch A runs IGMPv2 and Switch B runs IGMPv2 snooping. Multicast sources and hosts run 802.1X client.

A multicast source control policy is configured on Switch A to block multicast flows from Source 2 to 224.1.1.1.

A multicast user control policy is configured on Switch B so that Host A can join or leave only multicast group 224.1.1.1.

Figure 18 Network diagram

Configuration procedures

1. Configure IP addresses for interfaces:

Configure an IP address and subnet mask for each interface as per [Figure 18](#). (Details not shown.)

2. Configure Switch A:

Create VLAN 101 through VLAN 104 and assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to the four VLANs respectively.

```
<SwitchA> system-view
[SwitchA] vlan 101
[SwitchA-vlan101] port gigabitethernet 1/0/1
[SwitchA-vlan101] quit
[SwitchA] vlan 102
[SwitchA-vlan102] port gigabitethernet 1/0/2
[SwitchA-vlan102] quit
[SwitchA] vlan 103
[SwitchA-vlan103] port gigabitethernet 1/0/3
[SwitchA-vlan103] quit
[SwitchA] vlan 104
[SwitchA-vlan104] port gigabitethernet 1/0/4
[SwitchA-vlan104] quit
```

Enable IP multicast routing. Enable PIM-DM on VLAN-interface 101, VLAN-interface 102 and VLAN-interface 104, and enable IGMP on VLAN-interface 104.

```
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim dm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface vlan-interface 102
[SwitchA-Vlan-interface102] pim dm
[SwitchA-Vlan-interface102] quit
[SwitchA] interface vlan-interface 104

[SwitchB] user-profile profile2 enable
```

Create a RADIUS scheme **scheme2**; set the service type for the RADIUS server to **extended**; specify the IP addresses of the primary authentication/authorization server and accounting server as 3.1.1.1; set the shared keys to 321123; specify that a username sent to the RADIUS server carry no domain name.

```
[SwitchB] radius scheme scheme2
[SwitchB-radius-scheme2] server-type extended
[SwitchB-radius-scheme2] primary authentication 3.1.1.1
[SwitchB-radius-scheme2] key authentication 321123
[SwitchB-radius-scheme2] primary accounting 3.1.1.1
[SwitchB-radius-scheme2] key accounting 321123
[SwitchB-radius-scheme2] user-name-format without-domain
[SwitchB-radius-scheme2] quit
```

Create an ISP domain **domain2**; reference **scheme2** for the authentication, authorization, and accounting of LAN users; specify **domain2** as the default ISP domain.

```
[SwitchB] domain domain2
[SwitchB-isp-domian2] authentication lan-access radius-scheme scheme2
[SwitchB-isp-domian2] authorization lan-access radius-scheme scheme2
[SwitchB-isp-domian2] accounting lan-access radius-scheme scheme2
[SwitchB-isp-domian2] quit
[SwitchB] domain default enable domain2
```

Globally enable 802.1X and then enable it on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 respectively.

```
[SwitchB] dot1x
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] dot1x
[SwitchB-GigabitEthernet1/0/2] quit
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] dot1x
[SwitchB-GigabitEthernet1/0/3] quit
```

4. Configure the RADIUS server:

On the RADIUS server, configure the parameters related to Switch A and Switch B. For more information, see the configuration guide of the RADIUS server.

5. Verify the configuration:

After the configurations, the two multicast sources and hosts initiate 802.1X authentication. After passing authentication, Source 1 sends multicast flows to 224.1.1.1 and Source 2 sends multicast flows to 224.1.1.2; Host A sends messages to join multicast groups 224.1.1.1 and 224.1.1.2. Use the **display igmp-snooping group** command to display information about IGMP snooping groups. For example:

Display information about IGMP snooping groups in VLAN 104 on Switch B.

```
[SwitchB] display igmp-snooping group vlan 104 verbose
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
```

```

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
Subvlan flags: R-Real VLAN, C-Copy VLAN
Vlan(id):104.
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
Router port(s):total 1 port.
    GE1/0/1                (D) ( 00:01:30 )
IP group(s):the following ip group(s) match to one mac group.
  IP group address:224.1.1.1
    (0.0.0.0, 224.1.1.1):
      Attribute:    Host Port
      Host port(s):total 1 port.
        GE1/0/3                (D) ( 00:04:10 )
MAC group(s):
  MAC group address:0100-5e01-0101
  Host port(s):total 1 port.
    GE1/0/3

```

The output shows that GigabitEthernet 1/0/3 on Switch B has joined 224.1.1.1 but not 224.1.1.2.

Assume that Source 2 starts sending multicast traffic to 224.1.1.1. Use the **display multicast forwarding-table** to display the multicast forwarding table information.

Display information about 224.1.1.1 in the multicast forwarding table on Switch A.

```

[SwitchA] display multicast forwarding-table 224.1.1.1
Multicast Forwarding Table of VPN-Instance: public net

```

```
Total 1 entry
```

```
Total 1 entry matched
```

```

00001. (1.1.1.1, 224.1.1.1)
  MID: 0, Flags: 0x0:0
  Uptime: 00:08:32, Timeout in: 00:03:26
  Incoming interface: Vlan-interface101
  List of 1 outgoing interfaces:
    1: Vlan-interface104
  Matched 19648 packets(20512512 bytes), Wrong If 0 packets
  Forwarded 19648 packets(20512512 bytes)

```

The output shows that Switch A maintains a multicast forwarding entry for multicast packets from Source 1 to 224.1.1.1. No forwarding entry exists for packets from Source 2 to 224.1.1.1, which indicates that multicast packets from Source 2 are blocked.

Troubleshooting IGMP snooping

Layer 2 multicast forwarding cannot function

Symptom

Layer 2 multicast forwarding cannot function.

Analysis

IGMP snooping is not enabled.

Solution

1. Use the **display current-configuration** command to check the running status of IGMP snooping.
2. If IGMP snooping is not enabled, use the **igmp-snooping** command to enable IGMP snooping globally, and then use the **igmp-snooping enable** command to enable IGMP snooping in VLAN view.
3. If IGMP snooping is disabled only for the corresponding VLAN, use the **igmp-snooping enable** command in VLAN view to enable IGMP snooping in the corresponding VLAN.

Configured multicast group policy fails to take effect

Symptom

Although a multicast group policy has been configured to allow hosts to join specific multicast groups, the hosts can still receive multicast data addressed to other multicast groups.

Analysis

- The ACL rule is incorrectly configured.
- The multicast group policy is not correctly applied.
- The function of dropping unknown multicast data is not enabled, so unknown multicast data is flooded.

Solution

1. Use the **display acl** command to check the configured ACL rule. Make sure that the ACL rule conforms to the multicast group policy to be implemented.
2. Use the **display this** command in IGMP-snooping view or in the corresponding interface view to verify that the correct multicast group policy has been applied. If not, use the **group-policy** or **igmp-snooping group-policy** command to apply the correct multicast group policy.
3. Use the **display current-configuration** command to verify that the function of dropping unknown multicast data is enabled. If not, use the **drop-unknown** or **igmp-snooping drop-unknown** command to enable the function of dropping unknown multicast data.

Appendix

Processing of multicast protocol messages

With Layer 3 multicast routing enabled, an IGMP snooping-enabled switch processes multicast protocol messages differently under different conditions, as follows:

1. If only IGMP is enabled on the switch, or if both IGMP and PIM are enabled on the switch, the switch does the following:
 - Maintains dynamic member ports or dynamic router ports according to IGMP packets
 - Maintains dynamic router ports according to PIM hello packets
2. If only PIM is enabled on the switch, the following occur:
 - The switch broadcasts IGMP messages as unknown messages in the VLAN.
 - After receiving a PIM hello message, the switch maintains the corresponding dynamic router port.
3. If IGMP is disabled on the switch, one of the following occurs:
 - If PIM is disabled, the switch deletes all its dynamic member ports and dynamic router ports.
 - If PIM is enabled, the switch deletes only its dynamic member ports but not its dynamic router ports.

NOTE:

On a switch with Layer-3 multicast routing enabled, use the **display igmp group port-info** command to display Layer-2 port information. For more information about this command, see *IP Multicast Command Reference*.

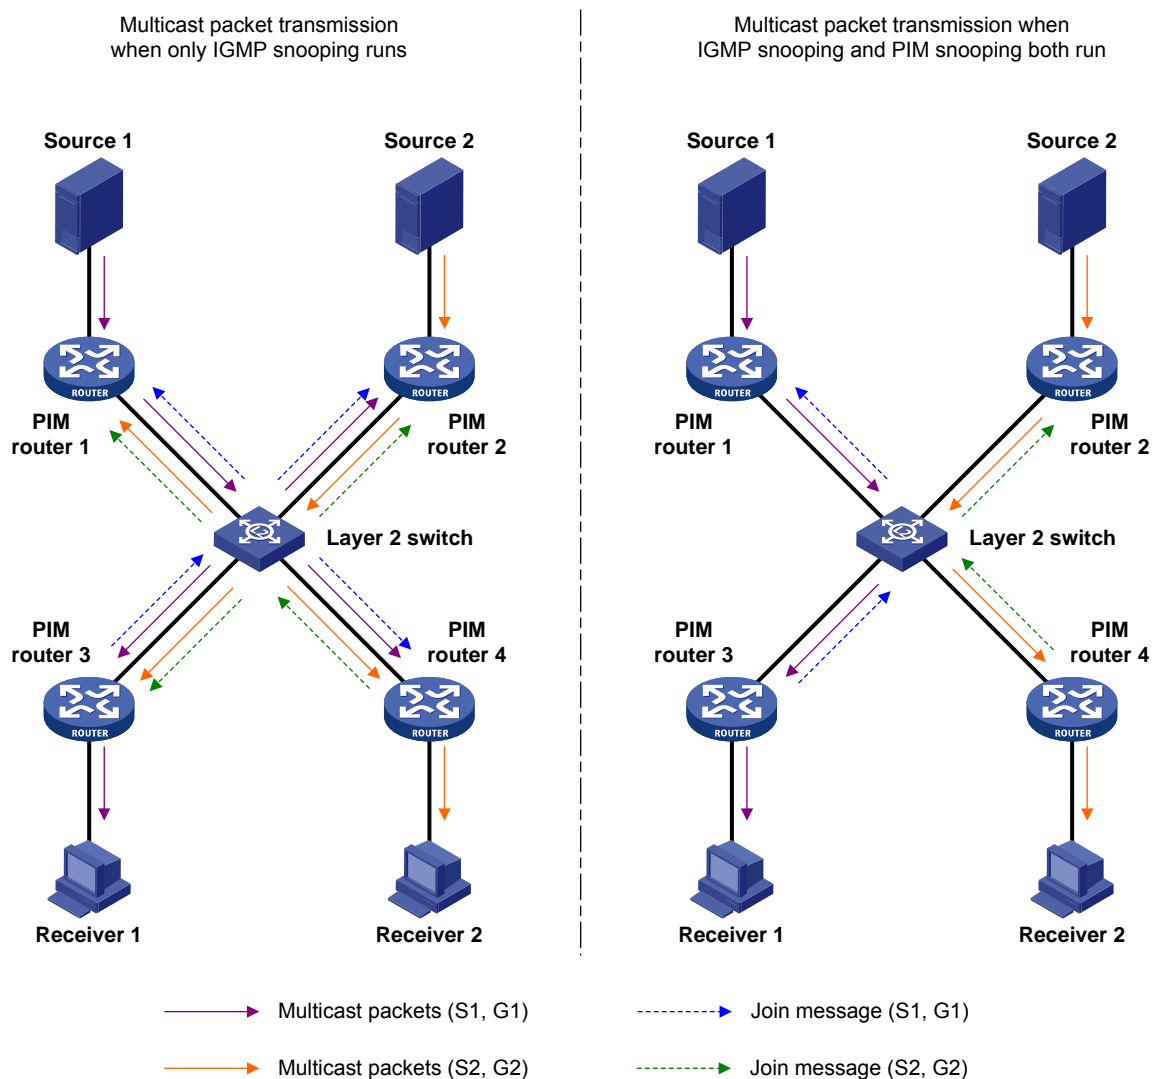

4. If PIM is disabled on the switch, one of the following occurs:
 - If IGMP is disabled, the switch deletes all its dynamic router ports.
 - If IGMP is enabled, the switch maintains all its dynamic member ports and dynamic router ports.

Configuring PIM snooping

Overview

Protocol Independent Multicast (PIM) snooping runs on Layer 2 devices. It determines which ports are interested in multicast data by analyzing the received PIM messages, and adds the ports to a multicast forwarding entry to make sure that multicast data can be forwarded to only the ports that are interested in the data.

Figure 19 Multicast packet transmission without or with PIM snooping

As shown in Figure 19, Source 1 sends multicast data to multicast group G1, and Source 2 sends multicast data to multicast group G2. Receiver 1 belongs to G1, and Receiver 2 belongs to G2. The Layer 2 switch's interfaces that connect to the PIM-capable routers are in the same VLAN.

- When the Layer 2 switch runs only IGMP snooping, it maintains the router ports according to the received PIM hello messages that PIM-capable routers send, broadcasts all other types of received

PIM messages in the VLAN, and forwards all multicast data to all router ports in the VLAN. Each PIM-capable router in the VLAN, whether interested in the multicast data or not, can receive all multicast data and all PIM messages except PIM hello messages.

- When the Layer 2 switch runs both IGMP snooping and PIM snooping, it determines whether PIM-capable routers are interested in the multicast data addressed to a multicast group according to PIM messages received from the routers, and adds only the ports for connecting the routers that are interested in the data to a multicast forwarding entry. Then, the Layer 2 switch forwards PIM messages and multicast data to only the routers that are interested in the data, saving network bandwidth.

For more information about IGMP snooping and the router port, see "[Configuring IGMP snooping](#) ."

For more information about PIM, see "[Configuring PIM \(available only on the HP 5500 EI\)](#)"

Configuring PIM snooping

Configuration guidelines

Before configuring PIM snooping for a VLAN, be sure to enable IGMP snooping globally and specifically for the VLAN.

After you enable PIM snooping in a VLAN, PIM snooping works only on the member interfaces of the VLAN.

PIM snooping does not work in the sub-VLANs of a multicast VLAN. For more information about multicast VLAN, see "[Configuring multicast VLANs](#)."

In a network with PIM snooping enabled switches, configure the size of each join/prune message no more than the path maximum transmission unit (MTU) on the PIM-enabled edge router on the receiver side. For more information about the join/prune messages, see "[Configuring PIM \(available only on the HP 5500 EI\)](#)."

Configuration procedure

To configure PIM snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IGMP snooping globally and enter IGMP-snooping view.	igmp-snooping	Disabled by default
3. Return to system view.	quit	N/A
4. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
5. Enable IGMP snooping in the VLAN.	igmp-snooping enable	Disabled by default
6. Enable PIM snooping in the VLAN.	pim-snooping enable	Disabled by default

For more information about the **igmp-snooping** and **igmp-snooping enable** commands, see *IP Multicast Command Reference*.

Displaying and maintaining PIM snooping

Task	Command	Remarks
Display PIM snooping neighbor information.	display pim-snooping neighbor [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display PIM snooping routing entries.	display pim-snooping routing-table [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the statistics information of PIM messages learned by PIM snooping.	display pim-snooping statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear the statistics information of PIM messages learned by PIM snooping.	reset pim-snooping statistics	Available in user view

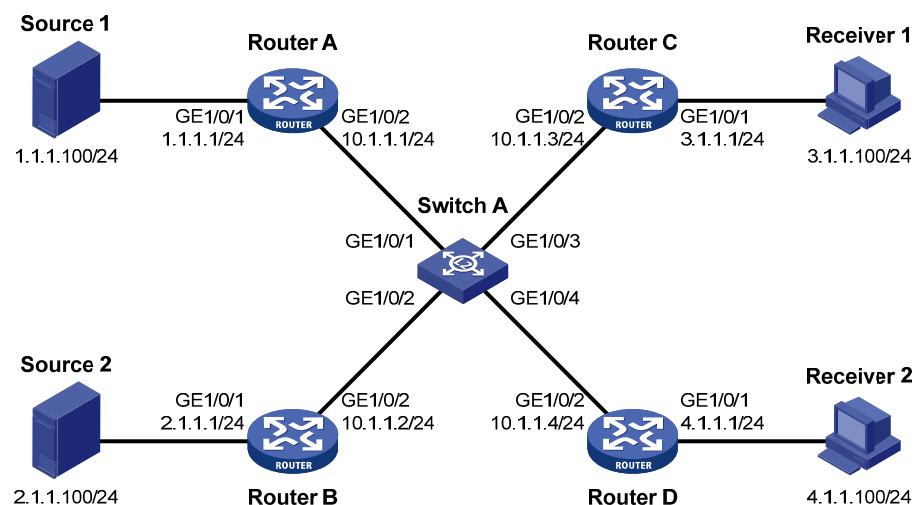

PIM snooping configuration example

Network requirements

As shown in Figure 20, Source 1 sends multicast data to multicast group 224.1.1.1, and Source 2 sends multicast data to multicast group 225.1.1.1. Receiver 1 belongs to multicast group 224.1.1.1, and Receiver 2 belongs to multicast group 225.1.1.1. Router C and Router D run IGMP on their interface GigabitEthernet 1/0/1. Router A, Router B, Router C, and Router D run PIM-SM, and interface GigabitEthernet 1/0/2 on Router A acts as a C-BSR and C-RP.

Configure IGMP snooping and PIM snooping on Switch A so that Switch A forwards PIM messages and multicast data to only the routers that are interested in the multicast data.

Figure 20 Network diagram

Configuration procedure

1. Assign IP addresses:

Configure an IP address and subnet mask for each interface according to [Figure 20](#). (Details not shown.)

2. Configure Router A:

Enable IP multicast routing, enable PIM-SM on each interface, and configure interface GigabitEthernet 1/0/2 as a C-BSR and C-RP.

```
<RouterA> system-view
[RouterA] multicast routing-enable
[RouterA] interface gigabitethernet 1/0/1
[RouterA-GigabitEthernet1/0/1] pim sm
[RouterA-GigabitEthernet1/0/1] quit
[RouterA] interface gigabitethernet 1/0/2
[RouterA-GigabitEthernet1/0/2] pim sm
[RouterA-GigabitEthernet1/0/2] quit
[RouterA] pim
[RouterA-pim] c-bsr gigabitethernet 1/0/2
[RouterA-pim] c-rp gigabitethernet 1/0/2
```

3. Configure Router B:

Enable IP multicast routing, and enable PIM-SM on each interface.

```
<RouterB> system-view
[RouterB] multicast routing-enable
[RouterB] interface gigabitethernet 1/0/1
[RouterB-GigabitEthernet1/0/1] pim sm
[RouterB-GigabitEthernet1/0/1] quit
[RouterB] interface gigabitethernet 1/0/2
[RouterB-GigabitEthernet1/0/2] pim sm
```

4. Configure Router C:

Enable IP multicast routing, enable PIM-SM on each interface, and enable IGMP on GigabitEthernet 1/0/1.

```
<RouterC> system-view
[RouterC] multicast routing-enable
[RouterC] interface gigabitethernet 1/0/1
[RouterC-GigabitEthernet1/0/1] pim sm
[RouterC-GigabitEthernet1/0/1] igmp enable
[RouterC-GigabitEthernet1/0/1] quit
[RouterC] interface gigabitethernet 1/0/2
[RouterC-GigabitEthernet1/0/2] pim sm
```

5. Configure Router D:

The configuration on Router D is similar to that on Router C. (Details not shown.)

6. Configure Switch A:

Enable IGMP snooping globally.

```
<SwitchA> system-view
[SwitchA] igmp-snooping
[SwitchA-igmp-snooping] quit
```

Create VLAN 100, assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to this VLAN, and enable IGMP snooping and PIM snooping in the VLAN.

```
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[SwitchA-vlan100] igmp-snooping enable
[SwitchA-vlan100] pim-snooping enable
[SwitchA-vlan100] quit
```

7. Verify the configuration:

On Switch A, display the PIM snooping neighbor information of VLAN 100.

```
[SwitchA] display pim-snooping neighbor vlan 100
Total number of neighbors: 4
```

```
VLAN ID: 100
Total number of neighbors: 4
Neighbor      Port          Expires      Option Flags
10.1.1.1      GE1/0/1       02:02:23    LAN Prune Delay
10.1.1.2      GE1/0/2       03:00:05    LAN Prune Delay
10.1.1.3      GE1/0/3       02:22:13    LAN Prune Delay
10.1.1.4      GE1/0/4       03:07:22    LAN Prune Delay
```

The output shows that Router A, Router B, Router C, and Router D are PIM snooping neighbors.

On Switch A, display the PIM snooping routing information of VLAN 100.

```
[SwitchA] display pim-snooping routing-table vlan 100 slot 1
Total 2 entry(ies)
FSM Flag: NI-no info, J-join, PP-prune pending
```

```
VLAN ID: 100
Total 2 entry(ies)
(*, 224.1.1.1)
  Upstream neighbor: 10.1.1.1
  Upstream port: GE1/0/1
  Total number of downstream ports: 1
    1: GE1/0/3
      Expires: 00:03:01, FSM: J
(*, 225.1.1.1)
  Upstream neighbor: 10.1.1.1
  Upstream port: GE1/0/2
  Total number of downstream ports: 1
    1: GE1/0/4
      Expires: 00:01:05, FSM: J
```

The output shows that Switch A will forward the multicast data intended for multicast group 224.1.1.1 to only Router C, and forward the multicast data intended for multicast group 225.1.1.1 to only Router D.

Troubleshooting PIM snooping

PIM snooping does not work

Symptom

PIM snooping does not work on the switch.

Analysis

IGMP snooping or PIM snooping is not enabled on the switch.

Solution

1. Use the **display current-configuration** command to check the status of IGMP snooping and PIM snooping.
2. If IGMP snooping is not enabled, enter system view and use the **igmp-snooping** command to enable IGMP snooping globally. Then, enter VLAN view and use the **igmp-snooping enable** and **pim-snooping enable** commands to enable IGMP snooping and PIM snooping in the VLAN.
3. If PIM snooping is not enabled, enter VLAN view and use the **pim-snooping enable** command to enable PIM snooping in the VLAN.

Some downstream PIM-capable routers cannot receive multicast data

Symptom

In a network with fragmented join/prune messages, some downstream PIM-capable routers cannot receive multicast data.

Analysis

PIM snooping cannot reassemble messages, and it cannot maintain the status of downstream routers that the join/prune message fragments carry. To ensure the normal operation of the system, PIM snooping must broadcast join/prune message fragments in the VLAN. However, if the VLAN has a PIM-capable router that has the join suppression function enabled, the broadcast join/prune message fragments might suppress the join messages of other PIM-capable routers in the VLAN. As a result, some PIM-capable routers cannot receive the multicast data destined for a specific multicast group because their join messages are suppressed. To solve this problem, disable the join suppression function on all PIM-capable routers that connect to the PIM snooping-capable switch in the VLAN.

Solution

1. Use the **pim hello-option neighbor-tracking** command to enable the neighbor tracking function on the interfaces of PIM routers that connect to the PIM snooping-capable switch.
2. If a PIM-capable router cannot be enabled with the neighbor tracking function, you have to disable PIM snooping on the switch.

Configuring multicast VLANs

Overview

In the traditional multicast programs-on-demand mode shown in [Figure 21](#), when hosts (Host A, Host B and Host C) that belong to different VLANs require multicast programs-on-demand service, the Layer 3 device, Router A, must forward a separate copy of the multicast traffic in each user VLAN to the Layer 2 device, Switch A. This results in not only waste of network bandwidth but also extra burden on the Layer 3 device.

Figure 21 Multicast transmission without multicast VLAN

The multicast VLAN feature configured on the Layer 2 device is the solution to this issue. With the multicast VLAN feature, the Layer 3 device replicates the multicast traffic only in the multicast VLAN instead of making a separate copy of the multicast traffic in each user VLAN. This saves network bandwidth and lessens the burden on the Layer 3 device.

The multicast VLAN feature can be implemented in sub-VLAN-based multicast VLAN and port-based multicast VLAN.

Sub-VLAN-based multicast VLAN

As shown in [Figure 22](#), Host A, Host B, and Host C are in different user VLANs. On Switch A, configure VLAN 10 as a multicast VLAN, configure all the user VLANs as sub-VLANs of VLAN 10, and enable IGMP snooping in the multicast VLAN.

Figure 22 Sub-VLAN-based multicast VLAN

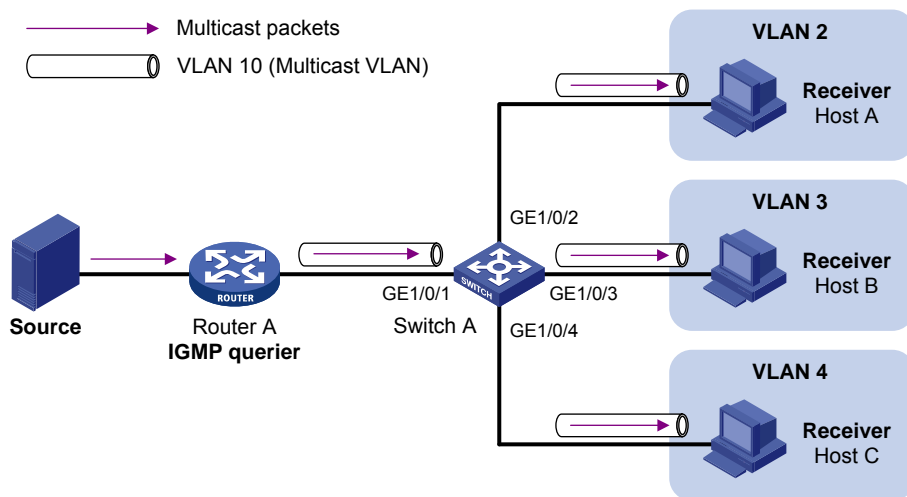

After the configuration, IGMP snooping manages router ports in the multicast VLAN and member ports in the sub-VLANs. When forwarding multicast data to Switch A, Router A sends only one copy of multicast data to Switch A in the multicast VLAN, and Switch A distributes the data to the multicast VLAN's sub-VLANs that contain receivers.

Port-based multicast VLAN

As shown in Figure 23, Host A, Host B, and Host C are in different user VLANs. All the user ports (ports with attached hosts) on Switch A are hybrid ports. On Switch A, configure VLAN 10 as a multicast VLAN, assign all the user ports to VLAN 10, and enable IGMP snooping in the multicast VLAN and all the user VLANs.

Figure 23 Port-based multicast VLAN

After the configuration, if Switch A receives an IGMP message on a user port, it tags the message with the multicast VLAN ID and relays it to the IGMP querier, so that IGMP snooping can uniformly manage the router port and member ports in the multicast VLAN. When Router A forwards multicast data to Switch A, it sends only one copy of multicast data to Switch A in the multicast VLAN, and Switch A distributes the data to all the member ports in the multicast VLAN.

For more information about IGMP snooping, router ports, and member ports, see "[Configuring IGMP snooping](#)."

For more information about VLAN tags, see *Layer 2—LAN Switching Configuration Guide*.

Multicast VLAN configuration task list

Task	Remarks
Configuring a sub-VLAN-based multicast VLAN	Required
Configuring a port-based multicast VLAN	Configuring user port attributes Configuring multicast VLAN ports

NOTE:

If you have configured both sub-VLAN-based multicast VLAN and port-based multicast VLAN on a device, the port-based multicast VLAN configuration is given preference.

Configuring a sub-VLAN-based multicast VLAN

Configuration prerequisites

Before you configure sub-VLAN-based multicast VLAN, complete the following tasks:

- Create VLANs as required.
- Enable IGMP snooping in the VLAN to be configured as a multicast VLAN.

Configuration guidelines

- You cannot configure multicast VLAN on a device with IP multicast routing enabled.
- The VLAN to be configured as a multicast VLAN must exist.
- The VLANs to be configured as sub-VLANs of the multicast VLAN must exist and must not be multicast VLANs or sub-VLANs of any other multicast VLAN.
- The total number of sub-VLANs of a multicast VLAN must not exceed the maximum number the system can support.

Configuration procedure

In this approach, you configure a VLAN as a multicast VLAN and configure user VLANs as sub-VLANs of the multicast VLAN.

To configure a sub-VLAN-based multicast VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the specified VLAN as a multicast VLAN and enter multicast VLAN view.	multicast-vlan <i>vlan-id</i>	By default, a VLAN is not a multicast VLAN.

Step	Command	Remarks
3. Configure the specified VLANs as sub-VLANs of the multicast VLAN.	subvlan <i>vlan-list</i>	By default, a multicast VLAN has no sub-VLANs.

Configuring a port-based multicast VLAN

When you configure a port-based multicast VLAN, you must configure the attributes of each user port and then assign the ports to the multicast VLAN.

A user port can be configured as a multicast VLAN port only if it is an Ethernet port, or Layer 2 aggregate interface.

In Ethernet interface view or Layer 2 aggregate interface view, configurations that you make are effective on only the current port. In port group view, configurations that you make are effective on all ports in the current port group.

Configuration prerequisites

Before you configure a port-based multicast VLAN, complete the following tasks:

- Create VLANs as required.
- Enable IGMP snooping in the VLAN to be configured as a multicast VLAN.
- Enable IGMP snooping in all the user VLANs.

Configuring user port attributes

Configure the user ports as hybrid ports that permit packets of the specified user VLAN to pass, and configure the user VLAN to which the user ports belong as the default VLAN.

Configure the user ports to permit packets of the multicast VLAN to pass and untag the packets. Thus, after receiving multicast packets tagged with the multicast VLAN ID from the upstream device, the Layer 2 device untags the multicast packets and forwards them to its downstream device.

To configure user port attributes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> • Enter interface view or port group view: interface <i>interface-type</i> <i>interface-number</i> • Enter interface view or port group view: port-group { manual <i>port-group-name</i> aggregation <i>agg-id</i> } 	Use either command.
3. Configure the user port link type as hybrid.	port link-type hybrid	Access by default

Step	Command	Remarks
4. Specify the user VLAN that comprises the current user ports as the default VLAN.	port hybrid pvid vlan <i>vlan-id</i>	VLAN 1 by default
5. Configure the current user ports to permit packets of the specified multicast VLANs to pass and untag the packets.	port hybrid vlan <i>vlan-id-list</i> untagged	By default, a hybrid port permits only packets of VLAN 1 to pass.

For more information about the **port link-type**, **port hybrid pvid vlan**, and **port hybrid vlan** commands, see *Layer 2—LAN Switching Command Reference*.

Configuring multicast VLAN ports

Configuration guidelines

In this approach, you configure a VLAN as a multicast VLAN and assign user ports to it. You can do this by either adding the user ports in the multicast VLAN or specifying the multicast VLAN on the user ports. These two methods provide the same result.

You cannot configure multicast VLAN on a device with multicast routing enabled.

The VLAN to be configured as a multicast VLAN must exist.

A port can belong to only one multicast VLAN.

Configuration procedure

To configure multicast VLAN ports in multicast VLAN view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the specified VLAN as a multicast VLAN and enter multicast VLAN view.	multicast-vlan <i>vlan-id</i>	By default, a VLAN is not a multicast VLAN.
3. Assign ports to the multicast VLAN.	port <i>interface-list</i>	By default, a multicast VLAN has no ports.

To configure multicast VLAN ports in interface view or port group view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the specified VLAN as a multicast VLAN and enter multicast VLAN view.	multicast-vlan <i>vlan-id</i>	By default, a VLAN is not a multicast VLAN.
3. Return to system view.	quit	N/A

Step	Command	Remarks
4. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
5. Configure the current port as a member port of the multicast VLAN.	port multicast-vlan <i>vlan-id</i>	By default, a user port does not belong to any multicast VLAN.

Displaying and maintaining multicast VLAN

Task	Command	Remarks
Display information about a multicast VLAN.	display multicast-vlan [<i>vlan-id</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view

Multicast VLAN configuration examples

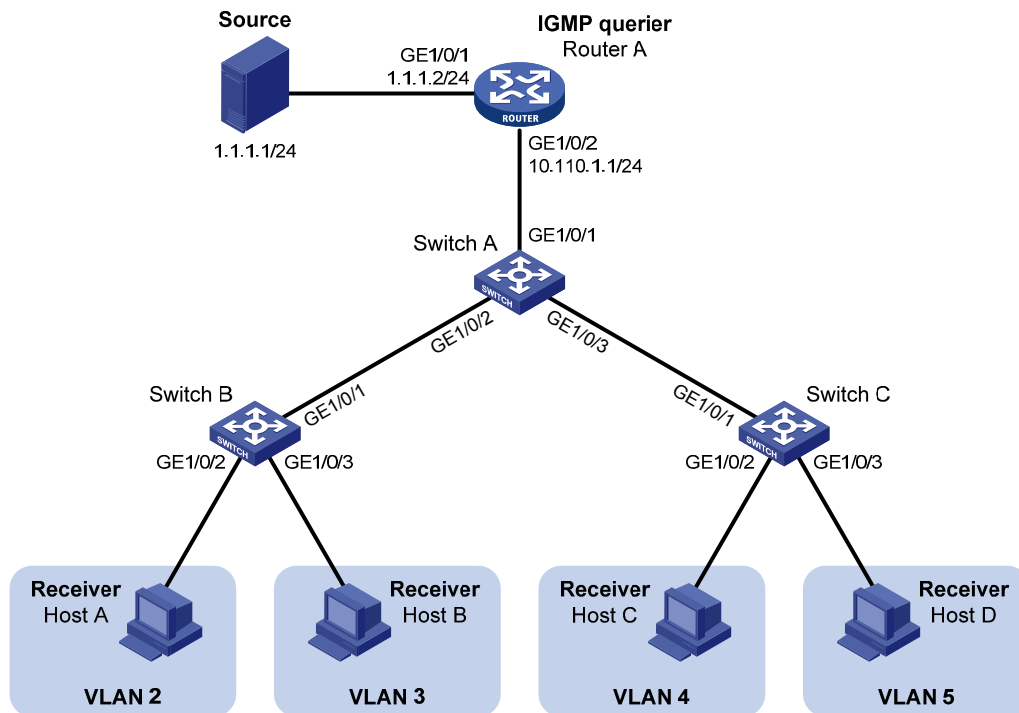

Sub-VLAN-based multicast VLAN configuration example

Network requirements

As shown in [Figure 24](#), IGMPv2 runs on Router A, and IGMPv2 snooping runs on Switch A, Switch B, and Switch C. Router A acts as the IGMP querier. The multicast source sends multicast data to multicast group 224.1.1.1. Host A, Host B, Host C, and Host D are receivers of the multicast group. The hosts belong to VLAN 2 through VLAN 5 respectively.

Configure the sub-VLAN-based multicast VLAN feature on Switch A so that Router A just sends multicast data to Switch A through the multicast VLAN and Switch A forwards the traffic to the receivers that belong to different user VLANs.

Figure 24 Network diagram

Configuration procedure

1. Configure IP addresses:
Configure an IP address and subnet mask for each interface as per Figure 24. (Details not shown.)
2. Configure Router A:
Enable IP multicast routing, enable PIM-DM on each interface and enable IGMP on the host-side interface GigabitEthernet 1/0/2.

```
<RouterA> system-view  
[RouterA] multicast routing-enable  
[RouterA] interface gigabitethernet 1/0/1  
[RouterA-GigabitEthernet1/0/1] pim dm  
[RouterA-GigabitEthernet1/0/1] quit  
[RouterA] interface gigabitethernet 1/0/2  
[RouterA-GigabitEthernet1/0/2] pim dm  
[RouterA-GigabitEthernet1/0/2] igmp enable
```
3. Configure Switch A:
Enable IGMP snooping globally.

```
<SwitchA> system-view  
[SwitchA] igmp-snooping  
[SwitchA-igmp-snooping] quit
```

Create VLAN 2 through VLAN 5.

```
[SwitchA] vlan 2 to 5
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign it to VLAN 2 and VLAN 3.

```
[SwitchA] interface gigabitethernet 1/0/2  
[SwitchA-GigabitEthernet1/0/2] port link-type trunk
```

```
[SwitchA-GigabitEthernet1/0/2] port trunk permit vlan 2 3
[SwitchA-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port, and assign it to VLAN 4 and VLAN 5.

```
[SwitchA] interface gigabitethernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] port link-type trunk
[SwitchA-GigabitEthernet1/0/3] port trunk permit vlan 4 5
[SwitchA-GigabitEthernet1/0/3] quit
```

Create VLAN 10, assign GigabitEthernet 1/0/1 to this VLAN and enable IGMP snooping in the VLAN.

```
[SwitchA] vlan 10
[SwitchA-vlan10] port gigabitethernet 1/0/1
[SwitchA-vlan10] igmp-snooping enable
[SwitchA-vlan10] quit
```

Configure VLAN 10 as a multicast VLAN and configure VLAN 2 through VLAN 5 as its sub-VLANs.

```
[SwitchA] multicast-vlan 10
[SwitchA-mvlan-10] subvlan 2 to 5
[SwitchA-mvlan-10] quit
```

4. Configure Switch B:

Enable IGMP snooping globally.

```
<SwitchB> system-view
[SwitchB] igmp-snooping
[SwitchB-igmp-snooping] quit
```

Create VLAN 2, assign GigabitEthernet 1/0/2 to VLAN 2, and enable IGMP snooping in the VLAN.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/2
[SwitchB-vlan2] igmp-snooping enable
[SwitchB-vlan2] quit
```

Create VLAN 3, assign GigabitEthernet 1/0/3 to VLAN 3, and enable IGMP snooping in the VLAN.

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/3
[SwitchB-vlan3] igmp-snooping enable
[SwitchB-vlan3] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port, and assign it to VLAN 2 and VLAN 3.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port link-type trunk
[SwitchB-GigabitEthernet1/0/1] port trunk permit vlan 2 3
```

5. Configure Switch C:

The configurations on Switch C are similar to those on Switch B.

6. Verify the configuration:

Display information about the multicast VLAN.

```
[SwitchA] display multicast-vlan
Total 1 multicast-vlan(s)
```

```
Multicast vlan 10
  subvlan list:
    vlan 2-5
  port list:
    no port
```

View the IGMP snooping multicast group information on Switch A.

```
[SwitchA] display igmp-snooping group
```

```
Total 5 IP Group(s).
Total 5 IP Source(s).
Total 5 MAC Group(s).
```

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port

Subvlan flags: R-Real VLAN, C-Copy VLAN

  Total 1 IP Source(s).
  Total 1 MAC Group(s).
  Router port(s):total 0 port(s).
IP group(s):the following ip group(s) match to one mac group.
  IP group address:224.1.1.1
    (0.0.0.0, 224.1.1.1):
      Host port(s):total 1 port(s).
        GE1/0/3                (D)
MAC group(s):
  MAC group address:0100-5e01-0101
    Host port(s):total 1 port(s).
      GE1/0/3

Vlan(id):10.
  Total 1 IP Group(s).
  Total 1 IP Source(s).
  Total 1 MAC Group(s).
  Router port(s):total 1 port(s).
    GE1/0/1                (D)
IP group(s):the following ip group(s) match to one mac group.
  IP group address:224.1.1.1
    (0.0.0.0, 224.1.1.1):
      Host port(s):total 0 port(s).
MAC group(s):
  MAC group address:0100-5e01-0101
    Host port(s):total 0 port(s).

```

The output shows that IGMP snooping is maintaining the router port in the multicast VLAN (VLAN 10) and the member ports in the sub-VLANs (VLAN 2 through VLAN 5).

Port-based multicast VLAN configuration example

Network requirements

As shown in [Figure 25](#), IGMPv2 runs on Router A. IGMPv2 Snooping runs on Switch A. Router A acts as the IGMP querier. The multicast source sends multicast data to multicast group 224.1.1.1. Host A, Host B, and Host C are receivers of the multicast group, and the hosts belong to VLAN 2 through VLAN 4 respectively.

Configure the port-based multicast VLAN feature on Switch A so that Router A just sends multicast data to Switch A through the multicast VLAN and Switch A forwards the multicast data to the receivers that belong to different user VLANs.

Figure 25 Network diagram

Configuration procedure

1. Configure IP addresses:
Configure the IP address and subnet mask for each interface as per Figure 25. (Details not shown.)
2. Configure Router A:
Enable IP multicast routing, enable PIM-DM on each interface, and enable IGMP on the host-side interface GigabitEthernet 1/0/2.

```
<RouterA> system-view
[RouterA] multicast routing-enable
[RouterA] interface gigabitethernet 1/0/1
[RouterA-GigabitEthernet1/0/1] pim dm
[RouterA-GigabitEthernet1/0/1] quit
[RouterA] interface gigabitethernet 1/0/2
[RouterA-GigabitEthernet1/0/2] pim dm
[RouterA-GigabitEthernet1/0/2] igmp enable
```
3. Configure Switch A:
Enable IGMP snooping globally.

```
<SwitchA> system-view
[SwitchA] igmp-snooping
[SwitchA-igmp-snooping] quit
```

Create VLAN 10, assign GigabitEthernet 1/0/1 to VLAN 10, and enable IGMP snooping in this VLAN.

```
[SwitchA] vlan 10
[SwitchA-vlan10] port gigabitethernet 1/0/1
[SwitchA-vlan10] igmp-snooping enable
[SwitchA-vlan10] quit
```

Create VLAN 2 and enable IGMP snooping in the VLAN.

```
[SwitchA] vlan 2
[SwitchA-vlan2] igmp-snooping enable
[SwitchA-vlan2] quit
```

The configuration for VLAN 3 and VLAN 4 is similar. (Details not shown.)

Configure GigabitEthernet 1/0/2 as a hybrid port. Configure VLAN 2 as the default VLAN. Configure GigabitEthernet 1/0/2 to permit packets of VLAN 2 and VLAN 10 to pass and untag the packets when forwarding them.

```
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] port link-type hybrid
[SwitchA-GigabitEthernet1/0/2] port hybrid pvid vlan 2
[SwitchA-GigabitEthernet1/0/2] port hybrid vlan 2 untagged
[SwitchA-GigabitEthernet1/0/2] port hybrid vlan 10 untagged
[SwitchA-GigabitEthernet1/0/2] quit
```

The configuration for GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 is similar. (Details not shown.)

Configure VLAN 10 as a multicast VLAN.

```
[SwitchA] multicast-vlan 10
```

Assign GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 to VLAN 10.

```
[SwitchA-mvlan-10] port gigabitethernet 1/0/2 to gigabitethernet 1/0/3
[SwitchA-mvlan-10] quit
```

Assign GigabitEthernet 1/0/4 to VLAN 10.

```
[SwitchA] interface gigabitethernet 1/0/4
[SwitchA-GigabitEthernet1/0/4] port multicast-vlan 10
[SwitchA-GigabitEthernet1/0/4] quit
```

4. Verify the configuration:

View the multicast VLAN information on Switch A.

```
[SwitchA] display multicast-vlan
Total 1 multicast-vlan(s)
```

```
Multicast vlan 10
  subvlan list:
    no subvlan
  port list:
    GE1/0/2                GE1/0/3                GE1/0/4
```

View the IGMP snooping multicast group information on Switch A.

```
[SwitchA] display igmp-snooping group
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
```

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port

Subvlan flags: R-Real VLAN, C-Copy VLAN

```
Vlan(id):10.
  Total 1 IP Group(s).
  Total 1 IP Source(s).
  Total 1 MAC Group(s).
```

```
Router port(s):total 1 port(s).
    GE1/0/1                (D)
IP group(s):the following ip group(s) match to one mac group.
IP group address:224.1.1.1
(0.0.0.0, 224.1.1.1):
    Host port(s):total 3 port(s).
        GE1/0/2            (D)
        GE1/0/3            (D)
        GE1/0/4            (D)
MAC group(s):
MAC group address:0100-5e01-0101
    Host port(s):total 3 port(s).
        GE1/0/2
        GE1/0/3
        GE1/0/4
```

The output shows that IGMP snooping is maintaining the router ports and member ports in VLAN 10.

Configuring multicast routing and forwarding (available only on the HP 5500 EI)

Overview

In multicast implementations, the following types of tables implement multicast routing and forwarding:

- **Multicast routing table of a multicast routing protocol**—Each multicast routing protocol has its own multicast routing table, such as PIM routing table.
- **General multicast routing table**—The multicast routing information of different multicast routing protocols forms a general multicast routing table.
- **Multicast forwarding table**—The multicast forwarding table guides the forwarding of multicast packets.

A multicast routing table consists of a set of (S, G) entries. Each entry indicates the routing information for delivering multicast data from a multicast source to a multicast group. If a router supports multiple multicast protocols, its multicast routing table includes routes generated by multiple protocols. The router chooses the optimal route from the multicast routing table based on the configured multicast routing and forwarding policy and adds the route entry to its multicast forwarding table.

The term "router" in this document refers to both routers and Layer 3 switches.

The term "interface" in the multicast routing and forwarding features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

RPF check mechanism

A multicast routing protocol relies on the existing unicast routes, MBGP routes, or static multicast routes in creating multicast routing entries. When creating multicast routing table entries, a multicast routing protocol uses the reverse path forwarding (RPF) check mechanism to ensure multicast data delivery along the correct paths. In addition, the RPF check mechanism also helps avoid data loops.

RPF check process

The basis for an RPF check is as follows:

- **Unicast routing table**—Contains the shortest path to each destination subnet.
- **MBGP routing table**—Contains multicast routing information.
- **Static multicast routing table**—Contains the RPF routing information defined by the user through static configuration.

MBGP multicast routing table and static multicast routing table are used for RPF check rather than multicast routing.

When a router performs an RPF check, it searches its unicast routing table, MBGP routing table, and static multicast routing table at the same time. The specific process is as follows:

1. The router chooses an optimal route from the unicast routing table, the MBGP routing table, and the static multicast routing table:
 - The router automatically chooses an optimal unicast route by searching its unicast routing table, and using the IP address of the packet source as the destination address. The outgoing interface in the corresponding routing entry is the RPF interface and the next hop is the RPF neighbor. The router considers the path along which the packet from the RPF neighbor arrived on the RPF interface to be the shortest path that leads back to the source.
 - The router automatically chooses an optimal MBGP route by searching its MBGP routing table, and using the IP address of the packet source as the destination address. The outgoing interface in the corresponding routing entry is the RPF interface and the next hop is the RPF neighbor.
 - The router automatically chooses an optimal static multicast route by searching its static multicast routing table, and using the IP address of the packet source as the destination address. The corresponding routing entry explicitly defines the RPF interface and the RPF neighbor.
2. The router selects one of these optimal routes as the RPF route. The selection process is as follows:
 - If configured to use the longest match principle, the router selects the longest match route from these optimal routes. If the three routes have the same mask, the router selects the route with the highest priority. If the three routes have the same priority, the router selects a route as the RPF route according to the sequence of static multicast route, MBGP route, and unicast route.
 - If not configured to use the longest match principle, the router selects the route with the highest priority. If the three routes have the same priority, the router selects a route as the RPF route according to the sequence of static multicast route, MBGP route, and unicast route.

The "packet source" means different things in different situations:

- For a packet traveling along the shortest path tree (SPT) from the multicast source to the receivers or the rendezvous point (RP), the packet source for RPF check is the multicast source.
- For a packet traveling along the rendezvous point tree (RPT) from the RP to the receivers, or along the source-side RPT from the multicast source to the RP, the packet source for RPF check is the RP.
- For a bootstrap message from the bootstrap router (BSR), the packet source for RPF check is the BSR.

For more information about the concepts of SPT, RPT, source-side RPT, RP, and BSR, see "[Configuring PIM \(available only on the HP 5500 EI\)](#)."

RPF check implementation in multicast

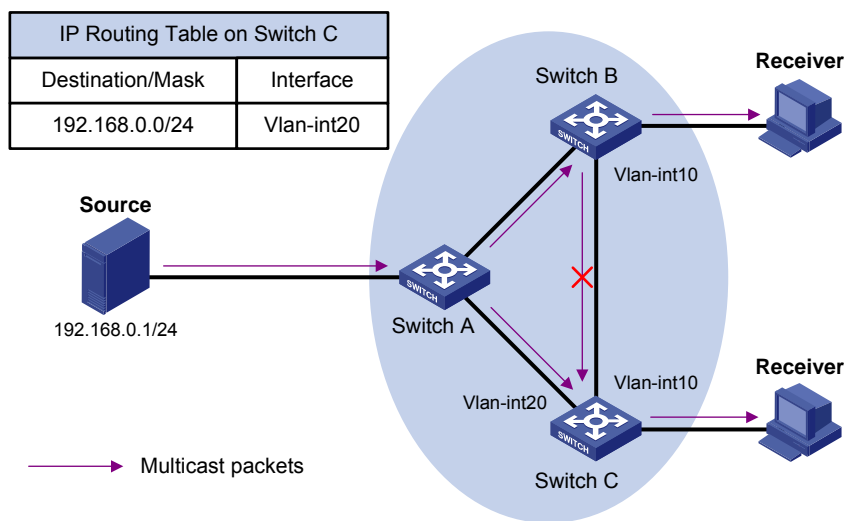

Implementing an RPF check on each received multicast data packet would be a big burden to the router. The use of a multicast forwarding table is the solution to this issue. When creating a multicast routing entry and a multicast forwarding entry for a multicast packet, the router sets the RPF interface of the packet as the incoming interface of the (S, G) entry. After receiving an (S, G) multicast packet, the router first searches its multicast forwarding table:

1. If the corresponding (S, G) entry does not exist in the multicast forwarding table, the packet undergoes an RPF check. The router creates a multicast routing entry based on the relevant routing information and adds the entry into the multicast forwarding table, with the RPF interface as the incoming interface.
 - If the interface that received the packet is the RPF interface, the RPF check succeeds and the router forwards the packet to all the outgoing interfaces.
 - If the interface that received the packet is not the RPF interface, the RPF check fails and the router discards the packet.
2. If the corresponding (S, G) entry exists, and the interface that received the packet is the incoming interface, the router forwards the packet to all the outgoing interfaces.

3. If the corresponding (S, G) entry exists, but the interface that received the packet is not the incoming interface in the multicast forwarding table, the multicast packet undergoes an RPF check.
 - If the RPF interface is the incoming interface of the (S, G) entry, it indicates that the (S, G) entry is correct but the packet arrived from a wrong path. The packet will be discarded.
 - If the RPF interface is not the incoming interface, it indicates that the (S, G) entry has expired, and router replaces the incoming interface with the RPF interface. If the interface on which the packet arrived is the RPF interface, the router forwards the packet to all the outgoing interfaces. Otherwise, it discards the packet.

Assume that unicast routes are available in the network, MBGP is not configured, and no static multicast routes have been configured on Switch C, as shown in [Figure 26](#). Multicast packets travel along the SPT from the multicast source to the receivers. The multicast forwarding table on Switch C contains the (S, G) entry, with VLAN-interface 20 as the incoming interface.

Figure 26 RPF check process

- When a multicast packet arrives on interface VLAN-interface 20 of Switch C, because the interface is the incoming interface of the (S, G) entry, the router forwards the packet to all outgoing interfaces.
- When a multicast packet arrives on interface VLAN-interface 10 of Switch C, because the interface is not the incoming interface of the (S, G) entry, the router performs an RPF check on the packet. The router searches its unicast routing table and finds that the outgoing interface to Source (the RPF interface) is VLAN-interface 20. This means the (S, G) entry is correct, and packet arrived along a wrong path. The RPF check fails and the packet is discarded.

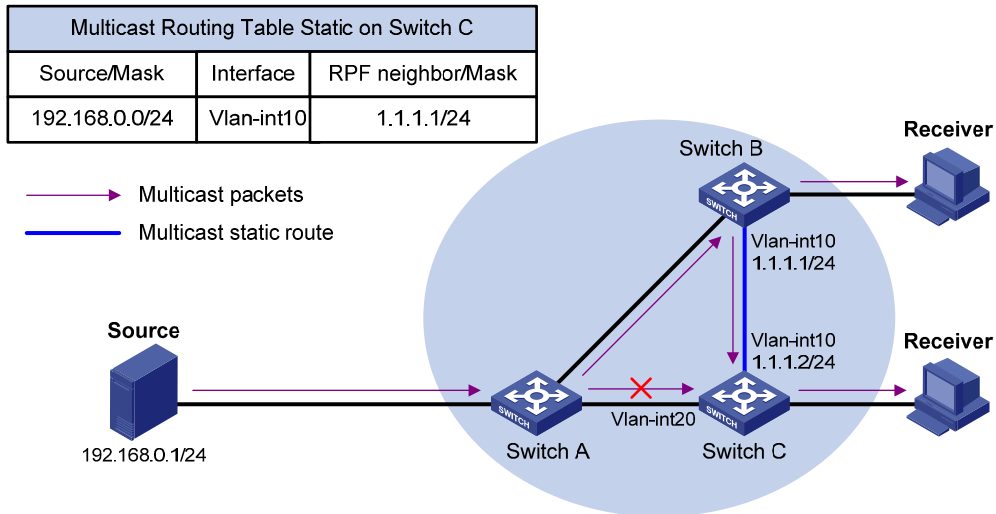

Static multicast routes

A static multicast route is an important basis for RPF check. Depending on the application environment, a static multicast route can change an RPF route and create an RPF route.

Changing an RPF route

Typically, the topology structure of a multicast network is the same as that of a unicast network, and multicast traffic follows the same transmission path as unicast traffic does. You can configure a static multicast route for a given multicast source to change the RPF route to create a transmission path for multicast traffic that is different from that for unicast traffic.

Figure 27 Changing an RPF route

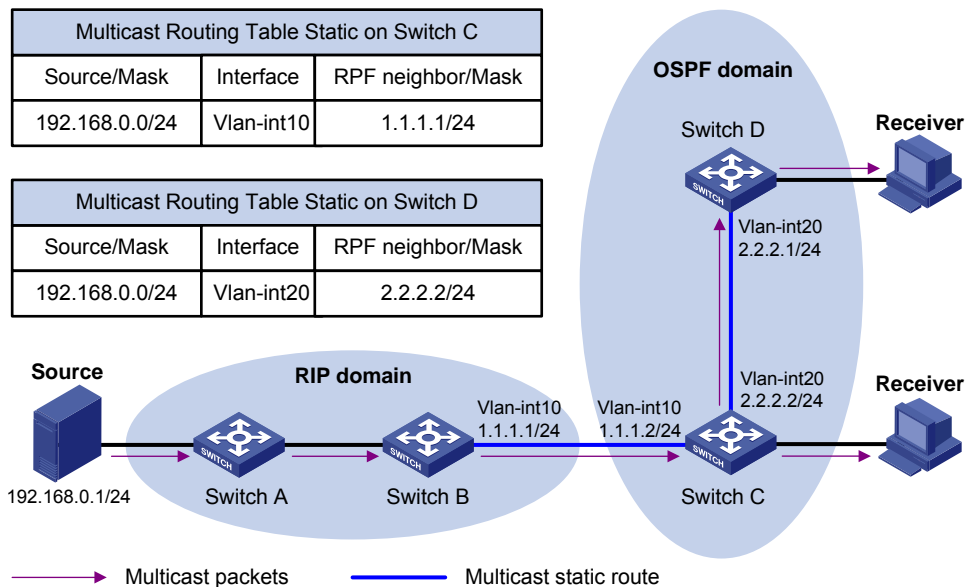

As shown in [Figure 27](#), when no static multicast route is configured, Switch C's RPF neighbor on the path back to Source is Switch A. The multicast information from Source travels along the path from Switch A to Switch C, which is the unicast route between the two routers. When a static multicast route is configured on Switch C and Switch B is configured as Switch C's RPF neighbor on the path back to Source, the multicast information from Source travels from Switch A to Switch B and then to Switch C.

Creating an RPF route

When a unicast route is blocked, multicast traffic forwarding might be stopped because of lack of an RPF route. By configuring a static multicast route for a given multicast source, you can create an RPF route so that a multicast routing entry is created to guide multicast traffic forwarding regardless of whether a unicast route is available.

Figure 28 Creating an RPF route

As shown in [Figure 28](#), the RIP domain and the OSPF domain are unicast isolated from each other. When no static multicast route is configured, the hosts (Receivers) in the OSPF domain cannot receive the multicast packets that the multicast source (Source) sent in the RIP domain. After you configure a static

multicast route on Switch C and Switch D, specifying Switch B as the RPF neighbor of Switch C and specifying Switch C as the RPF neighbor of Switch D, the receivers can receive multicast data that the multicast source sent.

NOTE:

- Static multicast routes only affect RPF check but cannot guide multicast forwarding.
 - A static multicast route is effective only on the multicast router on which it is configured, and will not be advertised throughout the network or redistributed to other routers.
-

Multicast traceroute

You can use the multicast traceroute utility to trace the path that a multicast stream flows down from the first-hop router to the last-hop router.

Concepts in multicast traceroute

- **Last-hop router**—If one of the interfaces of a router connects to the subnet that contains the given destination address, and if the router can forward multicast streams from the given multicast source onto that subnet, that router is called the "last-hop router".
- **First-hop router**—The router that directly connects to the multicast source is called the "first-hop router".
- **Querier**—The router that sends multicast traceroute requests is called the "querier".

Introduction to multicast traceroute packets

A multicast traceroute packet is a special IGMP packet that is different from common IGMP packets in that its IGMP Type field is set to 0x1F or 0x1E and its destination IP address is a unicast address. The following types of multicast traceroute packets are available:

- Query, with the IGMP Type field set to 0x1F,
- Request, with the IGMP Type field set to 0x1F, and
- Response, with the IGMP Type field set to 0x1E.

Process of multicast traceroute

1. The querier sends a query to the last-hop router.
2. After receiving the query, the last-hop router turns the query packet into a request packet by adding a response data block (which contains its interface addresses and packet statistics) to the end of the packet. It then forwards the request packet through unicast to the previous hop for the given multicast source and group.
3. From the last-hop router to the multicast source, each hop adds a response data block to the end of the request packet and unicasts it to the previous hop.
4. When the first-hop router receives the request packet, it changes the packet type to indicate a response packet. Then, it sends the completed packet through unicast to the querier.

Configuration task list

Task	Remarks
Enabling IP multicast routing	Required

Task	Remarks	
Configuring multicast routing and forwarding	Configuring static multicast routes	Optional
	Configuring a multicast routing policy	Optional
	Configuring a multicast forwarding range	Optional
	Configuring the multicast forwarding table size	Optional
	Tracing a multicast path	Optional

! **IMPORTANT:**

IP multicast does not support secondary IP address segments. Namely, multicast can be routed and forwarded only through primary IP addresses even if secondary addresses are configured on the ports. For more information about primary and secondary IP addresses, see *Layer 3— IP Services Configuration Guide*.

Enabling IP multicast routing

Before you configure any Layer 3 multicast functionality, you must enable IP multicast routing.

Enabling IP multicast routing for the public network

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IP multicast routing.	multicast routing-enable	Disabled by default

Enabling IP multicast routing in a VPN instance

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VPN instance and enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure a route distinguisher (RD) for the VPN instance.	route-distinguisher <i>route-distinguisher</i>	No RD is configured by default.
4. Enable IP multicast routing.	multicast routing-enable	Disabled by default.

For more information about the **ip vpn-instance** and **route-distinguisher** commands, see *IP Routing Command Reference*.

Configuring multicast routing and forwarding

Configuration prerequisites

Before you configure multicast routing and forwarding, complete the following tasks:

- Configure a unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Enable PIM (PIM-DM or PIM-SM).
- Determine the maximum number of downstream nodes for a single multicast forwarding table entry.
- Determine the maximum number of entries in the multicast forwarding table.

Configuring static multicast routes

By configuring a static multicast route for a given multicast source, you can specify an RPF interface or an RPF neighbor for multicast traffic from that source. If you want to remove a specific static multicast route, use the **undo ip rpf-route-static** command, if you want to remove all static multicast routes, use the **delete ip rpf-route-static** command.

To configure a static multicast route:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a static multicast route.	ip rpf-route-static [vpn-instance <i>vpn-instance-name</i>] <i>source-address</i> { <i>mask</i> <i>mask-length</i> } [<i>protocol</i> [<i>process-id</i>]] [route-policy <i>policy-name</i>] { <i>rpf-nbr-address</i> <i>interface-type</i> <i>interface-number</i> } [preference <i>preference</i>] [order <i>order-number</i>]	No static multicast route configured by default.
3. Delete static multicast routes.	delete ip rpf-route-static [vpn-instance <i>vpn-instance-name</i>]	Optional.

! IMPORTANT:

When you configure a static multicast route, you cannot specify an RPF neighbor by providing the type and number (*interface-type interface-number*) of the interface if the interface of the RPF neighbor is a Layer 3 Ethernet interface, Layer 3 aggregate interface, Loopback interface, or VLAN interface. Instead, you can specify such an RPF neighbor only by its address (*rpf-nbr-address*).

Configuring a multicast routing policy

You can configure the router to determine the RPF route based on the longest match principle. For more information about RPF route selection, see "[RPF check process](#)."

By configuring per-source or per-source-and-group load splitting, you can optimize the traffic delivery when multiple data flows are handled.

Configuring a multicast routing policy for the public network

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the device to select the RPF route based on the longest match.	multicast longest-match	The route with the highest priority is selected as the RPF route by default.
3. Configure multicast load splitting.	multicast load-splitting { source source-group }	Optional. Disabled by default.

Configuring a multicast routing policy in a VPN instance

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure the device to select the RPF route based on the longest match.	multicast longest-match	The route with the highest priority is selected as the RPF route by default.
4. Configure multicast load splitting.	multicast load-splitting { source source-group }	Optional. Disabled by default.

Configuring a multicast forwarding range

Multicast packets do not travel without a boundary in a network. The multicast data corresponding to each multicast group must be transmitted within a definite scope.

You can configure a forwarding boundary specific to a particular multicast group on all interfaces that support multicast forwarding. A multicast forwarding boundary sets the boundary condition for the multicast groups in the specified range. If the destination address of a multicast packet matches the set boundary condition, the packet will not be forwarded. After you configure an interface as a multicast boundary, the interface can no longer forward multicast packets—including packets sent from the local device—or receive multicast packets.

To configure a multicast forwarding range:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure a multicast forwarding boundary.	multicast boundary <i>group-address</i> { <i>mask</i> <i>mask-length</i> }	No forwarding boundary by default.

Configuring the multicast forwarding table size

Configuration guidelines

The switch maintains the corresponding forwarding entry for each multicast packet that it receives. Excessive multicast routing entries, however, can exhaust the switch's memory and cause lower performance. You can set a limit on the number of entries in the multicast forwarding table based on the networking situation and the performance requirements. If the configured maximum number of multicast forwarding table entries is smaller than the current value, the forwarding entries in excess are not deleted immediately. Instead, the multicast routing protocol that runs on the switch deletes them. The switch no longer adds new multicast forwarding entries until the number of existing multicast forwarding entries comes down below the configured value.

When forwarding multicast traffic, the switch replicates a copy of the multicast traffic for each downstream node and forwards the traffic. Therefore, each of these downstream nodes forms a branch of the multicast distribution tree. You can configure the maximum number of downstream nodes (the

maximum number of outgoing interfaces), for a single entry in the multicast forwarding table to lessen the burden on the switch for replicating multicast traffic. If the configured maximum number of downstream nodes for a single multicast forwarding entry is smaller than the current number, the downstream nodes in excess are not deleted immediately. Instead, the multicast routing protocol that runs on the switch deletes them. The switch no longer adds new multicast forwarding entries for newly added downstream nodes until the number of existing downstream nodes comes down below the configured value.

Configuration procedure

To configure the multicast forwarding table size for the public network:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the maximum number of entries in the multicast forwarding table.	multicast forwarding-table route-limit <i>limit</i>	Optional. 2000 by default.
3. Configure the maximum number of downstream nodes for a single multicast forwarding entry.	multicast forwarding-table downstream-limit <i>limit</i>	Optional. 128 by default.

To configure the multicast forwarding table size in a VPN instance:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure the maximum number of entries in the multicast forwarding table.	multicast forwarding-table route-limit <i>limit</i>	Optional. 2000 by default.
4. Configure the maximum number of downstream nodes for a single route in the multicast forwarding table.	multicast forwarding-table downstream-limit <i>limit</i>	Optional. 128 by default.

Tracing a multicast path

You can run the **mtracert** command to trace the path down which the multicast traffic flows from a given first-hop router to the last-hop router.

To trace a multicast path:

Task	Command	Remarks
Trace a multicast path.	mtracert <i>source-address</i> [[<i>last-hop-router-address</i>] <i>group-address</i>]	Available in any view

Displaying and maintaining multicast routing and forwarding

Task	Command	Remarks
Display multicast boundary information.	display multicast [all-instance vpn-instance <i>vpn-instance-name</i>] boundary [<i>group-address</i> [<i>mask</i> <i>mask-length</i>]] [interface <i>interface-type</i> <i>interface-number</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display multicast forwarding table information.	display multicast [all-instance vpn-instance <i>vpn-instance-name</i>] forwarding-table [<i>source-address</i> [mask { <i>mask</i> <i>mask-length</i> }] <i>group-address</i> [mask { <i>mask</i> <i>mask-length</i> }]] incoming-interface { <i>interface-type</i> <i>interface-number</i> register } outgoing-interface { exclude include match } { <i>interface-type</i> <i>interface-number</i> register } statistics slot <i>slot-number</i>] * [port-info] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display the DF information of the multicast forwarding table .	display multicast [all-instance vpn-instance <i>vpn-instance-name</i>] forwarding-table df-info [<i>rp-address</i>] [slot <i>slot-number</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display information about the multicast routing table.	display multicast [all-instance vpn-instance <i>vpn-instance-name</i>] routing-table [<i>source-address</i> [mask { <i>mask</i> <i>mask-length</i> }] <i>group-address</i> [mask { <i>mask</i> <i>mask-length</i> }]] incoming-interface { <i>interface-type</i> <i>interface-number</i> register } outgoing-interface { exclude include match } { <i>interface-type</i> <i>interface-number</i> register }] * [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display information about the static multicast routing table.	display multicast routing-table [all-instance vpn-instance <i>vpn-instance-name</i>] static [<i>source-address</i> { <i>mask-length</i> <i>mask</i> }] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display RPF route information about the specified multicast source.	display multicast [all-instance vpn-instance <i>vpn-instance-name</i>] rpf-info <i>source-address</i> [<i>group-address</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Clear forwarding entries from the multicast forwarding table.	reset multicast [all-instance vpn-instance <i>vpn-instance-name</i>] forwarding-table { { <i>source-address</i> [mask { <i>mask</i> <i>mask-length</i> }] <i>group-address</i> [mask { <i>mask</i> <i>mask-length</i> }]] incoming-interface { <i>interface-type</i> <i>interface-number</i> register } } * all }	Available in user view
Clear routing entries from the multicast routing table.	reset multicast [all-instance vpn-instance <i>vpn-instance-name</i>] routing-table { { <i>source-address</i> [mask { <i>mask</i> <i>mask-length</i> }] <i>group-address</i> [mask { <i>mask</i> <i>mask-length</i> }]] incoming-interface { <i>interface-type</i> <i>interface-number</i> register } } * all }	Available in user view

! **IMPORTANT:**

The **reset** command clears the information in the multicast routing table or the multicast forwarding table, and thus might cause failure of multicast transmission.

When a routing entry is deleted from the multicast routing table, the corresponding forwarding entry is also deleted from the multicast forwarding table.

When a forwarding entry is deleted from the multicast forwarding table, the corresponding routing entry is also deleted from the multicast routing table.

For more information about designated forwarder (DF), see "[Configuring PIM \(available only on the HP 5500 EI\)](#)."

Configuration examples

Changing an RPF route

Network requirements

PIM-DM runs in the network. All switches in the network support multicast. Switch A, Switch B, and Switch C run OSPF. Typically, Receiver can receive the multicast data from Source through the path: Switch A to Switch B, which is the same as the unicast route.

Perform the following configuration so that Receiver can receive the multicast data from Source through the path: Switch A to Switch C to Switch B, which is different from the unicast route.

Figure 29 Network diagram

Configuration procedure

1. Configure IP addresses and unicast routing:
Configure the IP address and subnet mask for each interface as per [Figure 29](#). (Details not shown.)

Enable OSPF on the switches in the PIM-DM domain. Ensure the network-layer interoperability among the switches in the PIM-DM domain. Make sure that the switches can dynamically update their routing information by leveraging the unicast routing protocol. (Details not shown.)

2. Enable IP multicast routing, and enable PIM-DM and IGMP:

Enable IP multicast routing on Switch B, enable PIM-DM on each interface, and enable IGMP on VLAN-interface 100.

```
<SwitchB> system-view
[SwitchB] multicast routing-enable
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] igmp enable
[SwitchB-Vlan-interface100] pim dm
[SwitchB-Vlan-interface100] quit
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] pim dm
[SwitchB-Vlan-interface101] quit
[SwitchB] interface vlan-interface 102
[SwitchB-Vlan-interface102] pim dm
[SwitchB-Vlan-interface102] quit
```

Enable IP multicast routing on Switch A, and enable PIM-DM on each interface.

```
<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] pim dm
[SwitchA-Vlan-interface200] quit
[SwitchA] interface vlan-interface 102
[SwitchA-Vlan-interface102] pim dm
[SwitchA-Vlan-interface102] quit
[SwitchA] interface vlan-interface 103
[SwitchA-Vlan-interface103] pim dm
[SwitchA-Vlan-interface103] quit
```

The configuration on Switch C is similar to the configuration on Switch A. (Details not shown.)

Use the **display multicast rpf-info** command to view the RPF route to Source on Switch B.

```
[SwitchB] display multicast rpf-info 50.1.1.100
RPF information about source 50.1.1.100:
  RPF interface: Vlan-interface102, RPF neighbor: 30.1.1.2
  Referenced route/mask: 50.1.1.0/24
  Referenced route type: igp
  Route selection rule: preference-preferred
  Load splitting rule: disable
```

The output shows that the current RPF route on Switch B is contributed by a unicast routing protocol and the RPF neighbor is Switch A.

3. Configure a static multicast route:

Configure a static multicast route on Switch B, specifying Switch C as its RPF neighbor on the route to Source.

```
[SwitchB] ip rpf-route-static 50.1.1.100 24 20.1.1.2
```

4. Verify the configuration:

Use the **display multicast rpf-info** command to view the information about the RPF route to Source on Switch B.

```
[SwitchB] display multicast rpf-info 50.1.1.100
RPF information about source 50.1.1.100:
  RPF interface: Vlan-interface101, RPF neighbor: 20.1.1.2
  Referenced route/mask: 50.1.1.0/24
  Referenced route type: static multicast
  Route selection rule: preference-preferred
  Load splitting rule: disable
```

The output shows that the RPF route on Switch B has changed. It is now the configured static multicast route, and the RPF neighbor is now Switch C.

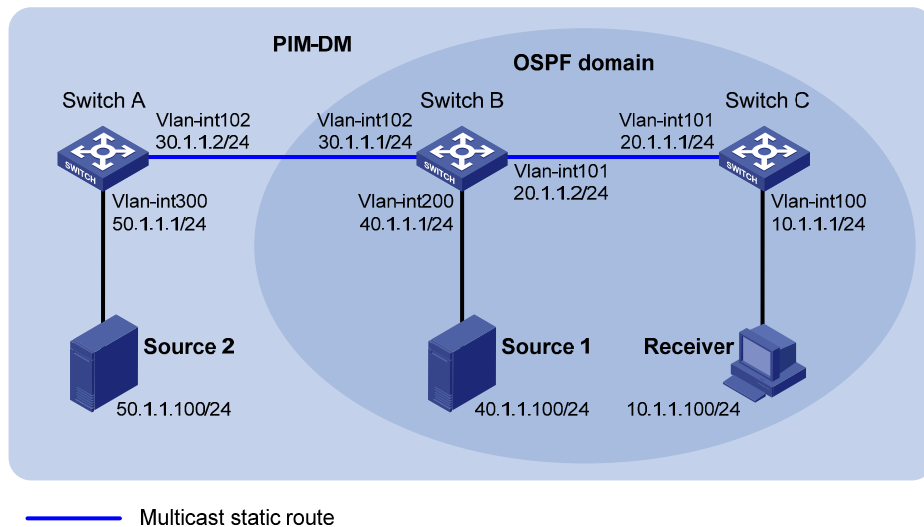

Creating an RPF route

Network requirements

PIM-DM runs in the network and all switches in the network support IP multicast. Switch B and Switch C run OSPF, and have no unicast routes to Switch A. Typically, Receiver can receive the multicast data from Source 1 in the OSPF domain.

Perform the following configuration so that Receiver can receive multicast data from Source 2, which is outside the OSPF domain.

Figure 30 Network diagram

Configuration procedure

1. Configure IP addresses and unicast routing:
Configure the IP address and subnet mask for each interface as per Figure 30. (Details not shown.)
Enable OSPF on Switch B and Switch C. Ensure the network-layer interoperation among Switch B and Switch C. Make sure that the switches can dynamically update their routing information by leveraging the unicast routing protocol. (Details not shown.)
2. Enable IP multicast routing, and enable PIM-DM and IGMP:
Enable IP multicast routing on Switch C, enable PIM-DM on each interface, and enable IGMP on VLAN-interface 100.

```

<SwitchC> system-view
[SwitchC] multicast routing-enable
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] igmp enable
[SwitchC-Vlan-interface100] pim dm
[SwitchC-Vlan-interface100] quit
[SwitchC] interface vlan-interface 101
[SwitchC-Vlan-interface101] pim dm
[SwitchC-Vlan-interface101] quit

```

Enable IP multicast routing on Switch A and enable PIM-DM on each interface.

```

<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 300
[SwitchA-Vlan-interface300] pim dm
[SwitchA-Vlan-interface300] quit
[SwitchA] interface vlan-interface 102
[SwitchA-Vlan-interface102] pim dm
[SwitchA-Vlan-interface102] quit

```

The configuration on Switch B is similar to that on Switch A. (Details not shown.)

Use the **display multicast rpf-info** command to view the RPF routes to Source 2 on Switch B and Switch C.

```

[SwitchB] display multicast rpf-info 50.1.1.100
[SwitchC] display multicast rpf-info 50.1.1.100

```

No information is displayed. This means that no RPF route to Source 2 exists on Switch B or Switch C.

3. Configure a static multicast route:

Configure a static multicast route on Switch B, specifying Switch A as its RPF neighbor on the route to Source 2.

```

[SwitchB] ip rpf-route-static 50.1.1.100 24 30.1.1.2

```

Configure a static multicast route on Switch C, specifying Switch B as its RPF neighbor on the route to Source 2.

```

[SwitchC] ip rpf-route-static 10.1.1.100 24 20.1.1.2

```

4. Verify the configuration:

Use the **display multicast rpf-info** command to view the RPF routes to Source 2 on Switch B and Switch C.

```

[SwitchB] display multicast rpf-info 50.1.1.100
RPF information about source 50.1.1.100:
  RPF interface: Vlan-interface102, RPF neighbor: 30.1.1.2
  Referenced route/mask: 50.1.1.0/24
  Referenced route type: static multicast
  Route selection rule: preference-preferred
  Load splitting rule: disable
[SwitchC] display multicast rpf-info 50.1.1.100
RPF information about source 50.1.1.100:
  RPF interface: Vlan-interface101, RPF neighbor: 20.1.1.2
  Referenced route/mask: 50.1.1.0/24
  Referenced route type: static multicast

```

```
Route selection rule: preference-preferred
Load splitting rule: disable
```

The output shows that the RPF routes to Source 2 exist on Switch B and Switch C. The routes are the configured static routes.

Troubleshooting multicast routing and forwarding

Static multicast route failure

Symptom

No dynamic routing protocol is enabled on the routers, and the physical status and link layer status of interfaces are both up, but the static multicast route fails.

Analysis

- If the static multicast route is not configured or updated correctly to match the current network conditions, the route entry and the configuration information of static multicast route do not exist in the multicast routing table.
- If a better route is found, the static multicast route might also fail.

Solution

1. Use the **display multicast routing-table static** command to view the information of static multicast routes to verify that the static multicast route has been correctly configured and that the route entry exists in the multicast routing table.
2. Check the type of the next hop interface of the static multicast route. If the interface is not a point-to-point interface, be sure to specify the next hop address for the outgoing interface when you configure the static multicast route.
3. Check that the static multicast route matches the specified routing protocol. If a protocol was specified in static multicast route configuration, enter the **display ip routing-table** command to check if an identical route was added by the protocol.
4. Check that the static multicast route matches the specified routing policy. If a routing policy was specified when the static multicast route was configured, enter the **display route-policy** command to check the configured routing policy.

Multicast data fails to reach receivers

Symptom

The multicast data can reach some routers but fails to reach the last-hop router.

Analysis

If a multicast forwarding boundary has been configured through the **multicast boundary** command, any multicast packet will be kept from crossing the boundary.

Solution

1. Use the **display pim routing-table** command to verify that the corresponding (S, G) entries exist on the router. If yes, the router has received the multicast data. Otherwise, the router has not received the data.

2. Use the **display multicast boundary** command to check the multicast boundary information on the interfaces. Use the **multicast boundary** command to change the multicast forwarding boundary setting.
3. In the case of PIM-SM, use the **display current-configuration** command to check the BSR and RP information.

Configuring IGMP (available only on the HP 5500 EI)

Overview

As a TCP/IP protocol responsible for IP multicast group member management, the Internet Group Management Protocol (IGMP) is used by IP hosts and adjacent multicast routers to establish and maintain their multicast group memberships.

The term "router" in this document refers to both routers and Layer 3 switches.

The term "interface" in the IGMP features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

IGMP versions

- IGMPv1 (defined in RFC 1112)
- IGMPv2 (defined in RFC 2236)
- IGMPv3 (defined in RFC 3376)

All IGMP versions support the Any-Source Multicast (ASM) model. In addition to the ASM model, IGMPv3 can directly implement the Source-Specific Multicast (SSM) model. IGMPv1 and IGMPv2 must work with the IGMP SSM mapping function to implement the SSM model.

For more information about the ASM and SSM models, see "[Multicast overview](#)."

Introduction to IGMPv1

IGMPv1 manages multicast group memberships mainly based on the query and response mechanism.

All multicast routers on the same subnet can receive IGMP membership report messages—often called "reports"—from hosts, but the subnet needs only one router for sending IGMP query messages—often called "queries". The querier election mechanism determines which router acts as the IGMP querier on the subnet.

In IGMPv1, the designated router (DR) elected by the working multicast routing protocol (such as PIM) serves as the IGMP querier.

For more information about DR, see "[Configuring PIM \(available only on the HP 5500 EI\)](#)"

Figure 31 IGMP queries and reports

Assume that Host B and Host C are interested in multicast data addressed to multicast group G1, and Host A is interested in multicast data addressed to G2, as shown in Figure 31. The following process describes how the hosts join the multicast groups and how the IGMP querier (Router B in the figure) maintains the multicast group memberships:

1. The hosts send unsolicited IGMP reports to the addresses of the multicast groups that they want to join, without having to wait for the IGMP queries from the IGMP querier.
2. The IGMP querier periodically multicasts IGMP queries (with the destination address of 224.0.0.1) to all hosts and routers on the local subnet.
3. After receiving a query message, Host B or Host C (the delay timer of whichever expires first) sends an IGMP report to the multicast group address of G1, to announce its membership for G1. Assume that Host B sends the report message. After receiving the report from Host B, Host C (which is on the same subnet as Host B) suppresses its own report for G1, because the IGMP routers (Router A and Router B) have already known that at least one host on the local subnet is interested in G1. This IGMP report suppression mechanism helps reduce traffic on the local subnet.
4. At the same time, because Host A is interested in G2, it sends a report to the multicast group address of G2.
5. Through the query/report process, the IGMP routers determine that members of G1 and G2 are attached to the local subnet, and the multicast routing protocol that is running on the routers (PIM, for example) generates (*, G1) and (*, G2) multicast forwarding entries. These entries will be the basis for subsequent multicast forwarding, where asterisk represents any multicast source.
6. When the multicast data addressed to G1 or G2 reaches an IGMP router, because the (*, G1) and (*, G2) multicast forwarding entries exist on the IGMP router, the router forwards the multicast data to the local subnet, and then the receivers on the subnet receive the data.

IGMPv1 does not specifically define a leave group message (often called a "leave message"). When an IGMPv1 host is leaving a multicast group, it stops sending reports to the address of the multicast group

that it listened to. If no member exists in a multicast group on the subnet, the IGMP router will not receive any report addressed to that multicast group. In this case, the router will delete the multicast forwarding entries for that multicast group after a period of time.

Enhancements in IGMPv2

Compared with IGMPv1, IGMPv2 has introduced a querier election mechanism and a leave-group mechanism.

Querier election mechanism

In IGMPv1, the DR elected by the Layer 3 multicast routing protocol (such as PIM) serves as the querier among multiple routers on the same subnet.

IGMPv2 introduced an independent querier election mechanism. The querier election process is as follows:

1. Initially, every IGMPv2 router assumes itself as the querier and sends IGMP general query messages (often called "general queries") to all hosts and routers on the local subnet. The destination address is 224.0.0.1.
2. After receiving a general query, every IGMPv2 router compares the source IP address of the query message with its own interface address. After comparison, the router with the lowest IP address wins the querier election, and all other IGMPv2 routers become non-queriers.
3. All the non-queriers start a timer, known as "other querier present timer". If a router receives an IGMP query from the querier before the timer expires, it resets this timer. Otherwise, it assumes the querier to have timed out and initiates a new querier election process.

"Leave group" mechanism

In IGMPv1, when a host leaves a multicast group, it does not send any notification to the multicast router. The multicast router relies on the host response timeout timer to determine whether a group has members. This adds to the leave latency.

In IGMPv2, when a host leaves a multicast group, the following steps occur:

1. This host sends a leave message to all routers on the local subnet. The destination address is 224.0.0.2.
2. After receiving the leave message, the querier sends a configurable number of group-specific queries to the group that the host is leaving. The destination address field and group address field of the message are both filled with the address of the multicast group that is being queried.
3. One of the remaining members (if any on the subnet) of the group that is being queried should send a membership report within the maximum response time set in the query messages.
4. If the querier receives a membership report for the group within the maximum response time, it will maintain the memberships of the group. Otherwise, the querier will assume that no hosts on the subnet are still interested in multicast traffic to that group and will stop maintaining the memberships of the group.

Enhancements in IGMPv3

IGMPv3 is based on and is compatible with IGMPv1 and IGMPv2. It provides hosts with enhanced control capabilities and provides enhancements of query and report messages.

Enhancements in control capability of hosts

IGMPv3 introduced two source filtering modes—Include and Exclude. These modes allow a host to join a designated multicast group and to choose whether to receive or reject multicast data from designated multicast sources. When a host joins a multicast group, one of the following situation occurs:

- If it needs to receive multicast data from specific sources like S1, S2, ..., it sends a report with the Filter-Mode denoted as "Include Sources (S1, S2, ...)".
- If it needs to reject multicast data from specific sources like S1, S2, ..., it sends a report with the Filter-Mode denoted as "Exclude Sources (S1, S2, ...)".

As shown in Figure 32, the network comprises two multicast sources, Source 1 (S1) and Source 2 (S2), both of which can send multicast data to multicast group G. Host B is only interested in the multicast data that Source 1 sends to G but not in the data from Source 2.

Figure 32 Flow paths of source-and-group-specific multicast traffic

In the case of IGMPv1 or IGMPv2, Host B cannot select multicast sources when it joins multicast group G. Therefore, multicast streams from both Source 1 and Source 2 will flow to Host B whether or not it needs them.

When IGMPv3 is running between the hosts and routers, Host B can explicitly express that it needs to receive the multicast data that Source 1 sends to multicast group G—denoted as (S1, G), rather than the multicast data that Source 2 sends to multicast group G—denoted as (S2, G). Thus, only multicast data from Source 1 will be delivered to Host B.

Enhancements in query and report capabilities

1. Query message carrying the source addresses

IGMPv3 supports not only general queries (feature of IGMPv1) and group-specific queries (feature of IGMPv2), but also group-and-source-specific queries.

- A general query does not carry a group address or a source address.
- A group-specific query carries a group address, but no source address.
- A group-and-source-specific query carries a group address and one or more source addresses.

2. Reports containing multiple group records

Unlike an IGMPv1 or IGMPv2 report message, an IGMPv3 report message is destined to 224.0.0.22 and contains one or more group records. Each group record contains a multicast group address and a multicast source address list.

Group records fall into the following categories:

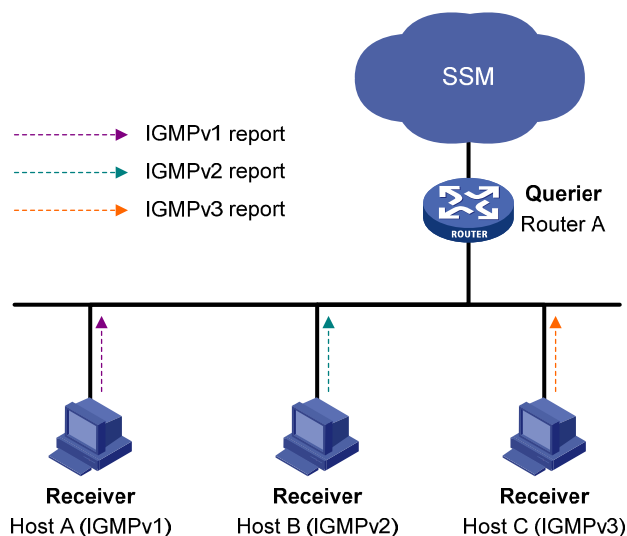

- **IS_IN**—The source filtering mode is Include. The report sender requests the multicast data from only the sources defined in the specified multicast source list.
- **IS_EX**—The source filtering mode is Exclude. The report sender requests the multicast data from any sources but those defined in the specified multicast source list.
- **TO_IN**—The filtering mode has changed from Exclude to Include.
- **TO_EX**—The filtering mode has changed from Include to Exclude.
- **ALLOW**—The Source Address fields in this group record contain a list of the additional sources that the system wants to obtain data from, for packets sent to the specified multicast address. If the change was to an Include source list, these sources are the addresses that were added to the list. If the change was to an Exclude source list, these sources are the addresses that were deleted from the list.
- **BLOCK**—The Source Address fields in this group record contain a list of the sources that the system no longer wants to obtain data from, for packets sent to the specified multicast address. If the change was to an Include source list, these sources are the addresses that were deleted from the list. If the change was to an Exclude source list, these sources are the addresses that were added to the list.

IGMP SSM mapping

The IGMP SSM mapping feature enables you to configure static IGMP SSM mappings on the last-hop router to provide SSM support for receiver hosts that are running IGMPv1 or IGMPv2. The SSM model assumes that the last-hop router has identified the desired multicast sources when receivers join multicast groups.

- When a host that is running IGMPv3 joins a multicast group, it can explicitly specify one or more multicast sources in its IGMPv3 report.
- A host that is running IGMPv1 or IGMPv2, however, cannot specify multicast source addresses in its report. In this case, you must configure the IGMP SSM mapping feature to translate the (*, G) information in the IGMPv1 or IGMPv2 report into (G, INCLUDE, (S1, S2...)) information.

Figure 33 Network diagram

As shown in [Figure 33](#), on an SSM network, Host A, Host B, and Host C are running IGMPv1, IGMPv2, and IGMPv3 respectively. To provide SSM service for all the hosts if IGMPv3 is not available on Host A and Host B, you must configure the IGMP SSM mapping feature on Router A.

With the IGMP SSM mapping feature configured, when Router A receives an IGMPv1 or IGMPv2 report, it checks the multicast group address *G* carried in the message and does the following:

- If *G* is not in the SSM group range, Router A cannot provide the SSM service but can provide the ASM service.
- If *G* is in the SSM group range but no IGMP SSM mappings that correspond to the multicast group *G* have been configured on Router A, Router A cannot provide SSM service and drops the message.
- If *G* is in the SSM group range and the IGMP SSM mappings have been configured on Router A for multicast group *G*, Router A translates the (*, *G*) information in the IGMP report into (*G*, INCLUDE, (S1, S2...)) information based on the configured IGMP SSM mappings and provides SSM service accordingly.

NOTE:

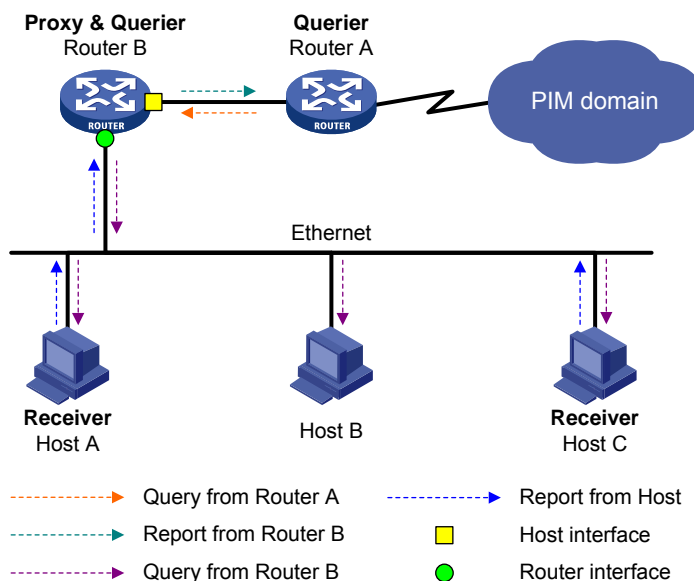

The IGMP SSM mapping feature does not process IGMPv3 reports.

For more information about the SSM group range, see "[Configuring PIM \(available only on the HP 5500 EI\)](#)"

IGMP proxying

In some simple tree-shaped topologies, it is not necessary to configure complex multicast routing protocols, such as PIM, on the boundary devices. Instead, you can configure IGMP proxying on these devices. With IGMP proxying configured, the device serves as a proxy for the downstream hosts to send IGMP messages, maintain group memberships, and implement multicast forwarding based on the memberships. In this case, each boundary device is a host but no longer a PIM neighbor to the upstream device.

Figure 34 Network diagram

As shown in [Figure 34](#), the following types of interfaces are defined on an IGMP proxy device:

- **Upstream interface**—Also called the "proxy interface". A proxy interface is an interface on which IGMP proxying is configured. It is in the direction toward the root of the multicast forwarding tree. An upstream interface acts as a host that is running IGMP. Therefore, it is also called the "host interface".
- **Downstream interface**—An interface that is running IGMP and is not in the direction toward the root of the multicast forwarding tree. A downstream interface acts as a router that is running IGMP. Therefore, it is also called the "router interface".

A device with IGMP proxying configured maintains a group membership database, which stores the group memberships on all the downstream interfaces. Each entry comprises the multicast address, filter mode, and source list. Such an entry is a collection of members in the same multicast group on each downstream interface.

A proxy device performs host functions on the upstream interface based on the database. It responds to queries according to the information in the database or sends join/leave messages when the database changes. On the other hand, the proxy device performs router functions on the downstream interfaces by participating in the querier election, sending queries, and maintaining memberships based on the reports.

IGMP support for VPNs

IGMP maintains group memberships on a per-interface base. After receiving an IGMP message on an interface, IGMP processes the packet within the VPN that the interface belongs to. If IGMP that runs in a VPN needs to exchange information with another multicast protocol, it passes the information only to the protocol that runs in this VPN.

Protocols and standards

- RFC 1112, *Host Extensions for IP Multicasting*
- RFC 2236, *Internet Group Management Protocol, Version 2*
- RFC 3376, *Internet Group Management Protocol, Version 3*
- RFC 4605, *Internet Group Management Protocol (IGMP)/Multicast Listener Discovery (MLD)-Based Multicast Forwarding ("IGMP/MLD Proxying")*

IGMP configuration task list

Task	Remarks	
Configuring basic IGMP functions	Enabling IGMP	Required
	Configuring IGMP versions	Optional
	Configuring static joining	Optional
	Configuring a multicast group filter	Optional
	Setting the maximum number of multicast groups that an interface can join	Optional
Adjusting IGMP performance	Configuring IGMP message options	Optional
	Configuring IGMP query and response parameters	Optional
	Configuring IGMP fast-leave processing	Optional

Task	Remarks	
	Enabling the IGMP host tracking function	Optional
	Setting the DSCP value for IGMP messages	Optional
Configuring IGMP SSM mapping	Enabling SSM mapping	Optional
	Configuring SSM mappings	Optional
Configuring IGMP proxying	Enabling IGMP proxying	Optional
	Configuring multicast forwarding on a downstream interface	Optional

For the configuration tasks in this section:

In IGMP view, the configuration is effective on all interfaces. In interface view, the configuration is effective on only the current interface.

If a feature is not configured on an interface in interface view, the global configuration in IGMP view will apply to that interface. If a feature is configured in both IGMP view and interface view, the configuration in interface view will be given priority.

Configuring basic IGMP functions

Configuration prerequisites

Before you configure basic IGMP functions, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Configure PIM-DM or PIM-SM.
- Determine the IGMP version.
- Determine the multicast group and multicast source addresses for static group member configuration.
- Determine the ACL rule for multicast group filtering.
- Determine the maximum number of multicast groups that an interface can join.

Enabling IGMP

To configure IGMP, you must enable IGMP on the interface for which the multicast group memberships will be established and maintained.

Enabling IGMP for the public network

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IP multicast routing.	multicast routing-enable	Disabled by default
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable IGMP.	igmp enable	Disabled by default

Enabling IGMP in a VPN instance

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VPN instance and enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure an RD for the VPN instance.	route-distinguisher <i>route-distinguisher</i>	No RD is configured by default.
4. Enable IP multicast routing.	multicast routing-enable	Disabled by default.
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Bind the interface with a VPN instance.	ip binding vpn-instance <i>vpn-instance-name</i>	By default, an interface belongs to the public network, and is not bound with any VPN instance.
7. Enable IGMP.	igmp enable	Disabled by default.

For more information about the **ip vpn-instance**, **route-distinguisher**, and **ip binding vpn-instance** commands, see *IP Routing Command Reference*.

For more information about the **multicast routing-enable** command, see *IP Multicast Command Reference*.

Configuring IGMP versions

Because the protocol packets of different IGMP versions vary in structure and type, you must configure the same IGMP version for all routers on the same subnet before IGMP can work properly.

Configuring an IGMP version globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network IGMP view or VPN instance IGMP view.	igmp [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure an IGMP version globally.	version <i>version-number</i>	IGMPv2 by default

Configuring an IGMP version on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an IGMP version on the interface.	igmp version <i>version-number</i>	IGMPv2 by default

Configuring static joining

Configuration guidelines

After an interface is configured as a static member of a multicast group or a multicast source group, it will act as a virtual member of the multicast group to receive multicast data addressed to that multicast group for the purpose of testing multicast data forwarding.

Before you can configure an interface of a PIM-SM switch as a static member of a multicast group or a multicast source and group, if the interface is PIM-SM enabled, it must be a PIM-SM DR. If the interface is enabled with IGMP but not with PIM-SM, it must be an IGMP querier. For more information about PIM-SM and DR, see "[Configuring PIM \(available only on the HP 5500 EI\)](#)"

A static member port does not respond to queries from the IGMP querier. When you configure a port as a static member port or remove this configuration on the port, the port does not unsolicitedly send any IGMP report or IGMP leave message. In other words, the port is not a real member of the multicast group or the multicast source and group.

Configuration procedure

To configure an interface as a statically connected member of a multicast group or a multicast source and group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the interface as a static member of a multicast group or a multicast source and group.	igmp static-group <i>group-address</i> [source <i>source-address</i>]	An interface is not a static member of any multicast group or multicast source and group by default.

Configuring a multicast group filter

To restrict the hosts on the network attached to an interface from joining certain multicast groups, you can set an ACL rule on the interface as a packet filter so that the interface maintains only the multicast groups the match the criteria.

To configure a multicast group filter:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure a multicast group filter.	igmp group-policy <i>acl-number</i> [<i>version-number</i>]	By default, no multicast group filter is configured on an interface, and hosts on an interface can join any valid multicast group.

Setting the maximum number of multicast groups that an interface can join

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the maximum number of multicast groups that the interface can join.	igmp group-limit <i>limit</i>	2000 by default.

NOTE:

This configuration takes effect for dynamically joined multicast groups but not for statically configured multicast groups.

Adjusting IGMP performance

For the configuration tasks described in this section:

- The configuration in IGMP view is effective on all interfaces, whereas the configuration in interface view is effective only on the current interface.
- If the same feature is configured in both IGMP view and interface view, the configuration in interface view is given priority, regardless of the configuration sequence.

Configuration prerequisites

Before adjusting IGMP performance, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Configure basic IGMP functions.
- Determine the startup query interval.
- Determine the startup query count.
- Determine the IGMP general query interval.
- Determine the IGMP querier's robustness variable.
- Determine the maximum response time for IGMP general queries.
- Determine the IGMP last-member query interval.
- Determine the other querier present interval.
- Determine the DSCP value for IGMP messages.

Configuring IGMP message options

IGMP queries include group-specific queries and group-and-source-specific queries, and multicast groups change dynamically, so a device cannot maintain the information for all multicast sources and groups. For this reason, when an IGMP router receives a multicast packet but cannot locate the outgoing

interface for the destination multicast group, it must use the Router-Alert option to pass the multicast packet to the upper-layer protocol for processing. For more information about the Router-Alert option, see RFC 2113.

An IGMP message is processed differently depending on whether it carries the Router-Alert option in the IP header:

- By default, for the consideration of compatibility, the switch does not verify the Router-Alert option but processes all the IGMP messages that it received. In this case, IGMP messages are directly passed to the upper-layer protocol, whether or not the IGMP messages carry the Router-Alert option.
- To enhance the switch performance and avoid unnecessary costs, and also for the consideration of protocol security, you can configure the switch to discard IGMP messages that do not carry the Router-Alert option.

Configuring IGMP packet options globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network IGMP view or VPN instance IGMP view.	igmp [<i>vpn-instance</i> <i>vpn-instance-name</i>]	N/A
3. Configure the router to discard any IGMP message that does not carry the Router-Alert option.	require-router-alert	By default, the switch does not check the Router-Alert option.
4. Enable insertion of the Router-Alert option into IGMP messages.	send-router-alert	By default, IGMP messages carry the Router-Alert option.

Configuring IGMP packet options on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the interface to discard any IGMP message that does not carry the Router-Alert option.	igmp require-router-alert	By default, the switch does not check the Router-Alert option.
4. Enable insertion of the Router-Alert option into IGMP messages.	igmp send-router-alert	By default, IGMP messages carry the Router-Alert option.

Configuring IGMP query and response parameters

IGMP query and response parameters

On startup, the IGMP querier sends IGMP general queries at the startup query interval, which is one-quarter of the IGMP general query interval. The number of queries, or the startup query count, is user configurable.

After startup, the IGMP querier periodically sends IGMP general queries at the IGMP general query interval to check for multicast group members on the network. You can modify the IGMP general query interval based on actual condition of the network.

The IGMPv2 querier sends IGMP group-specific queries at the IGMP last-member query interval when it receives an IGMP leave message. The IGMPv3 querier sends IGMP group-and-source-specific queries at the IGMP last-member query interval when it receives a multicast group and multicast mapping change report. The number of queries, or the last-member query count, equals the robustness variable—the maximum number of packet retransmissions.

A multicast listening host starts a delay timer for each multicast group it has joined when it receives an IGMP query (general query, group-specific query, or group-and-source-specific query). The timer is initialized to a random value in the range of 0 to the maximum response time derived in the IGMP query. When the timer value decreases to 0, the host sends an IGMP report to the corresponding multicast group.

Configuration guidelines

To speed up the response of hosts to IGMP queries and avoid simultaneous timer expirations causing IGMP report traffic bursts, you must properly set the maximum response time.

- For IGMP general queries, the maximum response time is set by the **max-response-time** command.
- For IGMP group-specific queries and IGMP group-and-source-specific queries, the maximum response time equals the IGMP last-member query interval.

When multiple multicast routers exist on the same subnet, the IGMP querier is responsible for sending IGMP queries. If a non-querier router receives no IGMP query from the querier when the other querier present interval expires, it considers that the querier as having failed and starts a new querier election. Otherwise, the non-querier router resets the other querier present timer.

In the configuration, make sure that the other querier present interval is greater than the IGMP general query interval. Otherwise, the IGMP querier might change frequently on the network.

Also make sure that the IGMP general query interval is greater than the maximum response time for IGMP general queries. Otherwise, multicast group members might be wrongly removed.

The configurations of the maximum response time for IGMP general queries, the IGMP last-member query interval and the IGMP other querier present interval are effective only for IGMPv2 and IGMPv3.

Configuration procedure

To configure IGMP query and response parameters globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network IGMP view or VPN instance IGMP view.	igmp [vpn-instance vpn-instance-name]	N/A
3. Configure the IGMP querier's robustness variable.	robust-count <i>robust-value</i>	2 by default.
4. Configure the startup query interval.	startup-query-interval <i>interval</i>	By default, the startup query interval is 1/4 of the "IGMP general query interval."
5. Configure the startup query count.	startup-query-count <i>value</i>	By default, the startup query count is set to the IGMP querier's robustness variable.

Step	Command	Remarks
6. Configure the IGMP general query interval.	timer query <i>interval</i>	60 seconds by default.
7. Configure the maximum response time for IGMP general queries.	max-response-time <i>interval</i>	10 seconds by default.
8. Configure the IGMP last-member query interval.	last-member-query-interval <i>interval</i>	1 second by default.
9. Configure the other querier present interval.	timer other-querier-present <i>interval</i>	By default, the other querier present interval is [IGMP general query interval] × [IGMP robustness variable] + [maximum response time for IGMP general queries] / 2.

To configure IGMP query and response parameters on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the IGMP querier's robustness variable.	igmp robust-count <i>robust-value</i>	2 by default.
4. Configure the startup query interval.	igmp startup-query-interval <i>interval</i>	By default, the startup query interval is 1/4 of the "IGMP general query interval."
5. Configure the startup query count.	igmp startup-query-count <i>value</i>	By default, the startup query count is set to the IGMP querier's robustness variable.
6. Configure the IGMP general query interval.	igmp timer query <i>interval</i>	60 seconds by default.
7. Configure the maximum response time for IGMP general queries.	igmp max-response-time <i>interval</i>	10 seconds by default.
8. Configure the IGMP last-member query interval.	igmp last-member-query-interval <i>interval</i>	1 second by default
9. Configure the other querier present interval.	igmp timer other-querier-present <i>interval</i>	By default, the other querier present interval is [IGMP general query interval] × [IGMP robustness variable] + [maximum response time for IGMP general queries] / 2.

Configuring IGMP fast-leave processing

In some applications, such as ADSL dial-up networking, only one multicast receiver host is attached to a port of the IGMP querier. To allow fast response to the leave messages of the host when it switches

frequently from one multicast group to another, you can enable IGMP fast-leave processing on the IGMP querier.

With fast-leave processing enabled, after receiving an IGMP leave message from a host, the IGMP querier directly sends a leave notification to the upstream without sending IGMP group-specific queries or IGMP group-and-source-specific queries. Thus, the leave latency is reduced on one hand, and the network bandwidth is saved on the other hand.

Configuring IGMP fast-leave processing globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network IGMP view or VPN instance IGMP view.	igmp [vpn-instance vpn-instance-name]	N/A
3. Configure IGMP fast-leave processing.	fast-leave [group-policy acl-number]	Disabled by default

Configuring IGMP fast-leave processing on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface interface-type interface-number	N/A
3. Configure IGMP fast-leave processing.	igmp fast-leave [group-policy acl-number]	Disabled by default

NOTE:

- The IGMP fast-leave processing configuration is effective only if the switch is running IGMPv2 or IGMPv3.
- The IGMP fast-leave processing configuration is effective on Layer 3 interfaces other than VLAN interfaces, including Layer 3 Ethernet ports, Layer 3 aggregate interfaces, and Tunnel interfaces.

Enabling the IGMP host tracking function

With the IGMP host tracking function, the switch can record the information of the member hosts that are receiving multicast traffic, including the host IP address, running duration, and timeout time. You can monitor and manage the member hosts according to the recorded information.

Enabling the IGMP host tracking function globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network IGMP view/VPN instance IGMP view.	igmp [vpn-instance vpn-instance-name]	N/A

Step	Command	Remarks
3.	Enable the IGMP host tracking function globally. host-tracking	Disabled by default

Enabling the IGMP host tracking function on an interface

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter interface view. interface <i>interface-type</i> <i>interface-number</i>	N/A
3.	Enable the IGMP host tracking function on the interface. igmp host-tracking	Disabled by default

Setting the DSCP value for IGMP messages

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter public network IGMP view or VPN instance IGMP view. igmp [vpn-instance <i>vpn-instance-name</i>]	N/A
3.	Set the DSCP value for IGMP messages. dscp <i>dscp-value</i>	Optional By default, the DSCP value in IGMP messages is 48.

Configuring IGMP SSM mapping

Because of some possible restrictions, some receiver hosts on an SSM network might run IGMPv1 or IGMPv2. To provide SSM service support for these receiver hosts, configure the IGMP mapping feature on the last-hop router.

Before you configure the IGMP SSM mapping feature, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Configure basic IGMP functions.

Enabling SSM mapping

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter interface view. interface <i>interface-type</i> <i>interface-number</i>	N/A
3.	Enable the IGMP SSM mapping feature. igmp ssm-mapping enable	Disabled by default

NOTE:

To ensure SSM service for all hosts on a subnet, regardless of the IGMP version running on the hosts, enable IGMPv3 on the interface that forwards multicast traffic onto the subnet.

Configuring SSM mappings

By performing this configuration multiple times, you can map a multicast group to different multicast sources.

If IGMPv3 is enabled on a VLAN interface of a switch, and if a port in that VLAN is configured as a simulated host, the simulated host will send IGMPv3 reports even if you did not specify a multicast source when you configure simulated joining with the **igmp-snooping host-join** command. In this case, the corresponding multicast group will not be created based on the configured IGMP SSM mappings. For more information about the **igmp-snooping host-join** command, see *IP Multicast Command Reference*.

To configure an IGMP SSM mapping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network IGMP view or VPN instance IGMP view.	igmp [vpn-instance vpn-instance-name]	N/A
3. Configure an IGMP SSM mapping.	ssm-mapping group-address { mask mask-length } source-address	No IGMP mappings are configured by default.

Configuring IGMP proxying

Configuration prerequisites

Before you configure the IGMP proxying feature, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Enable IP multicast routing.

Enabling IGMP proxying

You can enable IGMP proxying on the interface in the direction toward the root of the multicast forwarding tree to make the switch serve as an IGMP proxy.

Configuration guidelines

Each switch can have only one interface serving as the proxy interface. In scenarios with multiple instances, IGMP proxying is configured on only one interface per instance.

You cannot enable IGMP on an interface with IGMP proxying enabled. Moreover, only the **igmp require-router-alert**, **igmp send-router-alert**, and **igmp version** commands can take effect on such an interface.

You cannot enable other multicast routing protocols (such as PIM-DM or PIM-SM) on an interface with IGMP proxying enabled, or vice versa. However, the **source-lifetime**, **source-policy**, and **ssm-policy**

commands configured in PIM view can still take effect. In addition, in IGMPv1, the designated router (DR) is elected by the working multicast routing protocol (such as PIM) to serve as the IGMP querier. Therefore, a downstream interface running IGMPv1 cannot be elected as the DR and thus cannot serve as the IGMP querier.

You cannot enable IGMP proxying on a VLAN interface with IGMP snooping enabled, or vice versa.

Configuration procedure

To enable IGMP proxying:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the IGMP proxying feature.	igmp proxying enable	Disabled by default

Configuring multicast forwarding on a downstream interface

Only queriers can forward multicast traffic but non-queriers have no multicast forwarding capabilities. This design helps avoid duplicate multicast flows. It is the same on IGMP proxy switches. Only the downstream interfaces acting as a querier can forward multicast traffic to downstream hosts.

However, when a downstream interface of a proxy switch fails to win the querier election, you must enable multicast forwarding on this interface.

ⓘ IMPORTANT:

On a multi-access network with more than one IGMP proxy switch, you cannot enable multicast forwarding on any other non-querier downstream interface after one of the downstream interfaces of these IGMP proxy switches has been elected as the querier. Otherwise, duplicate multicast flows might be received on the multi-access network.

To enable multicast forwarding on a downstream interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable multicast forwarding on a non-querier downstream interface.	igmp proxying forwarding	Disabled by default

Displaying and maintaining IGMP

Task	Command	
Display IGMP group information.	display igmp [all-instance vpn-instance <i>vpn-instance-name</i>] group [<i>group-address</i> interface <i>interface-type interface-number</i>] [static verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the Layer 2 port information of IGMP groups.	display igmp group port-info [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the hosts tracked by IGMP on an interface.	display igmp host interface <i>interface-type interface-number</i> group <i>group-address</i> [source <i>source-address</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the hosts tracked by IGMP on the Layer 2 ports.	display igmp host port-info vlan <i>vlan-id</i> group <i>group-address</i> [source <i>source-address</i>] [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IGMP configuration and operation information.	display igmp [all-instance vpn-instance <i>vpn-instance-name</i>] interface [<i>interface-type interface-number</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information of IGMP proxying groups.	display igmp [all-instance vpn-instance <i>vpn-instance-name</i>] proxying group [<i>group-address</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information in the IGMP routing table.	display igmp [all-instance vpn-instance <i>vpn-instance-name</i>] routing-table [<i>source-address</i> [mask { <i>mask</i> <i>mask-length</i> }] <i>group-address</i> [mask { <i>mask</i> <i>mask-length</i> }] flags { act suc }] * [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IGMP SSM mappings.	display igmp [all-instance vpn-instance <i>vpn-instance-name</i>] ssm-mapping <i>group-address</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	
Display the multicast group information created from IGMPv1 and IGMPv2 reports based on the configured IGMP SSM mappings.	display igmp [all-instance vpn-instance <i>vpn-instance-name</i>] ssm-mapping group [<i>group-address</i> interface <i>interface-type interface-number</i>] [verbose] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display information about the hosts that join the group based on IGMP SSM mappings on an interface.	display igmp ssm-mapping host interface <i>interface-type interface-number</i> group <i>group-address</i> source <i>source-address</i> [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Remove all the dynamic IGMP group entries of IGMP groups.	reset igmp [all-instance vpn-instance <i>vpn-instance-name</i>] group { all interface <i>interface-type interface-number</i> } { all <i>group-address</i> [mask { <i>mask</i> <i>mask-length</i> }] [<i>source-address</i> [mask { <i>mask</i> <i>mask-length</i> }]] }	Available in user view
Remove all the dynamic Layer 2 port entries of IGMP groups.	reset igmp group port-info { all <i>group-address</i> } [vlan <i>vlan-id</i>]	Available in user view
Clear IGMP SSM mappings.	reset igmp [all-instance vpn-instance <i>vpn-instance-name</i>] ssm-mapping group { all interface <i>interface-type interface-number</i> } { all <i>group-address</i> [mask { <i>mask</i> <i>mask-length</i> }] [<i>source-address</i> [mask { <i>mask</i> <i>mask-length</i> }]] }	Available in user view

! **IMPORTANT:**

The **reset igmp group** command might cause an interruption of receivers' reception of multicast data.

The **reset igmp group** command cannot remove static IGMP group entries.

The **display igmp host interface** command can display information about the hosts tracked by IGMP on Layer 3 interfaces other than VLAN interfaces.

The **display igmp ssm-mapping host interface** command can display information about the hosts that join the group based on IGMP SSM mappings on Layer 3 interfaces other than VLAN interfaces.

IGMP configuration examples

Basic IGMP functions configuration example

Network requirements

Receivers receive VOD information through multicast. Receivers of different organizations form stub networks N1 and N2, and Host A and Host C are receivers in N1 and N2 respectively.

IGMPv2 runs between Switch A and N1. IGMPv2 runs between the other two switches and N2. Switch B acts as the IGMP querier in N2 because it has a lower IP address.

The hosts in N1 can join only multicast group 224.1.1.1, and the hosts in N2 can join any multicast groups.

Figure 35 Network diagram

Configuration procedure

1. Configure IP addresses and unicast routing:
 - # Configure the IP address and subnet mask of each interface as per Figure 35. (Details not shown.)
 - # Configure the OSPF protocol for interoperation on the PIM network. Ensure the network-layer interoperation on the PIM network and dynamic update of routing information among the switches through a unicast routing protocol. (Details not shown.)
2. Enable IP multicast routing, and enable PIM-DM and IGMP:
 - # Enable IP multicast routing on Switch A, enable PIM-DM on each interface, and enable IGMP on VLAN-interface 100.

```
<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] igmp enable
```

3. Configure a multicast group filter:

Configure a multicast group filter on Switch A, so that the hosts connected to VLAN-interface 100 can join only multicast group 224.1.1.1.

```
[SwitchA] acl number 2001
[SwitchA-acl-basic-2001] rule permit source 224.1.1.1 0
[SwitchA-acl-basic-2001] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] igmp group-policy 2001
[SwitchA-Vlan-interface100] quit
```

4. Verify the configuration:

Display IGMP information on VLAN-interface 200 of Switch B.

```
[SwitchB] display igmp interface vlan-interface 200
Vlan-interface200(10.110.2.1):
  IGMP is enabled
  Current IGMP version is 2
  Value of query interval for IGMP(in seconds): 60
  Value of other querier present interval for IGMP(in seconds): 125
  Value of maximum query response time for IGMP(in seconds): 10
  Querier for IGMP: 10.110.2.1 (this router)
Total 1 IGMP Group reported
```

SSM mapping configuration example

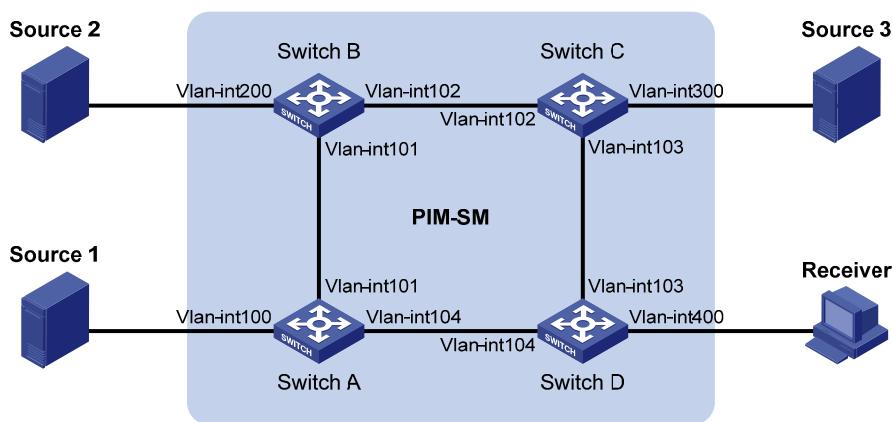

Network requirements

The PIM-SM domain applies both the ASM model and SSM model for multicast delivery. Switch D's VLAN-interface 104 serves as the C-BSR and C-RP. The SSM group range is 232.1.1.0/24.

IGMPv3 runs on Switch D's VLAN-interface 400. The receiver host runs IGMPv2, and does not support IGMPv3. Therefore, the Receiver host cannot specify expected multicast sources in its membership reports.

Source 1, Source 2, and Source 3 send multicast packets to multicast groups in the SSM group range. You can configure the IGMP SSM mapping feature on Switch D so that the receiver host will receive multicast data from Source 1 and Source 3 only.

Figure 36 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Source 1	—	133.133.1.1/24	Source 3	—	133.133.3.1/24
Source 2	—	133.133.2.1/24	Receiver	—	133.133.4.1/24
Switch A	Vlan-int100	133.133.1.2/24	Switch C	Vlan-int300	133.133.3.2/24
	Vlan-int101	192.168.1.1/24		Vlan-int103	192.168.3.1/24
	Vlan-int104	192.168.4.2/24		Vlan-int102	192.168.2.2/24
Switch B	Vlan-int200	133.133.2.2/24	Switch D	Vlan-int400	133.133.4.2/24
	Vlan-int101	192.168.1.2/24		Vlan-int103	192.168.3.2/24
	Vlan-int102	192.168.2.1/24		Vlan-int104	192.168.4.1/24

Configuration procedure

1. Configure IP addresses and unicast routing:
 - # Configure the IP address and subnet mask of each interface as per Figure 36. (Details not shown.)
 - # Configure OSPF for interoperability among the switches. Ensure the network-layer interoperation on the PIM-SM domain and dynamic update of routing information among the switches through a unicast routing protocol. (Details not shown.)
2. Enable IP multicast routing, enable PIM-SM on each interface, and enable IGMP and IGMP SSM mapping on the host-side interface:
 - # Enable IP multicast routing on Switch D, enable PIM-SM on each interface, and enable IGMPv3 and IGMP SSM mapping on VLAN-interface 400.

```

<SwitchD> system-view
[SwitchD] multicast routing-enable
[SwitchD] interface vlan-interface 400
[SwitchD-Vlan-interface400] igmp enable
[SwitchD-Vlan-interface400] igmp version 3
[SwitchD-Vlan-interface400] igmp ssm-mapping enable
[SwitchD-Vlan-interface400] pim sm
[SwitchD-Vlan-interface400] quit
[SwitchD] interface vlan-interface 103
[SwitchD-Vlan-interface103] pim sm
[SwitchD-Vlan-interface103] quit
[SwitchD] interface vlan-interface 104
[SwitchD-Vlan-interface104] pim sm
[SwitchD-Vlan-interface104] quit

```

Enable IP multicast routing on Switch A, and enable PIM-SM on each interface.

```

<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim sm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface vlan-interface 104
[SwitchA-Vlan-interface104] pim sm
[SwitchA-Vlan-interface104] quit

```

The configuration on Switch B and Switch C is similar to that on Switch A.

3. Configure a C-BSR and a C-RP:

Configure C-BSR and C-RP interfaces on Switch D.

```

[SwitchD] pim
[SwitchD-pim] c-bsr vlan-interface 104
[SwitchD-pim] c-rp vlan-interface 104
[SwitchD-pim] quit

```

4. Configure the SSM group range:

Configure the SSM group range 232.1.1.0/24 on Switch D.

```

[SwitchD] acl number 2000
[SwitchD-acl-basic-2000] rule permit source 232.1.1.0 0.0.0.255
[SwitchD-acl-basic-2000] quit
[SwitchD] pim
[SwitchD-pim] ssm-policy 2000
[SwitchD-pim] quit

```

The configuration on Switch A, Switch B and Switch C is similar to that on Switch D.

5. Configure IGMP SSM mappings:

Configure IGMP SSM mappings on Switch D.

```

[SwitchD] igmp
[SwitchD-igmp] ssm-mapping 232.1.1.0 24 133.133.1.1

```

```
[SwitchD-igmp] ssm-mapping 232.1.1.0 24 133.133.3.1
[SwitchD-igmp] quit
```

6. Verify the configuration:

Display the IGMP SSM mapping information for multicast group 232.1.1.1 on Switch D.

```
[SwitchD] display igmp ssm-mapping 232.1.1.1
Vpn-Instance: public net
Group: 232.1.1.1
Source list:
    133.133.1.1
    133.133.3.1
```

Display the IGMP group information created based on the IGMP SSM mappings on Switch D.

```
[SwitchD] display igmp ssm-mapping group
Total 1 IGMP SSM-mapping Group(s).
Interface group report information of VPN-Instance: public net
Vlan-interface400(133.133.4.2):
  Total 1 IGMP SSM-mapping Group reported
  Group Address      Last Reporter  Uptime      Expires
  232.1.1.1         133.133.4.1   00:02:04    off
```

Display PIM routing table information on Switch D.

```
[SwitchD] display pim routing-table
Vpn-instance: public net
Total 0 (*, G) entry; 2 (S, G) entry
```

```

IGMP proxying configuration example

Network requirements

PIM-DM is required to run on the core network. Host A and Host C in the stub network receive VOD information destined to multicast group 224.1.1.1.

Configure the IGMP proxying feature on Switch B so that Switch B can maintain group memberships and forward multicast traffic without running PIM-DM.

Figure 37 Network diagram

Configuration procedure

1. Configure IP addresses:

Configure the IP address and subnet mask of each interface as per Figure 37. (Details not shown.)

2. Enable IP multicast routing, PIM-DM, IGMP, and IGMP proxying:

Enable IP multicast routing on Switch A, PIM-DM on VLAN-interface 101, and IGMP on VLAN-interface 100.

```
<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim dm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] igmp enable
[SwitchA-Vlan-interface100] pim dm
[SwitchA-Vlan-interface100] quit
```

Enable IP multicast routing on Switch B, IGMP Proxying on VLAN-interface 100, and IGMP on VLAN-interface 200.

```
<SwitchB> system-view
[SwitchB] multicast routing-enable
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] igmp proxying enable
[SwitchB-Vlan-interface100] quit
[SwitchB] interface vlan-interface 200
```

```
[SwitchB-Vlan-interface200] igmp enable
[SwitchB-Vlan-interface200] quit
```

3. Verify the configuration:

Display IGMP information on VLAN-interface 100 of Switch B.

```
[SwitchB] display igmp interface vlan-interface 100 verbose
Vlan-interface100(192.168.1.2):
  IGMP proxy is enabled
  Current IGMP version is 2
  Multicast routing on this interface: enabled
  Require-router-alert: disabled
  Version1-querier-present-timer-expiry: 00:00:20
```

Display IGMP group information on Switch A.

```
[SwitchA] display igmp group
Total 1 IGMP Group(s).
Interface group report information of VPN-Instance: public net
Vlan-interface100(192.168.1.1):
  Total 1 IGMP Groups reported
  Group Address      Last Reporter      Uptime             Expires
  224.1.1.1          192.168.1.2       00:02:04           00:01:15
```

The output shows that IGMP reports from the hosts are forwarded to Switch A through the proxy interface, VLAN-interface 100 on Switch B.

Troubleshooting IGMP

No membership information on the receiver-side router

Symptom

When a host sends a report for joining multicast group G, no membership information of the multicast group G exists on the router closest to that host.

Analysis

- The correctness of networking and interface connections and whether the protocol layer of the interface is up directly affect the generation of group membership information.
- Multicast routing must be enabled on the router, and IGMP must be enabled on the interface connecting to the host.
- If the IGMP version on the router interface is lower than that on the host, the router will not be able to recognize the IGMP report from the host.
- If the **igmp group-policy** command has been configured on the interface, the interface cannot receive report messages that fail to pass filtering.

Solution

1. Use the **display igmp interface** command to verify that the networking, interface connection, and IP address configuration are correct. If no information is output, the interface is in an abnormal state. The reason is that you have configured the **shutdown** command on the interface, the interface is not properly connected, or the IP address configuration is not correct.

2. Check that . Use the **display current-configuration** command to verify that multicast routing is enabled. If not, carry out the **multicast routing-enable** command in system view to enable IP multicast routing. In addition, check that IGMP is enabled on the corresponding interfaces.
3. Use the **display igmp interface** command to verify that the IGMP version on the interface is lower than that on the host.
4. Use the **display current-configuration interface** command to verify that no ACL rule has been configured to restrict the host from joining the multicast group G. If the host is restricted from joining the multicast group G, the ACL rule must be modified to allow receiving the reports for the multicast group G.

Inconsistent memberships on routers on the same subnet

Symptom

Different memberships are maintained on different IGMP routers on the same subnet.

Analysis

- A router running IGMP maintains multiple parameters for each interface, and these parameters influence one another, forming very complicated relationships. Inconsistent IGMP interface parameter configurations for routers on the same subnet will surely result in inconsistency of memberships.
- In addition, although an IGMP router is compatible with a host that is running a different version of IGMP, all routers on the same subnet must run the same version of IGMP. Inconsistent IGMP versions running on routers on the same subnet also leads to inconsistency of IGMP memberships.

Solution

1. Use the **display current-configuration** command to verify the IGMP configuration information on the interfaces.
2. Use the **display igmp interface** command on all routers on the same subnet to verify the IGMP-related timer settings. The settings should be consistent on all the routers.
3. Use the **display igmp interface** command to verify that all the routers on the same subnet are running the same version of IGMP.

Configuring PIM (available only on the HP 5500 EI)

PIM overview

Protocol Independent Multicast (PIM) provides IP multicast forwarding by leveraging unicast static routes or unicast routing tables generated by any unicast routing protocol, such as routing information protocol (RIP), open shortest path first (OSPF), intermediate system to intermediate system (IS-IS), or border gateway protocol (BGP). Independent of the unicast routing protocols running on the device, multicast routing can be implemented as long as the corresponding multicast routing entries are created through unicast routes. PIM uses the reverse path forwarding (RPF) mechanism to implement multicast forwarding. When a multicast packet arrives on an interface of the device, it undergoes an RPF check. If the RPF check succeeds, the device creates the corresponding routing entry and forwards the packet. If the RPF check fails, the device discards the packet. For more information about RPF, see "[Configuring multicast routing and forwarding \(available only on the HP 5500 EI\)](#)."

Based on the implementation mechanism, PIM falls into the following categories:

- Protocol Independent Multicast–Dense Mode (PIM-DM)
- Protocol Independent Multicast–Sparse Mode (PIM-SM)
- Bidirectional Protocol Independent Multicast (BIDIR-PIM)
- Protocol Independent Multicast Source-Specific Multicast (PIM-SSM)

The term "router" in this document refers to both routers and Layer 3 switches.

The term "interface" in the PIM features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

PIM-DM overview

PIM-DM is a type of dense mode multicast protocol. It uses the push mode for multicast forwarding, and is suitable for small-sized networks with densely distributed multicast members.

The basic implementation of PIM-DM is as follows:

- PIM-DM assumes that at least one multicast group member exists on each subnet of a network. Therefore, multicast data is flooded to all nodes on the network. Then, branches without multicast forwarding are pruned from the forwarding tree, leaving only those branches that contain receivers. This flood-and-prune process takes place periodically. Pruned branches resume multicast forwarding when the pruned state times out. Data is then flooded again down these branches, and then the branches are pruned again.
- When a new receiver on a previously pruned branch joins a multicast group, to reduce the join latency, PIM-DM uses a graft mechanism to resume data forwarding to that branch.

Generally speaking, the multicast forwarding path is a source tree. That is, it is a forwarding tree with the multicast source as its "root" and multicast group members as its "leaves." Because the source tree is the shortest path from the multicast source to the receivers, it is also called a shortest path tree (SPT).

The working mechanism of PIM-DM is summarized as follows:

- Neighbor discovery
- SPT building
- Graft
- Assert

Neighbor discovery

In a PIM domain, a PIM router discovers PIM neighbors, maintains PIM neighboring relationships with other routers, and builds and maintains SPTs by periodically multicasting hello messages to all other PIM routers (224.0.0.13) on the local subnet.

NOTE:

Every PIM-enabled interface on a router sends hello messages periodically, and thus learns the PIM neighboring information pertinent to the interface.

SPT building

The process of building an SPT is the flood-and-prune process.

1. In a PIM-DM domain, when a multicast source S sends multicast data to multicast group G , the multicast packet is first flooded throughout the domain. The router first performs RPF check on the multicast packet. If the packet passes the RPF check, the router creates an (S, G) entry and forwards the data to all downstream nodes in the network. In the flooding process, an (S, G) entry is created on all the routers in the PIM-DM domain.
2. Then, nodes without receivers downstream are pruned. A router having no receivers downstream sends a prune message to the upstream node to "tell" the upstream node to delete the corresponding interface from the outgoing interface list in the (S, G) entry and stop forwarding subsequent packets addressed to that multicast group down to this node.

An (S, G) entry contains the multicast source address S , multicast group address G , outgoing interface list, and incoming interface.

For a given multicast stream, the interface that receives the multicast stream is referred to as "upstream," and the interfaces that forward the multicast stream are referred to as "downstream."

A prune process is first initiated by a leaf router. As shown in [Figure 38](#), a router without any receiver attached to it (the router connected with Host A, for example) sends a prune message. This prune process goes on until only necessary branches are left in the PIM-DM domain. These branches constitute the SPT.

Figure 38 SPT building

The flood-and-prune process takes place periodically. A pruned state timeout mechanism is provided. A pruned branch restarts multicast forwarding when the pruned state times out and then is pruned again when it no longer has any multicast receiver.

NOTE:

Pruning has a similar implementation in PIM-SM.

Graft

When a host attached to a pruned node joins a multicast group, to reduce the join latency, PIM-DM uses a graft mechanism to resume data forwarding to that branch. The process is as follows:

1. The node that needs to receive multicast data sends a graft message toward its upstream node as a request to join the SPT again.
2. After receiving this graft message, the upstream node puts the interface on which the graft was received into the forwarding state and responds with a graft-ack message to the graft sender.
3. If the node that sent a graft message does not receive a graft-ack message from its upstream node, it will keep sending graft messages at a configurable interval until it receives an acknowledgment from its upstream node.

Assert

Where more than one multicast router exists, the assert mechanism shuts off duplicate multicast flows onto the same multi-access network. It does this by electing a unique multicast forwarder on the multi-access network.

Figure 39 Assert mechanism

As shown in Figure 39, after Router A and Router B receive an (S, G) packet from the upstream node, they both forward the packet to the local subnet. As a result, the downstream node Router C receives two identical multicast packets, and both Router A and Router B, on their own local interface, receive a duplicate packet forwarded by the other. After detecting this condition, both routers send an assert message to all PIM routers (224.0.0.13) on the local subnet through the interface on which the packet was received. The assert message contains the multicast source address (S), the multicast group address (G), and the preference and metric of the unicast route/MBGP route/multicast static route to the source. By comparing these parameters, either Router A or Router B becomes the unique forwarder of the subsequent (S, G) packets on the multi-access subnet. The comparison process is as follows:

1. The router with a higher preference to the source wins;
2. If both routers have the same preference to the source, the router with a smaller metric to the source wins;
3. If a tie exists in route metric to the source, the router with a higher IP address of the local interface wins.

PIM-SM overview

PIM-DM uses the flood-and-prune principle to build SPTs for multicast data distribution. Although an SPT has the shortest path, it is built with a low efficiency. Therefore, the PIM-DM mode is not suitable for large- and medium-sized networks.

PIM-SM is a type of sparse mode multicast protocol. It uses the pull mode for multicast forwarding and is suitable for large-sized and medium-sized networks with sparsely and widely distributed multicast group members.

The basic implementation of PIM-SM is as follows:

- PIM-SM assumes that no hosts need to receive multicast data. In the PIM-SM mode, routers must specifically request a particular multicast stream before the data is forwarded to them. The core task for PIM-SM to implement multicast forwarding will build and maintain rendezvous point trees (RPTs). An RPT is rooted at a router in the PIM domain as the common node, or rendezvous point (RP), through which the multicast data travels along the RPT and reaches the receivers.
- When a receiver is interested in the multicast data addressed to a specific multicast group, the router connected to this receiver sends a join message to the RP that corresponds to that multicast group. The path along which the message goes hop by hop to the RP forms a branch of the RPT.
- When a multicast source sends multicast streams to a multicast group, the source-side designated router (DR) first registers the multicast source with the RP by sending register messages to the RP by

unicast until it receives a register-stop message from the RP. The arrival of a register message at the RP triggers the establishment of an SPT. Then, the multicast source sends subsequent multicast packets along the SPT to the RP. After reaching the RP, the multicast packet is duplicated and delivered to the receivers along the RPT.

NOTE:

Multicast traffic is duplicated only where the distribution tree branches, and this process automatically repeats until the multicast traffic reaches the receivers.

The working mechanism of PIM-SM is summarized as follows:

- Neighbor discovery
- DR election
- RP discovery
- RPT building
- Multicast source registration
- Switchover to SPT
- Assert

Neighbor discovery

PIM-SM uses a similar neighbor discovery mechanism as PIM-DM does. For more information, see "[Neighbor discovery](#)."

DR election

PIM-SM also uses hello messages to elect a DR for a multi-access network (such as Ethernet). The elected DR will be the only multicast forwarder on this multi-access network.

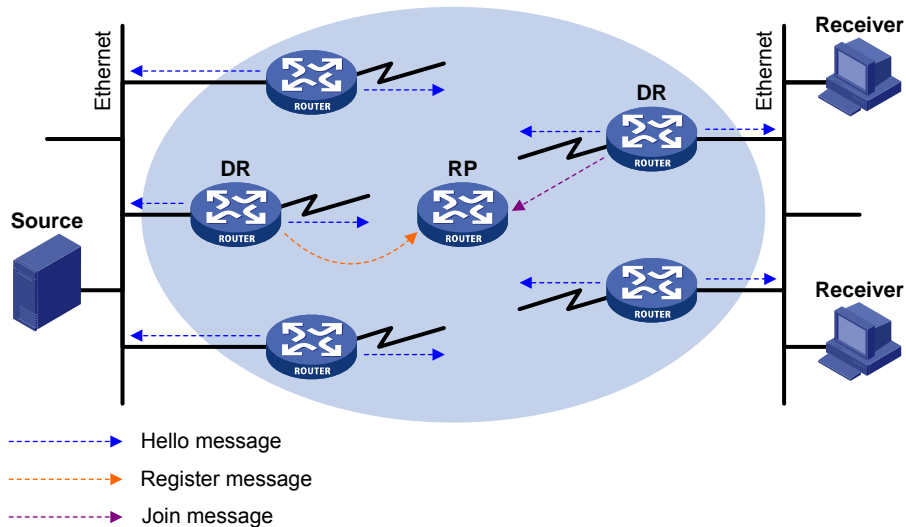

A DR must be elected in a multi-access network, no matter this network connects to multicast sources or to receivers. The receiver-side DR sends join messages to the RP. The source-side DR sends register messages to the RP.

A DR is elected on a multi-access subnet by means of comparison of the priorities and IP addresses carried in hello messages. An elected DR is substantially meaningful to PIM-SM. PIM-DM itself does not require a DR. However, if IGMPv1 runs on any multi-access network in a PIM-DM domain, a DR must be elected to act as the IGMPv1 querier on that multi-access network.

IGMP must be enabled on a device that acts as a receiver-side DR before receivers attached to this device can join multicast groups through this DR.

For more information about IGMP, see "[Configuring IGMP \(available only on the HP 5500 EI\)](#)."

Figure 40 DR election

As shown in Figure 40, the DR election process is as follows:

1. Routers on the multi-access network send hello messages to one another. The hello messages contain the router priority for DR election. The router with the highest DR priority will become the DR.
2. In the case of a tie in the router priority, or if any router in the network does not support carrying the DR-election priority in hello messages, the router with the highest IP address will win the DR election.

When the DR fails, a timeout in receiving a hello message triggers a new DR election process among the other routers.

RP discovery

The RP is the core of a PIM-SM domain. For a small-sized, simple network, one RP is enough for forwarding information throughout the network, and you can statically specify the position of the RP on each router in the PIM-SM domain. In most cases, however, a PIM-SM network covers a wide area and a huge amount of multicast traffic must be forwarded through the RP. To lessen the RP burden and optimize the topological structure of the RPT, you can configure multiple candidate-RPs (C-RPs) in a PIM-SM domain, among which an RP is dynamically elected through the bootstrap mechanism. Each elected RP serves a different multicast group range. For this purpose, you must configure a bootstrap router (BSR). The BSR serves as the administrative core of the PIM-SM domain. A PIM-SM domain can have only one BSR, but can have multiple candidate-BSRs (C-BSRs). If the BSR fails, a new BSR is automatically elected from the C-BSRs to avoid service interruption.

NOTE:

- An RP can serve multiple multicast groups or all multicast groups. Only one RP can serve a given multicast group at a time.
 - A device can serve as a C-RP and a C-BSR at the same time.
-

As shown in Figure 41, each C-RP periodically unicasts its advertisement messages (C-RP-Adv messages) to the BSR. A C-RP-Adv message contains the address of the advertising C-RP and the multicast group range that it serves. The BSR collects these advertisement messages and chooses the appropriate C-RP information for each multicast group to form an RP-set, which is a database of mappings between

multicast groups and RPs. The BSR then encapsulates the RP-set in the bootstrap messages (BSMs) that it periodically originates and floods the bootstrap messages to the entire PIM-SM domain.

Figure 41 BSR and C-RPs

Based on the information in the RP-sets, all routers in the network can calculate the location of the corresponding RPs based on the following rules:

1. The C-RP with the highest priority wins.
2. If all the C-RPs have the same priority, their hash values are calculated through the hashing algorithm. The C-RP with the largest hash value wins.
3. If all the C-RPs have the same priority and hash value, the C-RP that has the highest IP address wins.

The hashing algorithm used for RP calculation is "Value (G, M, C_i) = (1103515245 * ((1103515245 * (G & M) + 12345) XOR C_i) + 12345) mod 2³¹."

Values in the hashing algorithm

Value	Description
Value	Hash value
G	IP address of the multicast group
M	Hash mask length
C _i	IP address of the C-RP
&	Logical operator of "and"
XOR	Logical operator of "exclusive-or"
Mod	Modulo operator, which gives the remainder of an integer division

RPT building

Figure 42 RPT building in a PIM-SM domain

As shown in [Figure 42](#), the process of building an RPT is as follows:

1. When a receiver joins multicast group G , it uses an IGMP message to inform the directly connected DR.
2. After getting the receiver information, the DR sends a join message, which is forwarded hop by hop to the RP that corresponds to the multicast group.
3. The routers along the path from the DR to the RP form an RPT branch. Each router on this branch generates a $(*, G)$ entry in its forwarding table. The asterisk means any multicast source. The RP is the root of the RPT, and the DRs are the leaves of the RPT.

The multicast data addressed to the multicast group G flows through the RP, reaches the corresponding DR along the established RPT, and finally is delivered to the receiver.

When a receiver is no longer interested in the multicast data addressed to multicast group G , the directly connected DR sends a prune message, which goes hop by hop along the RPT to the RP. After receiving the prune message, the upstream node deletes the interface that connects to this downstream node from the outgoing interface list and determines whether it has receivers for that multicast group. If not, the router continues to forward the prune message to its upstream router.

Multicast source registration

The purpose of multicast source registration will inform the RP about the existence of the multicast source.

Figure 43 Multicast source registration

As shown in Figure 43, the multicast source registers with the RP as follows:

1. The multicast source S sends the first multicast packet to multicast group G. After receiving the multicast packet, the DR that directly connects to the multicast source encapsulates the packet in a PIM register message. Then it sends the message to the corresponding RP by unicast.
2. When the RP receives the register message, it extracts the multicast packet from the register message and forwards the multicast packet down the RPT, and sends an (S, G) join message hop by hop toward the multicast source. Thus, the routers along the path from the RP to the multicast source constitute an SPT branch. Each router on this branch generates an (S, G) entry in its forwarding table. The source-side DR is the root of the SPT, and the RP is the leaf of the SPT.
3. The subsequent multicast data from the multicast source travels along the established SPT to the RP. Then the RP forwards the data along the RPT to the receivers. When the multicast traffic arrives at the RP along the SPT, the RP sends a register-stop message to the source-side DR by unicast to stop the source registration process.

NOTE:

The RP is configured to initiate an SPT switchover as described in this section. Otherwise, the source-side DR keeps encapsulating multicast data in register messages, and the registration process will not stop unless no outgoing interfaces exist in the (S, G) entry on the RP.

Switchover to SPT

In a PIM-SM domain, a multicast group corresponds to one RP and RPT. Before the SPT switchover occurs, the source-side DR encapsulates all multicast data destined to the multicast group in register messages and sends these messages to the RP. After receiving these register messages, the RP extracts the multicast data and sends the multicast data down the RPT to the DRs at the receiver side. The RP acts as a transfer station for all multicast packets. The whole process involves the following issues:

- The source-side DR and the RP need to implement complicated encapsulation and de-encapsulation of multicast packets.
- Multicast packets are delivered along a path that might not be the shortest one.
- An increase in multicast traffic adds a great burden on the RP, increasing the risk of failure.

To solve the issues, PIM-SM allows an RP or the DR at the receiver side to initiate an SPT switchover process.

1. The RP initiates an SPT switchover process.

The RP can periodically check the passing-by IPv4 multicast packets. If it finds that the traffic rate exceeds a configurable threshold, the RP sends an (S, G) join message hop by hop toward the multicast source to establish an SPT between the DR at the source side and the RP. Subsequent multicast data travels along the established SPT to the RP.

For more information about the SPT switchover initiated by the RP, see "[Multicast source registration](#)."

2. The receiver-side DR initiates an SPT switchover process.

After receiving the first multicast packet, the receiver-side DR initiates an SPT switchover process, as follows:

- The receiver-side DR sends an (S, G) join message hop by hop toward the multicast source. When the join message reaches the source-side DR, all the routers on the path have installed the (S, G) entry in their forwarding table, and thus an SPT branch is established.
- When the multicast packets travel to the router where the RPT and the SPT deviate, the router drops the multicast packets received from the RPT and sends an RP-bit prune message hop by hop to the RP. After receiving this prune message, the RP sends a prune message toward the multicast source (suppose only one receiver exists). Thus, SPT switchover is completed.
- Multicast data is directly sent from the source to the receivers along the SPT.

PIM-SM builds SPTs through SPT switchover more economically than PIM-DM does through the flood-and-prune mechanism.

Assert

PIM-SM uses a similar assert mechanism as PIM-DM does. For more information, see "[Assert](#)."

BIDIR-PIM overview

In some many-to-many applications, such as multi-side video conference, there might be multiple receivers interested in multiple multicast sources simultaneously. With PIM-DM or PIM-SM, each router along the SPT must create an (S, G) entry for each multicast source, consuming a lot of system resources.

BIDIR-PIM addresses the problem. Derived from PIM-SM, BIDIR-PIM builds and maintains bidirectional RPTs, each of which is rooted at an RP and connects multiple multicast sources with multiple receivers. Traffic from the multicast sources is forwarded through the RPs to the receivers along the bidirectional RPTs. Each router needs to maintain only one (*, G) multicast routing entry, saving system resources.

BIDIR-PIM is suitable for networks with dense multicast sources and dense receivers.

The working mechanism of BIDIR-PIM is summarized as follows:

- Neighbor discovery
- RP discovery
- DF election
- Bidirectional RPT building

Neighbor discovery

BIDIR-PIM uses the same neighbor discovery mechanism as PIM-SM does. For more information, see "[Neighbor discovery](#)."

RP discovery

BIDIR-PIM uses the same RP discovery mechanism as PIM-SM does. For more information, see "[RP discovery](#)."

In PIM-SM, an RP must be specified with a real IP address. In BIDIR-PIM, however, an RP can be specified with a virtual IP address, which is called the rendezvous point address (RPA). The link corresponding to the RPA's subnet is called the rendezvous point link (RPL). All interfaces connected to the RPL can act as the RP, and they back up one another.

NOTE:

In BIDIR-PIM, an RPF interface is the interface pointing to an RP, and an RPF neighbor is the address of the next hop to the RP.

DF election

On a network segment with multiple multicast routers, the same multicast packets might be forwarded to the RP repeatedly. To address this issue, BIDIR-PIM uses a DF election mechanism to elect a unique designated forwarder (DF) for each RP on every network segment within the BIDIR-PIM domain, and allows only the DF to forward multicast data to the RP.

NOTE:

DF election is not necessary for an RPL.

Figure 44 DF election

As shown in [Figure 44](#), without the DF election mechanism, both Router B and Router C can receive multicast packets from Router A, and they might both forward the packets to downstream routers on the local subnet. As a result, the RP (Router E) receives duplicate multicast packets. With the DF election mechanism, once receiving the RP information, Router B and Router C initiate a DF election process for the RP:

1. Router B and Router C multicast DF election messages to all PIM routers (224.0.0.13). The election messages carry the RP's address, and the priority and metric of the unicast route, MBGP route, or multicast static route to the RP.
2. The router with a route of the highest priority becomes the DF.
3. In the case of a tie, the router with the route with the lowest metric wins the DF election.

4. In the case of a tie in the metric, the router with the highest IP address wins.

Bidirectional RPT building

A bidirectional RPT comprises a receiver-side RPT and a source-side RPT. The receiver-side RPT is rooted at the RP and takes the routers directly connected to the receivers as leaves. The source-side RPT is also rooted at the RP but takes the routers directly connected to the sources as leaves. The processes for building these two parts are different.

Figure 45 RPT building at the receiver side

As shown in [Figure 45](#), the process for building a receiver-side RPT is similar to that for building an RPT in PIM-SM:

1. When a receiver joins multicast group G , it uses an IGMP message to inform the directly connected router.
2. After getting the receiver information, the router sends a join message, which is forwarded hop by hop to the RP of the multicast group.
3. The routers along the path from the receiver's directly connected router to the RP form an RPT branch, and each router on this branch adds a $(*, G)$ entry to its forwarding table. The $*$ means any multicast source.

When a receiver is no longer interested in the multicast data addressed to multicast group G , the directly connected router sends a prune message, which goes hop by hop along the reverse direction of the RPT to the RP. After receiving the prune message, each upstream node deletes the interface connected to the downstream node from the outgoing interface list and checks whether it has receivers in that multicast group. If not, the router continues to forward the prune message to its upstream router.

Figure 46 RPT building at the multicast source side

As shown in Figure 46, the process for building a source-side RPT is relatively simple:

4. When a multicast source sends multicast packets to multicast group G, the DF in each network segment unconditionally forwards the packets to the RP.
5. The routers along the path from the source's directly connected router to the RP form an RPT branch. Each router on this branch adds a (*, G) entry to its forwarding table. The * means any multicast source.

After a bidirectional RPT is built, multicast traffic is forwarded along the source-side RPT and receiver-side RPT from sources to receivers.

NOTE:

If a receiver and a multicast source are at the same side of the RP, the source-side RPT and the receiver-side RPT might meet at a node before reaching the RP. In this case, multicast packets from the multicast source to the receiver are directly forwarded by the node to the receiver, instead of by the RP.

Administrative scoping overview

Division of PIM-SM domains

Typically, a PIM-SM domain or BIDIR-PIM domain contains only one BSR, which is responsible for advertising RP-set information within the entire PIM-SM/BIDIR-PIM domain. The information for all multicast groups is forwarded within the network scope that the BSR administers. This is called the "non-scoped BSR mechanism."

To implement refined management, you can divide a PIM-SM domain or BIDIR-PIM domain into one global scope zone and multiple administratively scoped zones (admin-scope zones). This is called the "administrative scoping mechanism."

The administrative scoping mechanism effectively releases stress on the management in a single-BSR domain and enables provision of zone-specific services through private group addresses.

Admin-scope zones are divided specific to multicast groups. Zone border routers (ZBRs) form the boundary of the admin-scope zone. Each admin-scope zone maintains one BSR, which serves multicast groups within a specific range. Multicast protocol packets, such as assert messages and bootstrap messages, for a specific group range cannot cross the admin-scope zone boundary. Multicast group ranges that different admin-scope zones serve can be overlapped. A multicast group is valid only within its local admin-scope zone, and functions as a private group address.

The global scope zone maintains a BSR, which serves the multicast groups that do not belong to any admin-scope zone.

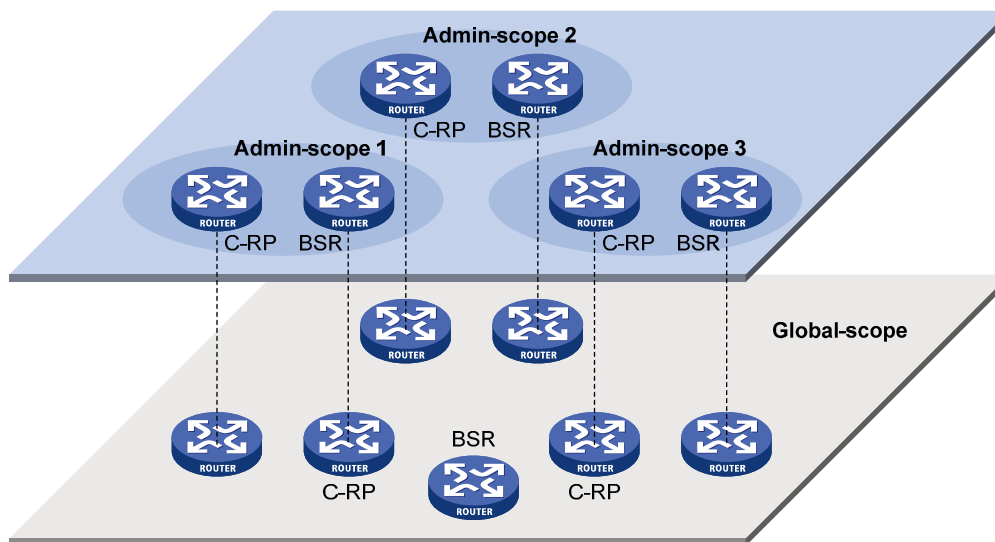

Relationship between admin-scope zones and the global scope zone

The global scope zone and each admin-scope zone have their own C-RPs and BSRs. These devices are effective only in their respective zones. That is, BSR election and RP election are implemented independently within each admin-scope zone. Each admin-scope zone has its own boundary. The multicast information cannot cross this boundary in either direction. A better understanding of the global scope zone and admin-scope zones should be based on geographical space and group address range.

1. Geographical space

Admin-scope zones are logical zones specific to particular multicast groups. The multicast packets of these multicast groups are confined within the local admin-scope zone and cannot cross the boundary of the zone.

Figure 47 Relationship between admin-scope zones and the global scope zone in geographic space

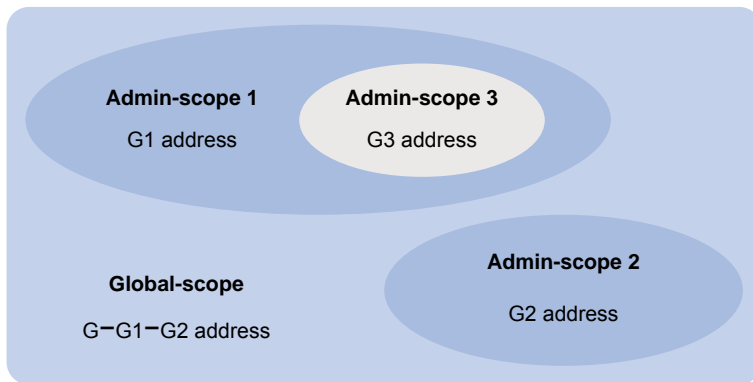

As shown in [Figure 47](#), for multicast groups in the same address range, admin-scope zones must be geographically separated from one another. Namely, a router must not serve different admin-scope zones. In other words, different admin-scope zones contain different routers, whereas the global scope zone covers all routers in the PIM-SM/BIDIR-PIM domain. Multicast packets that do not belong to any admin-scope zones can be transmitted in the entire PIM-SM/BIDIR-PIM domain.

2. Multicast group address ranges

Each admin-scope zone serves specific multicast groups. Usually, these addresses have no intersections. However, they might overlap one another.

Figure 48 Relationship between admin-scope zones and the global scope zone in group address ranges

In [Figure 48](#), the group address ranges of admin-scope 1 and 2 have no intersection, whereas the group address range of admin-scope 3 is a subset of the address range of admin-scope 1. The group address range of the global scope zone covers all the group addresses other than those of all the admin-scope zones. That is, the group address range of the global scope zone is G-G1-G2. In other words, a supplementary relationship exists between the global scope zone and all the admin-scope zones in terms of group address ranges.

PIM-SSM overview

The source-specific multicast (SSM) model and the any-source multicast (ASM) model are opposites. Presently, the ASM model includes the PIM-DM and PIM-SM modes. You can implement the SSM model by leveraging part of the PIM-SM technique. It is also called "PIM-SSM."

The SSM model provides a solution for source-specific multicast. It maintains the relationships between hosts and routers through IGMPv3.

In actual application, part of IGMPv3 or PIM-SM technique is adopted to implement the SSM model. In the SSM model, receivers locate a multicast source by means of advertisements, consultancy, and so on. No RP is needed, no RPT is required, no source registration process exists, and the multicast source discovery protocol (MSDP) is not needed for discovering sources in other PIM domains.

In PIM-SSM, the term "channel" refers to a multicast group, and the term "channel subscription" refers to a join message.

The working mechanism of PIM-SSM is summarized as follows:

- Neighbor discovery
- DR election
- SPT building

Neighbor discovery

PIM-SSM uses the same neighbor discovery mechanism as in PIM-DM and PIM-SM. See "[Neighbor discovery](#)."

DR election

PIM-SSM uses the same DR election mechanism as in PIM-SM. See "[DR election](#)."

SPT building

The decision to build an RPT for PIM-SM or an SPT for PIM-SSM depends on whether the multicast group the receiver will join falls into the SSM group range (SSM group range reserved by IANA is 232.0.0.0/8).

Figure 49 SPT building in PIM-SSM

As shown in Figure 49, Host B and Host C are multicast information receivers. They send IGMPv3 report messages to the respective DRs to express their interest in the information about the specific multicast source S.

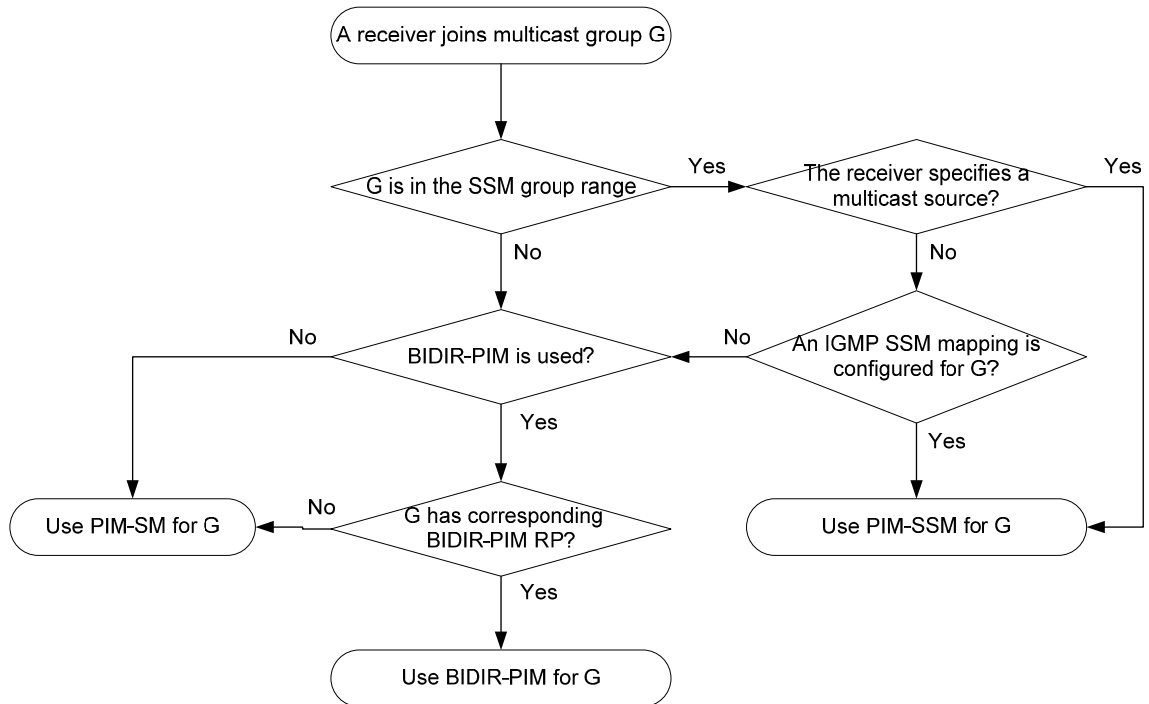

After receiving a report message, the DR first determines whether the group address in this message falls into the SSM group range and then does the following:

- If the group address in the message does fall into the SSM group range, the DR sends a subscribe message for channel subscription hop by hop toward the multicast source S. An (S, G) entry is created on all routers on the path from the DR to the source. An SPT is thereby built in the network, with the source S as its root and receivers as its leaves. This SPT is the transmission channel in PIM-SSM.
- If the group address in the message does not fall into the SSM group range, the receiver-side DR follows the PIM-SM process. The receiver-side DR sends a (*, G) join message to the RP, and the source-side DR registers the multicast source.

Relationships among PIM protocols

In a PIM network, PIM-DM cannot run together with PIM-SM, BIDIR-PIM, or PIM-SSM. However, PIM-SM, BIDIR-PIM, and PIM-SSM can run together. When they run together, which one is chosen for a receiver trying to join a group depends, as shown in Figure 50.

Figure 50 Relationships among PIM protocols

For more information about IGMP SSM mapping, see "[Configuring IGMP \(available only on the HP 5500 EI\)](#)."

PIM support for VPNs

To support PIM for VPNs, a multicast router that runs PIM maintains an independent set of PIM neighbor table, multicast routing table, BSR information, and RP-set information for each VPN.

After receiving a multicast data packet, the multicast router checks which VPN the data packet belongs to, and then forwards the packet according to the multicast routing table for that VPN or creates a multicast routing entry for that VPN.

Configuring PIM-DM

PIM-DM configuration task list

Task	Remarks
Enabling PIM-DM	Required
Enabling state-refresh capability	Optional
Configuring state-refresh parameters	Optional
Configuring PIM-DM graft retry period	Optional
Configuring PIM common features	Optional

Configuration prerequisites

Before you configure PIM-DM, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Determine the interval between state-refresh messages.
- Determine the minimum time to wait before receiving a new refresh message.
- Determine the TTL value of state-refresh messages.
- Determine the graft retry period.

Enabling PIM-DM

With PIM-DM enabled, a router sends hello messages periodically to discover PIM neighbors and processes messages from the PIM neighbors. When you deploy a PIM-DM domain, enable PIM-DM on all non-border interfaces of the routers.

ⓘ IMPORTANT:

- All the interfaces in the same VPN instance on the same device must operate in the same PIM mode.
- PIM-DM does not work with multicast groups in the SSM group range.

Enabling PIM-DM globally on the public network

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IP multicast routing.	multicast routing-enable	Disabled by default.
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable PIM-DM.	pim dm	Disabled by default.

Enabling PIM-DM in a VPN instance

Step	Command	Description
1. Enter system view.	system-view	N/A
2. Create a VPN instance and enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A

Step		Command	Description
3.	Configure an RD for the VPN instance.	route-distinguisher <i>route-distinguisher</i>	Not configured by default.
4.	Enable IP multicast routing.	multicast routing-enable	Disabled by default.
5.	Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6.	Bind the interface with a VPN instance.	ip binding vpn-instance <i>vpn-instance-name</i>	By default, an interface belongs to the public network, and is not bound with any VPN instance.
7.	Enable PIM-DM.	pim dm	Disabled by default.

For more information about the **ip vpn-instance**, **route-distinguisher**, and **ip binding vpn-instance** commands, see *IP Routing Command Reference*.

For more information about the **multicast routing-enable** command, see *IP Multicast Command Reference*.

Enabling state-refresh capability

Pruned interfaces resume multicast forwarding when the pruned state times out. To prevent this, the router with the multicast source attached periodically sends an (S, G) state-refresh message, which is forwarded hop by hop along the initial multicast flooding path of the PIM-DM domain, to refresh the prune timer state of all the routers on the path. A multi-access subnet can have the state-refresh capability only if the state-refresh capability is enabled on all PIM routers on the subnet.

To enable the state-refresh capability:

Step		Command	Remarks
1.	Enter system view.	system-view	N/A
2.	Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3.	Enable the state-refresh capability.	pim state-refresh-capable	Optional Enabled by default

Configuring state-refresh parameters

The router directly connected with the multicast source periodically sends state-refresh messages. You can configure the interval for sending such messages.

A router might receive multiple state-refresh messages within a short time, and some of them might be duplicated messages. To keep a router from receiving such duplicated messages, you can configure the time that the router must wait before it receives next state-refresh message. If the router receives a new state-refresh message within the waiting time, it discards the message. If this timer times out, the router will accept a new state-refresh message, refresh its own PIM-DM state, and reset the waiting timer.

The TTL value of a state-refresh message decrements by 1 whenever it passes a router before it is forwarded to the downstream node until the TTL value comes down to 0. In a small network, a state-refresh message might cycle in the network. To effectively control the propagation scope of state-refresh messages, configure an appropriate TTL value based on the network size.

Perform the following configurations on all routers in the PIM domain.

To configure state-refresh parameters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure the interval between state-refresh messages.	state-refresh-interval interval	Optional 60 seconds by default
4. Configure the time to wait before receiving a new state-refresh message.	state-refresh-rate-limit interval	Optional 30 seconds by default
5. Configure the TTL value of state-refresh messages.	state-refresh-ttl ttl-value	Optional 255 by default

Configuring PIM-DM graft retry period

In PIM-DM, graft is the only type of message that uses the acknowledgment mechanism. In a PIM-DM domain, if a router does not receive a graft-ack message from the upstream router within the specified time after it sends a graft message, the router keeps sending new graft messages at a configurable interval (namely graft retry period), until it receives a graft-ack message from the upstream router.

To configure the graft retry period:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface interface-type interface-number	N/A
3. Configure the graft retry period.	pim timer graft-retry interval	Optional 3 seconds by default

For more information about the configuration of other timers in PIM-DM, see "[Configuring PIM common timers](#)."

Configuring PIM-SM

PIM-SM configuration task list

Task	Remarks	
Enabling PIM-SM	Required.	
Configuring an RP	Configuring a static RP	
	Configuring a C-RP	Required.
	Enabling auto-RP	Use any approach.

Task	Remarks	
	Configuring C-RP timers globally	Optional.
	Configuring a C-BSR	Required.
Configuring a BSR	Configuring a PIM domain border	Optional.
	Configuring global C-BSR parameters	Optional.
	Configuring C-BSR timers	Optional.
	Disabling BSM semantic fragmentation	Optional.
	Enabling administrative scoping	Optional.
Configuring administrative scoping	Configuring an admin-scope zone boundary	Optional.
	Configuring C-BSRs for each admin-scope zone and the global-scope zone	Optional.
Configuring multicast source registration	Optional.	
Disabling SPT switchover	Optional.	
Configuring PIM common features	Optional.	

Configuration prerequisites

Before you configure PIM-SM, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Determine the IP address of a static RP and the ACL rule defining the range of multicast groups to be served by the static RP.
- Determine the C-RP priority and the ACL rule defining the range of multicast groups to be served by each C-RP.
- Determine the legal C-RP address range and the ACL rule defining the range of multicast groups to be served.
- Determine the C-RP-Adv interval.
- Determine the C-RP timeout.
- Determine the C-BSR priority.
- Determine the hash mask length.
- Determine the ACL rule defining a legal BSR address range.
- Determine the BS period.
- Determine the BS timeout.
- Determine the ACL rule for register message filtering.
- Determine the register suppression time.
- Determine the register probe time.
- Determine the ACL rule and sequencing rule for disabling an SPT switchover.

Enabling PIM-SM

With PIM-SM enabled, a router sends hello messages periodically to discover PIM neighbors and processes messages from the PIM neighbors. To deploy a PIM-SM domain, enable PIM-SM on all non-border interfaces of the routers.

! **IMPORTANT:**

All the interfaces in the same VPN instance on the same router must operate in the same PIM mode.

Enabling PIM-SM globally on the public network

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IP multicast routing.	multicast routing-enable	Disabled by default
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable PIM-SM.	pim sm	Disabled by default

Enabling PIM-SM in a VPN instance

Step	Command	Description
1. Enter system view.	system-view	N/A
2. Create a VPN instance and enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure an RD for the VPN instance.	route-distinguisher <i>route-distinguisher</i>	Not configured by default.
4. Enable IP multicast routing.	multicast routing-enable	Disabled by default.
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Bind the interface with a VPN instance.	ip binding vpn-instance <i>vpn-instance-name</i>	By default, an interface belongs to the public network, and is not bound with any VPN instance.
7. Enable PIM-SM.	pim sm	Disabled by default.

For more information about the **ip vpn-instance**, **route-distinguisher**, and **ip binding vpn-instance** commands, see *IP Routing Command Reference*.

For more information about the **multicast routing-enable** command, see *IP Multicast Command Reference*.

Configuring an RP

An RP can be manually configured or dynamically elected through the BSR mechanism. For a large PIM network, static RP configuration is a tedious job. Generally, static RP configuration is just a backup method for the dynamic RP election mechanism to enhance the robustness and operational manageability of a multicast network.

❗ **IMPORTANT:**

In a PIM network, if both PIM-SM and BIDIR-PIM are enabled, do not configure the same RP to serve PIM-SM and BIDIR-PIM simultaneously to avoid PIM routing table errors.

Configuring a static RP

If only one dynamic RP exists in a network, manually configuring a static RP can avoid communication interruption because of single-point failures. It can also avoid frequent message exchange between C-RPs and the BSR.

❗ **IMPORTANT:**

To enable a static RP to work normally, you must perform this configuration on all the routers in the PIM-SM domain and specify the same RP address.

Perform the following configuration on all the routers in the PIM-SM domain.

To configure a static RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure a static RP for PIM-SM.	static-rp rp-address [acl-number] [preferred]	No static RP by default

Configuring a C-RP

In a PIM-SM domain, you can configure routers that intend to become the RP as C-RPs. The BSR collects the C-RP information by receiving the C-RP-Adv messages from C-RPs or auto-RP announcements from other routers and organizes the information into an RP-set, which is flooded throughout the entire network. Then, the other routers in the network calculate the mappings between specific group ranges and the corresponding RPs based on the RP-set. HP recommends you to configure C-RPs on backbone routers.

To guard against C-RP spoofing, you must configure a legal C-RP address range and the range of multicast groups to be served on the BSR. In addition, because every C-BSR can become the BSR, you must configure the same filtering policy on all C-BSRs in the PIM-SM domain.

To configure a C-RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure an interface to be a C-RP for PIM-SM.	c-rp interface-type interface-number [group-policy acl-number priority priority holdtime hold-interval advertisement-interval adv-interval] *	No C-RPs are configured by default.
4. Configure a legal C-RP address range and the range of multicast groups to be served.	crp-policy acl-number	Optional. No restrictions by default.

NOTE:

- When you configure a C-RP, ensure a relatively large bandwidth between this C-RP and the other devices in the PIM-SM domain.
 - An RP can serve multiple multicast groups or all multicast groups. Only one RP can forward multicast traffic for a multicast group at a moment.
-

Enabling auto-RP

Auto-RP announcement and discovery messages are addressed to the multicast group addresses 224.0.1.39 and 224.0.1.40. With auto-RP enabled on a device, the device can receive these two types of messages and record the RP information carried in such messages.

To enable auto-RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Enable auto-RP.	auto-rp enable	Disabled by default

Configuring C-RP timers globally

To enable the BSR to distribute the RP-set information within the PIM-SM domain, C-RPs must periodically send C-RP-Adv messages to the BSR. The BSR learns the RP-set information from the received messages, and encapsulates its own IP address together with the RP-set information in its bootstrap messages. The BSR then floods the bootstrap messages to all PIM routers in the network.

Each C-RP encapsulates a timeout value in its C-RP-Adv messages. After receiving a C_RP-Adv message, the BSR obtains this timeout value and starts a C-RP timeout timer. If the BSR fails to hear a subsequent C-RP-Adv message from the C-RP when this timer times out, the BSR assumes the C-RP to have expired or become unreachable.

The C-RP timers need to be configured on C-RP routers.

To configure C-RP timers globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure the C-RP-Adv interval.	c-rp advertisement-interval interval	Optional 60 seconds by default
4. Configure C-RP timeout time.	c-rp holdtime interval	Optional 150 seconds by default

For more information about the configuration of other timers in PIM-SM, see "[Configuring PIM common timers.](#)"

Configuring a BSR

Configuration guidelines

Before you configure a BSR, make sure that you are familiar with BSR election process, BSR legal address against BSR spoofing, PIM domain border, global C-BSR parameters, C-BSR timers, and bootstrap message fragments (BSMFs).

- BSR election process

A PIM-SM domain can have only one BSR, but must have at least one C-BSR. Any router can be configured as a C-BSR. Elected from C-BSRs, the BSR is responsible for collecting and advertising RP information in the PIM-SM domain.

C-BSRs should be configured on routers in the backbone network. When you configure a router as a C-BSR, be sure to specify a PIM-SM-enabled interface on the router. The BSR election process is summarized as follows:

- a. Initially, every C-BSR assumes itself to be the BSR of this PIM-SM domain and uses its interface IP address as the BSR address to send bootstrap messages.
- b. When a C-BSR receives the bootstrap message of another C-BSR, it first compares its own priority with the other C-BSR's priority carried in the message. The C-BSR with a higher priority wins. If a tie exists in the priority, the C-BSR with a higher IP address wins. The loser uses the winner's BSR address to replace its own BSR address and no longer assumes itself to be the BSR, and the winner retains its own BSR address and continues to assume itself to be the BSR.

- BSR legal address against BSR spoofing

Configuring a legal range of BSR addresses enables filtering of bootstrap messages based on the address range, thereby preventing a maliciously configured host from masquerading as a BSR. You must make the same configuration on all routers in the PIM-SM domain. The typical BSR spoofing cases and the corresponding preventive measures are as follows:

- Some maliciously configured hosts can forge bootstrap messages to fool routers and change RP mappings. Such attacks often occur on border routers. Because a BSR is inside the network whereas hosts are outside the network, you can protect a BSR against attacks from external hosts by enabling the border routers to perform neighbor checks and RPF checks on bootstrap messages and to discard unwanted messages.
- When an attacker controls a router in the network or when an illegal router is present in the network, the attacker can configure this router as a C-BSR and make it win BSR election to control the right of advertising RP information in the network. After a router is configured as a C-BSR, it automatically floods the network with bootstrap messages. Because a bootstrap message has a TTL value of 1, the whole network will not be affected as long as the neighbor router discards these bootstrap messages. Therefore, with a legal BSR address range configured on all routers in the entire network, all these routers will discard bootstrap messages from out of the legal address range.

These preventive measures can partially protect the security of BSRs in a network. However, if an attacker controls a legal BSR, the problem will still occur.

Because a large amount of information needs to be exchanged between a BSR and the other devices in the PIM-SM domain, a relatively large bandwidth should be provided between the C-BSRs and the other devices in the PIM-SM domain.

- PIM domain border

As the administrative core of a PIM-SM domain, the BSR sends the collected RP-set information in the form of bootstrap messages to all routers in the PIM-SM domain.

A PIM domain border is a bootstrap message boundary. Each BSR has its specific service scope. A number of PIM domain border interfaces partition a network into different PIM-SM domains. Bootstrap messages cannot cross a domain border in either direction.

- C-BSR parameters

In each PIM-SM domain, a unique BSR is elected from C-BSRs. The C-RPs in the PIM-SM domain send advertisement messages to the BSR. The BSR summarizes the advertisement messages to form an RP-set and advertises it to all routers in the PIM-SM domain. All the routers use the same hash algorithm to get the RP address that corresponds to specific multicast groups.

You can configure the hash mask length and C-BSR priority globally, in an admin-scope zone, and in the global scope zone.

- The values configured in the global scope zone or admin-scope zone have preference over the global values.
- If you do not configure these parameters in the global scope zone or admin-scope zone, the corresponding global values will be used.

For configuration of C-BSR parameters for an admin-scope zone and global scope zone, see "[Configuring C-BSRs for each admin-scope zone and the global-scope zone.](#)"

- C-BSR timers

The BSR election winner multicasts its own IP address and RP-set information through bootstrap messages within the entire zone it serves. The BSR floods bootstrap messages throughout the network at the interval of BS (BSR state) period. Any C-BSR that receives a bootstrap message retains the RP-set for the length of BS timeout, during which no BSR election takes place. If no bootstrap message is received from the BSR before the BS timeout timer expires, a new BSR election process is triggered among the C-BSRs.

About the BS period:

- By default, the BS period is determined by this formula: $BS\ period = (BS\ timeout - 10) / 2$. The default BS timeout is 130 seconds, so the default BS period = $(130 - 10) / 2 = 60$ (seconds).
- If this parameter is manually configured, the system will use the configured value.

About the BS timeout timer:

- By default, the BS timeout value is determined by this formula: $BS\ timeout\ timer = BS\ period \times 2 + 10$. The default BS period is 60 seconds, so the default BS timeout timer = $60 \times 2 + 10 = 130$ (seconds).
- If this parameter is manually configured, the system will use the configured value.

In the configuration, make sure that the BS period value is smaller than the BS timeout value.

- Bootstrap message fragments (BSMFs)

Generally, a BSR periodically distributes the RP-set information in bootstrap messages within the PIM-SM domain. It encapsulates a BSM in an IP datagram and might split the datagram into fragments if the message exceeds the maximum transmission unit (MTU). In respect of such IP fragmentation, loss of a single IP fragment leads to unavailability of the entire message.

Semantic fragmentation of BSMs can solve this issue. When a BSM exceeds the MTU, it is split to multiple bootstrap message fragments (BSMFs).

- After receiving a BSMF that contains the RP-set information of one group range, a non-BSR router updates corresponding RP-set information directly.
- If the RP-set information of one group range is carried in multiple BSMFs, a non-BSR router updates corresponding RP-set information after receiving all these BSMFs.

Because the RP-set information contained in each segment is different, loss of some IP fragments will not result in dropping of the entire message.

The function of BSM semantic fragmentation is enabled by default. Devices not supporting this function might deem a fragment as an entire message and learn only part of the RP-set information. Therefore, if such devices exist in the PIM-SM domain, you need to disable the semantic fragmentation function on the C-BSRs.

Generally, a BSR performs BSM semantic fragmentation according to the MTU of its BSR interface. However, the semantic fragmentation of BSMs originated because of learning of a new PIM neighbor is performed according to the MTU of the outgoing interface.

Configuring a C-BSR

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure an interface as a C-BSR.	c-bsr <i>interface-type</i> <i>interface-number</i> [<i>hash-length</i> [<i>priority</i>]]	No C-BSRs are configured by default.
4. Configure a legal BSR address range.	bsr-policy <i>acl-number</i>	Optional. No restrictions on BSR address range by default.

Configuring a PIM domain border

Perform the following configuration on routers that you want to configure as a PIM domain border.

To configure a PIM domain border:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure a PIM domain border.	pim bsr-boundary	By default, no PIM domain border is configured.

Configuring global C-BSR parameters

Perform the following configuration on C-BSR routers.

To configure C-BSR parameters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the hash mask length.	c-bsr hash-length <i>hash-length</i>	Optional. 30 by default.

Step	Command	Remarks
4. Configure the C-BSR priority.	c-bsr priority <i>priority</i>	Optional. By default, the C-BSR priority is 64.

Configuring C-BSR timers

Perform the following configuration on C-BSR routers.

To configure C-BSR timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the BS period.	c-bsr interval <i>interval</i>	Optional. For the default value, see the note after this table.
4. Configure the BS timeout timer.	c-bsr holdtime <i>interval</i>	Optional. For the default value, see the note after this table.

Disabling BSM semantic fragmentation

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Disable the BSM semantic fragmentation function.	undo bsm-fragment enable	By default, the BSM semantic fragmentation function is enabled.

Configuring administrative scoping

When administrative scoping is disabled, a PIM-SM domain has only one BSR. The BSR manages the whole network. To manage your network more effectively and specifically, partition the PIM-SM domain into multiple admin-scope zones. Each admin-scope zone maintains a BSR, which serves a specific multicast group range. The global scope zone also maintains a BSR, which serves all the remaining multicast groups.

Enabling administrative scoping

Before you configure an admin-scope zone, you must enable administrative scoping.

Perform the following configuration on all routers in the PIM-SM domain.

To enable administrative scoping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2.	Enter public network PIM view or VPN instance PIM view. pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3.	Enable administrative scoping. c-bsr admin-scope	Disabled by default

Configuring an admin-scope zone boundary

ZBRs form the boundary of each admin-scope zone. Each admin-scope zone maintains a BSR, which serves a specific multicast group range. Multicast protocol packets (such as assert messages and bootstrap messages) that belong to this range cannot cross the admin-scope zone boundary.

Perform the following configuration on routers that you want to configure as a ZBR.

To configure an admin-scope zone boundary:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter interface view. interface <i>interface-type</i> <i>interface-number</i>	N/A
3.	Configure a multicast forwarding boundary. multicast boundary <i>group-address</i> { <i>mask</i> <i>mask-length</i> }	By default, no multicast forwarding boundary is configured.

NOTE:

The *group-address* { *mask* | *mask-length* } parameter of the **multicast boundary** command can be used to specify the multicast groups an admin-scope zone serves, in the range of 239.0.0.0/8. For more information about the **multicast boundary** command, see *IP Multicast Command Reference*.

Configuring C-BSRs for each admin-scope zone and the global-scope zone

In a network with administrative scoping enabled, group-range-specific BSRs are elected from C-BSRs. C-RPs in the network send advertisement messages to the specific BSR. The BSR summarizes the advertisement messages to form an RP-set and advertises it to all routers in the specific admin-scope zone. All the routers use the same hash algorithm to get the RP address corresponding to the specific multicast group.

Configure C-BSRs for each admin-scope zone and the global-scope zone.

You can configure the hash mask length and C-BSR priority globally, in an admin-scope zone, and in the global scope zone.

- The values configured in the global scope zone or admin-scope zone have preference over the global values.
- If you do not configure these parameters in the global scope zone or admin-scope zone, the corresponding global values will be used.

For configuration of global C-BSR parameters, see "[Configuring global C-BSR parameters](#)."

- Configure C-BSRs for each admin-scope zone
Perform the following configuration on the routers that you want to configure as C-BSRs in admin-scope zones.
To configure a C-BSR for an admin-scope zone:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure a C-BSR for an admin-scope zone.	c-bsr group <i>group-address</i> { <i>mask</i> <i>mask-length</i> } [hash-length <i>hash-length</i> priority <i>priority</i>] *	No C-BSRs are configured for an admin-scope zone by default.

NOTE:

The *group-address* { *mask* | *mask-length* } parameter of the **c-bsr group** command can specify the multicast groups the C-BSR serves, in the range of 239.0.0.0/8.

- Configure C-BSRs for the global-scope zone
Perform the following configuration on the routers that you want to configure as C-BSRs in the global-scope zone.
To configure a C-BSR for the global-scope zone:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure a C-BSR for the global-scope zone.	c-bsr global [hash-length <i>hash-length</i> priority <i>priority</i>] *	No C-BSRs are configured for the global-scope zone by default.

Configuring multicast source registration

Within a PIM-SM domain, the source-side DR sends register messages to the RP, and these register messages have different multicast source or group addresses. You can configure a filtering rule to filter register messages so that the RP can serve specific multicast groups. If the filtering rule denies an (S, G) entry, or if the filtering rule does not define the action for this entry, the RP will send a register-stop message to the DR to stop the registration process for the multicast data.

Configuration guidelines

In view of information integrity of register messages in the transmission process, you can configure the device to calculate the checksum based on the entire register messages. However, to reduce the workload of encapsulating data in register messages and for the sake of interoperability, do not use this method of checksum calculation.

When receivers stop receiving multicast data addressed to a certain multicast group through the RP (that is, the RP stops serving the receivers of that multicast group), or when the RP starts receiving multicast data from the multicast source along the SPT, the RP sends a register-stop message to the source-side DR. After receiving this message, the DR stops sending register messages encapsulated with multicast data and starts a register-stop timer. Before the register-stop timer expires, the DR sends a null register message (a register message without encapsulated multicast data) to the RP. If the DR receives a register-stop message during the register probe time, it will reset its register-stop timer. Otherwise, the DR starts sending register messages with encapsulated data again when the register-stop timer expires.

The register-stop timer is set to a random value chosen uniformly from the interval (0.5 times register_suppression_time, 1.5 times register_suppression_time) minus register_probe_time.

Configure a filtering rule for register messages on all C-RP routers and configure them to calculate the checksum based on the entire register messages. Configure the register suppression time and the register probe time on all routers that might become source-side DRs.

Configuration procedure

To configure register-related parameters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure a filtering rule for register messages.	register-policy acl-number	Optional. No register filtering rule by default.
4. Configure the device to calculate the checksum based on the entire register messages.	register-whole-checksum	Optional. By default, the checksum is calculated based on the header of register messages.
5. Configure the register suppression time.	register-suppression-timeout interval	Optional. 60 seconds by default.
6. Configure the register probe time.	probe-interval interval	Optional 5 seconds by default.

Disabling SPT switchover

If an HP 5500 EI switch acts as an RP or the receiver-side DR, it initiates an SPT switchover process by default upon receiving the first multicast packet along the RPT. You can disable the switchover from RPT to SPT.

ⓘ IMPORTANT:

For an HP 5500 EI switch, once a multicast forwarding entry is created, subsequent multicast data will not be encapsulated in register messages before being forwarded even if a register outgoing interface is available. To avoid forwarding failure, do not use the **spt-switch-threshold infinity** command on a switch that might become an RP (a static RP or a C-RP).

To configure SPT switchover:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A

Step	Command	Remarks
3. Disable SPT switchover.	<code>spt-switch-threshold infinity</code> [<code>group-policy acl-number</code> [<code>order order-value</code>]]	Optional. By default, the device switches to the SPT immediately after it receives the first multicast packet.

Configuring BIDIR-PIM

BIDIR-PIM configuration task list

Task	Remarks	
Enabling PIM-SM	Required.	
Enabling BIDIR-PIM	Required.	
Configuring an RP	Configuring a static RP	Required.
	Configuring a C-RP	Use any approach.
	Enabling auto-RP	
Configuring a BSR	Configuring C-RP timers globally	Optional.
	Configuring a C-BSR	Required.
	Configuring a BIDIR-PIM domain border	Optional.
	Configuring global C-BSR parameters	Optional.
	Configuring C-BSR timers	Optional.
Configuring an admin-scope zone boundary	Disabling BSM semantic fragmentation	Optional.
	Enabling administrative scoping	Optional.
	Configuring administrative scoping	Optional.
Configuring PIM common features	Configuring C-BSRs for each admin-scope zone and the global-scope zone	Optional.
		Optional.

Configuration prerequisites

Before you configure BIDIR-PIM, complete the following tasks:

- Configure a unicast routing protocol so that all devices in the domain can reach each other.
- Determine the IP address of a static RP and the ACL that defines the range of the multicast groups to be served by the static RP.
- Determine the C-RP priority and the ACL that defines the range of multicast groups to be served by each C-RP.
- Determine the legal C-RP address range and the ACL that defines the range of multicast groups to be served.
- Determine the C-RP-Adv interval.
- Determine the C-RP timeout.

- Determine the C-BSR priority.
- Determine the hash mask length.
- Determine the ACL defining the legal BSR address range.
- Determine the BS period.
- Determine the BS timeout.

Enabling PIM-SM

Because BIDIR-PIM is implemented on the basis of PIM-SM, you must enable PIM-SM before enabling BIDIR-PIM. To deploy a BIDIR-PIM domain, enable PIM-SM on all non-border interfaces of the domain.

ⓘ IMPORTANT:

On a router, all interfaces in the same VPN instance must operate in the same PIM mode.

Enabling PIM-SM globally for the public network

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IP multicast routing.	multicast routing-enable	Disabled by default
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable PIM-SM.	pim sm	Disabled by default

Enabling PIM-SM for a VPN instance

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VPN instance and enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure an RD for the VPN instance.	route-distinguisher <i>route-distinguisher</i>	Not configured by default.
4. Enable IP multicast routing.	multicast routing-enable	Disabled by default.
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Bind the interface with the VPN instance.	ip binding vpn-instance <i>vpn-instance-name</i>	By default, an interface belongs to the public network, and is not bound with any VPN instance.
7. Enable PIM-SM.	pim sm	Disabled by default.

For more information about the **ip vpn-instance**, **route-distinguisher**, and **ip binding vpn-instance** commands, see *IP Routing Command Reference*.

For more information about the **multicast routing-enable** command, see *IP Multicast Command Reference*.

Enabling BIDIR-PIM

Perform this configuration on all routers in the BIDIR-PIM domain.

To enable BIDIR-PIM:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Enable BIDIR-PIM.	bidir-pim enable	Disabled by default

Configuring an RP

An RP can be manually configured or dynamically elected through the BSR mechanism. For a large PIM network, static RP configuration is a tedious job. Generally, static RP configuration is just used as a backup means for the dynamic RP election mechanism to enhance the robustness and operation manageability of a multicast network.

⚠ CAUTION:

In a PIM network, if both PIM-SM and BIDIR-PIM are enabled, do not configure the same RP to serve PIM-SM and BIDIR-PIM simultaneously to avoid PIM routing table errors.

Configuring a static RP

If only one dynamic RP exists in a network, manually configuring a static RP can avoid communication interruption because of single-point failures and avoid frequent message exchange between C-RPs and the BSR.

In BIDIR-PIM, a static RP can be specified with a virtual IP address. For example, if the IP addresses of the interfaces at the two ends of a link are 10.1.1.1/24 and 10.1.1.2/24, you can specify a virtual IP address, like 10.1.1.100/24, for the static RP. As a result, the link becomes an RPL.

⚠ IMPORTANT:

You must perform static RP configuration on all routers in the PIM-SM domain and specify the same RP address.

Perform this configuration on all routers in the BIDIR-PIM domain.

To configure a static RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure a static RP for BIDIR-PIM.	static-rp rp-address [acl-number] [preferred] bidir	No static RP by default

Configuring a C-RP

In a BIDIR-PIM domain, you can configure routers that intend to become the RP as C-RPs. The BSR collects the C-RP information by receiving the C-RP-Adv messages from C-RPs or auto-RP announcements from other routers and organizes the information into an RP-set, which is flooded throughout the entire network. Then, the other routers in the network calculate the mappings between specific group ranges and the corresponding RPs based on the RP-set. HP recommends that you configure C-RPs on backbone routers.

To guard against C-RP spoofing, configure a legal C-RP address range and the range of multicast groups to be served on the BSR. In addition, because every C-BSR has a chance to become the BSR, you must configure the same filtering policy on all C-BSRs in the BIDIR-PIM domain.

To configure a C-RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure an interface to be a C-RP for BIDIR-PIM.	c-rp <i>interface-type interface-number</i> [group-policy <i>acl-number</i> priority <i>priority</i> holdtime <i>hold-interval</i> advertisement-interval <i>adv-interval</i>] * bidir	No C-RP is configured by default.

NOTE:

- When you configure a C-RP, ensure a relatively large bandwidth between this C-RP and the other devices in the BIDIR-PIM domain.
- An RP can serve multiple multicast groups or all multicast groups. Only one RP can forward multicast traffic for a multicast group at a moment.

Enabling auto-RP

Auto-RP announcement and discovery messages are addressed to the multicast group addresses 224.0.1.39 and 224.0.1.40. With auto-RP enabled on a device, the device can receive these two types of messages and record the RP information carried in such messages.

To enable auto-RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable auto-RP.	auto-rp enable	Disabled by default

Configuring C-RP timers globally

To enable the BSR to distribute the RP-set information within the BIDIR-PIM domain, C-RPs must periodically send C-RP-Adv messages to the BSR. The BSR learns the RP-set information from the received messages, and encapsulates its own IP address together with the RP-set information in its bootstrap messages. The BSR then floods the bootstrap messages to all PIM routers in the network.

Each C-RP encapsulates a timeout value in its C-RP-Adv messages. After receiving a C_RP-Adv message, the BSR obtains this timeout value and starts a C-RP timeout timer. If the BSR fails to hear a subsequent C-RP-Adv message from the C-RP within the timeout interval, the BSR assumes the C-RP to have expired or become unreachable.

The C-RP timers need to be configured on C-RP routers.

To configure C-RP timers globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure the C-RP-Adv interval.	c-rp advertisement-interval interval	Optional 60 seconds by default
4. Configure C-RP timeout time.	c-rp holdtime interval	Optional 150 seconds by default

For more information about the configuration of other timers in BIDIR-PIM, see "[Configuring PIM common timers.](#)"

Configuring a BSR

Configuration guidelines

Before you configure a BSR, make sure that you are familiar with BSR election process, BSR legal address against BSR spoofing, PIM domain border, global C-BSR parameters, C-BSR timers, and bootstrap message fragments (BSMFs). They operate the same way as in the PIM-SM domain. For more information, see "[Configuration guidelines.](#)"

Configuring a C-BSR

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure an interface as a C-BSR.	c-bsr interface-type interface-number [hash-length [priority]]	No C-BSRs are configured by default.
4. Configure a legal BSR address range.	bsr-policy acl-number	Optional. No restrictions on BSR address range by default.

Configuring a BIDIR-PIM domain border

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure a BIDIR-PIM domain border.	pim bsr-boundary	By default, no BIDIR-PIM domain border is configured.

Configuring global C-BSR parameters

Perform the following configuration on C-BSR routers.

To configure global C-BSR parameters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the hash mask length.	c-bsr hash-length <i>hash-length</i>	Optional. 30 by default.
4. Configure the C-BSR priority.	c-bsr priority <i>priority</i>	Optional. 64 by default.

Configuring C-BSR timers

Perform the following configuration on C-BSR routers.

To configure C-BSR timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the BS period.	c-bsr interval <i>interval</i>	Optional. For the default value, see the note after this table.
4. Configure the BS timeout timer.	c-bsr holdtime <i>interval</i>	Optional. For the default value, see the note after this table.

Disabling BSM semantic fragmentation

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Disable the BSM semantic fragmentation function.	undo bsm-fragment enable	By default, the BSM semantic fragmentation function is enabled.

Configuring administrative scoping

With administrative scoping disabled, a BIDIR-PIM domain has only one BSR. The BSR manages the whole network. To manage your network more effectively and specifically, partition the BIDIR-PIM domain into multiple admin-scope zones. Each admin-scope zone maintains a BSR, which serves a specific multicast group range. The global scope zone also maintains a BSR, which serves all the rest multicast groups.

Enabling administrative scoping

Before you configure an admin-scope zone, you must enable administrative scoping first.

Perform the following configuration on all routers in the BIDIR-PIM domain.

To enable administrative scoping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Enable administrative scoping.	c-bsr admin-scope	Disabled by default

Configuring an admin-scope zone boundary

The boundary of each admin-scope zone is formed by ZBRs. Each admin-scope zone maintains a BSR, which serves a specific multicast group range. Multicast protocol packets (such as assert messages and bootstrap messages) that belong to this range cannot cross the admin-scope zone boundary.

Perform the following configuration on routers that you want to configure as a ZBR.

To configure an admin-scope zone boundary:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure a multicast forwarding boundary.	multicast boundary <i>group-address</i> { <i>mask</i> <i>mask-length</i> }	By default, no multicast forwarding boundary is configured.

NOTE:

The *group-address* { *mask* | *mask-length* } part of the **multicast boundary** command can be used to specify the multicast groups an admin-scope zone serves, in the range of 239.0.0.0/8. For more information about the **multicast boundary** command, see *IP Multicast Command Reference*.

Configuring C-BSRs for each admin-scope zone and the global-scope zone

In a network with administrative scoping enabled, group-range-specific BSRs are elected from C-BSRs. C-RPs in the network send advertisement messages to the specific BSR. The BSR summarizes the advertisement messages to form an RP-set and advertises it to all routers in the specific admin-scope zone.

All the routers use the same hash algorithm to get the RP address corresponding to the specific multicast group.

Configure C-BSRs for each admin-scope zone and the global-scope zone.

You can configure the hash mask length and C-BSR priority globally, in an admin-scope zone, and in the global scope zone.

- The values configured in the global scope zone or admin-scope zone have preference over the global values.
- If you do not configure these parameters in the global scope zone or admin-scope zone, the corresponding global values will be used.

For configuration of global C-BSR parameters, see "[Configuring global C-BSR parameters.](#)"

- Configure C-BSRs for each admin-scope zone
Perform the following configuration on the routers that you want to configure as C-BSRs in admin-scope zones.

To configure a C-BSR for an admin-scope zone:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure a C-BSR for an admin-scope zone.	c-bsr group <i>group-address</i> { <i>mask</i> <i>mask-length</i> } [hash-length <i>hash-length</i> priority <i>priority</i>] *	No C-BSRs are configured for an admin-scope zone by default.

NOTE:

The *group-address* { *mask* | *mask-length* } parameter of the **c-bsr group** command can specify the multicast groups the C-BSR serves, in the range of 239.0.0.0/8.

- Configure C-BSRs for the global-scope zone
Perform the following configuration on the routers that you want to configure as C-BSRs in the global-scope zone.
To configure a C-BSR for the global-scope zone:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure a C-BSR for the global-scope zone.	c-bsr global [hash-length <i>hash-length</i> priority <i>priority</i>] *	No C-BSRs are configured for the global-scope zone by default.

Configuring PIM-SSM

! IMPORTANT:

PIM-SSM needs the support of IGMPv3. Be sure to enable IGMPv3 on PIM routers with multicast receivers.

PIM-SSM configuration task list

Task	Remarks
Enabling PIM-SM	Required
Configuring the SSM group range	Optional
Configuring PIM common features	Optional

Configuration prerequisites

Before you configure PIM-SSM, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Determine the SSM group range.

Enabling PIM-SM

The implementation of the SSM model is based on some subsets of PIM-SM. Therefore, you must enable PIM-SM before configuring PIM-SSM.

When deploying a PIM-SSM domain, enable PIM-SM on non-border interfaces of the routers.

 **IMPORTANT:**

All the interfaces in the same VPN instance on the same device must operate in the same PIM mode.

Enabling PIM-SM globally on the public network

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IP multicast routing.	multicast routing-enable	Disabled by default
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable PIM-SM.	pim sm	Disabled by default

Enabling PIM-SM in a VPN instance

Step	Command	Description
1. Enter system view.	system-view	N/A
2. Create a VPN instance and enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A
3. Configure an RD for the VPN instance.	route-distinguisher <i>route-distinguisher</i>	No RD is configured by default.
4. Enable IP multicast routing.	multicast routing-enable	Disabled by default.

Step	Command	Description
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Bind the interface with a VPN instance.	ip binding vpn-instance <i>vpn-instance-name</i>	By default, an interface belongs to the public network, and it is not bound with any VPN instance.
7. Enable PIM-SM.	pim sm	Disabled by default.

For more information about the **ip vpn-instance**, **route-distinguisher**, and **ip binding vpn-instance** commands, see *IP Routing Command Reference*.

For more information about the **multicast routing-enable** command, see *IP Multicast Command Reference*.

Configuring the SSM group range

Configuration guidelines

As for whether the information from a multicast source is delivered to the receivers based on the PIM-SSM model or the PIM-SM model, this depends on whether the group address in the (S, G) channel subscribed by the receivers falls into the SSM group range. All PIM-SM-enabled interfaces assume that multicast groups within this address range are using the PIM-SSM model.

Make sure that the same SSM group range is configured on all routers in the entire domain. Otherwise, multicast information cannot be delivered through the SSM model.

When a member of a multicast group in the SSM group range sends an IGMPv1 or IGMPv2 report message, the device does not trigger a (*, G) join.

Configuration procedure

Perform the following configuration on all routers in the PIM-SSM domain.

To configure an SSM multicast group range:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the SSM group range.	ssm-policy <i>acl-number</i>	Optional 232.0.0.0/8 by default

Configuring PIM common features

For the functions or parameters that can be configured in both PIM view and interface view described in this section:

- In PIM view, the configuration is effective on all interfaces. In interface view, the configuration is effective on only the current interface.

- If the same function or parameter is configured in both PIM view and interface view, the configuration in interface view has preference over the configuration in PIM view, regardless of the configuration sequence.

PIM common feature configuration task list

Task	Remarks
Configuring a multicast data filter	Optional
Configuring a hello message filter	Optional
Configuring PIM hello options	Optional
Configuring the prune delay	Optional
Configuring PIM common timers	Optional
Configuring join/prune message sizes	Optional
Configuring PIM to work with BFD	Optional
Setting the DSCP value for PIM messages	Optional

Configuration prerequisites

Before you configure PIM common features, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Configure PIM-DM, or PIM-SM, or PIM-SSM.
- Determine the ACL rule for filtering multicast data.
- Determine the ACL rule defining a legal source address range for hello messages.
- Determine the priority for DR election (global value/interface level value).
- Determine the PIM neighbor timeout time (global value/interface value).
- Determine the prune message delay (global value/interface level value).
- Determine the prune override interval (global value/interface level value).
- Determine the prune delay.
- Determine the hello interval (global value/interface level value).
- Determine the maximum delay between hello message (interface level value).
- Determine the assert timeout time (global value/interface value).
- Determine the join/prune interval (global value/interface level value).
- Determine the join/prune timeout (global value/interface value).
- Determine the multicast source lifetime.
- Determine the maximum size of join/prune messages.
- Determine the maximum number of (S, G) entries in a join/prune message.
- Determine the DSCP value for PIM messages.

Configuring a multicast data filter

In either a PIM-DM domain or a PIM-SM domain, routers can check passing-by multicast data based on the configured filtering rules and determine whether to continue forwarding the multicast data. In other words, PIM routers can act as multicast data filters. These filters can help implement traffic control on one hand, and control the information available to receivers downstream to enhance data security on the other hand.

Generally, a smaller distance from the filter to the multicast source results in a more remarkable filtering effect.

This filter works not only on independent multicast data but also on multicast data encapsulated in register messages.

To configure a multicast data filter:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure a multicast group filter.	source-policy <i>acl-number</i>	No multicast data filter by default

Configuring a hello message filter

Along with the wide applications of PIM, the security requirement for the protocol is becoming increasingly demanding. The establishment of correct PIM neighboring relationships is the prerequisite for secure application of PIM. You can configure a legal source address range for hello messages on interfaces of routers to ensure the correct PIM neighboring relationships, guarding against PIM message attacks.

To configure a hello message filter:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure a hello message filter.	pim neighbor-policy <i>acl-number</i>	No hello message filter is configured by default.

NOTE:

With the hello message filter configured, if hello messages of an existing PIM neighbor fail to pass the filter, the PIM neighbor will be removed automatically when it times out.

Configuring PIM hello options

PIM hello options

In either a PIM-DM domain or a PIM-SM domain, the hello messages sent among routers contain the following configurable options:

- **DR_Priority** (for PIM-SM only)—Priority for DR election. The device with the highest priority wins the DR election. You can configure this parameter on all the routers in a multi-access network directly connected to multicast sources or receivers.
- **Holdtime**—The timeout time of PIM neighbor reachability state. When this timer times out, if the router has received no hello message from a neighbor, it assumes that this neighbor has expired or become unreachable.
- **LAN_Prune_Delay**—The delay of prune messages on a multi-access network. This option consists of LAN-delay (namely, prune message delay), override-interval, and neighbor tracking flag. If the LAN-delay or override-interval values of different PIM routers on a multi-access subnet are different, the largest value takes effect. If you want to enable neighbor tracking, be sure to enable the neighbor tracking feature on all PIM routers on a multi-access subnet.

The LAN-delay setting will cause the upstream routers to delay processing received prune messages. The override-interval sets the length of time that a downstream router can wait before sending a prune override message. When a router receives a prune message from a downstream router, it does not perform the prune action immediately. Instead, it maintains the current forwarding state for a period of LAN-delay plus override-interval. If the downstream router needs to continue receiving multicast data, it must send a join message within the prune override interval. Otherwise, the upstream router will perform the prune action when the period of LAN-delay plus override-interval times out.

A hello message sent from a PIM router contains a generation ID option. The generation ID is a random value for the interface on which the hello message is sent. Normally, the generation ID of a PIM router does not change unless the status of the router changes (for example, when PIM is just enabled on the interface or the device is restarted). When the router starts or restarts sending hello messages, it generates a new generation ID. If a PIM router finds that the generation ID in a hello message from the upstream router has changed, it assumes that the status of the upstream neighbor is lost or that the upstream neighbor has changed. In this case, it triggers a join message for state update.

If you disable join suppression (namely, enable neighbor tracking), be sure to disable the join suppression feature on all PIM routers on a multi-access subnet. Otherwise, the upstream router will fail to explicitly track join messages from downstream routers.

Configuring hello options globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure the priority for DR election.	hello-option dr-priority priority	Optional. 1 by default.
4. Configure PIM neighbor timeout time.	hello-option holdtime interval	Optional. 105 seconds by default.
5. Configure the prune message delay time (LAN-delay).	hello-option lan-delay interval	Optional. 500 milliseconds by default.
6. Configure the prune override interval.	hello-option override-interval interval	Optional. 2500 milliseconds by default.
7. Disable join suppression.	hello-option neighbor-tracking	Enabled by default.

Configuring hello options on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the priority for DR election.	pim hello-option dr-priority <i>priority</i>	Optional. 1 by default.
4. Configure PIM neighbor timeout time.	pim hello-option holdtime <i>interval</i>	Optional. 105 seconds by default.
5. Configure the prune message delay time (LAN-delay).	pim hello-option lan-delay <i>interval</i>	Optional. 500 milliseconds by default.
6. Configure the prune override interval.	pim hello-option override-interval <i>interval</i>	Optional. 2,00 milliseconds by default.
7. Disable join suppression.	pim hello-option neighbor-tracking	Enabled by default.
8. Configure the interface to reject hello messages without a generation ID.	pim require-genid	By default, hello messages without Generation_ID are accepted.

Configuring the prune delay

Configuring a prune delay interval on an upstream router on a shared network segment can make the upstream router not perform the prune action immediately after it receives the prune message from its downstream router. Instead, the upstream router maintains the current forwarding state for a period of time that the prune delay interval defines. In this period, if the upstream router receives a join message from the downstream router, it cancels the prune action. Otherwise, it performs the prune action.

To configure the prune delay time:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure the prune delay interval.	prune delay <i>interval</i>	Optional. 3 seconds by default, which equals the prune pending time.

Configuring PIM common timers

PIM common timers

PIM routers discover PIM neighbors and maintain PIM neighboring relationships with other routers by periodically sending out hello messages.

After receiving a hello message, a PIM router waits a random period, which is smaller than the maximum delay between hello messages, before sending a hello message. This delay avoids collisions that occur when multiple PIM routers send hello messages simultaneously.

A PIM router periodically sends join/prune messages to its upstream for state update. A join/prune message contains the join/prune timeout time. The upstream router sets a join/prune timeout timer for each pruned downstream interface.

Any router that has lost assert election will prune its downstream interface and maintain the assert state for a period of time. When the assert state times out, the assert losers will resume multicast forwarding.

When a router fails to receive subsequent multicast data from multicast source S, the router does not immediately delete the corresponding (S, G) entry. Instead, it maintains the (S, G) entry for a period of time (namely, the multicast source lifetime) before deleting the (S, G) entry.

Configuring PIM common timers globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure the hello interval.	timer hello interval	Optional. 30 seconds by default.
4. Configure the join/prune interval.	timer join-prune interval	Optional. 60 seconds by default.
5. Configure the join/prune timeout time.	holdtime join-prune interval	Optional. 210 seconds by default.
6. Configure assert timeout time.	holdtime assert interval	Optional. 180 seconds by default.
7. Configure the multicast source lifetime.	source-lifetime interval	Optional. 210 seconds by default.

Configuring PIM common timers on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface interface-type interface-number	N/A
3. Configure the hello interval.	pim timer hello interval	Optional. 30 seconds by default.
4. Configure the maximum delay between hello messages.	pim triggered-hello-delay interval	Optional. 5 seconds by default.
5. Configure the join/prune interval.	pim timer join-prune interval	Optional. 60 seconds by default.

Step	Command	Remarks
6. Configure the join/prune timeout time.	pim holdtime join-prune interval	Optional. 210 seconds by default.
7. Configure assert timeout time.	pim holdtime assert interval	Optional. 180 seconds by default.

NOTE:

If no special networking requirements are raised, use the default settings.

Configuring join/prune message sizes

A large size of a join/prune message might result in loss of a larger amount of information if a message is lost. You can set a small value for the size of each join/prune message to reduce the impact in case of the loss of a message.

By controlling the maximum number of (S, G) entries in a join/prune message, you can effectively reduce the number of (S, G) entries sent per unit of time.

! **IMPORTANT:**

If PIM snooping-enabled switches are deployed in the PIM network, be sure to set a value no greater than the path MTU for the maximum size of each join/prune message on the receiver-side edge PIM devices

To configure join/prune message sizes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network PIM view or VPN instance PIM view.	pim [vpn-instance vpn-instance-name]	N/A
3. Configure the maximum size of each join/prune message.	ip-pkt-size packet-size	Optional. 8100 bytes by default.
4. Configure the maximum number of (S, G) entries in a join/prune message.	ip-queue-size queue-size	Optional. 1020 by default.

Configuring PIM to work with BFD

PIM uses hello messages to elect a DR for a multi-access network. The elected DR will be the only multicast forwarder on the multi-access network.

If the DR fails, a new DR election process will start after the DR is aged out. However, it might take a long period of time. To start a new DR election process immediately after the original DR fails, enable PIM to work with Bidirectional Forwarding Detection (BFD) on a multi-access network to detect failures of the links among PIM neighbors. You must enable PIM to work with BFD on all PIM-capable routers on a multi-access network, so that the PIM neighbors can fast detect DR failures and start a new DR election process.

For more information about BFD, see *High Availability Configuration Guide*.

Before you configure this feature on an interface, be sure to enable PIM-DM or PIM-SM on the interface. To enable PIM to work with BFD:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Enable PIM to work with BFD.	pim bfd enable	Disabled by default

Setting the DSCP value for PIM messages

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network IGMP view or VPN instance PIM view.	pim [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Set the DSCP value for PIM messages	dscp <i>dscp-value</i>	Optional. By default, the DSCP value in PIM messages is 48.

Displaying and maintaining PIM

Task	Command	Remarks
Display the BSR information in the PIM-SM domain and locally configured C-RP information in effect.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] bsr-info [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information of unicast routes used by PIM.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] claimed-route [<i>source-address</i>] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the number of PIM control messages.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] control-message counters [message-type { probe register register-stop }] [interface <i>interface-type interface-number</i> message-type { assert bsr crp graft graft-ack hello join-prune state-refresh }] *] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display the DF information of BIDIR-PIM.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] df-info [<i>rp-address</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information about unacknowledged PIM-DM graft messages.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] grafts [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the PIM information on an interface or all interfaces.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] interface [<i>interface-type</i> <i>interface-number</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information of join/prune messages to send.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] join-prune mode { sm [flags <i>flag-value</i>] ssm } [interface <i>interface-type</i> <i>interface-number</i> neighbor <i>neighbor-address</i>] * [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display PIM neighboring information.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] neighbor [interface <i>interface-type</i> <i>interface-number</i> <i>neighbor-address</i> verbose] * [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the content of the PIM routing table.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] routing-table [<i>group-address</i> [mask { <i>mask-length</i> <i>mask</i> }] <i>source-address</i> [mask { <i>mask-length</i> <i>mask</i> }]] incoming-interface [<i>interface-type</i> <i>interface-number</i> register] outgoing-interface { include exclude match } { <i>interface-type</i> <i>interface-number</i> register } mode <i>mode-type</i> flags <i>flag-value</i> fsm] * [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the RP information.	display pim [all-instance vpn-instance <i>vpn-instance-name</i>] rp-info [<i>group-address</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Reset PIM control message counters.	reset pim [all-instance vpn-instance <i>vpn-instance-name</i>] control-message counters [interface <i>interface-type</i> <i>interface-number</i>]	Available in user view

PIM configuration examples

PIM-DM configuration example

Network requirements

As shown in Figure 51, receivers receive VOD information through multicast. The receiver groups of different organizations form stub networks, and one or more receiver hosts exist in each stub network. The entire PIM domain is operating in the dense mode.

Host A and Host C are multicast receivers in two stub networks.

IGMPv2 runs between Switch A and N1 and between Switch B/Switch C and N2.

Figure 51 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	10.110.1.1/24	Switch D	Vlan-int300	10.110.5.1/24
	Vlan-int103	192.168.1.1/24		Vlan-int103	192.168.1.2/24
Switch B	Vlan-int200	10.110.2.1/24		Vlan-int101	192.168.2.2/24
	Vlan-int101	192.168.2.1/24		Vlan-int102	192.168.3.2/24
Switch C	Vlan-int200	10.110.2.2/24			
	Vlan-int102	192.168.3.1/24			

Configuration procedure

1. Configure IP addresses and unicast routing:

Configure the IP address and subnet mask for each interface as per [Figure 51](#). (Details not shown.)
Configure OSPF on the switches in the PIM-DM domain to ensure network-layer reachability among them. (Details not shown.)

2. Enable IP multicast routing, and enable PIM-DM and IGMP:

Enable IP multicast routing on Switch A, enable PIM-DM on each interface, and enable IGMP on VLAN-interface 100, which connects Switch A to the stub network.

```
<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] igmp enable
[SwitchA-Vlan-interface100] pim dm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 103
[SwitchA-Vlan-interface103] pim dm
[SwitchA-Vlan-interface103] quit
```

The configuration on Switch B and Switch C is similar to that on Switch A.

Enable IP multicast routing on Switch D, and enable PIM-DM on each interface.

```
<SwitchD> system-view
[SwitchD] multicast routing-enable
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] pim dm
[SwitchD-Vlan-interface300] quit
[SwitchD] interface vlan-interface 103
[SwitchD-Vlan-interface103] pim dm
[SwitchD-Vlan-interface103] quit
[SwitchD] interface vlan-interface 101
[SwitchD-Vlan-interface101] pim dm
[SwitchD-Vlan-interface101] quit
[SwitchD] interface vlan-interface 102
[SwitchD-Vlan-interface102] pim dm
[SwitchD-Vlan-interface102] quit
```

3. Verify the configuration:

Display PIM configuration information on Switch D.

```
[SwitchD] display pim interface
VPN-Instance: public net

```

Interface	NbrCnt	HelloInt	DR-Pri	DR-Address	
Vlan300	0	30	1	10.110.5.1	(local)
Vlan103	1	30	1	192.168.1.2	(local)
Vlan101	1	30	1	192.168.2.2	(local)
Vlan102	1	30	1	192.168.3.2	(local)

Display PIM neighboring relationships on Switch D.

```
[SwitchD] display pim neighbor
VPN-Instance: public net
Total Number of Neighbors = 3
```

Neighbor	Interface	Uptime	Expires	Dr-Priority
192.168.1.1	Vlan103	00:02:22	00:01:27	1
192.168.2.1	Vlan101	00:00:22	00:01:29	3
192.168.3.1	Vlan102	00:00:23	00:01:31	5

Assume that Host A needs to receive the information addressed to multicast group G (225.1.1.1). After multicast source S (10.110.5.100/24) sends multicast packets to the multicast group G, an SPT is established through traffic flooding. Switches on the SPT path (Switch A and Switch D) have their (S, G) entries. Host A sends an IGMP report to Switch A to join the multicast group G, and a (*, G) entry is generated on Switch A. You can use the **display pim routing-table** command to view the PIM routing table information on each switch. For example:

Display PIM routing table information on Switch A.

```
[SwitchA] display pim routing-table
VPN-Instance: public net
Total 1 (*, G) entry; 1 (S, G) entry

(*, 225.1.1.1)
  Protocol: pim-dm, Flag: WC
  UpTime: 00:04:25
  Upstream interface: NULL
    Upstream neighbor: NULL
    RPF prime neighbor: NULL
  Downstream interface(s) information:
  Total number of downstreams: 1
    1: Vlan-interface100
      Protocol: igmp, UpTime: 00:04:25, Expires: never

(10.110.5.100, 225.1.1.1)
  Protocol: pim-dm, Flag: ACT
  UpTime: 00:06:14
  Upstream interface: Vlan-interface103
    Upstream neighbor: 192.168.1.2
    RPF prime neighbor: 192.168.1.2
  Downstream interface(s) information:
  Total number of downstreams: 1
    1: Vlan-interface100
      Protocol: pim-dm, UpTime: 00:04:25, Expires: never
```

Display PIM routing table information on Switch D.

```
[SwitchD] display pim routing-table
VPN-Instance: public net
Total 0 (*, G) entry; 1 (S, G) entry

(10.110.5.100, 225.1.1.1)
  Protocol: pim-dm, Flag: LOC ACT
  UpTime: 00:03:27
  Upstream interface: Vlan-interface300
    Upstream neighbor: NULL
    RPF prime neighbor: NULL
```

```

Downstream interface(s) information:
Total number of downstreams: 2
  1: Vlan-interface103
      Protocol: pim-dm, UpTime: 00:03:27, Expires: never
  2: Vlan-interface102
      Protocol: pim-dm, UpTime: 00:03:27, Expires: never

```

PIM-SM non-scoped zone configuration example

Network requirements

As shown in [Figure 52](#), receivers receive VOD information through multicast. The receiver groups of different organizations form stub networks, and one or more receiver hosts exist in each stub network. The entire PIM-SM domain contains only one BSR.

Host A and Host C are multicast receivers in two stub networks.

VLAN-interface 105 on Switch D and VLAN-interface 102 on Switch E act as C-BSRs and C-RPs. The C-BSR on Switch E has a higher priority. The multicast group range served by the C-RP is 225.1.1.0/24. Modify the hash mask length to map a certain number of consecutive group addresses within the range to the two C-RPs.

IGMPv2 runs between Switch A and N1 and between Switch B/Switch C and N2.

Figure 52 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	10.110.1.1/24	Switch D	Vlan-int300	10.110.5.1/24
	Vlan-int101	192.168.1.1/24		Vlan-int101	192.168.1.2/24
	Vlan-int102	192.168.9.1/24		Vlan-int105	192.168.4.2/24
Switch B	Vlan-int200	10.110.2.1/24	Switch E	Vlan-int104	192.168.3.2/24

	Vlan-int103	192.168.2.1/24	Vlan-int103	192.168.2.2/24
Switch C	Vlan-int200	10.110.2.2/24	Vlan-int102	192.168.9.2/24
	Vlan-int104	192.168.3.1/24	Vlan-int105	192.168.4.1/24

Configuration procedure

1. Configure IP addresses and unicast routing:

Configure the IP address and subnet mask for each interface as per [Figure 52](#). (Details not shown.)

Configure OSPF on the switches in the PIM-SM domain to ensure network-layer reachability among them. (Details not shown.)

2. Enable IP multicast routing, and enable PIM-SM and IGMP:

Enable IP multicast routing on Switch A, enable PIM-SM on each interface, and enable IGMP on VLAN-interface 100, which connects Switch A to the stub network.

```
<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] igmp enable
[SwitchA-Vlan-interface100] pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim sm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface vlan-interface 102
[SwitchA-Vlan-interface102] pim sm
[SwitchA-Vlan-interface102] quit
```

The configuration on Switch B and Switch C is similar to that on Switch A. The configuration on Switch D and Switch E is also similar to that on Switch A except that it is not necessary to enable IGMP on the corresponding interfaces on these two switches.

3. Configure a C-BSR and a C-RP:

On Switch D, configure the service scope of RP, specify a C-BSR and a C-RP, and set the hash mask length to 32 and the priority of the C-BSR to 10.

```
<SwitchD> system-view
[SwitchD] acl number 2005
[SwitchD-acl-basic-2005] rule permit source 225.1.1.0 0.0.0.255
[SwitchD-acl-basic-2005] quit
[SwitchD] pim
[SwitchD-pim] c-bsr vlan-interface 105 32 10
[SwitchD-pim] c-rp vlan-interface 105 group-policy 2005
[SwitchD-pim] quit
```

On Switch E, configure the service scope of RP advertisements, specify a C-BSR and a C-RP, and set the hash mask length to 32 and the priority of the C-BSR to 20.

```
<SwitchE> system-view
[SwitchE] acl number 2005
[SwitchE-acl-basic-2005] rule permit source 225.1.1.0 0.0.0.255
[SwitchE-acl-basic-2005] quit
[SwitchE] pim
[SwitchE-pim] c-bsr vlan-interface 102 32 20
```

```
[SwitchE-pim] c-rp vlan-interface 102 group-policy 2005
[SwitchE-pim] quit
```

4. Verify the configuration:

Display PIM configuration information on Switch A.

```
[SwitchA] display pim interface
VPN-Instance: public net
Interface          NbrCnt HelloInt  DR-Pri  DR-Address
Vlan100            0       30       1       10.110.1.1 (local)
Vlan101            1       30       1       192.168.1.2
Vlan102            1       30       1       192.168.9.2
```

Display BSR information and the locally configured C-RP information in effect on Switch A.

```
[SwitchA] display pim bsr-info
VPN-Instance: public net
Elected BSR Address: 192.168.9.2
  Priority: 20
  Hash mask length: 32
  State: Accept Preferred
  Scope: Not scoped
  Uptime: 00:40:40
  Expires: 00:01:42
```

Display BSR information and the locally configured C-RP information in effect on Switch D.

```
[SwitchD] display pim bsr-info
VPN-Instance: public net
Elected BSR Address: 192.168.9.2
  Priority: 20
  Hash mask length: 32
  State: Accept Preferred
  Scope: Not scoped
  Uptime: 00:05:26
  Expires: 00:01:45
Candidate BSR Address: 192.168.4.2
  Priority: 10
  Hash mask length: 32
  State: Candidate
  Scope: Not scoped

Candidate RP: 192.168.4.2(Vlan-interface105)
  Priority: 192
  HoldTime: 150
  Advertisement Interval: 60
  Next advertisement scheduled at: 00:00:34
```

Display BSR information and the locally configured C-RP information in effect on Switch E.

```
[SwitchE] display pim bsr-info
VPN-Instance: public net
Elected BSR Address: 192.168.9.2
  Priority: 20
  Hash mask length: 32
```

```
State: Elected
Scope: Not scoped
Uptime: 00:01:18
Next BSR message scheduled at: 00:01:52
Candidate BSR Address: 192.168.9.2
Priority: 20
Hash mask length: 32
State: Elected
Scope: Not scoped
```

```
Candidate RP: 192.168.9.2(Vlan-interface102)
Priority: 192
HoldTime: 150
Advertisement Interval: 60
Next advertisement scheduled at: 00:00:48
```

Display RP information on Switch A.

```
[SwitchA] display pim rp-info
```

```
VPN-Instance: public net
PIM-SM BSR RP information:
Group/MaskLen: 225.1.1.0/24
RP: 192.168.4.2
Priority: 192
HoldTime: 150
Uptime: 00:51:45
Expires: 00:02:22
```

```
RP: 192.168.9.2
Priority: 192
HoldTime: 150
Uptime: 00:51:45
Expires: 00:02:22
```

Assume that Host A needs to receive information addressed to the multicast group G (225.1.1.0). The RP corresponding to the multicast group G is Switch E as a result of hash calculation, so an RPT will be built between Switch A and Switch E. When the multicast source S (10.110.5.100/24) registers with the RP, an SPT will be built between Switch D and Switch E. After receiving multicast data, Switch A immediately switches from the RPT to the SPT. Switches on the RPT path (Switch A and Switch E) have a (*, G) entry, and switches on the SPT path (Switch A and Switch D) have an (S, G) entry. You can use the **display pim routing-table** command to view the PIM routing table information on the switches. For example:

Display PIM routing table information on Switch A.

```
[SwitchA] display pim routing-table
```

```
VPN-Instance: public net
Total 1 (*, G) entry; 1 (S, G) entry
```

```
(*, 225.1.1.0)
RP: 192.168.9.2
Protocol: pim-sm, Flag: WC
UpTime: 00:13:46
```

```
Upstream interface: Vlan-interface102
  Upstream neighbor: 192.168.9.2
  RPF prime neighbor: 192.168.9.2
Downstream interface(s) information:
Total number of downstreams: 1
  1: Vlan-interface100
    Protocol: igmp, UpTime: 00:13:46, Expires: 00:03:06
```

```
(10.110.5.100, 225.1.1.0)
RP: 192.168.9.2
Protocol: pim-sm, Flag: SPT ACT
UpTime: 00:00:42
Upstream interface: Vlan-interface101
  Upstream neighbor: 192.168.1.2
  RPF prime neighbor: 192.168.1.2
Downstream interface(s) information:
Total number of downstreams: 1
  1: Vlan-interface100
    Protocol: pim-sm, UpTime: 00:00:42, Expires: 00:03:06
```

The information on Switch B and Switch C is similar to that on Switch A.

Display PIM routing table information on Switch D.

```
[SwitchD] display pim routing-table
VPN-Instance: public net
Total 0 (*, G) entry; 1 (S, G) entry
```

```
(10.110.5.100, 225.1.1.0)
RP: 192.168.9.2
Protocol: pim-sm, Flag: SPT LOC ACT
UpTime: 00:00:42
Upstream interface: Vlan-interface300
  Upstream neighbor: NULL
  RPF prime neighbor: NULL
Downstream interface(s) information:
Total number of downstreams: 1
  1: Vlan-interface105
    Protocol: pim-sm, UpTime: 00:00:42, Expires: 00:02:26
```

Display PIM routing table information on Switch E.

```
[SwitchE] display pim routing-table
VPN-Instance: public net
Total 1 (*, G) entry; 0 (S, G) entry
```

```
(*, 225.1.1.0)
RP: 192.168.9.2 (local)
Protocol: pim-sm, Flag: WC
UpTime: 00:13:16

  Upstream neighbor: 192.168.4.2
  RPF prime neighbor: 192.168.4.2
```

```
Downstream interface(s) information:
Total number of downstreams: 1
  1: Vlan-interface102
      Protocol: pim-sm, UpTime: 00:13:16, Expires: 00:03:22
```

PIM-SM admin-scope zone configuration example

Network requirements

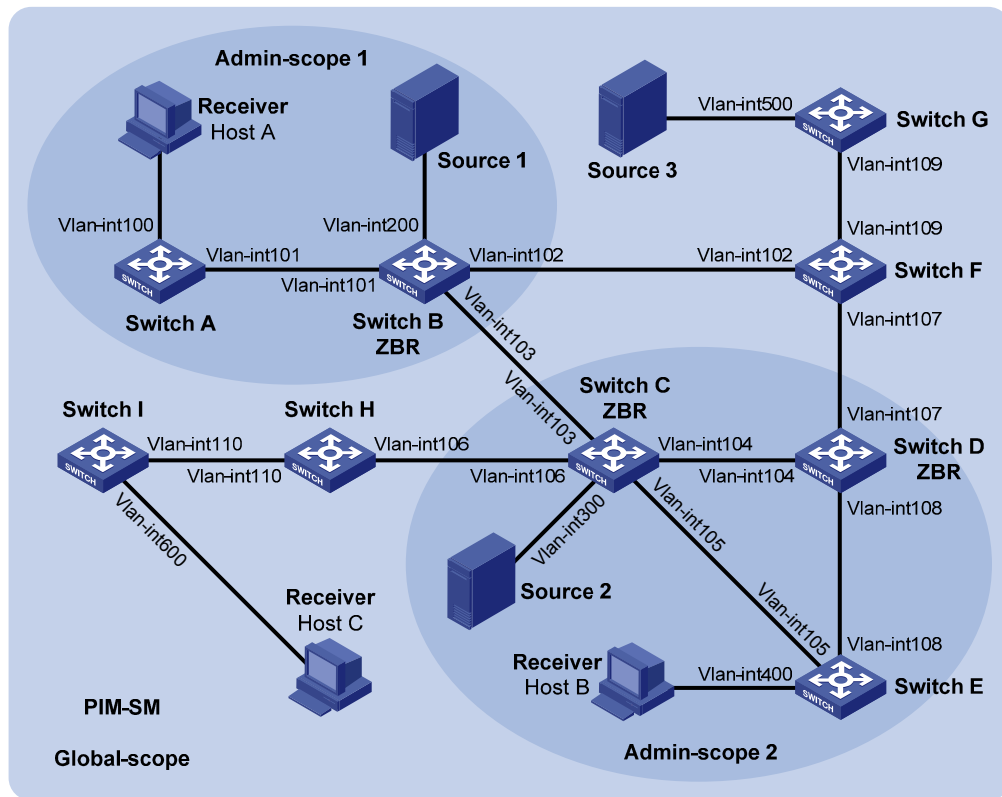

As shown in [Figure 53](#), receivers receive VOD information through multicast. The entire PIM-SM domain is divided into admin-scope zone 1, admin-scope zone 2, and the global zone. Switch B, Switch C, and Switch D are ZBRs of these three domains respectively.

Source 1 and Source 2 send different multicast information to multicast group 239.1.1.1. Host A receives the multicast information only from Source 1, and Host B receives the multicast information only from Source 2. Source 3 sends multicast information to multicast group 224.1.1.1. Host C is a multicast receiver for this multicast group.

VLAN-interface 101 of Switch B acts as a C-BSR and C-RP of admin-scope zone 1, which serves the multicast group range 239.0.0.0/8. VLAN-interface 104 of Switch D acts as a C-BSR and C-RP of admin-scope zone 2, which also serves the multicast group range 239.0.0.0/8. VLAN-interface 109 of Switch F acts as C-BSRs and C-RPs of the global scope zone, which serves all the multicast groups other than those in the 239.0.0.0/8 range.

IGMPv2 runs between Switch A, Switch E, Switch I, and their respective receivers.

Figure 53 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	192.168.1.1/24	Switch D	Vlan-int104	10.110.4.2/24
	Vlan-int101	10.110.1.1/24		Vlan-int108	10.110.7.1/24
Switch B	Vlan-int200	192.168.2.1/24	Switch E	Vlan-int400	192.168.4.1/24
	Vlan-int101	10.110.1.2/24		Vlan-int105	10.110.5.2/24
	Vlan-int103	10.110.2.1/24		Vlan-int108	10.110.7.2/24
	Vlan-int102	10.110.3.1/24	Switch F	Vlan-int109	10.110.9.1/24
Switch C	Vlan-int300	192.168.3.1/24		Vlan-int107	10.110.8.2/24
	Vlan-int104	10.110.4.1/24		Vlan-int102	10.110.3.2/24
	Vlan-int105	10.110.5.1/24	Switch G	Vlan-int500	192.168.5.1/24
	Vlan-int103	10.110.2.2/24		Vlan-int109	10.110.9.2/24
	Vlan-int106	10.110.6.1/24	Source 1	—	192.168.2.10/24
Switch H	Vlan-int110	10.110.10.1/24	Source 2	—	192.168.3.10/24
	Vlan-int106	10.110.6.2/24	Source 3	—	192.168.5.10/24
Switch I	Vlan-int600	192.168.6.1/24			
	Vlan-int110	10.110.10.2/24			

Configuration procedure

1. Configure IP addresses and unicast routing:
 Configure the IP address and subnet mask for each interface as per Figure 53. (Details not shown.)
 Configure OSPF on the switches in the PIM-SM domain to ensure network-layer reachability among them. (Details not shown.)
2. Enable IP multicast routing and administrative scoping, and enable PIM-SM and IGMP:

Enable IP multicast routing and administrative scoping on Switch A, enable PIM-SM on each interface, and enable IGMP on the host-side interface VLAN-interface 100.

```
<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] pim
[SwitchA-pim] c-bsr admin-scope
[SwitchA-pim] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] igmp enable
[SwitchA-Vlan-interface100] pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim sm
[SwitchA-Vlan-interface101] quit
```

The configuration on Switch E and Switch I is similar to the configuration on Switch A.

On Switch B, enable IP multicast routing and administrative scoping, and enable PIM-SM on each interface.

```
<SwitchB> system-view
[SwitchB] multicast routing-enable
[SwitchB] pim
[SwitchB-pim] c-bsr admin-scope
[SwitchB-pim] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] pim sm
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] pim sm
[SwitchB-Vlan-interface101] quit
[SwitchB] interface vlan-interface 102
[SwitchB-Vlan-interface102] pim sm
[SwitchB-Vlan-interface102] quit
[SwitchB] interface vlan-interface 103
[SwitchB-Vlan-interface103] pim sm
[SwitchB-Vlan-interface103] quit
```

The configuration on Switch C, Switch D, Switch F, Switch G, and Switch H is similar to the configuration on Switch B. (Details not shown.)

3. Configure an admin-scope zone boundary:

On Switch B, configure VLAN-interface 102 and VLAN-interface 103 to be the boundary of admin-scope zone 1.

```
[SwitchB] interface vlan-interface 102
[SwitchB-Vlan-interface102] multicast boundary 239.0.0.0 8
[SwitchB-Vlan-interface102] quit
[SwitchB] interface vlan-interface 103
[SwitchB-Vlan-interface103] multicast boundary 239.0.0.0 8
[SwitchB-Vlan-interface103] quit
```

On Switch C, configure VLAN-interface 103 and VLAN-interface 106 to be the boundary of admin-scope zone 2.

```

<SwitchC> system-view
[SwitchC] interface vlan-interface 103
[SwitchC-Vlan-interface103] multicast boundary 239.0.0.0 8
[SwitchC-Vlan-interface103] quit
[SwitchC] interface vlan-interface 106
[SwitchC-Vlan-interface106] multicast boundary 239.0.0.0 8
[SwitchC-Vlan-interface106] quit

```

On Switch D, configure VLAN-interface 107 to be the boundary of admin-scope zone 2.

```

<SwitchD> system-view
[SwitchD] interface vlan-interface 107
[SwitchD-Vlan-interface107] multicast boundary 239.0.0.0 8
[SwitchD-Vlan-interface107] quit

```

4. Configure C-BSRs and C-RPs:

On Switch B, configure the service scope of RP advertisements, and configure VLAN-interface 101 as a C-BSR and C-RP of admin-scope zone 1.

```

[SwitchB] acl number 2001
[SwitchB-acl-basic-2001] rule permit source 239.0.0.0 0.255.255.255
[SwitchB-acl-basic-2001] quit
[SwitchB] pim
[SwitchB-pim] c-bsr group 239.0.0.0 8
[SwitchB-pim] c-bsr vlan-interface 101
[SwitchB-pim] c-rp vlan-interface 101 group-policy 2001
[SwitchB-pim] quit

```

On Switch D, configure the service scope of RP advertisements, and configure VLAN-interface 104 as a C-BSR and C-RP of admin-scope zone 2.

```

[SwitchD] acl number 2001
[SwitchD-acl-basic-2001] rule permit source 239.0.0.0 0.255.255.255
[SwitchD-acl-basic-2001] quit
[SwitchD] pim
[SwitchD-pim] c-bsr group 239.0.0.0 8
[SwitchD-pim] c-bsr vlan-interface 104
[SwitchD-pim] c-rp vlan-interface 104 group-policy 2001
[SwitchD-pim] quit

```

On Switch F, configure VLAN-interface 109 as a C-BSR and C-RP in the global scope zone.

```

<SwitchF> system-view
[SwitchF] pim
[SwitchF-pim] c-bsr global
[SwitchF-pim] c-bsr vlan-interface 109
[SwitchF-pim] c-rp vlan-interface 109
[SwitchF-pim] quit

```

5. Verify the configuration:

Display BSR information and the locally configured C-RP information on Switch B.

```

[SwitchB] display pim bsr-info
VPN-Instance: public net
Elected BSR Address: 10.110.9.1
  Priority: 64
  Hash mask length: 30

```

```
State: Accept Preferred

Expires: 00:01:58

```

BIDIR-PIM configuration example

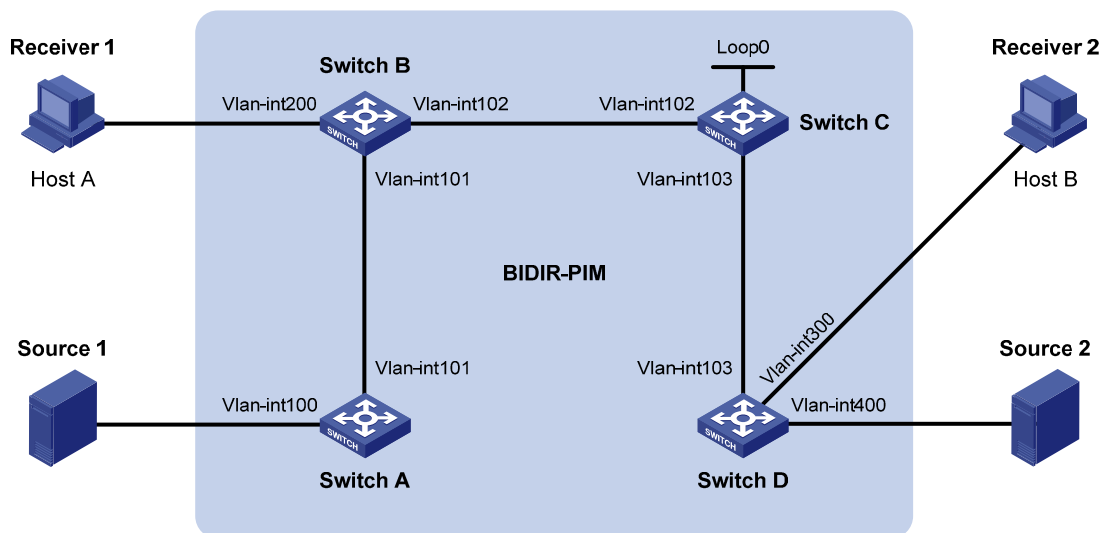

Network requirements

In the BIDIR-PIM domain shown in [Figure 54](#). Source 1 and Source 2 send different multicast information to multicast group 225.1.1.1. Host A and Host B receive multicast information from the two sources.

VLAN interface 102 of Switch C acts as a C-BSR, and loopback interface 0 of Switch C acts as a C-RP of the BIDIR-PIM domain.

IGMPv2 runs between Switch B and Host A, and between Switch D and Host B.

Figure 54 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	192.168.1.1/24	Switch D	Vlan-int300	192.168.3.1/24

	Vlan-int101	10.110.1.1/24		Vlan-int400	192.168.4.1/24
Switch B	Vlan-int200	192.168.2.1/24		Vlan-int103	10.110.3.2/24
	Vlan-int101	10.110.1.2/24	Source 1	-	192.168.1.100/24
	Vlan-int102	10.110.2.1/24	Source 2	-	192.168.4.100/24
Switch C	Vlan-int102	10.110.2.2/24	Receiver 1	-	192.168.2.100/24
	Vlan-int103	10.110.3.1/24	Receiver 2	-	192.168.3.100/24
	Loop0	1.1.1.1/32			

Configuration procedure

1. Configure IP addresses and unicast routing:
 - # Configure an IP address and subnet mask for each interface as per [Figure 54](#). (Details not shown.)
 - # Configure OSPF on the switches in the BIDIR-PIM domain to ensure network-layer reachability among them. (Details not shown.)

2. Enable IP multicast routing, PIM-SM, BIDIR-PIM, and IGMP:

On Switch A, enable IP multicast routing, enable PIM-SM on each interface, and enable BIDIR-PIM.

```
<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim sm
[SwitchA-Vlan-interface101] quit
[SwitchA] pim
[SwitchA-pim] bidir-pim enable
[SwitchA-pim] quit
```

On Switch B, enable IP multicast routing, enable PIM-SM on each interface, enable IGMP in VLAN interface 200, and enable BIDIR-PIM.

```
<SwitchB> system-view
[SwitchB] multicast routing-enable
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] igmp enable
[SwitchB-Vlan-interface200] pim sm
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] pim sm
[SwitchB-Vlan-interface101] quit
[SwitchB] interface vlan-interface 102
[SwitchB-Vlan-interface102] pim sm
[SwitchB-Vlan-interface102] quit
[SwitchB] pim
[SwitchB-pim] bidir-pim enable
[SwitchB-pim] quit
```

On Switch C, enable IP multicast routing, enable PIM-SM on each interface, and enable BIDIR-PIM.

```
<SwitchC> system-view
[SwitchC] multicast routing-enable
[SwitchC] interface vlan-interface 102
[SwitchC-Vlan-interface102] pim sm
[SwitchC-Vlan-interface102] quit
[SwitchC] interface vlan-interface 103
[SwitchC-Vlan-interface103] pim sm
[SwitchC-Vlan-interface103] quit
[SwitchC] interface loopback 0
[SwitchC-LoopBack0] pim sm
[SwitchC-LoopBack0] quit
[SwitchC] pim
[SwitchC-pim] bidir-pim enable
```

On Switch D, enable IP multicast routing, enable PIM-SM on each interface, enable IGMP in VLAN interface 300, and enable BIDIR-PIM.

```
<SwitchD> system-view
[SwitchD] multicast routing-enable
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] igmp enable
[SwitchD-Vlan-interface300] pim sm
[SwitchD-Vlan-interface300] quit
[SwitchD] interface vlan-interface 400
[SwitchD-Vlan-interface400] pim sm
[SwitchD-Vlan-interface400] quit
[SwitchD] interface vlan-interface 103
[SwitchD-Vlan-interface103] pim sm
[SwitchD-Vlan-interface103] quit
[SwitchD] pim
[SwitchD-pim] bidir-pim enable
[SwitchD-pim] quit
```

3. Configure C-BSR and C-RP:

On Switch C, configure VLAN interface 102 as a C-BSR, and loopback interface 0 as a C-RP for the entire BIDIR-PIM domain.

```
[SwitchC-pim] c-bsr vlan-interface 102
[SwitchC-pim] c-rp loopback 0 bidir
[SwitchC-pim] quit
```

4. Verify the configuration:

Display the DF information of BIDIR-PIM on Switch A.

```
[SwitchA] display pim df-info
VPN-Instance: public net
```

```
RP Address: 1.1.1.1
```

Interface	State	DF-Pref	DF-Metric	DF-Uptime	DF-Address

PIM-SSM configuration example

Network requirements

As shown in [Figure 55](#), receivers receive VOD information through multicast. The receiver groups of different organizations form stub networks, and one or more receiver hosts exist in each stub network. The entire PIM domain is operating in the SSM mode.

Host A and Host C are multicast receivers in two stub networks.

The SSM group range is 232.1.1.0/24.

IGMPv3 runs between Switch A and N1 and between Switch B/Switch C and N2.

Figure 55 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	10.110.1.1/24	Switch D	Vlan-int300	10.110.5.1/24
	Vlan-int101	192.168.1.1/24		Vlan-int101	192.168.1.2/24
	Vlan-int102	192.168.9.1/24		Vlan-int105	192.168.4.2/24
Switch B	Vlan-int200	10.110.2.1/24	Switch E	Vlan-int104	192.168.3.2/24
	Vlan-int103	192.168.2.1/24		Vlan-int103	192.168.2.2/24
Switch C	Vlan-int200	10.110.2.2/24		Vlan-int102	192.168.9.2/24
	Vlan-int104	192.168.3.1/24		Vlan-int105	192.168.4.1/24

Configuration procedure

1. Configure IP addresses and unicast routing:
Configure the IP address and subnet mask for each interface as per Figure 55. (Details not shown.)
Configure OSPF on the switches in the PIM-SSM domain to ensure network-layer reachability among them. (Details not shown.)
2. Enable IP multicast routing, and enable PIM-SM and IGMP:
Enable IP multicast routing on Switch A, enable PIM-SM on each interface, and run IGMPv3 on VLAN-interface 100, which connects Switch A to the stub network.

```

<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] igmp enable
[SwitchA-Vlan-interface100] igmp version 3
[SwitchA-Vlan-interface100] pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101

```

```
[SwitchA-Vlan-interface101] pim sm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface vlan-interface 102
[SwitchA-Vlan-interface102] pim sm
[SwitchA-Vlan-interface102] quit
```

The configuration on Switch B and Switch C is similar to that on Switch A. The configuration on Switch D and Switch E is also similar to that on Switch A except that it is not necessary to enable IGMP on the corresponding interfaces on these two switches.

3. Configure the SSM group range:

Configure the SSM group range to be 232.1.1.0/24 on Switch A.

```
[SwitchA] acl number 2000
[SwitchA-acl-basic-2000] rule permit source 232.1.1.0 0.0.0.255
[SwitchA-acl-basic-2000] quit
[SwitchA] pim
[SwitchA-pim] ssm-policy 2000
[SwitchA-pim] quit
```

The configuration on Switch B, Switch C, Switch D and Switch E is similar to that on Switch A.

4. Verify the configuration:

Display PIM configuration information on Switch A.

```
[SwitchA] display pim interface
VPN-Instance: public net
Interface           NbrCnt  HelloInt   DR-Pri     DR-Address
Vlan100             0        30         1          10.110.1.1    (local)
Vlan101             1        30         1          192.168.1.2
Vlan102             1        30         1          192.168.9.2
```

Assume that Host A needs to receive the information a specific multicast source S (10.110.5.100/24) sends to multicast group G (232.1.1.1). Switch A builds an SPT toward the multicast source. Switches on the SPT path (Switch A and Switch D) have generated an (S, G) entry, but Switch E, which is not on the SPT path, does not have multicast routing entries. You can use the **display pim routing-table** command to view the PIM routing table information on each switch. For example:

Display PIM routing table information on Switch A.

```
[SwitchA] display pim routing-table
VPN-Instance: public net
Total 0 (*, G) entry; 1 (S, G) entry

(10.110.5.100, 232.1.1.1)
  Protocol: pim-ssm, Flag:
  UpTime: 00:13:25
  Upstream interface: Vlan-interface101
    Upstream neighbor: 192.168.1.2
    RPF prime neighbor: 192.168.1.2
  Downstream interface(s) information:
  Total number of downstreams: 1
    1: Vlan-interface100
      Protocol: igmp, UpTime: 00:13:25, Expires: 00:03:25
```

Display PIM routing table information on Switch D.

```

[SwitchD] display pim routing-table
VPN-Instance: public net
Total 0 (*, G) entry; 1 (S, G) entry

(10.110.5.100, 232.1.1.1)
  Protocol: pim-ssm, Flag: LOC
  UpTime: 00:12:05
  Upstream interface: Vlan-interface300
    Upstream neighbor: NULL
    RPF prime neighbor: NULL
  Downstream interface(s) information:
  Total number of downstreams: 1
    1: Vlan-interface105
      Protocol: pim-ssm, UpTime: 00:12:05, Expires: 00:03:25

```

Troubleshooting PIM

A multicast distribution tree cannot be built correctly

Symptom

None of the routers in the network (including routers directly connected with multicast sources and receivers) have multicast forwarding entries. That is, a multicast distribution tree cannot be built correctly and clients cannot receive multicast data.

Analysis

- When PIM-DM runs on the entire network, multicast data is flooded from the first hop router connected with the multicast source to the last hop router connected with the clients. When the multicast data is flooded to a router, regardless of which router it is, the router creates (S, G) entries only if it has a route to the multicast source. If the router does not have a route to the multicast source, or if PIM-DM is not enabled on the router's RPF interface to the multicast source, the router cannot create (S, G) entries.
- When PIM-SM runs on the entire network and when a router will join the SPT, the router creates (S, G) entries only if it has a route to the multicast source. If the router does not have a route to the multicast source, or if PIM-DM is not enabled on the router's RPF interface to the multicast source, the router cannot create (S, G) entries.
- When a multicast router receives a multicast packet, it searches the existing unicast routing table for the optimal route to the RPF check object. The outgoing interface of this route will act as the RPF interface and the next hop will be taken as the RPF neighbor. The RPF interface completely relies on the existing unicast route, and is independent of PIM. The RPF interface must be PIM-enabled, and the RPF neighbor must also be a PIM neighbor. If PIM is not enabled on the router where the RPF interface or the RPF neighbor resides, the establishment of a multicast distribution tree will surely fail, causing abnormal multicast forwarding.
- Because a hello message does not carry the PIM mode information, a router that is running PIM cannot identify what PIM mode its PIM neighbor is running. If different PIM modes are enabled on the RPF interface and on the corresponding interface of the RPF neighbor router, the establishment of a multicast distribution tree will fail, causing abnormal multicast forwarding.
- The same PIM mode must run on the entire network. Otherwise, the establishment of a multicast distribution tree will fail, causing abnormal multicast forwarding.

Solution

1. Use the **display ip routing-table** command to verify that a unicast route exists from the receiver host to the multicast source.
2. Use the **display pim interface** command to verify that PIM is enabled on the interfaces, especially on the RPF interface. If PIM is not enabled on the interface, use the **pim dm** or **pim sm** command to enable PIM-DM or PIM-SM.
3. Use the **display pim neighbor** command to verify that the RPF neighbor is a PIM neighbor.
4. Verify that PIM and IGMP are enabled on the interfaces directly connecting to the multicast source and to the receivers.
5. Use the **display pim interface verbose** command to verify that the same PIM mode is enabled on the RPF interface and the corresponding interface of the RPF neighbor router.
6. Verify that the same PIM mode is enabled on all the routers in the entire network. Make sure that the same PIM mode is enabled on all the routers: PIM-SM on all routers, or PIM-DM on all routers. In the case of PIM-SM, also check that the BSR and RP configurations are correct.

Multicast data abnormally terminated on an intermediate router

Symptom

An intermediate router can receive multicast data successfully, but the data cannot reach the last hop router. An interface on the intermediate router receives data but no corresponding (S, G) entry is created in the PIM routing table.

Analysis

- If a multicast forwarding boundary has been configured through the **multicast boundary** command, any multicast packet will be kept from crossing the boundary, and no routing entry can be created in the PIM routing table.
- In addition, the **source-policy** command filters received multicast packets. If the multicast data fails to pass the ACL rule defined in this command, PIM cannot create the route entry either.

Solution

1. Use the **display current-configuration** command to verify the multicast forwarding boundary settings. Use the **multicast boundary** command to change the multicast forwarding boundary settings.
2. Use the **display current-configuration** command to verify the multicast filter configuration. Change the ACL rule defined in the **source-policy** command so that the source/group address of the multicast data can pass ACL filtering.

RPs cannot join SPT in PIM-SM

Symptom

An RPT cannot be established correctly, or the RPs cannot join the SPT to the multicast source.

Analysis

- As the core of a PIM-SM domain, the RPs serve specific multicast groups. Multiple RPs can coexist in a network. Make sure that the RP information on all routers is exactly the same and that a specific group is mapped to the same RP. Otherwise, multicast forwarding will fail.
- If the static RP mechanism is used, the same static RP command must be executed on all the routers in the entire network. Otherwise, multicast forwarding will fail.

Solution

1. Use the **display ip routing-table** command to verify that a route is available on each router to the RP.
2. Use the **display pim rp-info** command to verify that the RP information is consistent on all routers.
3. Use the **display pim rp-info** command to verify that the same static RP address has been configured on all the routers in the entire network.

RPT establishment failure or source registration failure in PIM-SM

Symptom

C-RPs cannot unicast advertise messages to the BSR. The BSR does not advertise bootstrap messages containing C-RP information and has no unicast route to any C-RP. An RPT cannot be established correctly, or the DR cannot perform source registration with the RP.

Analysis

- The C-RPs periodically send C-RP-Adv messages to the BSR by unicast. If a C-RP has no unicast route to the BSR, the BSR cannot receive C-RP-Adv messages from that C-RP and the bootstrap message of the BSR will not contain the information of that C-RP.
- In addition, if the BSR does not have a unicast route to a C-RP, it will discard the C-RP-Adv messages from that C-RP, and therefore the bootstrap messages of the BSR will not contain the information of that C-RP.
- The RP is the core of a PIM-SM domain. Make sure that the RP information on all routers is exactly the same, a specific group G is mapped to the same RP, and unicast routes are available to the RP.

Solution

1. Use the **display ip routing-table** command to verify that routes are available on each router to the RP and the BSR and whether a route is available between the RP and the BSR. Make sure that each C-RP has a unicast route to the BSR, the BSR has a unicast route to each C-RP, and all the routers in the entire network have a unicast route to the RP.
2. PIM-SM needs the support of the RP and BSR. Use the **display pim bsr-info** command to verify that the BSR information is available on each router, and then use the **display pim rp-info** command to verify that the RP information is correct.
3. Use the **display pim neighbor** command to verify that the normal PIM neighboring relationships have been established among the routers.

Configuring MSDP (available only on the HP 5500 EI)

Overview

Multicast source discovery protocol (MSDP) is an inter-domain multicast solution that addresses the interconnection of protocol independent multicast sparse mode (PIM-SM) domains. You can use it to discover multicast source information in other PIM-SM domains.

In the basic PIM-SM mode, a multicast source registers only with the RP in the local PIM-SM domain, and the multicast source information about a domain is isolated from that of another domain. As a result, the RP obtains the source information only within the local domain, and a multicast distribution tree is built only within the local domain to deliver multicast data from a local multicast source to local receivers. MSDP enables the RPs of different PIM-SM domains to share their multicast source information, so that the local RP can join multicast sources in other domains, and multicast data can be transmitted among different domains.

With MSDP peer relationships established between appropriate routers in the network, the RPs of different PIM-SM domains are interconnected with one another. These MSDP peers exchange source active (SA) messages, so that the multicast source information is shared among these different domains.

NOTE:

- MSDP is applicable only if the intra-domain multicast protocol is PIM-SM.
 - MSDP is meaningful only for the any-source multicast (ASM) model.
-

For more information about the concepts of designated router (DR), bootstrap router (BSR), candidate-BSR (C-BSR), rendezvous point (RP), candidate-RP (C-RP), shortest path tree (SPT) and rendezvous point tree (RPT) mentioned in this document, see "[Configuring PIM \(available only on the HP 5500 EI\)](#)"

The term "router" in this document refers to both routers and Layer 3 switches.

The term "interface" in the MSDP features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

How MSDP works

MSDP peers

Configuring one or more pairs of MSDP peers in the network forms an MSDP interconnection map, where the RPs of different PIM-SM domains are interconnected in series. An SA message that an RP sends and that these MSDP peers relay can be delivered to all other RPs.

Figure 56 Where MSDP peers are in the network

As shown in Figure 56, an MSDP peer can be created on any PIM-SM router. MSDP peers created on PIM-SM routers that assume different roles function differently.

1. MSDP peers on RPs include the following types:
 - **Source-side MSDP peer**—The MSDP peer nearest to the multicast source (Source), typically the source-side RP, like RP 1. The source-side RP creates SA messages and sends the messages to its remote MSDP peer to notify the MSDP peer of the locally registered multicast source information. A source-side MSDP peer must be created on the source-side RP. Otherwise it will not be able to advertise the multicast source information out of the PIM-SM domain.
 - **Receiver-side MSDP peer**—The MSDP peer nearest to the receivers, typically the receiver-side RP, like RP 3. After receiving an SA message, the receiver-side MSDP peer resolves the multicast source information carried in the message and joins the SPT rooted at the source across the PIM-SM domain. When multicast data from the multicast source arrives, the receiver-side MSDP peer forwards the data to the receivers along the RPT.
 - **Intermediate MSDP peer**—An MSDP peer with multicast remote MSDP peers, like RP 2. An intermediate MSDP peer forwards SA messages received from one remote MSDP peer to other remote MSDP peers, functioning as a relay of multicast source information.
2. MSDP peers created on common PIM-SM routers (other than RPs)

Router A and Router B are MSDP peers on common multicast routers. Such MSDP peers just forward received SA messages.

In a PIM-SM network running the BSR mechanism, the RP is dynamically elected from C-RPs. To enhance network robustness, a PIM-SM network typically has more than one C-RP. As the RP election result is unpredictable, MSDP peering relationships must be built among all C-RPs so that the winner C-RP is always on the "MSDP interconnection map," and loser C-RPs will assume the role of common PIM-SM routers on the "MSDP interconnection map."

Inter-domain multicast delivery through MSDP

As shown in Figure 57, an active source (Source) exists in the domain PIM-SM 1, and RP 1 has learned the existence of Source through multicast source registration. If RPs in PIM-SM 2 and PIM-SM 3 also seek the specific location of Source so that receiver hosts can receive multicast traffic that the source sends, HP recommends you to establish MSDP peering relationships between RP 1 and RP 3 and between RP 3 and RP 2, respectively.

Figure 57 Inter-domain multicast delivery through MSDP

The process of implementing PIM-SM inter-domain multicast delivery by leveraging MSDP peers is as follows:

1. When the multicast source in PIM-SM 1 sends the first multicast packet to multicast group G, DR 1 encapsulates the multicast data within a register message and sends the register message to RP 1. Then, RP 1 identifies the information related to the multicast source.
2. As the source-side RP, RP 1 creates SA messages and periodically sends the SA messages to its MSDP peer. An SA message contains the source address (S), the multicast group address (G), and the address of the RP that has created this SA message (namely, RP 1).
3. On MSDP peers, each SA message undergoes a reverse path forwarding (RPF) check and multicast policy-based filtering, so that only SA messages that have arrived along the correct path and passed the filtering are received and forwarded. This avoids delivery loops of SA messages. In addition, you can configure MSDP peers into an MSDP mesh group so as to avoid flooding of SA messages between MSDP peers.

An MSDP mesh group refers to a group of MSDP peers that have MSDP peering relationships among one another and share the same group name.

4. SA messages are forwarded from one MSDP peer to another, and finally the information about the multicast source traverses all PIM-SM domains with MSDP peers (PIM-SM 2 and PIM-SM 3, in this example).
5. After receiving the SA message that RP 1 created, RP 2 in PIM-SM 2 determines whether any receivers for the multicast group exist in the domain.
 - If receivers for the multicast group exist in the domain, the RPT for the multicast group G is maintained between RP 2 and the receivers. RP 2 creates an (S, G) entry and sends an (S, G) join message hop by hop toward DR 1 at the multicast source side, so that it can directly join the SPT rooted at the source over other PIM-SM domains. Then, the multicast data can flow along the SPT to RP 2 and RP 2 can forward the data to the receivers along the RPT. After receiving the multicast traffic, the DR at the receiver side (DR 2) determines whether to initiate an RPT-to-SPT switchover process.

- If no receivers for the group exist in the domain, RP 2 neither creates an (S, G) entry nor joins the SPT rooted at the source.

NOTE:

When using MSDP for inter-domain multicasting, once an RP receives information from a multicast source, it no longer relies on RPs in other PIM-SM domains. The receivers can override the RPs in other domains and directly join the multicast source-based SPT.

RPF check rules for SA messages

As shown in Figure 58, the autonomous systems in the network are AS 1 through AS 5, with IGP enabled on routers within each AS and BGP or MBGP as the interoperation protocol among different ASs. Each AS contains at least one PIM-SM domain, and each PIM-SM domain contains one or more RPs. MSDP peering relationships have been established among different RPs. RP 3, RP 4, and RP 5 are in an MSDP mesh group. On RP 7, RP 6 is configured as its static RPF peer.

NOTE:

When an RP receives an SA message from a static RPF peer, the RP accepts the SA message and forwards it to other peers without performing an RPF check.

Figure 58 Diagram for RPF check for SA messages

As shown in Figure 58, these MSDP peers dispose of SA messages according to the following RPF check rules:

1. When RP 2 receives an SA message from RP 1:

Because the source-side RP address carried in the SA message is the same as the MSDP peer address, which means that the MSDP peer where the SA is from is the RP that has created the SA message, RP 2 accepts the SA message and forwards it to its other MSDP peer (RP 3).
2. When RP 3 receives the SA message from RP 2:

Because the SA message is from an MSDP peer (RP 2) in the same AS, and the MSDP peer is the next hop on the optimal path to the source-side RP, RP 3 accepts the message and forwards it to other peers (RP 4 and RP 5).
3. When RP 4 and RP 5 receive the SA message from RP 3:

Because the SA message is from an MSDP peer (RP 3) in the same mesh group, RP 4 and RP 5 both accept the SA message, but they do not forward the message to other members in the mesh group. Instead, they forward it to other MSDP peers (RP 6 in this example) out of the mesh group.

4. When RP 6 receives the SA messages from RP 4 and RP 5 (suppose RP 5 has a higher IP address):
Although RP 4 and RP 5 are in the same AS (AS 3) and both are MSDP peers of RP 6, because RP 5 has a higher IP address, RP 6 accepts only the SA message from RP 5.
5. When RP 7 receives the SA message from RP 6:
Because the SA message is from a static RPF peer (RP 6), RP 7 accepts the SA message and forwards it to other peer (RP 8).
6. When RP 8 receives the SA message from RP 7:
A BGP or MBGP route exists between two MSDP peers in different ASs. Because the SA message is from an MSDP peer (RP 7) in a different AS, and the MSDP peer is the next hop on the BGP or MBGP route to the source-side RP, RP 8 accepts the message and forwards it to its other peer (RP 9).
7. When RP 9 receives the SA message from RP 8:
Because RP 9 has only one MSDP peer, RP 9 accepts the SA message.

SA messages from paths other than those described previously are not accepted or forwarded by MSDP peers.

Intra-domain Anycast RP through MSDP

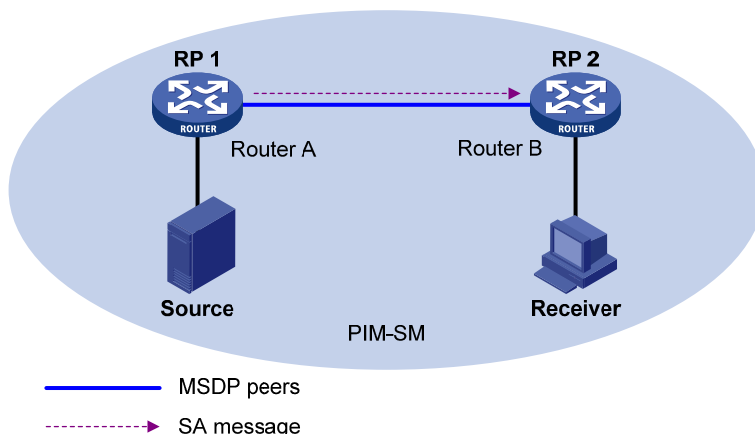

Anycast RP refers to an application that enables load balancing and redundancy backup between two or more RPs within a PIM-SM domain by configuring the same IP address for, and establishing MSDP peering relationships between, these RPs.

Usually an Anycast RP address is configured on a logic interface, like a loopback interface. An MSDP peer address must be different from the Anycast RP address.

Be sure to configure a 32-bit subnet mask (255.255.255.255) for the Anycast RP address sure, which means configure the Anycast RP address into a host address.

As shown in Figure 59, within a PIM-SM domain, a multicast source sends multicast data to multicast group G, and Receiver is a member of the multicast group. To implement Anycast RP, configure the same IP address (known as Anycast RP address, typically a private address) on Router A and Router B, configure these interfaces as C-RPs, and establish an MSDP peering relationship between Router A and Router B.

Figure 59 Intra-domain Anycast RP through MSDP

The work process of Anycast RP is as follows:

1. The multicast source registers with the nearest RP. In this example, Source registers with RP 1, with its multicast data encapsulated in the register message. When the register message arrives at RP 1, RP 1 de-encapsulates the message.
2. Receivers send join messages to the nearest RP to join in the RPT rooted at this RP. In this example, Receiver joins the RPT rooted at RP 2.
3. RPs share the registered multicast information by means of SA messages. In this example, RP 1 creates an SA message and sends it to RP 2, with the multicast data from Source encapsulated in the SA message. When the SA message reaches RP 2, RP 2 de-encapsulates the message.
4. Receivers receive the multicast data along the RPT and directly join the SPT rooted at the multicast source. In this example, RP 2 forwards the multicast data down the RPT. When Receiver receives the multicast data from Source, it directly joins the SPT rooted at Source.

The significance of Anycast RP is as follows:

- **Optimal RP path**—A multicast source registers with the nearest RP so that an SPT with the optimal path is built. A receiver joins the nearest RP so that an RPT with the optimal path is built.
- **Load balancing between RPs**—Each RP maintains just part of the source/group information within the PIM-SM domain and forward part of the multicast data, thereby achieving load balancing between different RPs.
- **Redundancy backup between RPs**—When an RP fails, the multicast source that previously registered with the RP or the receivers that previously joined the RP will register with or join another nearest RP, thereby achieving redundancy backup between RPs.

MSDP support for VPNs

The interfaces on the multicast routers in a VPN can set up MSDP peering relationships between each other. By exchanging SA messages between MSDP peers, multicast transmission in a VPN between different PIM-SM domains can be implemented.

To support MSDP for VPNs, a multicast router that runs MSDP maintains an independent set of MSDP mechanism for each VPN that it supports, including SA cache, peering connection, timers, sending cache, and cache for exchanging PIM messages. The information in one VPN is isolated from another, and MSDP and PIM-SM messages can be exchanged only within the same VPN.

Protocols and standards

- RFC 3618, *Multicast Source Discovery Protocol (MSDP)*
- RFC 3446, *Anycast Rendezvous Point (RP) mechanism using Protocol Independent Multicast (PIM) and Multicast Source Discovery Protocol (MSDP)*

MSDP configuration task list

Task	Remarks
Configuring basic MSDP functions	Enabling MSDP Required
	Creating an MSDP peer connection Required
	Configuring a static RPF peer Optional
Configuring an MSDP peer	Configuring MSDP peer description Optional

Task		Remarks
connection	Configuring an MSDP mesh group	Optional
	Configuring MSDP peer connection control	Optional
	Configuring SA message content	Optional
Configuring SA messages related parameters	Configuring SA request messages	Optional
	Configuring SA message filtering rules	Optional
	Configuring the SA cache mechanism	Optional

Configuring basic MSDP functions

ⓘ IMPORTANT:

All the configuration tasks should be carried out on RPs in PIM-SM domains, and each of these RPs acts as an MSDP peer.

Configuration prerequisites

Before you configure basic MSDP functions, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Configure PIM-SM to enable intra-domain multicast forwarding.
- Determine the IP addresses of MSDP peers.
- Determine the address prefix list for an RP address filtering policy.

Enabling MSDP

Enabling MSDP globally for the public network

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IP multicast routing.	multicast routing-enable	Disabled by default.
3. Enable MSDP and enter public network MSDP view.	msdp	Disabled by default.

Enabling MSDP in a VPN instance

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a VPN instance and enter VPN instance view.	ip vpn-instance <i>vpn-instance-name</i>	N/A

Step	Command	Remarks
3.	Configure a route-distinguisher (RD) for the VPN instance. route-distinguisher <i>route-distinguisher</i>	No RD is configured by default.
4.	Enable IP multicast routing. multicast routing-enable	Disabled by default.
5.	Return to system view. quit	N/A
6.	Enable MSDP and enter VPN instance MSDP view. msdp vpn-instance <i>vpn-instance-name</i>	Disabled by default.

For more information about the **ip vpn-instance** and **route-distinguisher** commands, see *IP Routing Command Reference*.

For more information about the **multicast routing-enable** command, see *IP Multicast Command Reference*.

Creating an MSDP peer connection

An MSDP peering relationship is identified by an address pair, namely, the address of the local MSDP peer and that of the remote MSDP peer. An MSDP peer connection must be created on both devices that are a pair of MSDP peers.

To create an MSDP peer connection:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter public network MSDP view or VPN instance MSDP view. msdp [vpn-instance <i>vpn-instance-name]</i>	N/A
3.	Create an MSDP peer connection. peer peer-address connect-interface <i>interface-type interface-number</i>	No MSDP peer connection is created by default.

NOTE:

If an interface of the router is shared by an MSDP peer and a BGP or MBGP peer at the same time, HP recommends you to configure the IP address of the MSDP peer the same as that of the BGP or MBGP peer.

Configuring a static RPF peer

Configuring static RPF peers avoids RPF check of SA messages.

To configure a static RPF peer:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter public network MSDP view or VPN instance MSDP view. msdp [vpn-instance <i>vpn-instance-name]</i>	N/A
3.	Configure a static RPF peer. static-rpf-peer peer-address <i>[rp-policy ip-prefix-name]</i>	No static RPF peer is configured by default.

NOTE:

If only one MSDP peer is configured on a router, this MSDP will be registered as a static RPF peer.

Configuring an MSDP peer connection

Configuration prerequisites

Before you configure an MSDP peer connection, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Configure basic MSDP functions.
- Determine the description of MSDP peers.
- Determine the name of an MSDP mesh group.
- Determine the MSDP peer connection retry interval.
- Determine the MD5 authentication password for the TCP connection to be established with an MSDP peer.

Configuring MSDP peer description

With the MSDP peer description information, the administrator can easily distinguish different MSDP peers to better manage MSDP peers.

To configure description for an MSDP peer:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network MSDP view or VPN instance MSDP view.	msdp [vpn-instance vpn-instance-name]	N/A
3. Configure description for an MSDP peer.	peer peer-address description text	No description is configured for an MSDP peer by default.

Configuring an MSDP mesh group

An AS can contain multiple MSDP peers. You can use the MSDP mesh group mechanism to avoid SA message flooding among these MSDP peers and optimize the multicast traffic.

An MSDP peer in an MSDP mesh group forwards SA messages (that have passed the RPF check) from outside the mesh group to the other members in the mesh group. A mesh group member accepts SA messages from inside the group without performing an RPF check, and does not forward the message within the mesh group. This mechanism not only avoids SA flooding but also simplifies the RPF check mechanism because you do not need to run BGP or MBGP between these MSDP peers.

By configuring the same mesh group name for multiple MSDP peers, you can create a mesh group that contains these MSDP peers.

! **IMPORTANT:**

- Before grouping multiple routers into an MSDP mesh group, make sure that these routers are interconnected with one another.
 - If you configure more than one mesh group name on an MSDP peer, only the last configuration is effective.
-

To create an MSDP mesh group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network MSDP view or VPN instance MSDP view.	msdp [vpn-instance vpn-instance-name]	N/A
3. Create an MSDP mesh group and assign an MSDP peer to that mesh group.	peer peer-address mesh-group name	An MSDP peer does not belong to any mesh group by default.

Configuring MSDP peer connection control

MSDP peers are interconnected over TCP (port number 639). You can flexibly control sessions between MSDP peers by manually deactivating and reactivating the MSDP peering connections. When the connection between two MSDP peers is deactivated, SA messages will no longer be delivered between them, and the TCP connection is closed without any connection setup retry. The configuration information, however, remain unchanged.

A TCP connection is required in the following situations:

- When a new MSDP peer is created
- When you reactivate a previously deactivated MSDP peer connection
- When a previously failed MSDP peer attempts to resume operation

You can adjust the interval between MSDP peering connection retries.

To enhance MSDP security, you can configure an MD5 authentication password for the TCP connection to be established with an MSDP peer. If the MD5 authentication fails, the TCP connection cannot be established.

! **IMPORTANT:**

The MSDP peers involved in the MD5 authentication must have the same authentication method and password. Otherwise, the authentication fails and the TCP connection cannot be established.

To configure MSDP peer connection control:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network MSDP view or VPN instance MSDP view.	msdp [vpn-instance vpn-instance-name]	N/A

Step	Command	Remarks
3. Deactivate an MSDP peer.	shutdown <i>peer-address</i>	Optional. Active by default.
4. Configure the interval between MSDP peer connection retries.	timer retry <i>interval</i>	Optional. 30 seconds by default.
5. Configure an MD5 authentication key for the TCP connection to be established with an MSDP peer.	peer <i>peer-address</i> password { cipher simple } <i>password</i>	Optional. By default, MD5 authentication is not performed before a TCP connection is established.

Configuring SA messages related parameters

Configuration prerequisites

Before you configure SA message delivery, complete the following tasks:

- Configure any unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Configure basic MSDP functions.
- Determine the ACL rules for filtering SA request messages.
- Determine the ACL rules as SA message creation rules.
- Determine the ACL rules for filtering SA messages to be received and forwarded.
- Determine the TTL threshold for multicast packet encapsulation in SA messages.
- Determine the maximum number of (S, G) entries learned from the specified MSDP peer that the router can cache.

Configuring SA message content

Some multicast sources send multicast data at an interval longer than the aging time of (S, G) entries. In this case, the source-side DR must encapsulate multicast data packet by packet in register messages and send them to the source-side RP. The source-side RP transmits the (S, G) information to the remote RP through SA messages. Then the remote RP joins the source-side DR and builds an SPT. Because the (S, G) entries have timed out, remote receivers can never receive the multicast data from the multicast source.

After the source-side RP is enabled to encapsulate multicast data in SA messages, if the RP wants to send a multicast packet, it encapsulates the multicast packet in an SA message and sends it. After receiving the SA message, the remote RP de-encapsulates the SA message and delivers the multicast packet to the receivers in the local domain along the RPT.

The MSDP peers deliver SA messages to one another. After receiving an SA message, a router performs RPF check on the message. If the router finds that the remote RP address is the same as the local RP address, it discards the SA message. In the Anycast RP application, however, you must configure RPs with the same IP address on two or more routers in the same PIM-SM domain and configure these routers as MSDP peers to one another. Therefore, a logic RP address (namely, the RP address on the logic interface) that is different from the actual RP address must be designated for SA messages so that the messages can pass the RPF check.

To configure the SA message content:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network MSDP view or VPN instance MSDP view.	msdp [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable encapsulation of multicast data in SA messages.	encap-data-enable	Optional. Disabled by default.
4. Configure the interface address as the RP address in SA messages.	originating-rp <i>interface-type</i> <i>interface-number</i>	Optional. PIM RP address by default.

Configuring SA request messages

By default, after receiving a new join message, a router does not send an SA request message to any MSDP peer. Instead, it waits for the next SA message from its MSDP peer. This will cause the receiver to delay obtaining multicast source information. To enable a new receiver to get the active multicast source information as early as possible, you can configure routers to send SA request messages to the designated MSDP peers after receiving a join message of a new receiver.

! IMPORTANT:

Before you can enable the device to send SA requests, be sure to disable the SA message cache mechanism.

To configure SA message transmission and filtering:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network MSDP view or VPN instance MSDP view.	msdp [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Enable the device to send SA request messages.	peer <i>peer-address</i> request-sa-enable	Optional. Disabled by default.
4. Configure a filtering rule for SA request messages.	peer <i>peer-address</i> sa-request-policy [acl <i>acl-number</i>]	Optional. SA request messages are not filtered by default.

Configuring SA message filtering rules

Configuration guidelines

By configuring an SA message creation rule, you can enable the router to filter the (S, G) entries to be advertised when creating an SA message, so that the propagation of messages of multicast sources is controlled.

By configuring a filtering rule for receiving or forwarding SA messages, you can enable the router to filter the (S, G) forwarding entries to be advertised when receiving or forwarding an SA message, so that the propagation of multicast source information is controlled at SA message reception or forwarding.

By configuring a TTL threshold for multicast data packet encapsulation in SA messages, you can control the multicast data packet encapsulation in SA messages and limit the propagation range of SA messages:

- Before creating an SA message with an encapsulated multicast data packet, the router checks the TTL value of the multicast data packet. If the TTL value is less than the threshold, the router does not create an SA message. If the TTL value is greater than or equal to the threshold, the router encapsulates the multicast data in an SA message and sends the SA message.
- After receiving an SA message with an encapsulated multicast data packet, the router decreases the TTL value of the multicast packet by 1 and then checks the TTL value. If the TTL value is less than the threshold, the router does not forward the SA message to the designated MSDP peer. If the TTL value is greater than or equal to the threshold, the router re-encapsulates the multicast data in an SA message and sends the SA message.

Configuration procedure

To configure a filtering rule for receiving or forwarding SA messages:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network MSDP view or VPN instance MSDP view.	msdp [vpn-instance <i>vpn-instance-name</i>]	N/A
3. Configure an SA message creation rule.	import-source [acl <i>acl-number</i>]	No restrictions on (S, G) entries by default.
4. Configure a filtering rule for receiving or forwarding SA messages.	peer <i>peer-address</i> sa-policy { import export } [acl <i>acl-number</i>]	No filtering rule by default.
5. Configure the TTL threshold for multicast data packet encapsulation in SA messages.	peer <i>peer-address</i> minimum-ttl <i>tll-value</i>	Optional. 0 by default.

Configuring the SA cache mechanism

To reduce the time spent in obtaining the multicast information, you can enable the SA cache mechanism to cache (S, G) entries contained in SA messages locally on the router. However, caching (S, G) entries uses memory space on the router.

When the SA cache mechanism is enabled and the router receives a new (*, G) join message, the router searches its SA cache first.

- If the corresponding (S, G) entry does not exist in the cache, the router waits for the SA message that its MSDP peer will send in the next cycle.
- If the corresponding (S, G) entry exists in the cache, the router joins the corresponding SPT rooted at S.

To protect the router effectively against denial of service (DoS) attacks, you can set a limit on the number of (S, G) entries the router can cache.

To configure the SA message cache:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter public network MSDP view or VPN instance MSDP view.	msdp [vpn-instance vpn-instance-name]	N/A
3. Enable the SA cache mechanism.	cache-sa-enable	Optional. Enabled by default.
4. Configure the maximum number of (S, G) entries learned from the specified MSDP peer that the router can cache.	peer peer-address sa-cache-maximum sa-limit	Optional. 8192 by default.

Displaying and maintaining MSDP

Step	Command	Remarks
1. Display brief information about MSDP peers.	display msdp [all-instance vpn-instance vpn-instance-name] brief [state { connect down listen shutdown up }] [{ begin exclude include } regular-expression]	Available in any view
2. Display detailed information about the status of MSDP peers.	display msdp [all-instance vpn-instance vpn-instance-name] peer-status [peer-address] [{ begin exclude include } regular-expression]	Available in any view
3. Display the (S, G) entry information in the SA cache.	display msdp [all-instance vpn-instance vpn-instance-name] sa-cache [group-address source-address as-number] * [{ begin exclude include } regular-expression]	Available in any view
4. Display the number of (S, G) entries in the SA cache.	display msdp [all-instance vpn-instance vpn-instance-name] sa-count [as-number] [{ begin exclude include } regular-expression]	Available in any view
5. Reset the TCP connection with an MSDP peer.	reset msdp [all-instance vpn-instance vpn-instance-name] peer [peer-address]	Available in user view
6. Clear (S, G) entries in the SA cache.	reset msdp [all-instance vpn-instance vpn-instance-name] sa-cache [group-address]	Available in user view
7. Clear statistics for an MSDP peer.	reset msdp [all-instance vpn-instance vpn-instance-name] statistics [peer-address]	Available in user view

MSDP configuration examples

PIM-SM Inter-domain multicast configuration

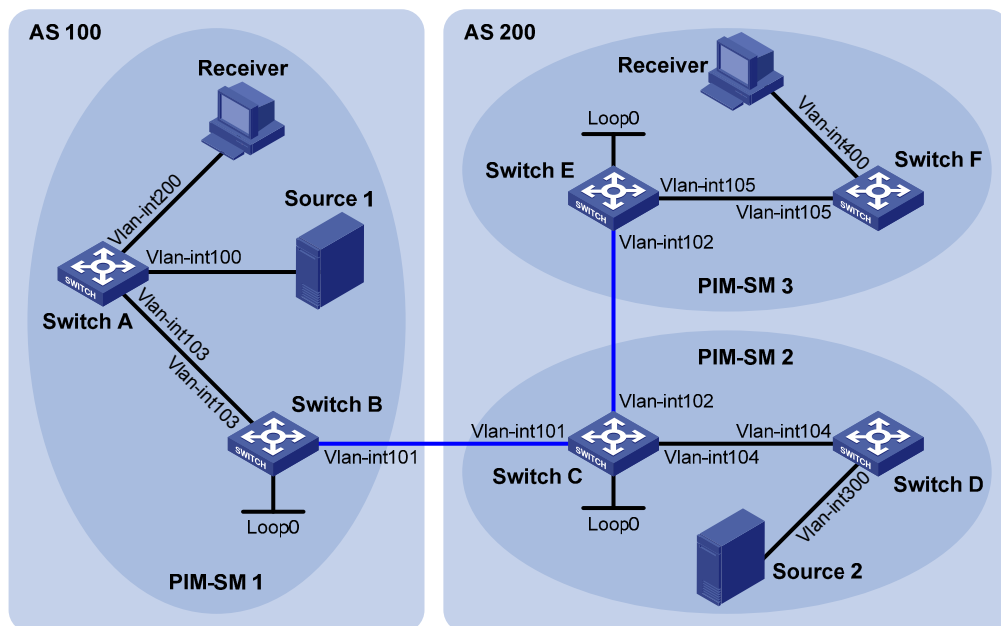

Network requirements

As shown in Figure 60, AS 100 and AS 200 run OSPF within each AS, and run BGP between each other. PIM-SM 1 belongs to AS 100, and PIM-SM 2 and PIM-SM 3 belong to AS 200. Each PIM-SM domain has at least one multicast source or receiver.

Loopback 0 is configured as the C-BSR and C-RP of the related PIM-SM domain on Switch B, Switch C, and Switch E, respectively.

An MSDP peering relationship is set up between the RPs of the PIM-SM domains to share multicast source information among the PIM-SM domains.

Figure 60 Network diagram

— MSDP peers

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int103	10.110.1.2/24	Switch D	Vlan-int104	10.110.4.2/24
	Vlan-int100	10.110.2.1/24		Vlan-int300	10.110.5.1/24
	Vlan-int200	10.110.3.1/24	Switch E	Vlan-int105	10.110.6.1/24
Switch B	Vlan-int103	10.110.1.1/24		Vlan-int102	192.168.3.2/24
	Vlan-int101	192.168.1.1/24		Loop0	3.3.3.3/32
	Loop0	1.1.1.1/32	Switch F	Vlan-int105	10.110.6.2/24
Switch C	Vlan-int104	10.110.4.1/24		Vlan-int400	10.110.7.1/24
	Vlan-int102	192.168.3.1/24	Source 1	—	10.110.2.100/24
	Vlan-int101	192.168.1.2/24	Source 2	—	10.110.5.100/24
	Loop0	2.2.2.2/32			

Configuration procedure

1. Configure IP addresses and unicast routing:

Configure the IP address and subnet mask for each interface as per [Figure 60](#). (Details not shown.)

Configure OSPF for interconnection between switches in each AS. Ensure the network-layer interoperability among each AS, and ensure the dynamic update of routing information between the switches through a unicast routing protocol. (Details not shown.)

2. Enable IP multicast routing, enable PIM-SM on each interface, and configure a PIM-SM domain border:

Enable IP multicast routing on Switch A, enable PIM-SM on each interface, and enable IGMP on the host-side interface VLAN-interface 200.

```
<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 103
[SwitchA-Vlan-interface103] pim sm
[SwitchA-Vlan-interface103] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] igmp enable
[SwitchA-Vlan-interface200] pim sm
[SwitchA-Vlan-interface200] quit
```

The configuration on Switch B, Switch C, Switch D, Switch E, and Switch F is similar to the configuration on Switch A.

Configure a PIM domain border on Switch B.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] pim bsr-boundary
[SwitchB-Vlan-interface101] quit
```

The configuration on Switch C and Switch E is similar to the configuration on Switch B.

3. Configure C-BSRs and C-RPs:

Configure Loopback 0 as a C-BSR and a C-RP on Switch B.

```
[SwitchB] pim
[SwitchB-pim] c-bsr loopback 0
[SwitchB-pim] c-rp loopback 0
[SwitchB-pim] quit
```

The configuration on Switch C and Switch E is similar to the configuration on Switch B.

4. Configure BGP for mutual route redistribution between BGP and OSPF:

Configure an EBGP peer, and redistribute OSPF routes on Switch B.

```
[SwitchB] bgp 100
[SwitchB-bgp] router-id 1.1.1.1
[SwitchB-bgp] peer 192.168.1.2 as-number 200
[SwitchB-bgp] import-route ospf 1
[SwitchB-bgp] quit
```

Configure an EBGP peer, and redistribute OSPF routes on Switch C.

```
[SwitchC] bgp 200
```

```
[SwitchC-bgp] router-id 2.2.2.2
[SwitchC-bgp] peer 192.168.1.1 as-number 100
[SwitchC-bgp] import-route ospf 1
[SwitchC-bgp] quit
```

Redistribute BGP routes into OSPF on Switch B.

```
[SwitchB] ospf 1
[SwitchB-ospf-1] import-route bgp
[SwitchB-ospf-1] quit
```

Redistribute BGP routes into OSPF on Switch C.

```
[SwitchB] ospf 1
[SwitchB-ospf-1] import-route bgp
[SwitchB-ospf-1] quit
```

5. Configure MSDP peers:

Configure an MSDP peer on Switch B.

```
[SwitchB] msdp
[SwitchB-msdp] peer 192.168.1.2 connect-interface vlan-interface 101
[SwitchB-msdp] quit
```

Configure an MSDP peer on Switch C.

```
[SwitchC] msdp
[SwitchC-msdp] peer 192.168.1.1 connect-interface vlan-interface 101
[SwitchC-msdp] peer 192.168.3.2 connect-interface vlan-interface 102
[SwitchC-msdp] quit
```

Configure MSDP peers on Switch E.

```
[SwitchE] msdp
[SwitchE-msdp] peer 192.168.3.1 connect-interface vlan-interface 102
[SwitchE-msdp] quit
```

6. Verify the configuration:

Use the **display bgp peer** command to view the BGP peering relationships between the switches. For example:

Display information about BGP peering relationships on Switch B.

```
[SwitchB] display bgp peer
```

```
BGP local router ID : 1.1.1.1
Local AS number : 100
Total number of peers : 1                Peers in established state : 1

Peer                AS  MsgRcvd  MsgSent  OutQ  PrefRcv  Up/Down  State
-----
192.168.1.2         200    24      21      0      6 00:13:09  Established
```

Display information about BGP peering relationships on Switch C.

```
[SwitchC] display bgp peer
```

```
BGP local router ID : 2.2.2.2
Local AS number : 200
Total number of peers : 1                Peers in established state : 1
```

```

Peer                AS  MsgRcvd  MsgSent  OutQ  PrefRcv  Up/Down  State
192.168.1.1         100      18       16    0        1 00:12:04 Established

```

To view the BGP routing table information on the switches, use the **display bgp routing-table** command. For example:

```
# Display BGP routing table information on Switch C.
```

```
[SwitchC] display bgp routing-table
```

```
Total Number of Routes: 5
```

```
BGP Local router ID is 2.2.2.2
```

```
Status codes: * - valid, ^ - VPNv4 best, > - best, d - damped,
              h - history, i - internal, s - suppressed, S - Stale
Origin : i - IGP, e - EGP, ? - incomplete
```

	Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
* >	1.1.1.1/32	192.168.1.1	0		0	100?

* >	192.168.1.0	0.0.0.0	0		0	?
* >	192.168.1.1/32	0.0.0.0	0		0	?
* >	192.168.1.2/32	0.0.0.0	0		0	?

When the multicast source in PIM-SM 1 (Source 1) and the multicast source in PIM-SM 2 (Source 2) send multicast information, receivers in PIM-SM 1 and PIM-SM 3 can receive the multicast data. You can use the **display msdp brief** command to view the brief information of MSDP peering relationships between the switches. For example:

```
# Display brief information about MSDP peering relationships on Switch B.
```

```
[SwitchB] display msdp brief
```

```
MSDP Peer Brief Information of VPN-Instance: public net
```

Configured	Up	Listen	Connect	Shutdown	Down
1	1	0	0	0	0

Peer's Address	State	Up/Down time	AS	SA Count	Reset Count
192.168.1.2	Up	00:12:27	200	13	0

```
# Display brief information about MSDP peering relationships on Switch C.
```

```
[SwitchC] display msdp brief
```

```
MSDP Peer Brief Information of VPN-Instance: public net
```

Configured	Up	Listen	Connect	Shutdown	Down
2	2	0	0	0	0

Peer's Address	State	Up/Down time	AS	SA Count	Reset Count
192.168.3.2	Up	00:15:32	200	8	0
192.168.1.1	Up	00:06:39	100	13	0

```
# Display brief information about MSDP peering relationships on Switch E.
```

```
[SwitchE] display msdp brief
```

```
MSDP Peer Brief Information of VPN-Instance: public net
```

Configured	Up	Listen	Connect	Shutdown	Down

```

1          1          0          0          0          0
Peer's Address   State   Up/Down time   AS     SA Count   Reset Count
192.168.3.1     Up     01:07:08      200    8          0

```

Display detailed MSDP peer information on Switch B.

```

[SwitchB] display msdp peer-status
MSDP Peer Information of VPN-Instance: public net
MSDP Peer 192.168.1.2, AS 200
Description:
Information about connection status:
  State: Up
  Up/down time: 00:15:47
  Resets: 0
  Connection interface: Vlan-interface101 (192.168.1.1)
  Number of sent/received messages: 16/16
  Number of discarded output messages: 0
  Elapsed time since last connection or counters clear: 00:17:51
Information about (Source, Group)-based SA filtering policy:
  Import policy: none
  Export policy: none
Information about SA-Requests:
  Policy to accept SA-Request messages: none
  Sending SA-Requests status: disable
Minimum TTL to forward SA with encapsulated data: 0
SAs learned from this peer: 0, SA-cache maximum for the peer: none
Input queue size: 0, Output queue size: 0
Counters for MSDP message:
  Count of RPF check failure: 0
  Incoming/outgoing SA messages: 0/0
  Incoming/outgoing SA requests: 0/0
  Incoming/outgoing SA responses: 0/0
  Incoming/outgoing data packets: 0/0

```

Inter-AS multicast configuration by leveraging static RPF peers

Network requirements

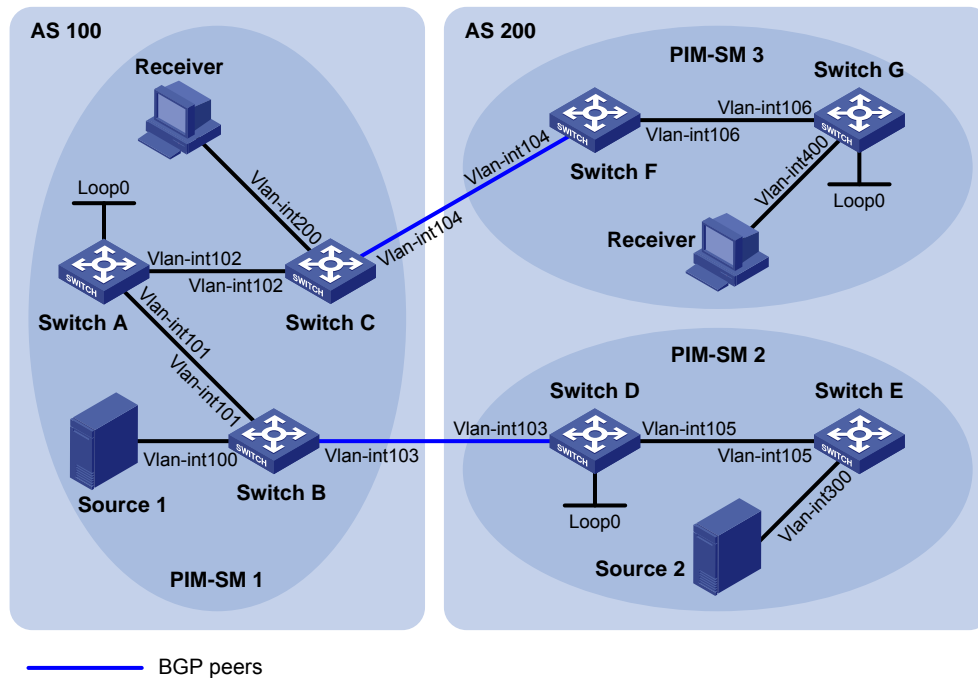

As shown in [Figure 61](#), AS 100 and AS 200 run OSPF within each AS, and run BGP between each other.

PIM-SM 1 belongs to AS 100, and PIM-SM 2 and PIM-SM 3 belong to AS 200. Each PIM-SM domain has at least one multicast source or receiver.

Loopback 0 is configured as a C-BSR and a C-RP of the related PIM-SM domain on Switch A, Switch D, and Switch G, respectively.

According to the RPF principle, the device can receive SA messages that pass the filtering policy from its static RPF peers. To share multicast source information among PIM-SM domains without changing the unicast topology structure, configure MSDP peering relationships for the RPs of the PIM-SM domains and configure static RPF peering relationships for the MSDP peers to share multicast source information among the PIM-SM domains.

Figure 61 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Source 1	-	192.168.1.100/24	Switch D	Vlan-int105	10.110.5.1/24
Source 2	-	192.168.3.100/24		Vlan-int103	10.110.3.2/24
Switch A	Vlan-int101	10.110.1.1/24	Switch E	Loop0	2.2.2.2/32
	Vlan-int102	10.110.2.1/24		Vlan-int105	10.110.5.2/24
	Loop0	1.1.1.1/32		Vlan-int300	192.168.3.1/24
Switch B	Vlan-int101	10.110.1.2/24	Switch F	Vlan-int106	10.110.6.1/24
	Vlan-int100	192.168.1.1/24		Vlan-int104	10.110.4.2/24
	Vlan-int103	10.110.3.1/24		Switch G	Vlan-int106
Switch C	Vlan-int102	10.110.2.2/24	Vlan-int400		192.168.4.1/24
	Vlan-int200	192.168.2.1/24	Loop0	3.3.3.3/32	
	Vlan-int104	10.110.4.1/24			

Configuration procedure

- Configure IP addresses and unicast routing:
Configure the IP address and subnet mask for each interface as per Figure 61. (Details not shown.)
Configure OSPF for interconnection between the switches. Ensure the network-layer interoperability in each AS, and ensure the dynamic update of routing information among the switches through a unicast routing protocol. (Details not shown.)
- Enable IP multicast routing, enable PIM-SM and IGMP, and configure a PIM-SM domain border:
Enable IP multicast routing on Switch C, enable PIM-SM on each interface, and enable IGMP on the host-side interface VLAN-interface 200.

```

<SwitchC> system-view
[SwitchC] multicast routing-enable
[SwitchC] interface vlan-interface 102
[SwitchC-Vlan-interface102] pim sm
[SwitchC-Vlan-interface102] quit

```

```
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] igmp enable
[SwitchC-Vlan-interface200] pim sm
[SwitchC-Vlan-interface200] quit
[SwitchC] interface vlan-interface 104
[SwitchC-Vlan-interface104] pim sm
[SwitchC-Vlan-interface104] quit
```

The configuration on Switch A, Switch B, Switch D, Switch E, Switch F, and Switch G is similar to that on Switch C. (Details not shown.)

Configure PIM domain borders on Switch B.

```
[SwitchB] interface vlan-interface 103
[SwitchB-Vlan-interface103] pim bsr-boundary
[SwitchB-Vlan-interface103] quit
```

The configuration on Switch C, Switch D, and Switch F is similar to that on Switch B. (Details not shown.)

3. Configure C-BSRs and C-RPs:

Configure Loopback 0 as a C-BSR and a C-RP on Switch A.

```
[SwitchA] pim
[SwitchA-pim] c-bsr loopback 0
[SwitchA-pim] c-rp loopback 0
[SwitchA-pim] quit
```

The configuration on Switch D and Switch G is similar to that on Switch A. (Details not shown.)

4. Configure BGP, and redistribute BGP routing information into OSPF, and OSPF routing information into BGP:

Configure the EBGP peer, and redistribute OSPF routing information on Switch B.

```
[SwitchB] bgp 100
[SwitchB-bgp] router-id 1.1.1.2
[SwitchB-bgp] peer 10.110.3.2 as-number 200
[SwitchB-bgp] import-route ospf 1
[SwitchB-bgp] quit
```

Configure the EBGP peer, and redistribute OSPF routing information on Switch D.

```
[SwitchD] bgp 200
[SwitchD-bgp] router-id 2.2.2.2
[SwitchD-bgp] peer 10.110.3.1 as-number 100
[SwitchD-bgp] import-route ospf 1
[SwitchD-bgp] quit
```

Configure the EBGP peer, and redistribute OSPF routing information on Switch C.

```
[SwitchC] bgp 100
[SwitchC-bgp] router-id 1.1.1.3
[SwitchC-bgp] peer 10.110.4.2 as-number 200
[SwitchC-bgp] import-route ospf 1
[SwitchC-bgp] quit
```

Configure the EBGP peer, and redistribute OSPF routing information on Switch F.

```
[SwitchF] bgp 200
[SwitchF-bgp] router-id 3.3.3.1
[SwitchF-bgp] peer 10.110.4.1 as-number 100
```

```

[SwitchF-bgp] import-route ospf 1
[SwitchF-bgp] quit
# Redistribute BGP routing information into OSPF on Switch B.
[SwitchB] ospf 1
[SwitchB-ospf-1] import-route bgp
[SwitchB-ospf-1] quit
# Redistribute BGP routing information into OSPF on Switch D.
[SwitchD] ospf 1
[SwitchD-ospf-1] import-route bgp
[SwitchD-ospf-1] quit
# Redistribute BGP routing information into OSPF on Switch C.
[SwitchC] ospf 1
[SwitchC-ospf-1] import-route bgp
[SwitchC-ospf-1] quit
# Redistribute BGP routing information into OSPF on Switch F.
[SwitchF] ospf 1
[SwitchF-ospf-1] import-route bgp
[SwitchF-ospf-1] quit

```

5. Configure MSDP peers and static RPF peers:

```

# Configure Switch D and Switch G as the MSDP peers and static RPF peers of Switch A.
[SwitchA] ip ip-prefix list-dg permit 10.110.0.0 16 greater-equal 16 less-equal 32
[SwitchA] msdp
[SwitchA-msdp] peer 10.110.3.2 connect-interface vlan-interface 101
[SwitchA-msdp] peer 10.110.6.2 connect-interface vlan-interface 102
[SwitchA-msdp] static-rpf-peer 10.110.3.2 rp-policy list-dg
[SwitchA-msdp] static-rpf-peer 10.110.6.2 rp-policy list-dg
[SwitchA-msdp] quit
# Configure Switch A as the MSDP peer and static RPF peer of Switch D.
[SwitchD] ip ip-prefix list-a permit 10.110.0.0 16 greater-equal 16 less-equal 32
[SwitchD] msdp
[SwitchD-msdp] peer 10.110.1.1 connect-interface vlan-interface 103
[SwitchD-msdp] static-rpf-peer 10.110.1.1 rp-policy list-a
[SwitchD-msdp] quit
# Configure Switch A as the MSDP peer and static RPF peer of Switch G.
[SwitchG] ip ip-prefix list-a permit 10.110.0.0 16 greater-equal 16 less-equal 32
[SwitchG] msdp
[SwitchG-msdp] peer 10.110.2.1 connect-interface vlan-interface 106
[SwitchG-msdp] static-rpf-peer 10.110.2.1 rp-policy list-a
[SwitchG-msdp] quit

```

6. Verify the configuration:

Use the **display bgp peer** command to view the BGP peering relationships between the switches. If the command gives no output information on Switch A, it means that no BGP peering relationship has been established between Switch A and Switch D, or between Switch A and Switch G.

When the multicast source in PIM-SM 1 (Source 1) and the multicast source in PIM-SM 2 (Source 2) send multicast information, receivers in PIM-SM 1 and PIM-SM 3 can receive the multicast data.

You can use the **display msdp brief** command to view the brief information of MSDP peering relationships between the switches. For example:

Display brief MSDP peer information on Switch A.

```
[SwitchA] display msdp brief
```

```
MSDP Peer Brief Information of VPN-Instance: public net
```

Configured	Up	Listen	Connect	Shutdown	Down
2	2	0	0	0	0

Peer's Address	State	Up/Down time	AS	SA Count	Reset Count
10.110.3.2	Up	01:07:08	?	8	0
10.110.6.2	Up	00:16:39	?	13	0

Display brief MSDP peer information on Switch D.

```
[SwitchD] display msdp brief
```

```
MSDP Peer Brief Information of VPN-Instance: public net
```

Configured	Up	Listen	Connect	Shutdown	Down
1	1	0	0	0	0

Peer's Address	State	Up/Down time	AS	SA Count	Reset Count
10.110.1.1	Up	01:07:09	?	8	0

Display brief MSDP peer information on Switch G.

```
[SwitchG] display msdp brief
```

```
MSDP Peer Brief Information of VPN-Instance: public net
```

Configured	Up	Listen	Connect	Shutdown	Down
1	1	0	0	0	0

Peer's Address	State	Up/Down time	AS	SA Count	Reset Count
10.110.2.1	Up	00:16:40	?	13	0

Anycast RP configuration

Network requirements

As shown in [Figure 62](#), the PIM-SM domain has multiple multicast sources and receivers. OSPF runs within the domain to provide unicast routes.

Configure the Anycast RP application so that the receiver-side DRs and the source-side DRs can initiate a join message to their respective RPs that are the topologically nearest to them.

On Switch B and Switch D, configure the interface Loopback 10 as a C-BSR, and Loopback 20 as a C-RP.

The router ID of Switch B is 1.1.1.1, and the router ID of Switch D is 2.2.2.2. Set up an MSDP peering relationship between Switch B and Switch D.

Figure 62 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Source 1	—	10.110.5.100/24	Switch C	Vlan-int101	192.168.1.2/24
Source 2	—	10.110.6.100/24		Vlan-int102	192.168.2.2/24
Switch A	Vlan-int300	10.110.5.1/24	Switch D	Vlan-int200	10.110.3.1/24
	Vlan-int103	10.110.2.2/24		Vlan-int104	10.110.4.1/24
Switch B	Vlan-int100	10.110.1.1/24		Vlan-int102	192.168.2.1/24
	Vlan-int103	10.110.2.1/24		Loop0	2.2.2.2/32
	Vlan-int101	192.168.1.1/24		Loop10	4.4.4.4/32
	Loop0	1.1.1.1/32		Loop20	10.1.1.1/32
	Loop10	3.3.3.3/32	Switch E	Vlan-int400	10.110.6.1/24
	Loop20	10.1.1.1/32		Vlan-int104	10.110.4.2/24

Configuration procedure

1. Configure IP addresses and unicast routing:
Configure the IP address and subnet mask for each interface as per Figure 62. (Details not shown.)
Configure OSPF for interconnection between the switches. Ensure the network-layer interoperation among the switches, and ensure the dynamic update of routing information between the switches through a unicast routing protocol. (Details not shown.)

2. Enable IP multicast routing, and enable PIM-SM and IGMP:

Enable IP multicast routing on Switch B, enable PIM-SM on each interface, and enable IGMP on the host-side interface VLAN-interface 100.

```
<SwitchB> system-view
[SwitchB] multicast routing-enable
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] igmp enable
[SwitchB-Vlan-interface100] pim sm
[SwitchB-Vlan-interface100] quit
```

```

[SwitchB] interface vlan-interface 103
[SwitchB-Vlan-interface103] pim sm
[SwitchB-Vlan-interface103] quit
[SwitchB] interface Vlan-interface 101
[SwitchB-Vlan-interface101] pim sm
[SwitchB-Vlan-interface101] quit
[SwitchB] interface loopback 0
[SwitchB-LoopBack0] pim sm
[SwitchB-LoopBack0] quit
[SwitchB] interface loopback 10
[SwitchB-LoopBack10] pim sm
[SwitchB-LoopBack10] quit
[SwitchB] interface loopback 20
[SwitchB-LoopBack20] pim sm
[SwitchB-LoopBack20] quit

```

The configuration on Switch A, Switch C, Switch D, and Switch E is similar to the configuration on Switch B.

3. Configure C-BSRs and C-RPs:

Configure Loopback 10 as a C-BSR and Loopback 20 as a C-RP on Switch B.

```

[SwitchB] pim
[SwitchB-pim] c-bsr loopback 10
[SwitchB-pim] c-rp loopback 20
[SwitchB-pim] quit

```

The configuration on Switch D is similar to the configuration on Switch B.

4. Configure MSDP peers:

Configure an MSDP peer on Loopback 0 of Switch B.

```

[SwitchB] msdp
[SwitchB-msdp] originating-rp loopback 0
[SwitchB-msdp] peer 2.2.2.2 connect-interface loopback 0
[SwitchB-msdp] quit

```

Configure an MSDP peer on Loopback 0 of Switch D.

```

[SwitchD] msdp
[SwitchD-msdp] originating-rp loopback 0
[SwitchD-msdp] peer 1.1.1.1 connect-interface loopback 0
[SwitchD-msdp] quit

```

5. Verify the configuration:

You can use the **display msdp brief** command to view the brief information of MSDP peering relationships between the switches.

Display brief MSDP peer information on Switch B.

```
[SwitchB] display msdp brief
```

MSDP Peer Brief Information of VPN-Instance: public net

Configured	Up	Listen	Connect	Shutdown	Down
1	1	0	0	0	0

Peer's Address	State	Up/Down time	AS	SA Count	Reset Count
2.2.2.2	Up	00:10:17	?	0	0

Display brief MSDP peer information on Switch D.

```
[SwitchD] display msdp brief
MSDP Peer Brief Information of VPN-Instance: public net
  Configured   Up           Listen       Connect      Shutdown     Down
  1            1           0           0           0           0

  Peer's Address   State   Up/Down time   AS   SA Count   Reset Count
  1.1.1.1         Up     00:10:18      ?   0         0
```

To view the PIM routing information on the switches, use the **display pim routing-table** command. When Source 1 (10.110.5.100/24) sends multicast data to multicast group G (225.1.1.1), Host A joins multicast group G. By comparing the PIM routing information displayed on Switch B with that displayed on Switch D, you can see that Switch B acts now as the RP for Source 1 and Host A.

Display PIM routing information on Switch B.

```
[SwitchB] display pim routing-table
VPN-Instance: public net
Total 1 (*, G) entry; 1 (S, G) entry

(*, 225.1.1.1)
  RP: 10.1.1.1 (local)
  Protocol: pim-sm, Flag: WC
  UpTime: 00:15:04
  Upstream interface: Register
    Upstream neighbor: NULL
    RPF prime neighbor: NULL
  Downstream interface(s) information:
  Total number of downstreams: 1
    1: Vlan-interface100
      Protocol: igmp, UpTime: 00:15:04, Expires: -

(10.110.5.100, 225.1.1.1)
  RP: 10.1.1.1 (local)
  Protocol: pim-sm, Flag: SPT 2MSDP ACT
  UpTime: 00:46:28
  Upstream interface: Vlan-interface103
    Upstream neighbor: 10.110.2.2
    RPF prime neighbor: 10.110.2.2
  Downstream interface(s) information:
  Total number of downstreams: 1
    1: Vlan-interface100
      Protocol: pim-sm, UpTime: - , Expires: -
```

Display PIM routing information on Switch D.

```
[SwitchD] display pim routing-table
```

No information is output on Switch D.

Host A has left multicast group G. Source 1 has stopped sending multicast data to multicast group G. When Source 2 (10.110.6.100/24) sends multicast data to G, Host B joins G. By comparing the PIM routing information displayed on Switch B with that displayed on Switch D, you can see that Switch D acts now as the RP for Source 2 and Host B.

```

# Display PIM routing information on Switch B.
[SwitchB] display pim routing-table
No information is output on Switch B.
# Display PIM routing information on Switch D.
[SwitchD] display pim routing-table
VPN-Instance: public net

    1: Vlan-interface200
      Protocol: pim-sm, UpTime: - , Expires: -

```

SA message filtering configuration

Network requirements

As shown in [Figure 63](#), three PIM-SM domains exist in the network, and OSPF runs within and among the domains to provide unicast routing.

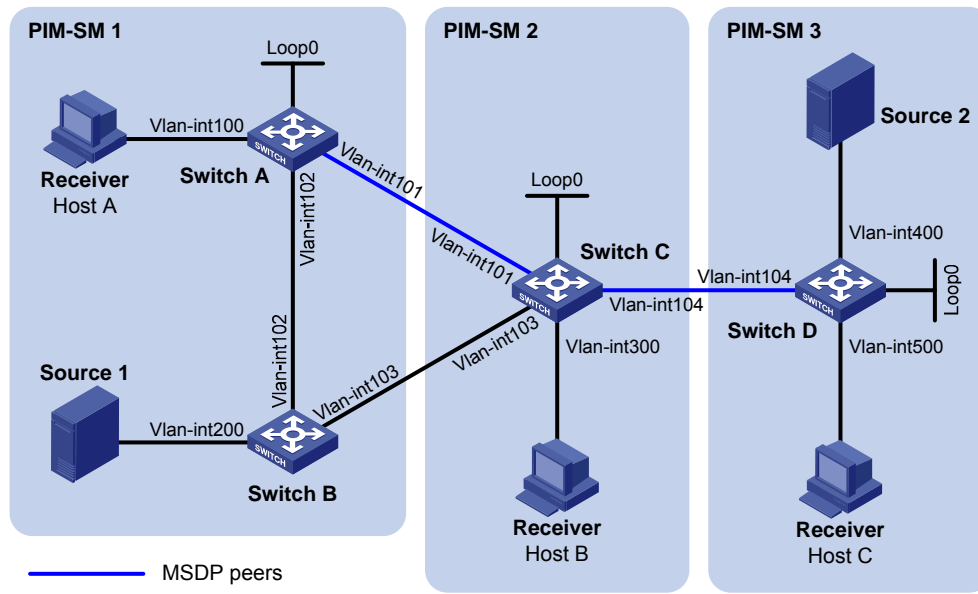

Loopback 0 is configured as a C-BSR and a C-RP in the related PIM-SM domains on Switch A, Switch C, and Switch D, respectively.

An MSDP peering relationship is set up between Switch A and Switch C and between Switch C and Switch D.

Source 1 sends multicast data to multicast groups 225.1.1.0/30 and 226.1.1.0/30, and Source 2 sends multicast data to multicast group 227.1.1.0/30.

Configure SA message filtering rules so that receivers Host A and Host B can receive only the multicast data addressed to multicast groups 225.1.1.0/30 and 226.1.1.0/30, and Host can receive only the multicast data addressed to multicast groups 226.1.1.0/30 and 227.1.1.0/30.

Figure 63 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Source 1	—	10.110.3.100/24	Switch C	Vlan-int300	10.110.4.1/24
Source 2	—	10.110.6.100/24		Vlan-int104	10.110.5.1/24
Switch A	Vlan-int100	10.110.1.1/24		Vlan-int101	192.168.1.2/24
	Vlan-int102	10.110.2.1/24		Vlan-int103	192.168.2.2/24
	Vlan-int101	192.168.1.1/24		Loop0	2.2.2.2/32
	Loop0	1.1.1.1/32	Switch D	Vlan-int400	10.110.6.1/24
Switch B	Vlan-int200	10.110.3.1/24		Vlan-int500	10.110.7.1/24
	Vlan-int102	10.110.2.2/24		Vlan-int104	10.110.5.2/24
	Vlan-int103	192.168.2.1/24		Loop0	3.3.3.3/32

Configuration Procedure

- Configure IP addresses and unicast routing:
Configure the IP address and subnet mask for each interface as per Figure 63. (Details not shown.)
Configure OSPF for interoperation among the switches. Ensure the network-layer interoperation within and between the PIM-SM domains and ensure dynamic update of routing information among the switches by leveraging unicast routing. (Details not shown.)
- Enable IP multicast routing, PIM-SM and IGMP, and configure a PIM domain border:
On Switch A, enable IP multicast routing, enable PIM-SM on each interface, and enable IGMP on the host-side interface, VLAN-interface 100.

```

<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] igmp enable
[SwitchA-Vlan-interface100] pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim sm
[SwitchA-Vlan-interface101] quit

```

```
[SwitchA] interface vlan-interface 102
[SwitchA-Vlan-interface102] pim sm
[SwitchA-Vlan-interface102] quit
[SwitchA] interface loopback 0
[SwitchA-LoopBack0] pim sm
[SwitchA-LoopBack0] quit
```

The configuration on Switch B, Switch C and Switch D is similar to the configuration on Switch A. (Details not shown.)

Configure a PIM domain border on Switch C.

```
[SwitchC] interface vlan-interface 101
[SwitchC-Vlan-interface101] pim bsr-boundary
[SwitchC-Vlan-interface101] quit
[SwitchC] interface vlan-interface 103
[SwitchC-Vlan-interface103] pim bsr-boundary
[SwitchC-Vlan-interface103] quit
[SwitchC] interface vlan-interface 104
[SwitchC-Vlan-interface104] pim bsr-boundary
[SwitchC-Vlan-interface104] quit
```

The configuration on Switch A, Switch B and Switch D is similar to the configuration on Switch C. (Details not shown.)

3. Configure C-BSRs and C-RPs:

Configure Loopback 0 as a C-BSR and a C-RP on Switch A.

```
[SwitchA] pim
[SwitchA-pim] c-bsr loopback 0
[SwitchA-pim] c-rp loopback 0
[SwitchA-pim] quit
```

The configuration on Switch C and Switch D is similar to the configuration on Switch A. (Details not shown.)

4. Configure MSDP peers:

Configure an MSDP peer on Switch A.

```
[SwitchA] msdp
[SwitchA-msdp] peer 192.168.1.2 connect-interface vlan-interface 101
[SwitchA-msdp] quit
```

Configure MSDP peers on Switch C.

```
[SwitchC] msdp
[SwitchC-msdp] peer 192.168.1.1 connect-interface vlan-interface 101
[SwitchC-msdp] peer 10.110.5.2 connect-interface vlan-interface 104
[SwitchC-msdp] quit
```

Configure an MSDP peer on Switch D.

```
[SwitchD] msdp
[SwitchD-msdp] peer 10.110.5.1 connect-interface vlan-interface 104
[SwitchD-msdp] quit
```

5. Configure SA message filtering rules:

Configure an SA message rule on Switch C so that Switch C will not forward SA messages for (Source 1, 225.1.1.0/30) to Switch D.

```
[SwitchC] acl number 3001
```

```
[SwitchC-acl-adv-3001] rule deny ip source 10.110.3.100 0 destination 225.1.1.0
0.0.0.3
[SwitchC-acl-adv-3001] rule permit ip source any destination any
[SwitchC-acl-adv-3001] quit
[SwitchC] msdp
[SwitchC-msdp] peer 10.110.5.2 sa-policy export acl 3001
[SwitchC-msdp] quit
```

Configure an SA message rule on Switch D so that Switch D will not create SA messages for Source 2.

```
[SwitchD] acl number 2001
[SwitchD-acl-basic-2001] rule deny source 10.110.6.100 0
[SwitchD-acl-basic-2001] quit
[SwitchD] msdp
[SwitchD-msdp] import-source acl 2001
[SwitchD-msdp] quit
```

6. Verify the configuration:

View the (S, G) entries cached in the SA cache on the switches using the **display msdp sa-cache** command. For example:

Display the (S, G) entries cached in the SA cache on Switch C.

```
[SwitchC] display msdp sa-cache
MSDP Source-Active Cache Information of VPN-Instance: public net
MSDP Total Source-Active Cache - 8 entries
MSDP matched 8 entries
```

(Source, Group)	Origin RP	Pro	AS	Uptime	Expires
(10.110.3.100, 225.1.1.0)	1.1.1.1	?	?	02:03:30	00:05:31
(10.110.3.100, 225.1.1.1)	1.1.1.1	?	?	02:03:30	00:05:31

(10.110.3.100, 226.1.1.0)	1.1.1.1	?	?	02:03:30	00:05:31
(10.110.3.100, 226.1.1.1)	1.1.1.1	?	?	02:03:30	00:05:31
(10.110.3.100, 226.1.1.2)	1.1.1.1	?	?	02:03:30	00:05:31
(10.110.3.100, 226.1.1.3)	1.1.1.1	?	?	02:03:30	00:05:31

Display the (S, G) entries cached in the SA cache on Switch D.

```
[SwitchD] display msdp sa-cache
MSDP Source-Active Cache Information of VPN-Instance: public net
MSDP Total Source-Active Cache - 4 entries
MSDP matched 4 entries
```

(Source, Group)	Origin RP	Pro	AS	Uptime	Expires

Troubleshooting MSDP

MSDP peers stay in down state

Symptom

The configured MSDP peers stay in the down state.

Analysis

- A TCP connection-based MSDP peering relationship is established between the local interface address and the MSDP peer after the configuration.
- The TCP connection setup will fail if the local interface address is not consistent with the MSDP peer address configured on the peer router.
- If no route is available between the MSDP peers, the TCP connection setup will fail.

Solution

1. Verify that a route is available between the routers. Use the **display ip routing-table** command to determine whether the unicast route between the routers is correct.
2. Verify that a unicast route is available between the two routers that will become MSDP peers to each other.
3. Verify the interface address consistency between the MSDP peers. Use the **display current-configuration** command to verify that the local interface address and the MSDP peer address of the remote router are the same.

No SA entries in the switch's SA cache

Symptom

MSDP fails to send (S, G) entries through SA messages.

Analysis

- The **import-source** command controls sending (S, G) entries through SA messages to MSDP peers. If this command is executed without the *acl-number* argument, all the (S, G) entries are filtered out. That is, no (S, G) entries of the local domain is advertised.
- If the **import-source** command is not executed, the system will advertise all the (S, G) entries of the local domain. If MSDP fails to send (S, G) entries through SA messages, verify that the **import-source** command has been correctly configured.

Solution

1. Use the **display ip routing-table** command to verify that the unicast route between the routers is correct.
2. Verify that a unicast route is available between the two routers that will become MSDP peers to each other.
3. Verify the configuration of the **import-source** command and its *acl-number* argument and be sure that ACL rule can filter appropriate (S, G) entries.

Inter-RP communication faults in Anycast RP application

Symptom

RPs fail to exchange their locally registered (S, G) entries with one another in the Anycast RP application.

Analysis

- In the Anycast RP application, RPs in the same PIM-SM domain are configured to be MSDP peers to achieve load balancing among the RPs.
- An MSDP peer address must be different from the Anycast RP address, and the C-BSR and C-RP must be configured on different devices or interfaces.
- If the **originating-rp** command is executed, MSDP will replace the RP address in the SA messages with the address of the interface specified in the command.
- When an MSDP peer receives an SA message, it performs RPF check on the message. If the MSDP peer finds that the remote RP address is the same as the local RP address, it will discard the SA message.

Solution

1. Use the **display ip routing-table** command to verify that the unicast route between the routers is correct.
2. Verify that a unicast route is available between the two routers that will become MSDP peer to each other.
3. Verify the configuration of the **originating-rp** command. In the Anycast RP application environment, be sure to use the **originating-rp** command to configure the RP address in the SA messages, which must be the local interface address.
4. Verify that the C-BSR address is different from the Anycast RP address.

Configuring MBGP (available only on the HP 5500 EI)

MBGP overview

This chapter covers configuration tasks related to multiprotocol BGP for IP multicast only. For more information about BGP, see *Layer 3—IP Routing Configuration Guide*. The term "router" in this chapter refers to both routers and Layer 3 switches.

BGP-4 can carry routing information for IPv4 only. IETF defined Multiprotocol Border Gateway Protocol (MP-BGP) to extend BGP-4 so that BGP can carry routing information for multiple network-layer protocols.

For a network, the topology for multicast might be different from that for unicast. To distinguish them, the MP-BGP enables BGP to carry the unicast Network Layer Reachability Information (NLRI) and multicast NLRI separately. The multicast NLRI performs reverse path forwarding (RPF) exclusively. In this way, route selection for a destination through the unicast routing table and through the multicast routing table have different results, ensuring consistent unicast forwarding and normal multicast between domains. For more information about RPF, see "[Configuring multicast routing and forwarding \(available only on the HP 5500 EI\)](#)."

MP-BGP is defined in RFC 2858 (Multiprotocol Extensions for BGP-4). The application of MP-BGP on multicast is called Multicast BGP (MBGP).

Protocols and standards

- RFC 2858, *Multiprotocol Extensions for BGP-4*
- RFC 3392, *Capabilities Advertisement with BGP-4*
- draft-ietf-idmr-bgp-mcast-attr-00, *BGP Attributes for Multicast Tree Construction*
- RFC 4271, *A Border Gateway Protocol 4 (BGP-4)*
- RFC 5291, *Outbound Route Filtering Capability for BGP-4*
- RFC 5292, *Address-Prefix-Based Outbound Route Filter for BGP-4*

MBGP configuration task list

Task	Remarks	
Configuring basic MBGP functions	Required	
Configuring MBGP route redistribution	Required	
Controlling route advertisement and reception	Configuring default route redistribution into MBGP	Optional
	Configuring MBGP route summarization	Optional
	Advertising a default route to an IPv4 MBGP peer or peer group	Optional
	Configuring outbound MBGP route filtering	Optional

Task		Remarks
	Configuring inbound MBGP route filtering	Optional
	Configuring MBGP route dampening	Optional
Configuring MBGP route attributes	Configuring MBGP route preferences	
	Configuring the default local preference	
	Configuring the MED attribute	Optional
	Configuring the next hop attribute	
	Configuring the AS-PATH attributes	
Tuning and optimizing MBGP networks	Configuring MBGP soft reset	Optional
	Enabling the MBGP ORF capability	Optional
	Configuring the maximum number of MBGP routes for load balancing	Optional
Configuring a large scale MBGP network	Configuring IPv4 MBGP peer groups	Optional
	Configuring MBGP community	Optional
	Configuring an MBGP route reflector	Optional

Configuring basic MBGP functions

Configuration prerequisites

Before you configure MBGP, be sure that neighboring nodes can access each other at the network layer.

Configuration procedure

To configure basic MBGP functions:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Specify a peer or peer group and its AS number.	peer { <i>group-name</i> <i>ip-address</i> } as-number <i>as-number</i>	Not specified by default.
4. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
5. Enable a peer or peer group created in IPv4 unicast view.	peer { <i>group-name</i> <i>ip-address</i> } enable	Not enabled by default.
6. Specify a preferred value for routes from an IPv4 MBGP peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } preferred-value <i>value</i>	Optional. The default preferred value is 0.

Controlling route advertisement and reception

Configuration prerequisites

You need to configure basic MBGP functions before configuring this task.

Configuring MBGP route redistribution

MBGP can advertise routing information in the local AS to neighboring ASs. It redistributes such routing information from IGP into its routing table rather than learning the information by itself.

To configure MBGP route redistribution:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Configure MBGP route redistribution.	<p>Enable route redistribution from another routing protocol:</p> <pre>import-route <i>protocol</i> [{ <i>process-id</i> all-processes } [allow-direct med <i>med-value</i> route-policy <i>route-policy-name</i>] *]</pre> <p>Inject a network into the MBGP routing table:</p> <pre>network <i>ip-address</i> [<i>mask</i> <i>mask-length</i>] [short-cut route-policy <i>route-policy-name</i>]</pre>	<p>Use either command</p> <p>No route redistribution is configured by default.</p> <p>The allow-direct keyword is available only when the specified routing protocol is OSPF.</p> <p>The Origin attribute of routes redistributed into the MBGP routing table with the import-route command is Incomplete.</p> <p>The Origin attribute of routes injected into the MBGP routing table with the network command is IGP.</p>

NOTE:

The networks to be injected must exist in the local IP routing table, and using a routing policy makes route control more flexible.

Configuring default route redistribution into MBGP

You cannot use the **import-route** command to redistribute any default route into the MBGP routing table. This task allows you to redistribute default routes in another way.

To configure MBGP to redistribute a default route from another protocol:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A

Step	Command	Remarks
3. Enter MBGP address family view.	ipv4-family multicast	N/A
4. Enable route redistribution from another routing protocol.	import-route <i>protocol</i> [{ <i>process-id</i> all-processes } [allow-direct med <i>med-value</i> route-policy <i>route-policy-name</i>] *]	No route redistribution is configured by default. The allow-direct keyword is available only when the specified routing protocol is OSPF.
5. Enable default route redistribution into the MBGP routing table.	default-route imported	Not enabled by default.

Configuring MBGP route summarization

To reduce the routing table size on medium and large MBGP networks, you need to configure route summarization on peers. MBGP supports automatic and manual summarization modes:

- **Automatic summarization**—Summarizes subnets redistributed from IGP. With the feature configured, MBGP advertises only summary natural networks rather than subnets. The default routes and routes injected with the **network** command are not summarized.
- **Manual summarization**—Summarizes MBGP local routes. A manual summary route has a higher priority than an automatic one.

To configure MBGP route summarization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Configure MBGP route summarization.	Enable automatic route summarization: summary automatic Configure manual route summarization: aggregate <i>ip-address</i> { <i>mask</i> <i>mask-length</i> } [as-set attribute-policy <i>route-policy-name</i> detail-suppressed origin-policy <i>route-policy-name</i> suppress-policy <i>route-policy-name</i>] *	Use either command No route summarization is configured by default. If the two commands are both configured, the manual route summarization takes effect.

Advertising a default route to an IPv4 MBGP peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Advertise a default route to an MBGP peer or peer group.	peer { <i>group-name</i> <i>ip-address</i> } default-route-advertise [route-policy <i>route-policy-name</i>]	Not advertised by default.

NOTE:

With the **peer default-route-advertise** command executed, the router sends a default route with the next hop as itself to the specified MBGP peer or peer group, whether the default route is available or not in the routing table.

Configuring outbound MBGP route filtering

If several filtering policies are configured, they are applied in the following sequence:

1. **filter-policy export**
2. **peer filter-policy export**
3. **peer as-path-acl export**
4. **peer ip-prefix export**
5. **peer route-policy export**

Only the routes that have passed all the configured policies can be advertised.

To configure BGP route distribution filtering policies:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A

Step	Command	Remarks
4. Configure BGP route distribution filtering policies.	<ul style="list-style-type: none"> Configure the filtering of redistributed routes: filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } export [direct isis <i>process-id</i> ospf <i>process-id</i> rip <i>process-id</i> static] Apply a routing policy to advertisements to an IPv4 MBGP peer or a peer group: peer { <i>group-name</i> <i>peer-address</i> } route-policy <i>route-policy-name</i> export Reference an ACL to filter advertisements to an IPv4 MBGP peer or a peer group: peer { <i>group-name</i> <i>ip-address</i> } filter-policy <i>acl-number</i> export Reference an AS path ACL to filter route advertisements to an IPv4 MBGP peer or a peer group: peer { <i>group-name</i> <i>ip-address</i> } as-path-acl <i>as-path-acl-number</i> export Reference an IP prefix list to filter route advertisements to an IPv4 MBGP peer or a peer group: peer { <i>group-name</i> <i>ip-address</i> } ip-prefix <i>ip-prefix-name</i> export 	Use one of these commands No outbound route filtering is configured by default.

Configuring inbound MBGP route filtering

By configuring MBGP route reception filtering policies, you can filter out unqualified routes from an MBGP peer or peer group. Members of a peer group can have different route reception filtering policies from the peer group.

If several filtering policies are configured, they are applied in the following sequence:

1. **filter-policy import**
2. **peer filter-policy import**
3. **peer as-path-acl import**
4. **peer ip-prefix import**
5. **peer route-policy import**

Only the routes that have passed all the configured policies can be advertised.

To configure MBGP route reception filtering policies:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A

Step	Command	Remarks
4. Configure MBGP route reception filtering policies.	<ul style="list-style-type: none"> Filter incoming routes using an ACL or IP prefix list: filter-policy { <i>acl-number</i> ip-prefix <i>ip-prefix-name</i> } import Reference a routing policy to routes from an IPv4 MBGP peer or a peer group: peer { <i>group-name</i> <i>ip-address</i> } route-policy <i>policy-name</i> import Reference an ACL to filter routing information from an IPv4 MBGP peer or a peer group: peer { <i>group-name</i> <i>ip-address</i> } filter-policy <i>acl-number</i> import Reference an AS path ACL to filter routing information from an IPv4 MBGP peer or a peer group: peer { <i>group-name</i> <i>ip-address</i> } as-path-acl <i>as-path-acl-number</i> import Reference an IP prefix list to filter routing information from an IPv4 MBGP peer or a peer group: peer { <i>group-name</i> <i>ip-address</i> } ip-prefix <i>ip-prefix-name</i> import 	Use one of these command No inbound route filtering is configured by default.
5. Specify the maximum number of routes that can be received from an IPv4 MBGP peer or a peer group.	peer { <i>group-name</i> <i>ip-address</i> } route-limit <i>limit</i> [<i>percentage</i>]	Optional The number is unlimited by default.

Configuring MBGP route dampening

By configuring MBGP route dampening, you can suppress unstable routes from being added to the MBGP routing table or being advertised to MBGP peers.

To configure BGP route dampening:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A

Step	Command	Remarks
4. Configure BGP route dampening parameters.	dampening [<i>half-life-reachable</i> <i>half-life-unreachable reuse</i> <i>suppress ceiling</i> route-policy <i>route-policy-name</i>] *	Not configured by default.

Configuring MBGP route attributes

You can modify MBGP route attributes to affect route selection.

Configuration prerequisites

Before you configure this task, you need to configure basic MBGP functions.

Configuring MBGP route preferences

You can reference a routing policy to set preferences for routes matching it. Routes not matching it use the default preferences.

To configure MBGP route preferences:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Configure preferences for external, internal, and local MBGP routes.	preference { <i>external-preference</i> <i>internal-preference</i> <i>local-preference</i> route-policy <i>route-policy-name</i> }	Optional. The default preferences of multicast MBGP EBGP, MBGP IBGP, and local MBGP routes are 255, 255, and 130, respectively.

Configuring the default local preference

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Configure the default local preference.	default local-preference <i>value</i>	Optional. 100 by default.

Configuring the MED attribute

When other conditions of routes to a destination are identical, the route with the smallest MED is selected.

To configure the MED attribute:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Configure the default MED value.	default med <i>med-value</i>	Optional. 0 by default.
5. Enable the comparison of the MED of routes from different ASs.	compare-different-as-med	Optional. Not enabled by default.
6. Enable the comparison of the MED of routes from each AS.	bestroute compare-med	Optional. Not enabled by default.
7. Enable the comparison of the MED of routes from confederation peers.	bestroute med-confederation	Optional. Not enabled by default.

Configuring the next hop attribute

You can use the **peer next-hop-local** command to specify the local router as the next hop of routes sent to an MBGP IBGP peer or peer group. If load balancing is configured, the router specifies itself as the next hop of route advertisements to the multicast IBGP peer or peer group regardless of whether the **peer next-hop-local** command is configured.

In a third-party next-hop network (that is, when the local router has two multicast EBGP peers in a broadcast network), the router does not specify itself as the next hop of routing information sent to the EBGP peers unless the **peer next-hop-local** command is configured.

To specify the router as the next hop of routes sent to a peer or a peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Specify the router as the next hop of routes sent to a peer or a peer group.	peer { <i>group-name</i> <i>ip-address</i> } next-hop-local	Optional. By default, IPv6 MBGP specifies the local router as the next hop for routes sent to an EBGP peer or a peer group, but not for routes sent to an MBGP IBGP peer or a peer group.

Configuring the AS-PATH attributes

In general, MBGP checks whether the AS-PATH attribute of a route from a peer contains the local AS number. If it does, it discards the route to avoid routing loops.

To configure the AS-PATH attributes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Allow the local AS number to appear in the AS-PATH of routes from a peer or a peer group and specify the number of times that the local AS number can appear in the AS-PATH of routes from the peer or the peer group.	peer { <i>group-name</i> <i>ip-address</i> } allow-as-loop [<i>number</i>]	Optional. By default, the local AS number cannot appear in routes from a peer or a peer group.
5. Disable BGP from considering the AS_PATH during best route selection.	bestroute as-path-neglect	Optional. By default, BGP considers AS_PATH during best route selection.
6. Configure updates to a peer or a peer group not to keep private AS numbers.	peer { <i>group-name</i> <i>ip-address</i> } public-as-only	Optional. By default, BGP updates carry private AS numbers.

Tuning and optimizing MBGP networks

This task involves resetting MBGP connections and configuring load balancing.

Configuration prerequisites

You need to configure basic MBGP functions before configuring this task.

Configuring MBGP soft reset

After modifying a route selection policy, you have to reset MBGP connections to make it take effect.

The current MBGP implementation supports the route refresh feature that enables dynamic route refresh without terminating MBGP connections.

However, if a peer that does not support route refresh exists in the network, you must configure the **peer keep-all-routes** command to save all routes from the peer. When the routing policy is changed, the system updates the MBGP routing table and applies the new policy.

Performing soft reset through route refresh

If the peer is enabled with route refresh, when the MBGP route selection policy is modified on a router, the router advertises a route-refresh message to its MBGP peers, which resend their routing information

to the router after receiving the message. Therefore, the local router can perform dynamic route update and apply the new policy without terminating MBGP connections.

To perform soft reset through route refresh:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enable BGP route refresh for a peer or a peer group.	peer { group-name ip-address } capability-advertise route-refresh	Optional. Enabled by default.

Performing soft reset manually

If the peer does not support route refresh, you can use the **peer keep-all-routes** command to save all the route updates from the peer, and then use the **refresh bgp ipv4 multicast** command to soft-reset MBGP connections to refresh the MBGP routing table and apply the new policy without terminating MBGP connections.

To perform a manual soft reset:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Disable BGP route refresh and multiprotocol extensions for a peer or a peer group.	peer { group-name ip-address } capability-advertise conventional	Optional. Enabled by default.
4. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
5. Keep all original routes from a peer or a peer group regardless of whether they pass the inbound filtering policies.	peer { group-name ip-address } keep-all-routes	Not kept by default.
6. Return to user view.	return	N/A
7. Soft-reset MBGP connections manually.	refresh bgp ipv4 multicast { all ip-address group group-name external internal } { export import }	Optional.

Enabling the MBGP ORF capability

The MBGP Outbound Router Filter (ORF) feature enables an MBGP speaker to send a set of ORFs to its MBGP peer through route-refresh messages. The peer then applies the ORFs, in addition to its local routing policies (if any), to filter updates to the MBGP speaker, reducing update messages and saving network resources.

After you enable the BGP ORF capability, the local BGP router negotiates the ORF capability with the BGP peer through Open messages. That is, the BGP router determines whether to carry ORF information in messages and, if so, whether to carry nonstandard ORF information in the packets. After completing

the negotiation process and establishing the neighboring relationship, the BGP router and its BGP peer can exchange ORF information through specific route-refresh messages.

For the parameters configured on both sides for ORF capability negotiation, see [Table 7](#).

To enable the MBGP ORF capability:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enable BGP route refresh for a peer or a peer group.	peer { group-name ip-address } capability-advertise route-refresh	Optional. Enabled by default. If this feature is not enabled, you need to configure this command. For more information about the command, see <i>Layer 3—IP Routing Command Reference</i> .
4. Enable the non-standard BGP ORF capability for a BGP peer or a peer group.	peer { group-name ipv6-address } capability-advertise orf non-standard	Optional. By default, standard BGP ORF capability defined in RFC 5291 and RFC 5292 is supported. If this feature is not enabled, you need to configure this command. For more information about the command, see <i>Layer 3—IP Routing Command Reference</i> .
5. Enter MBGP address family view.	ipv4-family multicast	N/A
6. Enable the ORF IP prefix negotiation capability for an MBGP peer or a peer group.	peer { group-name ip-address } capability-advertise orf ip-prefix { both receive send }	Optional. Not enabled by default.

Table 7 Description of the both, send, and receive parameters and the negotiation result

Local parameter	Peer parameter	Negotiation result
send	<ul style="list-style-type: none"> • receive • both 	The ORF sending capability is enabled locally and the ORF receiving capability is enabled on the peer.
receive	<ul style="list-style-type: none"> • send • both 	The ORF receiving capability is enabled locally and the ORF sending capability is enabled on the peer.
both	both	Both the ORF sending and receiving capabilities are enabled locally and on the peer, respectively.

Configuring the maximum number of MBGP routes for load balancing

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Configure the maximum number of MBGP routes for load balancing.	balance <i>number</i>	Not configured by default.

Configuring a large scale MBGP network

Configuration prerequisites

Before you configure this task, you must make peering nodes accessible to each other at the network layer.

Configuring IPv4 MBGP peer groups

In a large-scale network, configuration and maintenance become difficult because of large numbers of MBGP peers. You can configure peer groups to make management easier and improve route distribution efficiency.

ⓘ IMPORTANT:

- To configure an MBGP peer group, you must enable the corresponding IPv4 BGP unicast peer group in IPv4 MBGP address family view.
- Before adding an MBGP peer to an MBGP peer group, you must add the corresponding IPv4 unicast peer to the IPv4 BGP peer group.

To configure an IPv4 MBGP peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Create a BGP peer group.	group <i>group-name</i> [external internal]	Not created by default.
4. Add a peer into the peer group.	peer <i>ip-address</i> group <i>group-name</i> [as-number <i>as-number</i>]	No peer is added by default.
5. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
6. Enable the IPv4 unicast peer group.	peer <i>group-name</i> enable	N/A
7. Add an IPv4 MBGP peer to the peer group.	peer <i>ip-address</i> group <i>group-name</i>	Not configured by default.

Configuring MBGP community

The community attribute can be advertised between MBGP peers in different ASs. Routers in the same community share the same policy.

You can reference a routing policy to modify the community attribute for routes sent to a peer. In addition, you can define extended community attributes as needed.

When you configure MBGP community, you must reference a routing policy to define the specific community attributes, and apply the routing policy for route advertisement. For routing policy configuration, see *Layer 3—IP Routing Configuration Guide*.

To configure MBGP community:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Advertise the community attribute to an MBGP peer or a peer group.	<ul style="list-style-type: none">Advertise the community attribute to an MBGP peer or a peer group: peer { group-name ip-address } advertise-communityAdvertise the extended community attribute to an MBGP peer or a peer group: peer { group-name ip-address } advertise-ext-community	<ul style="list-style-type: none">Use either commandNot configured by default.
5. Apply a routing policy to routes advertised to an MBGP peer or a peer group.	peer { group-name ip-address } route-policy route-policy-name export	Not configured by default.

Configuring an MBGP route reflector

To guarantee the connectivity between multicast IBGP peers in an AS, you need to make them fully meshed. But this becomes unpractical when large numbers of multicast IBGP peers exist. Configuring route reflectors can solve this problem.

In general, it is not required that clients of a route reflector be fully meshed. The route reflector forwards routing information between clients. If clients are fully meshed, you can disable route reflection between clients to reduce routing costs.

In general, a cluster has only one route reflector, and the router ID of the route reflector identifies the cluster. You can configure multiple route reflectors to improve network stability. In this case, you need to specify the same cluster ID for these route reflectors to avoid routing loops.

To configure an MBGP route reflector:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv4 MBGP address family view.	ipv4-family multicast	N/A
4. Configure the router as a route reflector and specify an MBGP peer or a peer group as its client.	peer { <i>group-name</i> <i>peer-address</i> } reflect-client	Not configured by default.
5. Enable route reflection between clients.	reflect between-clients	Optional. Enabled by default.
6. Configure the cluster ID of the route reflector.	reflector cluster-id <i>cluster-id</i>	Optional. By default, a route reflector uses its router ID as the cluster ID.

Displaying and maintaining MBGP

Displaying MBGP

Task	Command	Remarks
Display the IPv4 MBGP routing table.	display ip multicast routing-table [<i>verbose</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the IPv4 MBGP routing information matching the specified destination IP address.	display ip multicast routing-table <i>ip-address</i> [<i>mask-length</i> <i>mask</i>] [longer-match] [<i>verbose</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MBGP peer group information.	display bgp multicast group [<i>group-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the advertised networks.	display bgp multicast network [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display AS path information.	display bgp multicast paths [<i>as-regular-expression</i> { begin exclude include } <i>regular-expression</i>]	Available in any view
Display MBGP peer information or peer group information.	display bgp multicast peer [[<i>ip-address</i>] <i>verbose</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the prefix entries in the ORF information from the specified BGP peer.	display bgp multicast peer <i>ip-address</i> received ip-prefix [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MBGP routing information.	display bgp multicast routing-table [<i>ip-address</i> [{ <i>mask</i> <i>mask-length</i> } [longer-prefixes]]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MBGP routing information matching the AS path ACL.	display bgp multicast routing-table as-path-acl <i>as-path-acl-number</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display MBGP CIDR routing information.	display bgp multicast routing-table cidr [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MBGP routing information matching the specified BGP community.	display bgp multicast routing-table community [aa:nn&<1-13>] [no-advertise no-export no-export-subconfed] * [whole-match] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MBGP routing information matching an MBGP community list.	display bgp multicast routing-table community-list { { <i>basic-community-list-number</i> <i>comm-list-name</i> } [whole-match] <i>adv-community-list-number</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MBGP dampened routing information.	display bgp multicast routing-table dampened [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MBGP dampening parameter information.	display bgp multicast routing-table dampening parameter [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MBGP routing information originating from different ASs.	display bgp multicast routing-table different-origin-as [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv4 MBGP routing flap statistics.	display bgp multicast routing-table flap-info [<i>regular-expression as-regular-expression</i> [as-path-acl <i>as-path-acl-number</i> <i>ip-address</i> [{ <i>mask</i> <i>mask-length</i> } [longer-match]]] [{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display IPv4 MBGP routing information sent to or received from an MBGP peer.	display bgp multicast routing-table peer <i>ip-address</i> { advertised-routes received-routes } [<i>network-address</i> [<i>mask</i> <i>mask-length</i>] statistic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv4 MBGP routing information matching an AS regular expression.	display bgp multicast routing-table regular-expression <i>as-regular-expression</i>	Available in any view
Display IPv4 MBGP routing statistics.	display bgp multicast routing-table statistic [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Resetting MBGP connections

Task	Command	Remarks
Reset specified MBGP connections.	reset bgp ipv4 multicast { all <i>as-number</i> <i>ip-address</i> group <i>group-name</i> external internal }	Available in user view

Clearing MBGP information

Task	Command	Remarks
Clear dampened routing information and release suppressed routes.	reset bgp ipv4 multicast dampening [<i>ip-address</i> [<i>mask</i> <i>mask-length</i>]]	Available in user view

Task	Command	Remarks
Clear MBGP route flap statistics.	<code>reset bgp ipv4 multicast flap-info [regexp as-path-regexp as-path-acl as-path-acl-number ip-address [mask mask-length]]</code>	Available in user view

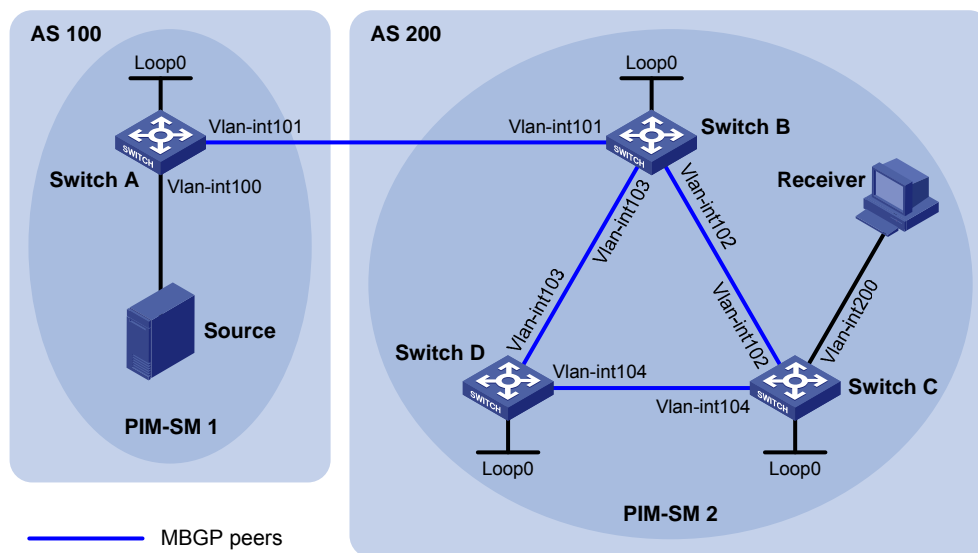

MBGP configuration example

Network requirements

As shown in the following figure:

- PIM-SM 1 is in AS 100, and PIM-SM 2 is in AS 200. OSPF is the IGP in the two ASs, and MBGP runs between the two ASs to exchange multicast route information.
- The multicast source belongs to PIM-SM 1, and the receiver belongs to PIM-SM 2.
- Configure the respective Loopback 0 of Switch A and Switch B as the C-BSR and C-RP of the respective PIM-SM domains.
- Set up an MSDP peer relationship between Switch A and Switch B through MBGP.

Figure 64 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Source	N/A	10.110.1.100/24	Switch C	Vlan-int200	10.110.2.1/24
Switch A	Vlan-int100	10.110.1.1/24	Switch C	Vlan-int102	192.168.2.2/24
	Vlan-int101	192.168.1.1/24		Vlan-int104	192.168.4.1/24
	Loop0	1.1.1.1/32		Loop0	3.3.3.3/32
Switch B	Vlan-int101	192.168.1.2/24	Switch D	Vlan-int103	192.168.3.2/24
	Vlan-int102	192.168.2.1/24		Vlan-int104	192.168.4.2/24
	Vlan-int103	192.168.3.1/24		Loop0	4.4.4.4/32
	Loop0	2.2.2.2/32			

Configuration procedure

1. Configure IP addresses for interfaces as shown in Figure 64. (Details not shown.)
2. Configure OSPF. (Details not shown.)

3. Enable IP multicast routing, PIM-SM and IGMP, and configure a PIM-SM domain border:

Enable IP multicast routing on Switch A, and enable PIM-SM on each interface.

```
<SwitchA> system-view
[SwitchA] multicast routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim sm
[SwitchA-Vlan-interface101] quit
```

The configuration on Switch B and Switch D is similar to the configuration on Switch A.

Enable IP multicast routing on Switch C, enable PIM-SM on each interface, and enable IGMP on the host-side interface VLAN-interface 200.

```
<SwitchC> system-view
[SwitchC] multicast routing-enable
[SwitchC] interface vlan-interface 102
[SwitchC-Vlan-interface102] pim sm
[SwitchC-Vlan-interface102] quit
[SwitchC] interface vlan-interface 104
[SwitchC-Vlan-interface104] pim sm
[SwitchC-Vlan-interface104] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] pim sm
[SwitchC-Vlan-interface200] igmp enable
[SwitchC-Vlan-interface200] quit
```

Configure a PIM domain border on Switch A.

```
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim bsr-boundary
[SwitchA-Vlan-interface101] quit
```

Configure a PIM domain border on Switch B.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] pim bsr-boundary
[SwitchB-Vlan-interface101] quit
```

4. Configure Loopback 0 and the position of C-BSR, and C-RP:

Configure Loopback 0 and configure it as the C-BSR and C-RP on Switch A.

```
[SwitchA] interface loopback 0
[SwitchA-LoopBack0] ip address 1.1.1.1 32
[SwitchA-LoopBack0] pim sm
[SwitchA-LoopBack0] quit
[SwitchA] pim
[SwitchA-pim] c-bsr loopback 0
[SwitchA-pim] c-rp loopback 0
[SwitchA-pim] quit
```

Configure Loopback 0 and configure it as the C-BSR and C-RP on Switch B.

```
[SwitchB] interface loopback 0
[SwitchB-LoopBack0] ip address 2.2.2.2 32
[SwitchB-LoopBack0] pim sm
```

```
[SwitchB-LoopBack0] quit
[SwitchB] pim
[SwitchB-pim] c-bsr loopback 0
[SwitchB-pim] c-rp loopback 0
[SwitchB-pim] quit
```

5. Configure BGP, specify the MBGP peer and enable direct route redistribution:

On Switch A, configure the MBGP peer and enable direct route redistribution.

```
[SwitchA] bgp 100
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] peer 192.168.1.2 as-number 200
[SwitchA-bgp] import-route direct
[SwitchA-bgp] ipv4-family multicast
[SwitchA-bgp-af-mul] peer 192.168.1.2 enable
[SwitchA-bgp-af-mul] import-route direct
[SwitchA-bgp-af-mul] quit
[SwitchA-bgp] quit
```

On Switch B, configure the MBGP peer and enable route redistribution from OSPF.

```
[SwitchB] bgp 200
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] peer 192.168.1.1 as-number 100
[SwitchB-bgp] import-route ospf 1
[SwitchB-bgp] ipv4-family multicast
[SwitchB-bgp-af-mul] peer 192.168.1.1 enable
[SwitchB-bgp-af-mul] import-route ospf 1
[SwitchB-bgp-af-mul] quit
[SwitchB-bgp] quit
```

6. Configure MSDP peer:

Specify the MSDP peer on Switch A.

```
[SwitchA] msdp
[SwitchA-msdp] peer 192.168.1.2 connect-interface vlan-interface 101
[SwitchA-msdp] quit
```

Specify the MSDP peer on Switch B.

```
[SwitchB] msdp
[SwitchB-msdp] peer 192.168.1.1 connect-interface vlan-interface 101
[SwitchB-msdp] quit
```

7. Verify the configuration:

You can use the **display bgp multicast peer** command to display MBGP peers on a switch. For example, display MBGP peers on Switch B.

```
[SwitchB] display bgp multicast peer
```

```
BGP local router ID : 2.2.2.2
Local AS number : 200
Total number of peers : 3                Peers in established state : 3
```

Peer	AS	MsgRcvd	MsgSent	OutQ	PrefRcv	Up/Down	State
192.168.1.1	100	56	56	0	0	00:40:54	Established

You can use the **display msdp brief** command to display MSDP peers on a switch. For example, display brief information about MSDP peers on Switch B.

```
[SwitchB] display msdp brief
```

```
MSDP Peer Brief Information of VPN-Instance: public net
```

Configured	Up	Listen	Connect	Shutdown	Down
1	1	0	0	0	0
Peer's Address	State	Up/Down time	AS	SA Count	Reset Count
192.168.1.1	Up	00:07:17	100	1	0

Configuring MLD snooping

Overview

Multicast Listener Discovery (MLD) snooping is an IPv6 multicast constraining mechanism that runs on Layer 2 devices to manage and control IPv6 multicast groups.

By analyzing received MLD messages, a Layer 2 device that runs MLD snooping establishes mappings between ports and multicast MAC addresses and forwards IPv6 multicast data based on these mappings.

As shown in [Figure 65](#), when MLD snooping does not run on the Layer 2 switch, IPv6 multicast packets are flooded to all devices at Layer 2. When MLD snooping runs on the Layer 2 switch, multicast packets for known IPv6 multicast groups are multicast to the receivers, rather than flooded to all hosts at Layer 2.

Figure 65 Before and after MLD snooping is enabled on the Layer 2 device

MLD snooping enables the Layer 2 switch to forward IPv6 multicast data to only the receivers that require the data at Layer 2. It has the following advantages:

- Reducing Layer 2 broadcast packets, thus saving network bandwidth
- Enhancing the security of multicast traffic
- Facilitating the implementation of per-host accounting

Basic concepts in MLD snooping

MLD snooping related ports

As shown in [Figure 66](#), Router A connects to the multicast source, MLD snooping runs on Switch A and Switch B, and Host A and Host C are receiver hosts (namely, members of an IPv6 multicast group).

Figure 66 MLD snooping related ports

Ports involved in MLD snooping, as shown in Figure 66, are described as follows:

- Router port**—A router port is a port on the Ethernet switch that leads switch toward the Layer-3 multicast device (designated router or MLD querier). In the figure, GigabitEthernet 1/0/1 of Switch A and GigabitEthernet 1/0/1 of Switch B are router ports. The switch registers all its local router ports in its router port list.

In this document, a router port is port on a switch that leads the switch toward a Layer 3 multicast device. It is not a port on an ordinary router.

- Member port**—A member port (also known as IPv6 multicast group member port) is a port on the Ethernet switch that leads toward multicast group members. In the figure, GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 of Switch A and GigabitEthernet 1/0/2 of Switch B are member ports. The switch registers all the member ports on the local device in its MLD snooping forwarding table.

Unless otherwise specified, router ports and member ports in this document include both static and dynamic router ports and member ports.

NOTE:

An MLD snooping-enabled switch deems that the all its ports that receive MLD general queries with the source address other than 0::0 or that receive IPv6 PIM hello messages are dynamic router ports. For more information about IPv6 PIM hello messages, see "[Configuring IPv6 PIM \(available only on the HP 5500 EI\)](#)."

Aging timers for dynamic ports in MLD snooping and related messages and actions

Timer	Description	Message before expiry	Action after expiry
Dynamic router port aging timer	For each dynamic router port, the switch sets an aging timer. When the timer expires, the dynamic router port ages out.	MLD general query of which the source address is not 0::0 or IPv6 PIM hello.	The switch removes this port from its router port list.

Timer	Description	Message before expiry	Action after expiry
Dynamic member port aging timer	When a port dynamically joins a multicast group, the switch starts an aging timer for the port. When the timer expires, the dynamic member port ages out.	MLD report message.	The switch removes this port from the MLD snooping forwarding table.

NOTE:

In MLD snooping, only dynamic ports age out. Static ports never age out.

How MLD snooping works

In this section, the involved ports are dynamic ports. For information about how to configure and remove static ports, see "[Configuring static ports.](#)"

A switch that runs MLD snooping performs different actions when it receives different MLD messages, as follows:

When receiving a general query

The MLD querier periodically sends MLD general queries to all hosts and routers (FF02::1) on the local subnet to determine whether any active IPv6 multicast group members exist on the subnet.

After receiving an MLD general query, the switch forwards it to all ports in the VLAN, except the port that received the query. The switch also performs the following judgment:

- If the port that received the query is a dynamic router port in the router port list of the switch, the switch restarts the aging timer for the port.
- If the port is not in the router port list, the switch adds it into the router port list as a dynamic router port and starts an aging timer for the port.

When receiving a membership report

A host sends an MLD report to the MLD querier in the following circumstances:

- If the host has been a member of an IPv6 multicast group, after receiving an MLD query, the host responds to the query with an MLD report.
- When the host wants to join an IPv6 multicast group, it sends an MLD report to the MLD querier, specifying the IPv6 multicast group to join.

After receiving an MLD report, the switch forwards it through all the router ports in the VLAN, resolves the address of the reported IPv6 multicast group, and performs the following judgment:

- If no forwarding entry matches the group address, the switch creates a forwarding entry for the group, adds the port that received the MLD report as a dynamic member port to the forwarding entry for the group, and starts an aging timer for the port.
- If a forwarding entry matches the group address, but the port that received the MLD report is not in the forwarding entry for the group, the switch adds the port as a dynamic member port to the forwarding entry, and starts an aging timer for the port.
- If a forwarding entry matches the group address and the port that received the MLD report is in the forwarding entry for the group, the switch restarts the aging timer for the port.

A switch does not forward an MLD report through a non-router port. The reason is that if the switch forwards a report message through a member port, all the attached hosts that monitor the reported IPv6

multicast address suppress their own reports after receiving this report according to the MLD report suppression mechanism. This prevents the switch from confirming whether the reported multicast group still has active members attached to that port.

For more information about the MLD report suppression mechanism of hosts, see "[Configuring MLD \(available only on the HP 5500 EI\)](#)."

When receiving a done message

When a host leaves an IPv6 multicast group, the host sends an MLD done message to the multicast routers. When the switch receives the MLD done message on a dynamic member port, the switch first checks whether a forwarding entry matches the IPv6 multicast group address in the message, and, if a match is found, whether the forwarding entry contains the dynamic member port.

- If no forwarding entry matches the IPv6 multicast group address, or if the forwarding entry does not contain the port, the switch directly discards the MLD done message.
- If a forwarding entry matches the IPv6 multicast group address and contains the port, the switch forwards the done message to all router ports in the native VLAN. Because the switch does not know whether any other hosts attached to the port are still listening to that IPv6 multicast group address, the switch does not immediately remove the port from the forwarding entry for that group. Instead, it restarts the aging timer for the port.

After receiving the MLD done message, the MLD querier resolves the IPv6 multicast group address in the message and sends an MLD multicast-address-specific query to that IPv6 multicast group through the port that received the MLD done message. After receiving the MLD multicast-address-specific query, the switch forwards it through all its router ports in the VLAN and all member ports of the IPv6 multicast group. The switch also performs the following judgment for the port that received the MLD done message:

- If the port (assuming that it is a dynamic member port) receives an MLD report in response to the MLD multicast-address-specific query before its aging timer expires, it indicates that some host attached to the port is receiving or expecting to receive IPv6 multicast data for that IPv6 multicast group. The switch restarts the aging timer for the port.
- If the port receives no MLD report in response to the MLD multicast-address-specific query before its aging timer expires, it indicates that no hosts attached to the port are still monitoring that IPv6 multicast group address. The switch removes the port from the forwarding entry for the IPv6 multicast group when the aging timer expires.

MLD snooping proxying

You can configure the MLD snooping proxying function on an edge device to reduce the number of MLD reports and done messages sent to its upstream device. The device configured with MLD snooping proxying is called an MLD snooping proxy. It is a host from the perspective of its upstream device.

NOTE:

Even though an MLD snooping proxy is a host from the perspective of its upstream device, the MLD membership report suppression mechanism for hosts does not take effect on it. For more information about the MLD report suppression mechanism for hosts, see "[Configuring MLD \(available only on the HP 5500 EI\)](#)."

Figure 67 Network diagram

As shown in [Figure 67](#), Switch A works as an MLD snooping proxy. As a host from the perspective of the querier Router A, Switch A represents its attached hosts to send their membership reports and done messages to Router A.

[Table 8](#) describes how an MLD snooping proxy processes MLD messages.

Table 8 MLD message processing on an MLD snooping proxy

MLD message	Actions
General query	When receiving an MLD general query, the proxy forwards it to all ports but the receiving port. In addition, the proxy generates a report according to the group memberships that it maintains and sends the report out of all router ports.
Multicast-address-specific query	In response to the MLD group-specific query for a certain IPv6 multicast group, the proxy sends the report to the group out of all router ports if the forwarding entry for the group still contains a member port.
Report	<p>When receiving a report for an IPv6 multicast group, the proxy looks up the multicast forwarding table for the entry for the multicast group.</p> <ul style="list-style-type: none"> • If a forwarding entry matches the IPv6 multicast group, and contains the receiving port as a dynamic member port, the proxy restarts the aging timer for the port. • If a forwarding entry matches the IPv6 multicast group but does not contain the receiving port, the proxy adds the port to the forwarding entry as a dynamic member port and starts an aging timer for the port. • If no forwarding entry matches the IPv6 multicast group, the proxy creates a forwarding entry for the group, adds the receiving port to the forwarding entry as a dynamic member port, and starts an aging timer for the port. <p>Then, the switch sends the report to the group out of all router ports.</p>
Done	In response to a done message for an IPv6 multicast group, the proxy sends a multicast-address-specific query for the group out of the receiving port. After making sure that no member port is contained in the forwarding entry for the IPv6 multicast group, the proxy sends a done message for the group out of all router ports.

Protocols and standards

RFC 4541, *Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches*

MLD snooping configuration task list

Task	Remarks	
Configuring basic MLD snooping functions	Enabling MLD snooping	Required
	Specifying the version of MLD snooping	Optional
	Configuring IPv6 static multicast MAC address entries	Optional
Configuring MLD snooping port functions	Configuring aging timers for dynamic ports	Optional
	Configuring static ports	Optional
	Configuring a port as a simulated member host	Optional
	Enabling fast-leave processing	Optional
	Disabling a port from becoming a dynamic router port	Optional
Configuring MLD snooping querier	Enabling MLD snooping querier	Optional
	Configuring parameters for MLD queries and responses	Optional
	Configuring the source IPv6 addresses for MLD queries	Optional
Configuring MLD snooping proxying	Enabling MLD snooping proxying	Optional
	Configuring the source IPv6 addresses for the MLD messages sent by the proxy	Optional
Configuring an MLD snooping policy	Configuring an IPv6 multicast group filter	Optional
	Configuring IPv6 multicast source port filtering	Optional
	Enabling dropping unknown IPv6 multicast data	Optional
	Configuring MLD report suppression	Optional
	Setting the maximum number of multicast groups that a port can join	Optional
	Enabling IPv6 multicast group replacement	Optional
	Setting the 802.1p precedence for MLD messages	Optional
	Configuring an IPv6 multicast user control policy	Optional
	Enabling the MLD snooping host tracking function	Optional
Setting the DSCP value for MLD messages	Optional	

For the configuration tasks in this section:

- In MLD-snooping view, configurations that you make are effective in all VLANs . In VLAN view, configurations that you make are effective only on the ports that belong to the current VLAN. For a given VLAN, a configuration that you make in MLD-snooping view is effective only if you do not make the same configuration in VLAN view.

- In MLD-snooping view, configurations that you make are effective on all ports. In Layer 2 Ethernet interface view or Layer 2 aggregate interface view, configurations that you make are effective only on the current port. In port group view, configurations that you make are effective on all ports in only the current port group. For a given port, a configuration that you make in MLD-snooping view is effective only if you do not make the same configuration in Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.
- For MLD snooping, configurations that you make on a Layer 2 aggregate interface do not interfere with those made on its member ports, nor do they participate in aggregation calculations. Configurations that you make on a member port of the aggregate group will not take effect until the port leaves the aggregate group.

Configuring basic MLD snooping functions

Configuration prerequisites

Before you configure basic MLD snooping functions, complete the following tasks:

- Enable IPv6 forwarding.
- Configure the corresponding VLANs.
- Determine the version of MLD snooping.

Enabling MLD snooping

Configuration guidelines

- You must enable MLD snooping globally before you enable it for a VLAN.
- After you enable MLD snooping for a VLAN, you cannot enable MLD or IPv6 PIM on the corresponding VLAN interface, and vice versa.
- MLD snooping for a VLAN works only on the ports in this VLAN.

Configuration procedure

To enable MLD snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable MLD snooping globally and enter MLD-snooping view.	mld-snooping	Disabled by default
3. Return to system view.	quit	N/A
4. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
5. Enable MLD snooping for the VLAN.	mld-snooping enable	Disabled by default

Specifying the version of MLD snooping

Configuration guidelines

Different versions of MLD snooping can process different versions of MLD messages:

- MLDv1 snooping can process MLDv1 messages, but flood MLDv2 messages in the VLAN instead of processing them.
- MLDv2 snooping can process MLDv1 and MLDv2 messages.

If you change MLDv2 snooping to MLDv1 snooping, the system clears all MLD snooping forwarding entries that are dynamically created, and also does the following:

- Keeps static MLDv2 snooping forwarding entries (*, G).
- Clears static MLDv2 snooping forwarding entries (S, G), which will be restored when MLDv1 snooping is changed back to MLDv2 snooping.

For more information about static joining, see "[Configuring static ports.](#)"

Configuration procedure

To specify the version of MLD snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Specify the version of MLD snooping.	mld-snooping version <i>version-number</i>	Version 1 by default

Configuring IPv6 static multicast MAC address entries

In Layer-2 multicast, a Layer-2 IPv6 multicast protocol (such as, MLD snooping) can dynamically add IPv6 multicast MAC address entries. Or, you can manually configure IPv6 multicast MAC address entries.

Configuration guidelines

The configuration that you make in system view is effective on the specified interfaces. The configuration that you make in interface view or port group view is effective only on the current interface or interfaces in the current port group.

Any legal IPv6 multicast MAC address except 3333-xxxx-xxxx (where x represents a hexadecimal number from 0 to F) can be manually added to the MAC address table. IPv6 multicast MAC addresses are the MAC addresses whose the least significant bit of the most significant octet is 1.

Configuration procedure

To configure an IPv6 static multicast MAC address entry in system view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a static multicast MAC address entry.	mac-address multicast <i>mac-address interface interface-list</i> vlan <i>vlan-id</i>	No static multicast MAC address entries exist by default.

To configure an IPv6 static multicast MAC address entry in interface view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	In Ethernet interface view or Layer 2 aggregate interface view, the configuration is effective on only the current interface. In port group view, the configuration is effective on all ports in the port group.
3. Configure a static multicast MAC address entry.	mac-address multicast <i>mac-address</i> vlan <i>vlan-id</i>	No static multicast MAC address entries exist by default.

For more information about the **mac-address multicast** command, see *IP Multicast Command Reference*.

Configuring MLD snooping port functions

Configuration prerequisites

Before you configure MLD snooping port functions, complete the following tasks:

- Enable MLD snooping in the VLAN.
- Configure the corresponding port groups.
- Determine the aging time of dynamic router ports.
- Determine the aging time of dynamic member ports.
- Determine the IPv6 multicast group and IPv6 multicast source addresses.

Configuring aging timers for dynamic ports

If a switch receives no MLD general queries or IPv6 PIM hello messages on a dynamic router port when the aging timer of the port expires, the switch removes the port from the router port list.

If the switch receives no MLD reports for an IPv6 multicast group on a dynamic member port when the aging timer of the port expires, the switch removes the port from the forwarding entry for the IPv6 multicast group.

If the memberships of IPv6 multicast groups change frequently, you can set a relatively small value for the aging timer of the dynamic member ports. If the memberships of IPv6 multicast groups change rarely, you can set a relatively large value.

Setting the global aging timers for dynamic ports

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD-snooping view.	mld-snooping	N/A
3. Set the global aging timer for dynamic router ports.	router-aging-time <i>interval</i>	260 seconds by default

Step	Command	Remarks
4.	Set the global aging timer for dynamic member ports. host-aging-time <i>interval</i>	260 seconds by default

Setting the aging timers for the dynamic ports in a VLAN

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter VLAN view. vlan <i>vlan-id</i>	N/A
3.	Set the aging timer for the dynamic router ports. mld-snooping router-aging-time <i>interval</i>	260 seconds by default
4.	Set the aging timer for the dynamic member ports. mld-snooping host-aging-time <i>interval</i>	260 seconds by default

Configuring static ports

Configuration guidelines

If all hosts attached to a port are interested in the IPv6 multicast data addressed to a particular IPv6 multicast group, configure the port as a static member port for that IPv6 multicast group.

You can configure a port as a static router port, through which the switch can forward all IPv6 multicast data that it received.

A static member port does not respond to queries from the MLD querier; when you configure a port as a static member port or cancel this configuration on the port, the port does not send an unsolicited MLD report or an MLD done message.

Static member ports and static router ports never age out. To remove such a port, you use the corresponding **undo** command.

Configuration procedure

To configure static ports:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view. <ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3.	Configure the port as a static member port. mld-snooping static-group <i>ipv6-group-address</i> [source-ip <i>ipv6-source-address</i>] vlan <i>vlan-id</i>	No static member ports exist by default.

Step	Command	Remarks
4. Configure the port as a static router port.	mld-snooping static-router-port vlan <i>vlan-id</i>	No static router ports exist by default.

Configuring a port as a simulated member host

Generally, a host that runs MLD can respond to MLD queries. If a host fails to respond, the multicast router might deem that the IPv6 multicast group has no members on the subnet, and removes the corresponding forwarding path.

To avoid this situation, you can configure a port on the switch as a simulated member host for an IPv6 multicast group. A simulated host is equivalent to an independent host. For example, when a simulated member host receives an MLD query, it gives a response separately. Therefore, the switch can continue receiving IPv6 multicast data.

A simulated host acts like a real host in the following ways:

- When a port is configured as a simulated member host, the switch sends an unsolicited MLD report through the port, and can respond to MLD general queries with MLD reports through the port.
- When the simulated joining configuration is canceled on the port, the switch sends an MLD done message through that port.

To configure a port as a simulated member host:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, port group view.	<ul style="list-style-type: none"> • Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Configure the port as a simulated member host.	mld-snooping host-join <i>ipv6-group-address</i> [source-ip <i>ipv6-source-address</i>] vlan <i>vlan-id</i>	Not configured by default.

NOTE:

Unlike a static member port, a port that you configure as a simulated member host ages out like a dynamic member port.

Enabling fast-leave processing

The fast-leave processing feature enables the switch to process MLD done messages quickly. After the fast-leave processing feature is enabled, when the switch receives an MLD done message on a port, it immediately removes that port from the forwarding entry for the multicast group specified in the message. Then, when the switch receives MLD multicast-address-specific queries for that multicast group, it does not forward them to that port.

On a port that has only one host attached, you can enable fast-leave processing to save bandwidth and resources. However, on a port that has multiple hosts attached, you should not enable fast-leave processing if you have enabled dropping unknown IPv6 multicast data globally or for the port. Otherwise, if a host on the port leaves an IPv6 multicast group, the other hosts attached to the port in the same IPv6 multicast group cannot receive the IPv6 multicast data for the group.

Enabling fast-leave processing globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD-snooping view.	mld-snooping	N/A
3. Enable fast-leave processing.	fast-leave [vlan <i>vlan-list</i>]	Disabled by default

Enabling fast-leave processing on a port

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable fast-leave processing.	mld-snooping fast-leave [vlan <i>vlan-list</i>]	Disabled by default.

Disabling a port from becoming a dynamic router port

The following problems exist in a multicast access network:

- After receiving an MLD general query or IPv6 PIM hello message from a connected host, a router port becomes a dynamic router port. Before its timer expires, this dynamic router port receives all multicast packets within the VLAN where the port belongs, and forwards them to the host, affecting normal multicast reception of the host.
- In addition, the MLD general query and IPv6 PIM hello message that the host sends affects the multicast routing protocol state on Layer 3 devices, such as the MLD querier or DR election, and might further cause network interruption.

To solve these problems, disable that router port from becoming a dynamic router port after the port receives an MLD general query or IPv6 PIM hello message, so as to improve network security and control over multicast users.

To disable a port from becoming a dynamic router port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Disable the port from becoming a dynamic router port.	mld-snooping router-port-deny [vlan <i>vlan-list</i>]	By default, a port can become a dynamic router port.

NOTE:

This configuration does not affect the static router port configuration.

Configuring MLD snooping querier

Configuration prerequisites

Before you configure MLD snooping querier, complete the following tasks:

- Enable MLD snooping in the VLAN.
- Determine the MLD general query interval.
- Determine the MLD last-member query interval.
- Determine the maximum response time for MLD general queries.
- Determine the source IPv6 address of MLD general queries.
- Determine the source IPv6 address of MLD multicast-address-specific queries.

Enabling MLD snooping querier

In an IPv6 multicast network that runs MLD, a multicast router or Layer 3 multicast switch sends MLD queries, so that all Layer 3 multicast devices can establish and maintain multicast forwarding entries, in order to forward multicast traffic correctly at the network layer. This router or Layer 3 switch is called the "MLD querier." For more information about MLD querier, see "[Configuring MLD \(available only on the HP 5500 E1\)](#)."

However, a Layer 2 multicast switch does not support MLD. Therefore, it cannot send MLD general queries by default. When you enable MLD snooping querier on a Layer 2 switch in a VLAN where multicast traffic is switched only at Layer 2 and no Layer 3 multicast devices are present, the Layer 2 switch sends MLD queries, so that multicast forwarding entries can be created and maintained at the data link layer.

! **IMPORTANT:**

It is meaningless to configure an MLD snooping querier in an IPv6 multicast network that runs MLD. Although an MLD snooping querier does not participate in MLD querier elections, it might affect MLD querier elections because it sends MLD general queries with a low source IPv6 address.

To enable the MLD snooping querier:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Enable the MLD snooping querier.	mld-snooping querier	Disabled by default

Configuring parameters for MLD queries and responses

Configuration guidelines

You can modify the MLD general query interval based on the actual condition of the network.

A multicast listening host starts a timer for each IPv6 multicast group that it has joined when it receives an MLD query (general query or multicast-address-specific query). This timer is initialized to a random value in the range of 0 to the maximum response delay advertised in the MLD query message. When the timer value decreases to 0, the host sends an MLD report to the IPv6 multicast group.

To speed up the response of hosts to MLD queries and avoid simultaneous timer expirations causing MLD report traffic bursts, you must properly set the maximum response delay.

- The maximum response delay for MLD general queries is set by the **max-response-time** command.
- The maximum response delay for MLD multicast-address-specific queries equals the MLD last-listener query interval.

In the configuration, make sure that the interval for sending MLD general queries is greater than the maximum response delay for MLD general queries. Otherwise, undesired deletion of IPv6 multicast members might occur.

Configuration procedure

To configure MLD queries and responses globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD-snooping view.	mld-snooping	N/A
3. Set the maximum response delay for MLD general queries.	max-response-time <i>interval</i>	10 seconds by default
4. Set the MLD last-member query interval.	last-listener-query-interval <i>interval</i>	1 second by default

To configure the parameters for MLD queries and responses in a VLAN

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Set the MLD query interval.	mld-snooping query-interval <i>interval</i>	125 seconds by default

Step	Command	Remarks
4. Set the maximum response delay for MLD general queries.	mld-snooping max-response-time <i>interval</i>	10 seconds by default
5. Set the MLD last-member query interval.	mld-snooping last-listener-query-interval <i>interval</i>	1 second by default

Configuring the source IPv6 addresses for MLD queries

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Configure the source IPv6 address of MLD general queries.	mld-snooping general-query source-ip { <i>ipv6-address</i> current-interface }	FE80::02FF:FFFF:FE00:0001 by default
4. Configure the source IPv6 address of MLD multicast-address-specific queries.	mld-snooping special-query source-ip { <i>ipv6-address</i> current-interface }	FE80::02FF:FFFF:FE00:0001 by default

IMPORTANT:

The source IPv6 address of MLD query messages might affect MLD querier election within the subnet.

Configuring MLD snooping proxying

Configuration prerequisites

Before you configure MLD snooping proxying in a VLAN, complete the following tasks:

- Enable MLD snooping in the VLAN.
- Determine the source IPv6 address for the MLD reports sent by the proxy.
- Determine the source IPv6 address for the MLD done messages sent by the proxy.

Enabling MLD snooping proxying

The MLD snooping proxying function works on a per-VLAN basis. After you enable the function in a VLAN, the device works as the MLD snooping proxy for the downstream hosts and upstream router in the VLAN.

To enable MLD snooping proxying in a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A

Step	Command	Remarks
3.	Enable MLD snooping proxying in the VLAN. mld-snooping proxying enable	Disabled by default

Configuring the source IPv6 addresses for the MLD messages sent by the proxy

You can set the source IPv6 addresses for the MLD reports and done messages that the MLD snooping proxy sends on behalf of its attached hosts.

To configure the source IPv6 addresses for the MLD messages that the MLD snooping proxy sends in a VLAN:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter VLAN view. vlan <i>vlan-id</i>	N/A
3.	Configure a source IPv6 address for the MLD reports that the proxy sends. mld-snooping report source-ip { <i>ipv6-address</i> current-interface }	The default is FE80::02FF:FFFF:FE00:0001.
4.	Configure a source IPv6 address for the MLD done messages that the proxy sends. mld-snooping done source-ip { <i>ipv6-address</i> current-interface }	The default is FE80::02FF:FFFF:FE00:0001.

Configuring an MLD snooping policy

Configuration prerequisites

Before you configure an MLD snooping policy, complete the following tasks:

- Enable MLD snooping in the VLAN.
- Determine the IPv6 ACL rule for IPv6 multicast group filtering.
- Determine the maximum number of IPv6 multicast groups that a port can join.
- Determine the 802.1p precedence for MLD messages.

Configuring an IPv6 multicast group filter

On an MLD snooping-enabled switch, you can configure an IPv6 multicast group filter to limit multicast programs available to users.

Configuration guidelines

In an application, when a user requests a multicast program, the user's host initiates an MLD report. After receiving this report message, the switch resolves the IPv6 multicast group address in the report and looks up the ACL. If a match is found to permit the port that received the report to join the IPv6 multicast group, the switch creates an MLD snooping forwarding entry for the IPv6 multicast group and adds the port to

the forwarding entry. Otherwise, the switch drops this report message, in which case, the IPv6 multicast data for the IPv6 multicast group is not sent to this port, and the user cannot retrieve the program.

When you configure a multicast group filter in an IPv6 multicast VLAN, be sure to configure the filter in the sub-VLANs of the IPv6 multicast VLAN. Otherwise, the configuration does not take effect.

In MLDv2, when a host is enabled to join multiple multicast groups, the multicast group filter cannot correctly filter multicast groups because the host that runs MLDv2 sends multiple multicast groups that it wants to join in one membership report.

Configuration procedure

To configure an IPv6 multicast group globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD-snooping view.	mld-snooping	N/A
3. Configure an IPv6 multicast group filter.	group-policy <i>acl6-number</i> [vlan <i>vlan-list</i>]	By default, no IPv6 group filter is globally configured. That is, the hosts in a VLAN can join any valid multicast group.

To configure an IPv6 multicast group filter for a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Configure an IPv6 multicast group filter.	mld-snooping group-policy <i>acl6-number</i> [vlan <i>vlan-list</i>]	By default, no IPv6 group filter is configured on an interface. That is, the hosts on the interface can join any valid multicast group.

Configuring IPv6 multicast source port filtering

When the IPv6 multicast source port filtering feature is enabled on a port, the port can connect only to IPv6 multicast receivers rather than multicast sources. The reason is that the port blocks all IPv6 multicast data packets but it permits multicast protocol packets to pass.

If this feature is disabled on a port, the port can connect to both multicast sources and IPv6 multicast receivers.

Configuring IPv6 multicast source port filtering globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD-snooping view.	mld-snooping	N/A
3. Enable IPv6 multicast source port filtering.	source-deny port <i>interface-list</i>	Disabled by default

Configuring IPv6 multicast source port filtering for a port

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable IPv6 multicast source port filtering.	mld-snooping source-deny	Disabled by default.

NOTE:

Some models of devices, when enabled to filter IPv6 multicast data based on the source ports, are automatically enabled to filter IPv4 multicast data based on the source ports.

Enabling dropping unknown IPv6 multicast data

Configuration guidelines

Unknown IPv6 multicast data refers to IPv6 multicast data for which no entries exist in the MLD snooping forwarding table. When the switch receives such IPv6 multicast traffic, one of the following occurs:

- When the function of dropping unknown IPv6 multicast data is disabled, the switch floods unknown IPv6 multicast data in the VLAN to which the unknown IPv6 multicast data belongs.
- When the function of dropping unknown IPv6 multicast data is enabled, the switch forwards unknown multicast data to its router ports instead of flooding it in the VLAN. If no router ports exist, the switch drops the unknown multicast data.

Configuration procedure

To enable dropping unknown IPv6 multicast data in a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Enable dropping unknown IPv6 multicast data.	mld-snooping drop-unknown	Disabled by default

Configuring MLD report suppression

Configuration guidelines

When a Layer 2 switch receives an MLD report from an IPv6 multicast group member, the Layer 2 switch forwards the message to the Layer 3 device that directly connects to the Layer 2 switch. When multiple members of an IPv6 multicast group are attached to the Layer 2 switch, the Layer 3 device might receive duplicate MLD reports for the IPv6 multicast group from these members.

With the MLD report suppression function enabled, within a query interval, the Layer 2 switch forwards only the first MLD report for the IPv6 multicast group to the Layer 3 device. It does not forward subsequent MLD reports for the same IPv6 multicast group to the Layer 3 device. This helps reduce the number of packets being transmitted over the network.

On an MLD snooping proxy, MLD reports for an IPv6 multicast group from downstream hosts are suppressed if the forwarding entry for the multicast group exists on the proxy, whether the suppression function is enabled or not.

Configuration procedure

To configure MLD report suppression:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD-snooping view.	mld-snooping	N/A
3. Enable MLD report suppression.	report-aggregation	Enabled by default

Setting the maximum number of multicast groups that a port can join

You can set the maximum number of IPv6 multicast groups that a port can join to regulate the traffic on the port.

When you configure this maximum number, if the number of IPv6 multicast groups the port has joined exceeds the configured maximum value, the system deletes all the forwarding entries for the port from the MLD snooping forwarding table, and the hosts on this port join IPv6 multicast groups again until the number of IPv6 multicast groups that the port joins reaches the maximum value. When the port joins an IPv6 multicast group, if the port has been configured as a static member port, the system applies the configurations to the port again. If you have configured simulated joining on the port, the system establishes corresponding forwarding entry for the port after receiving a report from the simulated member host.

To configure the maximum number of IPv6 multicast groups that a port can join:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Set the maximum number of IPv6 multicast groups that a port can join.	mld-snooping group-limit <i>limit</i> [vlan <i>vlan-list</i>]	1000 by default.

Enabling IPv6 multicast group replacement

For various reasons, the number of IPv6 multicast groups that a switch or a port can join might exceed the upper limit. In addition, in some specific applications, an IPv6 multicast group that the switch newly joins must replace an existing IPv6 multicast group automatically. A typical example is channel switching. To view a new TV channel, a user switches from the current IPv6 multicast group to the new one.

To realize such requirements, you can enable the IPv6 multicast group replacement function on the switch or on a certain port. When the number of IPv6 multicast groups that the switch or the port has joined reaches the limit, one of the following occurs:

- If the IPv6 multicast group replacement feature is disabled, new MLD reports are automatically discarded.
- If the IPv6 multicast group replacement feature is enabled, the IPv6 multicast group that the switch or the port newly joins automatically replaces an existing IPv6 multicast group that has the lowest IPv6 address.

⚠ IMPORTANT:

Be sure to configure the maximum number of IPv6 multicast groups allowed on a port (see "[Setting the maximum number of multicast groups that a port can join](#)") before enabling IPv6 multicast group replacement. Otherwise, the IPv6 multicast group replacement functionality will not take effect.

Enabling IPv6 multicast group replacement globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD-snooping view.	mld-snooping	N/A
3. Enable IPv6 multicast group replacement.	overflow-replace [vlan <i>vlan-list</i>]	Disabled by default

Enabling IPv6 multicast group replacement for a port

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or port group view.	<ul style="list-style-type: none"> Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view: interface <i>interface-type interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Enable IPv6 multicast group replacement.	mld-snooping overflow-replace [vlan <i>vlan-list</i>]	Disabled by default.

Setting the 802.1p precedence for MLD messages

You can change the 802.1p precedence of MLD messages so that they can be assigned higher forwarding priority when congestion occurs on their outgoing ports.

Setting the 802.1p precedence for MLD messages globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD-snooping view.	mld-snooping	N/A
3. Set the 802.1p precedence for MLD messages.	dot1p-priority <i>priority-number</i>	The default 802.1p precedence for MLD messages is 0.

Setting the 802.1p precedence for MLD messages in a VLAN

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
3. Set the 802.1p precedence for MLD messages.	mld-snooping dot1p-priority <i>priority-number</i>	The default 802.1p precedence for MLD messages is 0.

Configuring an IPv6 multicast user control policy

IPv6 multicast user control policies are configured on access switches to allow only authorized users to receive requested IPv6 multicast data. This helps restrict users from ordering certain multicast-on-demand programs.

Configuration guidelines

In practice, a device first needs to perform authentication (for example, 802.1X authentication) for the connected hosts through a RADIUS server. Then, the device uses the configured multicast user control policy to perform multicast access control for authenticated users as follows.

- After receiving an MLD report from a host, the access switch matches the IPv6 multicast group address and multicast source address carried in the report with the configured policies. If a match

is found, the user is allowed to join the multicast group. Otherwise, the join report is dropped by the access switch.

- After receiving a done message from a host, the access switch matches the IPv6 multicast group address and source address against the policies. If a match is found, the host is allowed to leave the group. Otherwise, the done message is dropped by the access switch.

An IPv6 multicast user control policy is functionally similar to an IPv6 multicast group filter. A difference lies in that a control policy can control both multicast joining and leaving of users based on authentication and authorization, but a multicast group filter is configured on a port to control only multicast joining but not leaving of users without authentication or authorization.

Configuration procedure

To configure a multicast user control policy

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a user profile and enter its view.	user-profile <i>profile-name</i>	N/A
3. Configure a multicast user control policy.	mld-snooping access-policy <i>acl6-number</i>	No policy is configured by default. That is, a host can join or leave a valid multicast group at any time.
4. Return to system view.	quit	N/A
5. Enable the created user profile.	user-profile <i>profile-name</i> enable	Not enabled by default.

For more information about the **user-profile** and **user-profile enable** commands, see *Security Command Reference*.

Enabling the MLD snooping host tracking function

With the MLD snooping host tracking function, the switch can record the information of the member hosts that are receiving IPv6 multicast traffic, including the host IPv6 address, running duration, and timeout time. You can monitor and manage the member hosts according to the recorded information.

Enabling the MLD snooping host tracking function globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD-snooping view.	mld-snooping	N/A
3. Enable the MLD snooping host tracking function globally.	host-tracking	Disabled by default

Enabling the MLD snooping host tracking function in a VLAN

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter VLAN view.	vlan <i>vlan-id</i>	N/A

Step	Command	Remarks
3.	Enable the MLD snooping host tracking function in the VLAN. mld-snooping host-tracking	Disabled by default

Setting the DSCP value for MLD messages

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter MLD-snooping view. mld-snooping	N/A
3.	Set the DSCP value for MLD messages. dscp dscp-value	By default, the DSCP value in MLD messages is 48.

NOTE:

This configuration applies to only the MLD messages that the local switch generates rather than those forwarded ones.

Displaying and maintaining MLD snooping

Task	Command	Remarks
Display MLD snooping group information.	display mld-snooping group [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the hosts tracked by MLD snooping.	display mld-snooping host vlan <i>vlan-id</i> group <i>ipv6-group-address</i> [source <i>ipv6-source-address</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 static multicast MAC address entries.	display mac-address [<i>mac-address</i> [vlan <i>vlan-id</i>] [multicast] [vlan <i>vlan-id</i>] [count]] [{ begin exclude include } <i>regular-expression</i>]	Available in user view
Display statistics for the MLD messages learned through MLD snooping.	display mld-snooping statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Remove dynamic group entries of a specified MLD snooping group or all MLD snooping groups.	reset mld-snooping group { <i>ipv6-group-address</i> all } [vlan <i>vlan-id</i>]	Available in user view
Clear statistics for the MLD messages learned through MLD snooping.	reset mld-snooping statistics	Available in user view

NOTE:

- The **reset mld-snooping group** command works only on an MLD snooping-enabled VLAN, but not in a VLAN with MLD enabled on its VLAN interface.
 - The **reset mld-snooping group** command cannot remove the static group entries of MLD snooping groups.
-

For more information about the **display mac-address multicast** command, see *IP Multicast Command Reference*.

MLD snooping configuration examples

IPv6 group policy and simulated joining configuration example

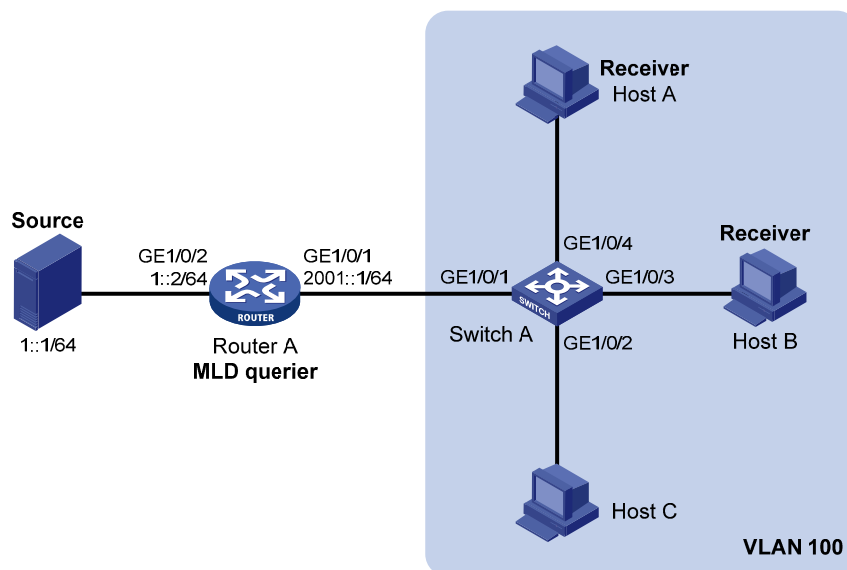

Network requirements

As shown in [Figure 68](#), MLDv1 runs on Router A, MLDv1 snooping required on Switch A, and Router A acts as the MLD querier on the subnet.

The receivers, Host A and Host B can receive IPv6 multicast traffic addressed to IPv6 multicast group FF1E::101 only.

IPv6 multicast data for group FF1E::101 can be forwarded through GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 of Switch A even if Host A and Host B accidentally, temporarily stop receiving IPv6 multicast data, and that Switch A drops unknown IPv6 multicast data and does not broadcast the data to the VLAN where Switch A resides.

Figure 68 Network diagram

Configuration procedure

1. Enable IPv6 forwarding and configure IPv6 addresses:
Enable IPv6 forwarding and configure an IPv6 address and prefix length for each interface as per [Figure 68](#). (Details not shown.)
2. Configure Router A:

Enable IPv6 multicast routing, enable IPv6 PIM-DM on each interface, and enable MLDv1 on GigabitEthernet 1/0/1.

```
<RouterA> system-view
[RouterA] multicast ipv6 routing-enable
[RouterA] interface gigabitethernet 1/0/1
[RouterA-GigabitEthernet1/0/1] mld enable
[RouterA-GigabitEthernet1/0/1] pim ipv6 dm
[RouterA-GigabitEthernet1/0/1] quit
[RouterA] interface gigabitethernet 1/0/2
[RouterA-GigabitEthernet1/0/2] pim ipv6 dm
[RouterA-GigabitEthernet1/0/2] quit
```

3. Configure Switch A:

Enable MLD snooping globally.

```
<SwitchA> system-view
[SwitchA] mld-snooping
[SwitchA-mld-snooping] quit
```

Create VLAN 100, assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to this VLAN, and enable MLD snooping and the function of dropping IPv6 unknown multicast traffic in the VLAN.

```
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[SwitchA-vlan100] mld-snooping enable
[SwitchA-vlan100] mld-snooping drop-unknown
[SwitchA-vlan100] quit
```

Configure an IPv6 multicast group filter so that the hosts in VLAN 100 can join only the IPv6 multicast group FF1E::101.

```
[SwitchA] acl ipv6 number 2001
[SwitchA-acl6-basic-2001] rule permit source ff1e::101 128
[SwitchA-acl6-basic-2001] quit
[SwitchA] mld-snooping
[SwitchA-mld-snooping] group-policy 2001 vlan 100
[SwitchA-mld-snooping] quit
```

Configure GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 as simulated hosts for IPv6 multicast group FF1E::101.

```
[SwitchA] interface gigabitethernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] mld-snooping host-join ff1e::101 vlan 100
[SwitchA-GigabitEthernet1/0/3] quit
[SwitchA] interface gigabitethernet 1/0/4
[SwitchA-GigabitEthernet1/0/4] mld-snooping host-join ff1e::101 vlan 100
[SwitchA-GigabitEthernet1/0/4] quit
```

4. Verify the configuration:

Display detailed MLD snooping group information in VLAN 100 on Switch A.

```
[SwitchA] display mld-snooping group vlan 100 verbose
  Total 1 IP Group(s).
  Total 1 IP Source(s).
  Total 1 MAC Group(s).
```

```

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
Subvlan flags: R-Real VLAN, C-Copy VLAN
Vlan(id):100.
  Total 1 IP Group(s).
  Total 1 IP Source(s).
  Total 1 MAC Group(s).
  Router port(s):total 1 port(s).
    GE1/0/1                (D) ( 00:01:30 )
IP group(s):the following ip group(s) match to one mac group.
  IP group address:FF1E::101
  (::, FF1E::101):
  Attribute:      Host Port
  Host port(s):total 2 port(s).
    GE1/0/3                (D) ( 00:03:23 )
    GE1/0/4                (D) ( 00:04:10 )
MAC group(s):
  MAC group address:3333-0000-0101
  Host port(s):total 2 port(s).
    GE1/0/3
    GE1/0/4

```

The output shows that GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 of Switch A have joined IPv6 multicast group FF1E::101.

Static port configuration example

Network requirements

As shown in [Figure 69](#), MLDv1 runs on Router A, and MLDv1 snooping runs on Switch A, Switch B and Switch C. Router A acts as the MLD querier.

Host A and Host C are permanent receivers of IPv6 multicast group FF1E::101. GigabitEthernet 1/0/3 and GigabitEthernet 1/0/5 on Switch C are required to be configured as static member ports for multicast group FF1E::101 to enhance the reliability of multicast traffic transmission.

Suppose STP runs on the network. To avoid data loops, the forwarding path from Switch A to Switch C is blocked under normal conditions, and IPv6 multicast traffic flows to the receivers attached to Switch C only along the path of Switch A—Switch B—Switch C.

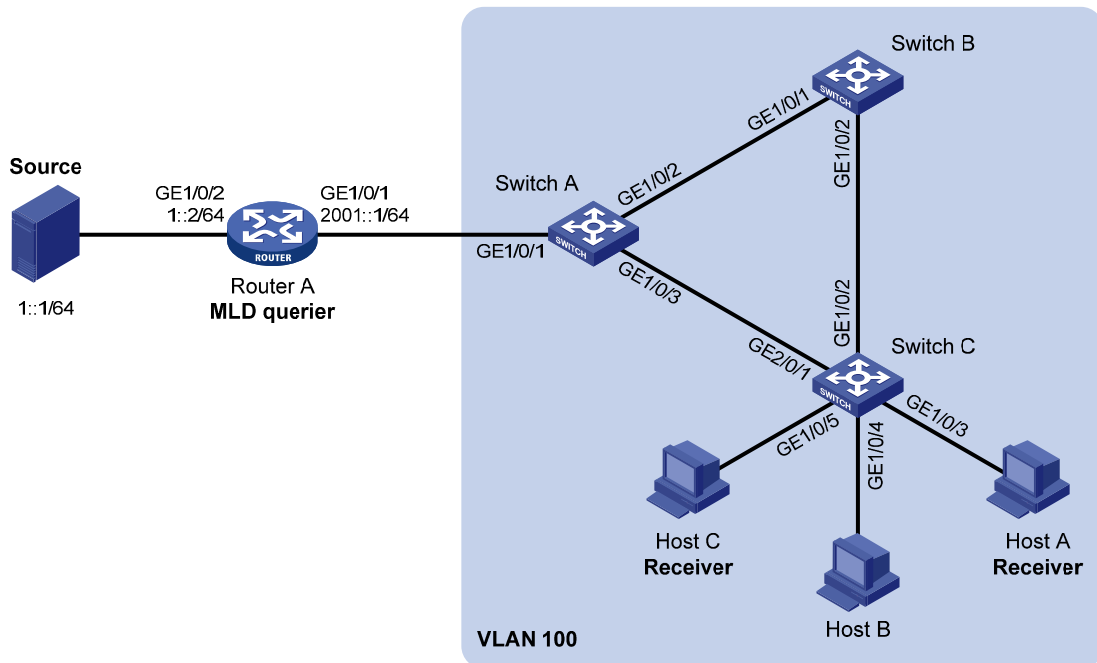

Configure GigabitEthernet 1/0/3 on Switch C as a static router port, so that IPv6 multicast traffic can flow to the receivers nearly uninterruptedly along the path of Switch A—Switch C in the case that the path of Switch A—Switch B—Switch C becomes blocked.

NOTE:

If no static router port is configured, when the path of Switch A—Switch B—Switch C becomes blocked, at least one MLD query-response cycle must be completed before the IPv6 multicast data can flow to the receivers along the new path of Switch A—Switch C. Namely, IPv6 multicast delivery will be interrupted during this process.

For more information about the Spanning Tree Protocol (STP), see *Layer 2—LAN Switching Configuration Guide*.

Figure 69 Network diagram

Configuration procedure

1. Enable IPv6 forwarding and configure IPv6 addresses:
Enable IPv6 forwarding and configure an IPv6 address and prefix length for each interface as per Figure 69.
2. Configure Router A:
Enable IPv6 multicast routing, enable IPv6 PIM-DM on each interface, and enable MLD on GigabitEthernet 1/0/1.

```

<RouterA> system-view
[RouterA] multicast ipv6 routing-enable
[RouterA] interface gigabitethernet 1/0/1
[RouterA-GigabitEthernet1/0/1] mld enable
[RouterA-GigabitEthernet1/0/1] pim ipv6 dm
[RouterA-GigabitEthernet1/0/1] quit
[RouterA] interface gigabitethernet 1/0/2
[RouterA-GigabitEthernet1/0/2] pim ipv6 dm
[RouterA-GigabitEthernet1/0/2] quit

```
3. Configure Switch A:
Enable MLD snooping globally.

```

<SwitchA> system-view
[SwitchA] mld-snooping
[SwitchA-mld-snooping] quit

```

Create VLAN 100, assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to this VLAN, and enable MLD snooping in the VLAN.

```

[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/3
[SwitchA-vlan100] mld-snooping enable

```

```
[SwitchA-vlan100] quit
# Configure GigabitEthernet 1/0/3 to be a static router port.
[SwitchA] interface gigabitEthernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] mld-snooping static-router-port vlan 100
[SwitchA-GigabitEthernet1/0/3] quit
```

4. Configure Switch B:

Enable MLD snooping globally.

```
<SwitchB> system-view
[SwitchB] mld-snooping
[SwitchB-mld-snooping] quit
```

Create VLAN 100, assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to this VLAN, and enable MLD snooping in the VLAN.

```
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitEthernet 1/0/1 gigabitEthernet 1/0/2
[SwitchB-vlan100] mld-snooping enable
[SwitchB-vlan100] quit
```

5. Configure Switch C:

Enable MLD snooping globally.

```
<SwitchC> system-view
[SwitchC] mld-snooping
[SwitchC-mld-snooping] quit
```

Create VLAN 100, assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 to this VLAN, and enable MLD snooping in the VLAN.

```
[SwitchC] vlan 100
[SwitchC-vlan100] port gigabitEthernet 1/0/1 to gigabitEthernet 1/0/5
[SwitchC-vlan100] mld-snooping enable
[SwitchC-vlan100] quit
```

Configure GigabitEthernet 1/0/3 and GigabitEthernet 1/0/5 as static member ports for IPv6 multicast group FF1E::101.

```
[SwitchC] interface GigabitEthernet 1/0/3
[SwitchC-GigabitEthernet1/0/3] mld-snooping static-group ff1e::101 vlan 100
[SwitchC-GigabitEthernet1/0/3] quit
[SwitchC] interface GigabitEthernet 1/0/5
[SwitchC-GigabitEthernet1/0/5] mld-snooping static-group ff1e::101 vlan 100
[SwitchC-GigabitEthernet1/0/5] quit
```

6. Verify the configuration:

Display detailed MLD snooping group information in VLAN 100 on Switch A.

```
[SwitchA] display mld-snooping group vlan 100 verbose
  Total 1 IP Group(s).
  Total 1 IP Source(s).
  Total 1 MAC Group(s).
```

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port

Subvlan flags: R-Real VLAN, C-Copy VLAN

Vlan(id):100.

```
  Total 1 IP Group(s).
```

```

Total 1 IP Source(s).
Total 1 MAC Group(s).
Router port(s):total 2 port(s).
    GE1/0/1          (D) ( 00:01:30 )
    GE1/0/3          (S)
IP group(s):the following ip group(s) match to one mac group.
IP group address:FF1E::101
  (::, FF1E::101):
  Attribute:      Host Port
  Host port(s):total 1 port(s).
    GE1/0/2          (D) ( 00:03:23 )
MAC group(s):
MAC group address:3333-0000-0101
Host port(s):total 1 port(s).
  GE1/0/2

```

The output shows that GigabitEthernet 1/0/3 of Switch A has become a static router port.

Display detailed MLD snooping group information in VLAN 100 on Switch C.

```
[SwitchC] display mld-snooping group vlan 100 verbose
```

```

Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
Subvlan flags: R-Real VLAN, C-Copy VLAN
Vlan(id):100.
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
Router port(s):total 1 port(s).
    GE1/0/2          (D) ( 00:01:23 )
IP group(s):the following ip group(s) match to one mac group.
IP group address:FF1E::101
  (::, FF1E::101):
  Attribute:      Host Port
  Host port(s):total 2 port(s).
    GE1/0/3          (S)
    GE1/0/5          (S)
MAC group(s):
MAC group address:3333-0000-0101
Host port(s):total 2 port(s).
  GE1/0/3
  GE1/0/5

```

The output shows that GigabitEthernet 1/0/3 and GigabitEthernet 1/0/5 on Switch C have become static member ports for IPv6 multicast group FF1E::101.

MLD snooping querier configuration example

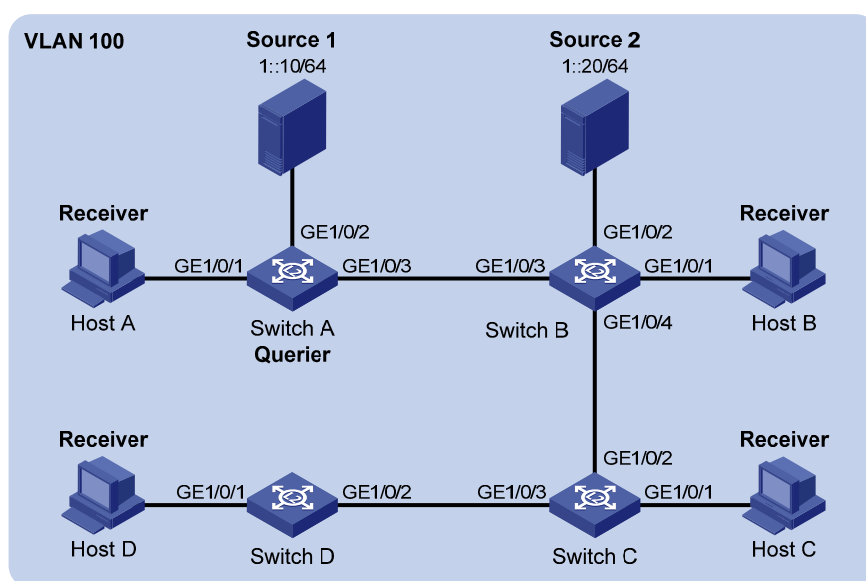

Network requirements

As shown in Figure 70, in a Layer-2-only network environment, two multicast sources (Source 1 and Source 2) send IPv6 multicast data to multicast groups FF1E::101 and FF1E::102 respectively, Host A and Host C are receivers of multicast group FF1E::101 and Host B and Host D are receivers of multicast group FF1E::102.

MLDv1 runs on all the receivers and MLDv1 snooping runs on all the switches. Switch A, which is close to the multicast sources, is chosen as the MLD snooping querier.

To prevent flooding of unknown multicast traffic within the VLAN, configure all the switches to drop unknown multicast data packets.

Figure 70 Network diagram

Configuration procedure

1. Configure Switch A:

Enable IPv6 forwarding and enable MLD snooping globally.

```
<SwitchA> system-view
[SwitchA] ipv6
[SwitchA] mld-snooping
[SwitchA-mld-snooping] quit
```

Create VLAN 100 and assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to VLAN 100.

```
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/3
```

Enable MLD snooping and the function of dropping unknown IPv6 multicast data packets in VLAN 100.

```
[SwitchA-vlan100] mld-snooping enable
[SwitchA-vlan100] mld-snooping drop-unknown
```

Configure MLD snooping querier feature in VLAN 100.

```
[SwitchA-vlan100] mld-snooping querier
```

```
[SwitchA-vlan100] quit
```

2. Configure Switch B:

Enable IPv6 forwarding and enable MLD snooping globally.

```
<SwitchB> system-view
```

```
[SwitchB] ipv6
```

```
[SwitchB] mld-snooping
```

```
[SwitchB-mld-snooping] quit
```

Create VLAN 100, add GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 into VLAN 100.

```
[SwitchB] vlan 100
```

```
[SwitchB-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/4
```

Enable the MLD snooping feature and the function of dropping unknown IPv6 multicast data packets in VLAN 100.

```
[SwitchB-vlan100] mld-snooping enable
```

```
[SwitchB-vlan100] mld-snooping drop-unknown
```

```
[SwitchB-vlan100] quit
```

Configurations of Switch C and Switch D are similar to the configuration of Switch B.

3. Verify the configuration:

When the MLD snooping querier starts to work, all the switches but the querier receive MLD general queries. Use the **display mld-snooping statistics** command to view the statistics information of these MLD messages received.

Display the MLD message statistics on Switch B.

```
[SwitchB-vlan100] display mld-snooping statistics
```

```
Received MLD general queries:3.
```

```
Received MLDv1 specific queries:0.
```

```
Received MLDv1 reports:12.
```

```
Received MLD dones:0.
```

```
Sent MLDv1 specific queries:0.
```

```
Received MLDv2 reports:0.
```

```
Received MLDv2 reports with right and wrong records:0.
```

```
Received MLDv2 specific queries:0.
```

```
Received MLDv2 specific sg queries:0.
```

```
Sent MLDv2 specific queries:0.
```

```
Sent MLDv2 specific sg queries:0.
```

```
Received error MLD messages:0.
```

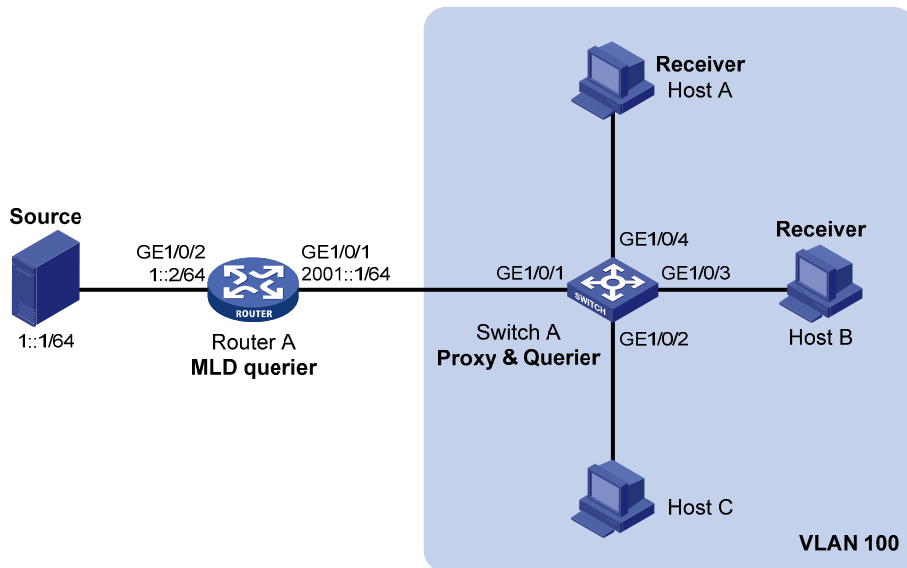

MLD snooping proxying configuration example

Network requirements

As shown in [Figure 71](#), MLDv1 runs on Router A and MLDv1 snooping runs on Switch A. Router A acts as the MLD querier.

Configure MLD snooping proxying on Switch A. This enables the switch to forward MLD reports and done messages on behalf of the attached hosts and to respond to MLD queries from Router A and then forward the queries to the hosts on behalf of Router A.

Figure 71 Network diagram

Configuration procedure

1. Configure IPv6 addresses for interfaces:
Configure an IP address and prefix length for each interface as per [Figure 71](#). (Details not shown.)
2. Configure Router A:
Enable IPv6 multicast routing, enable IPv6 PIM-DM on each interface, and enable MLD on port GigabitEthernet 1/0/1.

```
<RouterA> system-view  
[RouterA] multicast ipv6 routing-enable  
[RouterA] interface gigabitethernet 1/0/1  
[RouterA-GigabitEthernet1/0/1] mld enable  
[RouterA-GigabitEthernet1/0/1] pim ipv6 dm  
[RouterA-GigabitEthernet1/0/1] quit  
[RouterA] interface gigabitethernet 1/0/2  
[RouterA-GigabitEthernet1/0/2] pim ipv6 dm  
[RouterA-GigabitEthernet1/0/2] quit
```
3. Configure Switch A:
Enable MLD snooping globally.

```
<SwitchA> system-view  
[SwitchA] mld-snooping  
[SwitchA-mld-snooping] quit
```

Create VLAN 100, assign ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to this VLAN, and enable MLD snooping and MLD snooping proxying in the VLAN.

```
[SwitchA] vlan 100  
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/4  
[SwitchA-vlan100] mld-snooping enable  
[SwitchA-vlan100] mld-snooping proxying enable  
[SwitchA-vlan100] quit
```
4. Verify the configuration:

After the configuration is completed, Host A and Host B send MLD join messages addressed to group FF1E::101. When receiving the messages, Switch A sends a join message for the group out of port GigabitEthernet 1/0/1 (a router port) to Router A. Use the **display mld-snooping group** command and the **display mld group** command to display information about MLD snooping groups and MLD multicast groups. For example:

Display information about MLD snooping groups on Switch A.

```
[SwitchA] display mld-snooping group
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
Subvlan flags: R-Real VLAN, C-Copy VLAN
Vlan(id):100.
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
Router port(s):total 1 port(s).
    GE1/0/1                (D)
IP group(s):the following ip group(s) match to one mac group.
IP group address:FF1E::101
(::, FF1E::101):
    Host port(s):total 2 port(s).
        GE1/0/3            (D)
        GE1/0/4            (D)
MAC group(s):
    MAC group address:3333-0000-0101
    Host port(s):total 2 port(s).
        GE1/0/3
        GE1/0/4
```

Display information about MLD multicast groups on Router A.

```
[RouterA] display mld group
Total 1 MLD Group(s).
Interface group report information
GigabitEthernet1/0/1(2001::1):
Total 1 MLD Group reported
Group Address: FF1E::1
Last Reporter: FE80::2FF:FFFF:FE00:1
Uptime: 00:00:03
Expires: 00:04:17
```

When Host A leaves the IPv6 multicast group, it sends an MLD done message to Switch A. Receiving the message, Switch A removes port GigabitEthernet 1/0/4 from the member port list of the forwarding entry for the group; however, it does not remove the group or forward the done message to Router A because Host B is still in the group. Use the **display mld-snooping group** command to display information about MLD snooping groups. For example:

Display information about MLD snooping groups on Switch A.

```
[SwitchA] display mld-snooping group
Total 1 IP Group(s).
```

```

Total 1 IP Source(s).
Total 1 MAC Group(s).
Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
Subvlan flags: R-Real VLAN, C-Copy VLAN
Vlan(id):100.
    Total 1 IP Group(s).
    Total 1 IP Source(s).
    Total 1 MAC Group(s).
Router port(s):total 1 port(s).
    GE1/0/1                (D)
IP group(s):the following ip group(s) match to one mac group.
    IP group address:FF1E::101
    (:, FF1E::101):
        Host port(s):total 1 port(s).
        GE1/0/3            (D)
MAC group(s):
    MAC group address:3333-0000-0101
    Host port(s):total 1 port(s).
    GE1/0/3

```

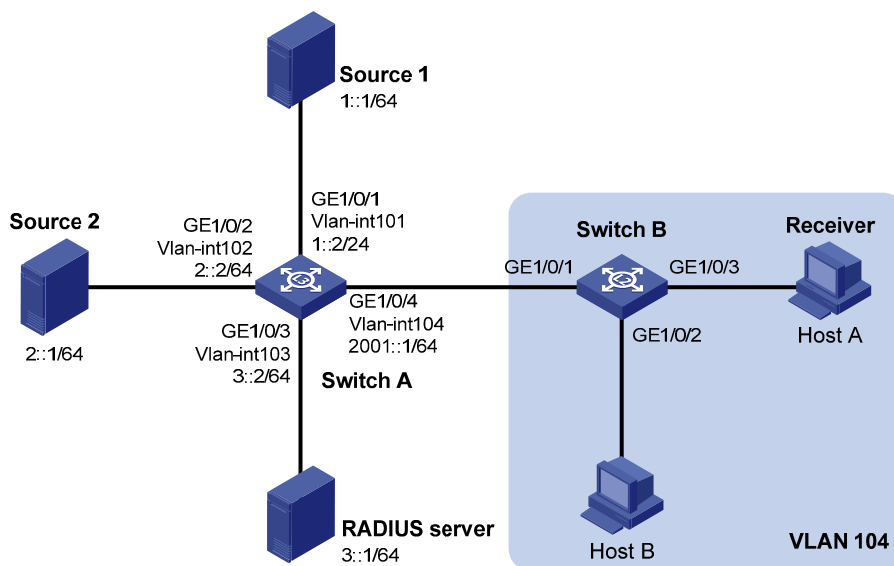

IPv6 multicast source and user control policy configuration example

Network requirements

As shown in [Figure 72](#), Switch A is a Layer-3 switch. MLDv1 runs on Switch A and MLDv1 snooping runs on Switch B. Multicast sources and hosts run 802.1X client.

An IPv6 multicast source control policy is configured on Switch A to block multicast flows from Source 2 to FF1E::101. An IPv6 multicast user control policy is configured on Switch B so that Host A can join or leave only multicast group FF1E::101.

Figure 72 Network diagram

Configuration procedures

1. Configure IP addresses for interfaces:

Enable IPv6 forwarding and configure an IP address and prefix length for each interface as per [Figure 72](#). (Details not shown.)

2. Configure Switch A:

Create VLAN 101 through VLAN 104 and assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to the four VLANs respectively.

```
<SwitchA> system-view
[SwitchA] vlan 101
[SwitchA-vlan101] port gigabitethernet 1/0/1
[SwitchA-vlan101] quit
[SwitchA] vlan 102
[SwitchA-vlan102] port gigabitethernet 1/0/2
[SwitchA-vlan102] quit
[SwitchA] vlan 103
[SwitchA-vlan103] port gigabitethernet 1/0/3
[SwitchA-vlan103] quit
[SwitchA] vlan 104

[SwitchB-user-profile-profile2] mld-snooping access-policy 2001
[SwitchB-user-profile-profile2] quit
[SwitchB] user-profile profile2 enable
```

Create a RADIUS scheme **scheme2**; set the service type for the RADIUS server to **extended**; specify the IP addresses of the primary authentication/authorization server and accounting server as 3::1; set the shared keys to 321123; specify that a username sent to the RADIUS server carry no domain name.

```
[SwitchB] radius scheme scheme2
[SwitchB-radius-scheme2] server-type extended
[SwitchB-radius-scheme2] primary authentication 3::1
[SwitchB-radius-scheme2] key authentication 321123
[SwitchB-radius-scheme2] primary accounting 3::1
[SwitchB-radius-scheme2] key accounting 321123
[SwitchB-radius-scheme2] user-name-format without-domain
[SwitchB-radius-scheme2] quit
```

Create an ISP domain **domain2**; reference **scheme2** for the authentication, authorization, and accounting for LAN users; specify **domain2** as the default ISP domain.

```
[SwitchB] domain domain2
[SwitchB-isp-domian2] authentication lan-access radius-scheme scheme2
[SwitchB-isp-domian2] authorization lan-access radius-scheme scheme2
[SwitchB-isp-domian2] accounting lan-access radius-scheme scheme2
[SwitchB-isp-domian2] quit
[SwitchB] domain default enable domain2
```

Globally enable 802.1X and then enable it on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

```
[SwitchB] dot1x
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] dot1x
[SwitchB-GigabitEthernet1/0/2] quit
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] dot1x
[SwitchB-GigabitEthernet1/0/3] quit
```

4. Configure RADIUS server:

On the RADIUS server, configure the parameters related to Switch A and Switch B. For more information, see the configuration guide of the RADIUS server.

5. Verify the configuration:

After the configurations, the two multicast sources and hosts initiate 802.1X authentication. After passing the authentication, Source 1 sends multicast flows to FF1E::101 and Source 2 sends multicast flows to FF1E::102; Host A sends report messages to join IPv6 multicast groups FF1E::101 and FF1E::102. Use the **display mld-snooping group** command to display information about MLD snooping groups. For example:

Display information about MLD snooping groups in VLAN 104 on Switch B.

```
[SwitchB] display mld-snooping group vlan 104 verbose
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).

Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
Subvlan flags: R-Real VLAN, C-Copy VLAN
Vlan(id):104.
Total 1 IP Group(s).
Total 1 IP Source(s).
Total 1 MAC Group(s).
Router port(s):total 1 port(s).
    GE1/0/1                (D) ( 00:01:30 )
IP group(s):the following ip group(s) match to one mac group.
  IP group address:FF1E::101
    (::, FF1E::101):
      Attribute:    Host Port
      Host port(s):total 1 port(s).
        GE1/0/3                (D) ( 00:04:10 )
MAC group(s):
  MAC group address:3333-0000-0101
  Host port(s):total 1 port(s).
    GE1/0/3
```

The output shows that GigabitEthernet 1/0/3 on Switch B has joined FF1E::101 but not FF1E::102.

Assume that Source 2 starts sending multicast traffic to FF1E::101. Use the **display multicast ipv6 forwarding-table** to display the IPv6 multicast forwarding table information.

Display the information about FF1E::101 in the IPv6 multicast forwarding table on Switch A.

```
[SwitchA] display multicast ipv6 forwarding-table ff1e::101
IPv6 Multicast Forwarding Table

Total 1 entry

Total 1 entry matched
00001. (1::1, FF1E::101)
  MID: 0, Flags: 0x0:0
  Uptime: 00:08:32, Timeout in: 00:03:26
  Incoming interface: Vlan-interface101
  List of 1 outgoing interfaces:
    1: Vlan-interface104
  Matched 19648 packets(20512512 bytes), Wrong If 0 packets
  Forwarded 19648 packets(20512512 bytes)
```

The output shows that Switch A maintains a multicast forwarding entry for multicast packets from Source 1 to FF1E::101. No forwarding entry exists for packets from Source 2 to FF1E::101, which indicates that IPv6 multicast packets from Source 2 are blocked.

Troubleshooting MLD snooping

Layer 2 multicast forwarding cannot function

Symptom

Layer 2 multicast forwarding cannot function.

Analysis

MLD snooping is not enabled.

Solution

1. Use the **display current-configuration** command to display the running status of MLD snooping.
2. If MLD snooping is not enabled, use the **mld-snooping** command to enable MLD snooping globally, and then use **mld-snooping enable** command to enable MLD snooping in VLAN view.
3. If MLD snooping is disabled only for the corresponding VLAN, use the **mld-snooping enable** command in VLAN view to enable MLD snooping in the corresponding VLAN.

Configured IPv6 multicast group policy fails to take effect

Symptom

Although an IPv6 multicast group policy has been configured to allow hosts to join specific IPv6 multicast groups, the hosts can still receive IPv6 multicast data addressed to other groups.

Analysis

- The IPv6 ACL rule is incorrectly configured.
- The IPv6 multicast group policy is not correctly applied.
- The function of dropping unknown IPv6 multicast data is not enabled, so unknown IPv6 multicast data is flooded.

Solution

1. Use the **display acl ipv6** command to check the configured IPv6 ACL rule. Make sure that the IPv6 ACL rule conforms to the IPv6 multicast group policy to be implemented.
2. Use the **display this** command in MLD-snooping view or the corresponding interface view to verify that the correct IPv6 multicast group policy has been applied. If not, use the **group-policy** or **mld-snooping group-policy** command to apply the correct IPv6 multicast group policy.
3. Use the **display current-configuration** command to verify that the function of dropping unknown IPv6 multicast data is enabled. If not, use the **drop-unknown** or **mld-snooping drop-unknown** command to enable the function of dropping unknown IPv6 multicast data.

Appendix

Processing of IPv6 multicast protocol messages

With Layer 3 multicast routing enabled, an MLD snooping-enabled switch processes IPv6 multicast protocol messages differently under different conditions, as follows:

1. If only MLD is enabled on the switch, or if both MLD and IPv6 PIM are enabled on the switch, the switch does the following:
 - Maintains dynamic member ports or dynamic router ports according to MLD packets
 - Maintains dynamic router ports according to IPv6 PIM hello packets
2. If only IPv6 PIM is enabled on the switch, the following occurs:
 - The switch broadcasts MLD messages as unknown messages in the VLAN.
 - After receiving an IPv6 PIM hello message, the switch maintains the corresponding dynamic router port.
3. If MLD is disabled on the switch, one of the following occurs:
 - If IPv6 PIM is disabled, the switch deletes all its dynamic member ports and dynamic router ports.
 - If IPv6 PIM is enabled, the switch deletes only its dynamic member ports but not its dynamic router ports.

NOTE:

On a switch with Layer-3 IPv6 multicast routing enabled, use the **display mld group port-info** command to display Layer-2 port information. For more information about the **display mld group port-info** command, see *IP Multicast Command Reference*.

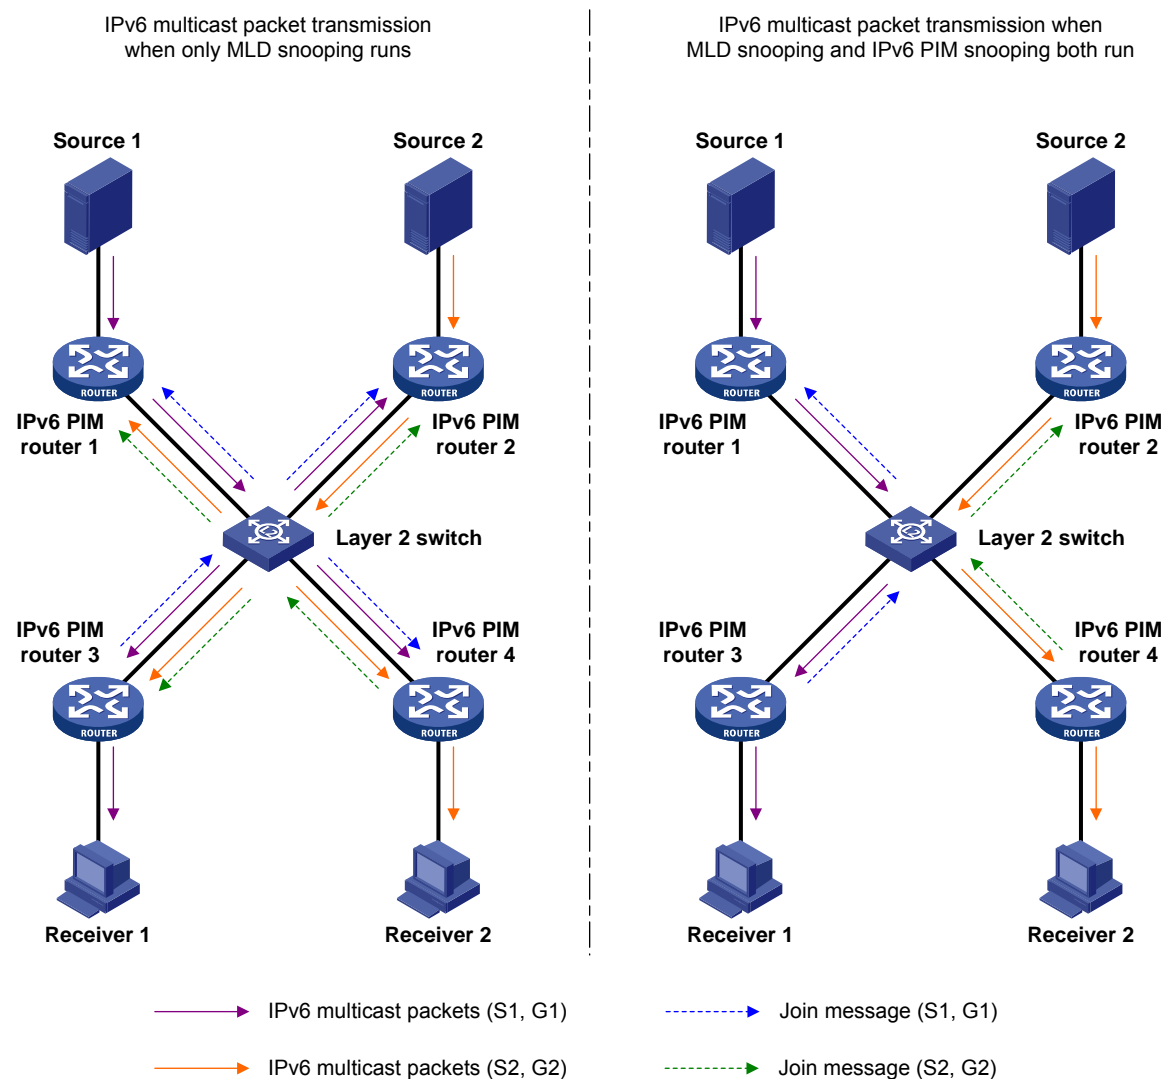

4. If IPv6 PIM is disabled on the switch, one of the following occurs:
 - If MLD is disabled, the switch deletes all its dynamic router ports.
 - If MLD is enabled, the switch maintains all its dynamic member ports and dynamic router ports.

Configuring IPv6 PIM snooping

Overview

IPv6 Protocol Independent Multicast (PIM) snooping runs on Layer 2 devices. It determines which ports are interested in multicast data by analyzing the received IPv6 PIM messages, and adds the ports to a multicast forwarding entry to make sure that multicast data can be forwarded to only the ports that are interested in the data.

Figure 73 Multicast packet transmission without or with IPv6 PIM snooping

As shown in Figure 73, Source 1 sends multicast data to multicast group G1, and Source 2 sends multicast data to multicast group G2. Receiver 1 belongs to G1, and Receiver 2 belongs to G2. The Layer 2 switch's interfaces that connect to the IPv6 PIM-capable routers are in the same VLAN.

- When running MLD snooping without IPv6 PIM snooping, the Layer 2 switch maintains the router ports according to IPv6 PIM hello messages received from IPv6 PIM-capable routers, broadcasts all

other types of received IPv6 PIM messages in the VLAN, and forwards all multicast data to all router ports in the VLAN. Each IPv6 PIM-capable router in the VLAN, whether interested in the multicast data or not, will receive all multicast data and all IPv6 PIM messages except for IPv6 PIM hello messages.

- If the Layer 2 switch runs both MLD snooping and IPv6 PIM snooping, it determines whether an IPv6 PIM-capable router is interested in the multicast data destined for a multicast group according to the received IPv6 PIM messages that the router sends, and adds the port that connects to the router to a multicast forwarding entry. Then, the Layer 2 switch can correctly forward IPv6 PIM messages and the multicast data only to the router according to the multicast forwarding entry, saving network bandwidth.

For more information about MLD snooping and the router port, see "[Configuring MLD snooping](#)."

For more information about IPv6 PIM, see "[Configuring IPv6 PIM \(available only on the HP 5500 EI\)](#)"

Configuring IPv6 PIM snooping

Configuration guidelines

Before you configure IPv6 PIM snooping for a VLAN, you must enable IPv6 forwarding and MLD snooping globally and enable MLD snooping in the VLAN.

IPv6 PIM snooping does not work in the sub-VLANs of a multicast VLAN. For more information about IPv6 multicast VLAN, see "[Configuring IPv6 multicast VLANs](#)."

In a network with IPv6 PIM snooping enabled switches, configure the size of each join/prune message no more than the path maximum transmission unit (MTU) on the IPv6 PIM-enabled edge router on the receiver side. For more information about the join/prune messages, see "[Configuring IPv6 PIM \(available only on the HP 5500 EI\)](#)."

After you enable IPv6 PIM snooping in a VLAN, IPv6 PIM snooping works only on the member interfaces of the VLAN.

Configuration procedure

To configure IPv6 PIM snooping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6 forwarding globally.	ipv6	Disabled by default
3. Enable MLD snooping globally and enter MLD-snooping view.	mld-snooping	Disabled by default
4. Return to system view.	quit	N/A
5. Enter VLAN view.	vlan <i>vlan-id</i>	N/A
6. Enable MLD snooping in the VLAN	mld-snooping enable	Disabled by default
7. Enable IPv6 PIM snooping in the VLAN	pim-snooping ipv6 enable	Disabled by default

For more information about the **mld-snooping** and **mld-snooping enable** commands, see *IP Multicast Command Reference*.

Displaying and maintaining IPv6 PIM snooping

Task	Command	Remarks
Display IPv6 PIM snooping neighbor information.	display pim-snooping ipv6 neighbor [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 PIM snooping routing entries.	display pim-snooping ipv6 routing-table [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the statistics information of IPv6 PIM messages learned by IPv6 PIM snooping..	display pim-snooping ipv6 statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear the statistics information of IPv6 PIM messages learned by IPv6 PIM snooping..	reset pim-snooping ipv6 statistics	Available in user view

IPv6 PIM snooping configuration example

Network requirements

As shown in Figure 74, Source 1 sends multicast data to IPv6 multicast group FF1E::101, and Source 2 sends multicast data to IPv6 multicast group FF2E::101. Receiver 1 belongs to multicast group FF1E::101, and Receiver 2 belongs to multicast group FF2E::101. Router C and Router D run MLD on their interface GigabitEthernet 1/0/1. Router A, Router B, Router C, and Router D run IPv6 PIM-SM, and interface GigabitEthernet 1/0/2 on Router A acts as a C-BSR and C-RP.

Configure MLD snooping and IPv6 PIM snooping on Switch A so that Switch A forwards IPv6 PIM messages and multicast data to only the routers that are interested in the multicast data.

Figure 74 Network diagram

Configuration procedure

1. Enable IPv6 forwarding, and assign IPv6 addresses:

Enable IPv6 forwarding on the devices, configure an IPv6 address and prefix length for each interface according to [Figure 74](#). (Details not shown.)

2. Configure Router A:

Enable IPv6 multicast routing, enable IPv6 PIM-SM on each interface, and configure interface GigabitEthernet 1/0/2 as a C-BSR and C-RP.

```
<RouterA> system-view
[RouterA] multicast ipv6 routing-enable
[RouterA] interface gigabitethernet 1/0/1
[RouterA-GigabitEthernet1/0/1] pim ipv6 sm
[RouterA-GigabitEthernet1/0/1] quit
[RouterA] interface gigabitethernet 1/0/2
[RouterA-GigabitEthernet1/0/2] pim ipv6 sm
[RouterA-GigabitEthernet1/0/2] quit
[RouterA] pim ipv6
[RouterA-pim6] c-bsr 1001::1
[RouterA-pim6] c-rp 1001::1
```

3. Configure Router B:

Enable IPv6 multicast routing, and enable IPv6 PIM-SM on each interface.

```
<RouterB> system-view
[RouterB] multicast ipv6 routing-enable
[RouterB] interface gigabitethernet 1/0/1
[RouterB-GigabitEthernet1/0/1] pim ipv6 sm
[RouterB-GigabitEthernet1/0/1] quit
[RouterB] interface gigabitethernet 1/0/2
[RouterB-GigabitEthernet1/0/2] pim ipv6 sm
```

4. Configure Router C:

Enable IPv6 multicast routing, enable IPv6 PIM-SM on each interface, and enable MLD on GigabitEthernet 1/0/1.

```
<RouterC> system-view
[RouterC] multicast ipv6 routing-enable
[RouterC] interface gigabitethernet 1/0/1
[RouterC-GigabitEthernet1/0/1] pim ipv6 sm
[RouterC-GigabitEthernet1/0/1] mld enable
[RouterC-GigabitEthernet1/0/1] quit
[RouterC] interface gigabitethernet 1/0/2
[RouterC-GigabitEthernet1/0/2] pim ipv6 sm
```

5. Configure Router D:

The configuration on Router D is similar to that on Router C. (Details not shown.)

6. Configure Switch A:

Enable MLD snooping globally.

```
<SwitchA> system-view
[SwitchA] mld-snooping
[SwitchA-mld-snooping] quit
```

Create VLAN 100, assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to this VLAN, and enable MLD snooping and IPv6 PIM snooping in the VLAN.

```
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[SwitchA-vlan100] mld-snooping enable
[SwitchA-vlan100] pim-snooping ipv6 enable
[SwitchA-vlan100] quit
```

7. Verify the configuration:

On Switch A, display the IPv6 PIM snooping neighbor information of VLAN 100.

```
[SwitchA] display pim-snooping ipv6 neighbor vlan 100
Total number of neighbors: 4
```

```
VLAN ID: 100
Total number of neighbors: 4
Neighbor      Port          Expires      Option Flags
FE80::1       GE1/0/1       02:02:23    LAN Prune Delay
FE80::2       GE1/0/2       03:00:05    LAN Prune Delay
FE80::3       GE1/0/3       02:22:13    LAN Prune Delay
FE80::4       GE1/0/4       03:07:22    LAN Prune Delay
```

The output shows that Router A, Router B, Router C, and Router D are IPv6 PIM snooping neighbors.

On Switch A, display the IPv6 PIM snooping routing information of VLAN 100.

```
[SwitchA] display pim-snooping ipv6 routing-table vlan 100 slot 1
Total 2 entry(ies)
FSM Flag: NI-no info, J-join, PP-prune pending
```

```
VLAN ID: 100
Total 2 entry(ies)
(*, FF1E::101)
  Upstream neighbor: FE80::1
  Upstream port: GE1/0/1
  Total number of downstream ports: 1
  1: GE1/0/3
  Expires: 00:03:01, FSM: J
(*, FF2E::101)
  Upstream neighbor: FE80::1
  Upstream port: GE1/0/2
  Total number of downstream ports: 1
  1: GE1/0/4
  Expires: 00:01:05, FSM: J
```

The output shows that Switch A will forward the multicast data intended for IPv6 multicast group FF1E::101 to only Router C, and forward the multicast data intended for IPv6 multicast group FF2E::101 to only Router D.

Troubleshooting IPv6 PIM snooping

IPv6 PIM snooping does not work

Symptom

IPv6 PIM snooping does not work.

Analysis

MLD snooping or IPv6 PIM snooping is not enabled on the switch.

Solution

1. Use the **display current-configuration** command to check the status of MLD snooping and IPv6 PIM snooping.
2. If MLD snooping is not enabled, enter system view and use the **mld-snooping** command to enable MLD snooping globally. Then, enter VLAN view and use the **mld-snooping enable** and **pim-snooping ipv6 enable** commands to enable MLD snooping and IPv6 PIM snooping in the VLAN.
3. If IPv6 PIM snooping is not enabled, enter VLAN view and use the **pim-snooping ipv6 enable** command to enable IPv6 PIM snooping in the VLAN.

Some downstream IPv6 PIM-capable routers cannot receive multicast data

Symptom

In a network with fragmented join/prune messages, some downstream IPv6 PIM-capable routers cannot receive multicast data.

Analysis

IPv6 PIM snooping cannot reassemble messages, and it cannot maintain the status of downstream routers that the join/prune message fragments carry. To ensure the normal operation of the system, IPv6 PIM snooping must broadcast join/prune message fragments in the VLAN. However, if the VLAN has an IPv6 PIM-capable router that has the join suppression function enabled, the broadcast join/prune message fragments might suppress the join messages of other IPv6 PIM-capable routers in the VLAN. As a result, some IPv6 PIM-capable routers cannot receive the multicast data addressed to a specific multicast group because their join messages are suppressed. To solve this problem, disable the join suppression function on all IPv6 PIM-capable routers that connect to the IPv6 PIM snooping-capable switch in the VLAN.

Solution

1. Use the **pim ipv6 hello-option neighbor-tracking** command to enable the neighbor tracking function on the interfaces of IPv6 PIM-capable routers that connect to the IPv6 PIM snooping-capable switch.
2. If the network has an IPv6 PIM-capable router that cannot be enabled with the neighbor tracking function, be sure to disable IPv6 PIM snooping on the IPv6 PIM snooping-capable switch.

Configuring IPv6 multicast VLANs

Overview

As shown in [Figure 75](#), in the traditional IPv6 multicast programs-on-demand mode, when hosts (Host A, Host B, and Host C), which belong to different VLANs, require IPv6 multicast programs on demand service, the Layer 3 device, Router A, must forward a separate copy of the multicast traffic in each user VLAN to the Layer 2 device, Switch A. This results in not only waste of network bandwidth but also extra burden on the Layer 3 device.

Figure 75 Multicast transmission without IPv6 multicast VLAN

The IPv6 multicast VLAN feature configured on the Layer 2 device is the solution to this issue. With the IPv6 multicast VLAN feature, the Layer 3 device needs to replicate the multicast traffic only in the IPv6 multicast VLAN instead of making a separate copy of the multicast traffic in each user VLAN. This saves the network bandwidth and lessens the burden of the Layer 3 device.

The IPv6 multicast VLAN feature can be implemented in sub-VLAN-based IPv6 multicast VLAN and port-based IPv6 multicast VLAN.

Sub-VLAN-based IPv6 multicast VLAN

As shown in [Figure 76](#), Host A, Host B and Host C are in different user VLANs. On Switch A, configure VLAN 10 as an IPv6 multicast VLAN, configure all the user VLANs as sub-VLANs of VLAN 10, and enable MLD snooping in the IPv6 multicast VLAN.

Figure 76 Sub-VLAN-based IPv6 multicast VLAN

After the configuration, MLD snooping manages router ports in the IPv6 multicast VLAN and member ports in the sub-VLANs. When forwarding multicast data to Switch A, Router A sends only one copy of multicast data to Switch A in the IPv6 multicast VLAN, and Switch A distributes the data to the sub-VLANs that contain receivers.

Port-based IPv6 multicast VLAN

As shown in Figure 77, Host A, Host B, and Host C are in different user VLANs. All the user ports are hybrid ports. On Switch A, configure VLAN 10 as an IPv6 multicast VLAN, assign all the user ports to VLAN 10, and enable MLD snooping in the IPv6 multicast VLAN and all user VLANs.

Figure 77 Port-based IPv6 multicast VLAN

After the configuration, if Switch A receives an MLD message on a user port, it tags the message with the IPv6 multicast VLAN ID and relays it to the MLD querier, so that MLD snooping can uniformly manage the router ports and member ports in the IPv6 multicast VLAN. When Router A forwards multicast data to Switch A, it sends only one copy of multicast data to Switch A in the IPv6 multicast VLAN, and Switch A distributes the data to all member ports in the IPv6 multicast VLAN.

For more information about MLD snooping, router ports, and member ports, see "[Configuring MLD snooping.](#)"

For more information about VLAN tags, see *Layer 2—LAN Switching Configuration Guide*.

IPv6 multicast VLAN configuration task list

Configuration task	Remarks
Configuring a sub-VLAN-based IPv6 multicast VLAN	Required
Configuring a port-based IPv6 multicast VLAN	Configuring user port attributes Configuring IPv6 multicast VLAN ports

NOTE:

If you have configured both sub-VLAN-based IPv6 multicast VLAN and port-based IPv6 multicast VLAN on a device, the port-based IPv6 multicast VLAN configuration is given preference.

Configuring a sub-VLAN-based IPv6 multicast VLAN

Configuration prerequisites

Before you configure a sub-VLAN-based IPv6 multicast VLAN, complete the following tasks:

- Create VLANs as required.
- Enable MLD snooping in the VLAN to be configured as an IPv6 multicast VLAN.

Configuration guidelines

- You cannot configure an IPv6 multicast VLAN on a device with IP multicast routing enabled.
- The VLAN to be configured as an IPv6 multicast VLAN must exist.
- The VLANs to be configured as the sub-VLANs of the IPv6 multicast VLAN must exist and must not be IPv6 multicast VLANs or sub-VLANs of any other IPv6 multicast VLAN.
- The total number of sub-VLANs of an IPv6 multicast VLAN must not exceed the maximum number the system can support.

Configuration procedure

In this approach, you configure a VLAN as an IPv6 multicast VLAN, and configure user VLANs as sub-VLANs of the IPv6 multicast VLAN.

To configure a sub-VLAN-based IPv6 multicast VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the specified VLAN as an IPv6 multicast VLAN and enter IPv6 multicast VLAN view.	multicast-vlan ipv6 <i>vlan-id</i>	No IPv6 multicast VLAN configured by default.

Step	Command	Remarks
3. Configure the specified VLANs as sub-VLANs of the IPv6 multicast VLAN.	subvlan <i>vlan-list</i>	By default, an IPv6 multicast VLAN has no sub-VLANs.

Configuring a port-based IPv6 multicast VLAN

When you configure a port-based IPv6 multicast VLAN, you need to configure the attributes of each user port and then assign the ports to the IPv6 multicast VLAN.

A user port can be configured as a multicast VLAN port only if it is an Ethernet port or Layer 2 aggregate interface.

In Ethernet interface view or Layer 2 aggregate interface view, configurations that you make are effective only on the current interface. In port group view, configurations that you make are effective on all ports in the current port group.

Configuration prerequisites

Before you configure a port-based IPv6 multicast VLAN, complete the following tasks:

- Create VLANs as required.
- Enable MLD snooping in the VLAN to be configured as an IPv6 multicast VLAN.
- Enable MLD snooping in all the user VLANs.

Configuring user port attributes

Configure the user ports as hybrid ports to permit packets of the specified user VLAN to pass and configure the user VLAN to which the user ports belong as the default VLAN.

Configure the user ports to permit packets of the IPv6 multicast VLAN to pass and untag the packets. After receiving multicast packets tagged with the IPv6 multicast VLAN ID from the upstream device, the Layer 2 device untags the multicast packets and forwards them to its downstream device.

To configure user port attributes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> • Enter interface view: interface <i>interface-type</i> <i>interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.
3. Configure the user port link type as hybrid.	port link-type hybrid	Access by default.
4. Specify the user VLAN that comprises the current user ports as the default VLAN.	port hybrid pvid vlan <i>vlan-id</i>	VLAN 1 by default.

Step	Command	Remarks
5. Configure the current user ports to permit packets of the specified IPv6 multicast VLAN to pass and untag the packets.	port hybrid vlan <i>vlan-id-list</i> { tagged untagged }	By default, a hybrid port permits only packets of VLAN 1 to pass.

For more information about the **port link-type**, **port hybrid pvid vlan**, and **port hybrid vlan** commands, see *Layer 2—LAN Switching Command Reference*.

Configuring IPv6 multicast VLAN ports

Configuration guidelines

In this approach, you configure a VLAN as an IPv6 multicast VLAN and assign user ports to it. You can do this by either adding the user ports in the IPv6 multicast VLAN or specifying the IPv6 multicast VLAN on the user ports. These two methods provide the same result.

You cannot configure an IPv6 multicast VLAN on a device with multicast routing enabled.

The VLAN to be configured as an IPv6 multicast VLAN must exist.

A port can belong to only one IPv6 multicast VLAN.

Configuration procedure

To configure IPv6 multicast VLAN ports in IPv6 multicast VLAN view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the specified VLAN as an IPv6 multicast VLAN and enter IPv6 multicast VLAN view.	multicast-vlan ipv6 <i>vlan-id</i>	No IPv6 multicast VLAN configured by default.
3. Configure the ports as member ports of the IPv6 multicast VLAN.	port <i>interface-list</i>	By default, an IPv6 multicast VLAN has no member ports.

To configure IPv6 multicast VLAN ports in interface view or port group view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the specified VLAN as an IPv6 multicast VLAN and enter IPv6 multicast VLAN view.	multicast-vlan ipv6 <i>vlan-id</i>	Not an IPv6 multicast VLAN by default.
3. Return to system view.	quit	N/A
4. Enter interface view or port group view.	<ul style="list-style-type: none"> • Enter interface view: interface <i>interface-type interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use either command.

Step	Command	Remarks
5. Configure the ports as member ports of the IPv6 multicast VLAN.	port multicast-vlan ipv6 <i>vlan-id</i>	By default, a user port does not belong to any IPv6 multicast VLAN.

Displaying and maintaining IPv6 multicast VLAN

Task	Command	Remarks
Display information about an IPv6 multicast VLAN.	display multicast-vlan ipv6 [<i>vlan-id</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

IPv6 multicast VLAN configuration examples

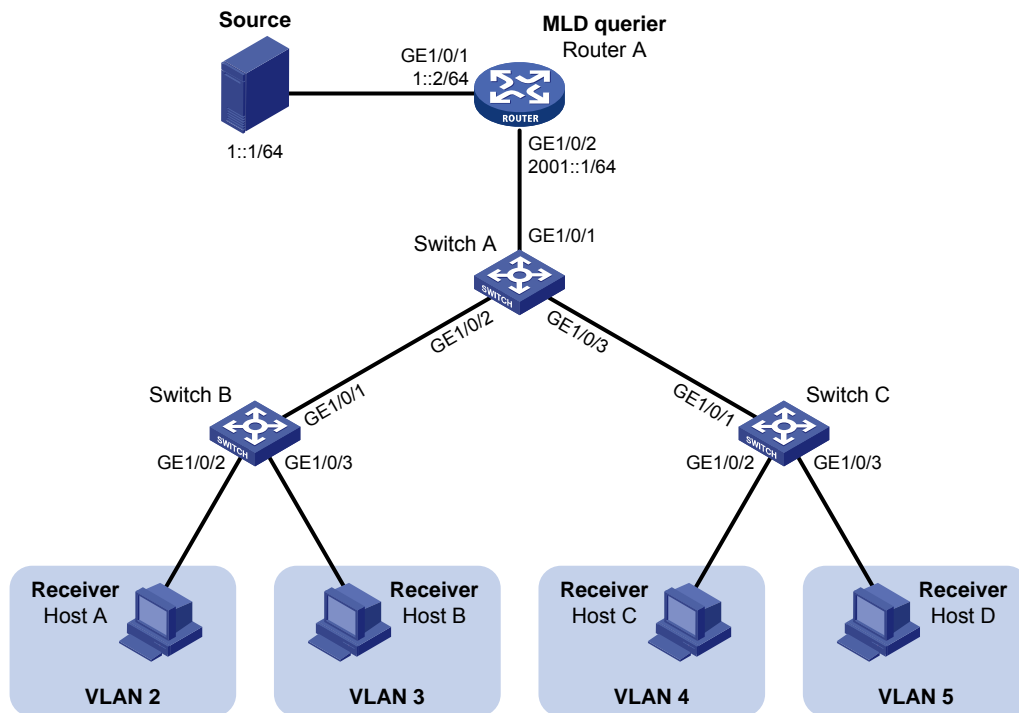

Sub-VLAN-based multicast VLAN configuration example

Network requirements

As shown in [Figure 78](#), MLDv1 runs on Router A, and MLDv1 snooping runs on Switch A. Router A acts as the MLD querier. The IPv6 multicast source sends IPv6 multicast data to the IPv6 multicast group FF1E::101. Host A, Host B, Host C, and Host D are receivers of the IPv6 multicast group. The hosts belong to VLAN 2 through VLAN 5 respectively.

Configure the sub-VLAN-based IPv6 multicast VLAN feature on Switch A so that Router A just sends IPv6 multicast data to Switch A through the IPv6 multicast VLAN and Switch A forwards the traffic to the receivers that belong to different user VLANs.

Figure 78 Network diagram

Configuration procedure

1. Enable IPv6 forwarding and configure IPv6 addresses:
Enable IPv6 forwarding on each device and configure an IPv6 address and address prefix for each interface as per Figure 78. (Details not shown.)
2. Configure Router A:
Enable IPv6 multicast routing, enable IPv6 PIM-DM on each interface and enable MLD on the host-side interface GigabitEthernet 1/0/2.

```
<RouterA> system-view  
[RouterA] multicast ipv6 routing-enable  
[RouterA] interface gigabitethernet 1/0/1  
[RouterA-GigabitEthernet1/0/1] pim ipv6 dm  
[RouterA-GigabitEthernet1/0/1] quit  
[RouterA] interface gigabitethernet 1/0/2  
[RouterA-GigabitEthernet1/0/2] pim ipv6 dm  
[RouterA-GigabitEthernet1/0/2] mld enable
```
3. Configure Switch A:
Enable MLD snooping globally.

```
<SwitchA> system-view  
[SwitchA] mld-snooping  
[SwitchA-mld-snooping] quit
```

Create VLAN 2 through VLAN 5.

```
[SwitchA] vlan 2 to 5
```

Configure GigabitEthernet 1/0/2 as a trunk port that permits packets from VLAN 2 and VLAN 3 to pass through.

```
[SwitchA] interface gigabitethernet 1/0/2
```

```
[SwitchA-GigabitEthernet1/0/2] port link-type trunk
[SwitchA-GigabitEthernet1/0/2] port trunk permit vlan 2 3
[SwitchA-GigabitEthernet1/0/2] quit
# Configure GigabitEthernet 1/0/3 as a trunk port that permits packets from VLAN 4 and VLAN 5 to pass through.
```

```
[SwitchA] interface gigabitethernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] port link-type trunk
[SwitchA-GigabitEthernet1/0/3] port trunk permit vlan 4 5
[SwitchA-GigabitEthernet1/0/3] quit
```

Create VLAN 10, assign GigabitEthernet 1/0/1 to this VLAN and enable MLD snooping in the VLAN.

```
[SwitchA] vlan 10
[SwitchA-vlan10] port gigabitethernet 1/0/1
[SwitchA-vlan10] mld-snooping enable
[SwitchA-vlan10] quit
```

Configure VLAN 10 as an IPv6 multicast VLAN and configure VLAN 2 through VLAN 5 as its sub-VLANs.

```
[SwitchA] multicast-vlan ipv6 10
[SwitchA-ipv6-mvlan-10] subvlan 2 to 5
[SwitchA-ipv6-mvlan-10] quit
```

4. Configure Switch B:

Enable MLD snooping globally.

```
<SwitchB> system-view
[SwitchB] mld-snooping
[SwitchB-mld-snooping] quit
```

Create VLAN 2, assign GigabitEthernet 1/0/2 to VLAN 2, and enable MLD snooping in the VLAN.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/2
[SwitchB-vlan2] mld-snooping enable
[SwitchB-vlan2] quit
```

Create VLAN 3, assign GigabitEthernet 1/0/3 to VLAN 3, and enable MLD snooping in the VLAN.

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/3
[SwitchB-vlan3] mld-snooping enable
[SwitchB-vlan3] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port that permits packets from VLAN 2 and VLAN 3 to pass through.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port link-type trunk
[SwitchB-GigabitEthernet1/0/1] port trunk permit vlan 2 3
```

5. Configure Switch C:

The configurations required on Switch C are similar to those on Switch B.

6. Verify the configuration:

Display information about the IPv6 multicast VLAN.

```
[SwitchA] display multicast-vlan ipv6
```

```
Total 1 IPv6 multicast-vlan(s)
```

```
IPv6 Multicast vlan 10
```

```
  subvlan list:
```

```
    vlan 2-5
```

```
  port list:
```

```
    no port
```

View the MLD snooping IPv6 multicast group information on Switch A.

```
[SwitchA] display mld-snooping group

  Router port(s):total 1 port(s).
    GE1/0/1                (D)
  IP group(s):the following ip group(s) match to one mac group.
    IP group address:FF1E::101
      (::, FF1E::101):
        Host port(s):total 0 port(s).
    MAC group(s):
      MAC group address:3333-0000-0101
        Host port(s):total 0 port(s).

```

The output shows that MLD snooping is maintaining the router port in the IPv6 multicast VLAN (VLAN 10) and the member ports in the sub-VLANs (VLAN 2 through VLAN 5).

Port-based multicast VLAN configuration example

Network requirements

As shown in [Figure 79](#), MLDv1 runs on Router A. MLDv1 snooping runs on Switch A. Router A acts as the MLD querier. The IPv6 multicast source sends IPv6 multicast data to IPv6 multicast group FF1E::101. Host A, Host B, and Host C are receivers of the IPv6 multicast group. The hosts belong to VLAN 2 through VLAN 4 respectively.

Configure the port-based IPv6 multicast VLAN feature on Switch A so that Router A sends IPv6 multicast data to Switch A through the IPv6 multicast VLAN, and Switch A forwards the IPv6 multicast data to the receivers that belong to different user VLANs.

Figure 79 Network diagram

Configuration procedure

1. Enable IPv6 forwarding, and configure IPv6 addresses:
Enable IPv6 forwarding on each device, and configure the IPv6 address and address prefix for each interface as per [Figure 79](#). (Details not shown.)
2. Configure Router A:
Enable IPv6 multicast routing, enable IPv6 PIM-DM on each interface, and enable MLD on the host-side interface GigabitEthernet 1/0/2.

```
<RouterA> system-view
[RouterA] multicast ipv6 routing-enable
[RouterA] interface gigabitethernet 1/0/1
[RouterA-GigabitEthernet1/0/1] ipv6 pim dm
[RouterA-GigabitEthernet1/0/1] quit
[RouterA] interface gigabitethernet 1/0/2
[RouterA-GigabitEthernet1/0/2] ipv6 pim dm
[RouterA-GigabitEthernet1/0/2] mld enable
```
3. Configure Switch A:
Enable MLD snooping globally.

```
<SwitchA> system-view
[SwitchA] mld-snooping
[SwitchA-mld-snooping] quit
```

Create VLAN 10, assign GigabitEthernet 1/0/1 to VLAN 10, and enable MLD snooping in this VLAN.

```
[SwitchA] vlan 10
[SwitchA-vlan10] port gigabitethernet 1/0/1
[SwitchA-vlan10] mld-snooping enable
```

```
[SwitchA-vlan10] quit
```

Create VLAN 2 and enable MLD snooping in the VLAN.

```
[SwitchA] vlan 2
```

```
[SwitchA-vlan2] mld-snooping enable
```

```
[SwitchA-vlan2] quit
```

The configuration for VLAN 3 and VLAN 4 is similar. (Details not shown.)

Configure GigabitEthernet 1/0/2 as a hybrid port. Configure VLAN 2 as the default VLAN. Configure GigabitEthernet 1/0/2 to permit packets of VLAN 2 to pass and untag the packets when forwarding them.

```
[SwitchA] interface gigabitethernet 1/0/2
```

```
[SwitchA-GigabitEthernet1/0/2] port link-type hybrid
```

```
[SwitchA-GigabitEthernet1/0/2] port hybrid pvid vlan 2
```

```
[SwitchA-GigabitEthernet1/0/2] port hybrid vlan 2 untagged
```

```
[SwitchA-GigabitEthernet1/0/2] port hybrid vlan 10 untagged
```

```
[SwitchA-GigabitEthernet1/0/2] quit
```

The configuration for GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 is similar. (Details not shown.)

Configure VLAN 10 as an IPv6 multicast VLAN.

```
[SwitchA] multicast-vlan ipv6 10
```

Assign GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 to IPv6 multicast VLAN 10.

```
[SwitchA-ipv6-mvlan-10] port gigabitethernet 1/0/2 to gigabitethernet 1/0/3
```

```
[SwitchA-ipv6-mvlan-10] quit
```

Assign GigabitEthernet 1/0/4 to IPv6 multicast VLAN 10.

```
[SwitchA] interface gigabitethernet 1/0/4
```

```
[SwitchA-GigabitEthernet1/0/4] port multicast-vlan ipv6 10
```

```
[SwitchA-GigabitEthernet1/0/4] quit
```

4. Verify the configuration:

View the IPv6 multicast VLAN information on Switch A.

```
[SwitchA] display multicast-vlan ipv6
```

```
Total 1 IPv6 multicast-vlan(s)
```

```
IPv6 Multicast vlan 10
```

```
  subvlan list:
```

```
    no subvlan
```

```
  port list:
```

```
    GE1/0/2
```

```
    GE1/0/3
```

```
    GE1/0/4
```

View the MLD snooping multicast group information on Switch A.

```
[SwitchA] display mld-snooping group
```

```
Total 1 IP Group(s).
```

```
Total 1 IP Source(s).
```

```
Total 1 MAC Group(s).
```

```
Port flags: D-Dynamic port, S-Static port, C-Copy port, P-PIM port
```

```
Subvlan flags: R-Real VLAN, C-Copy VLAN
```

```
Vlan(id):10.
```

```
  Total 1 IP Group(s).
```

```
  Total 1 IP Source(s).
```

```
Total 1 MAC Group(s).
Router port(s):total 1 port(s).
    GE1/0/1                (D)
IP group(s):the following ip group(s) match to one mac group.
  IP group address:FF1E::101
    (::, FF1E::101):
      Host port(s):total 3 port(s).
        GE1/0/2            (D)
        GE1/0/3            (D)
        GE1/0/4            (D)
MAC group(s):
  MAC group address:3333-0000-0101
    Host port(s):total 3 port(s).
      GE1/0/2
      GE1/0/3
      GE1/0/4
```

The output shows that MLD snooping is maintaining router ports and member ports in VLAN 10.

Configuring IPv6 multicast routing and forwarding (available only on the HP 5500 EI)

Overview

In IPv6 multicast implementations, the following types of tables implement multicast routing and forwarding:

- **Multicast routing table of an IPv6 multicast routing protocol**—Each IPv6 multicast routing protocol has its own multicast routing table, such as IPv6 PIM routing table.
- **General IPv6 multicast routing table**—The multicast routing information of different IPv6 multicast routing protocols forms a general IPv6 multicast routing table.
- **IPv6 multicast forwarding table**—The IPv6 multicast forwarding table guides the forwarding of IPv6 multicast packets.

An IPv6 multicast forwarding table consists of a set of (S, G) entries. Each entry indicates the routing information for delivering multicast data from a multicast source to a multicast group. If a router supports multiple IPv6 multicast protocols, its IPv6 multicast routing table will include routes that these protocols have generated. The router chooses the optimal route from the IPv6 multicast routing table based on the configured multicast routing and forwarding policy and installs the route entry into its IPv6 multicast forwarding table.

The term "router" in this document refers to both routers and Layer 3 switches.

The term "interface" in the IPv6 multicast routing and forwarding features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

RPF check mechanism

An IPv6 multicast routing protocol relies on the existing IPv6 unicast routing information or IPv6 MBGP routes in creating IPv6 multicast routing entries. When creating IPv6 multicast routing table entries, an IPv6 multicast routing protocol uses the reverse path forwarding (RPF) check mechanism to ensure IPv6 multicast data delivery along the correct path. The RPF check mechanism also helps avoid data loops caused by various reasons.

RPF check process

An RPF check is based on one of the following routing tables:

- **IPv6 unicast routing table**—Contains the shortest path to each destination subnet
- **IPv6 MBGP routing table**—Contains IPv6 multicast routing information

When a router performs an RPF check, it searches its IPv6 unicast routing table and IPv6 MBGP routing table at the same time. The specific process is as follows:

1. The router chooses each optimal route from the IPv6 unicast routing table and the IPv6 MBGP routing table:

- The router searches its IPv6 unicast routing table by using the IPv6 address of the packet source as the destination address and automatically selects the optimal route as the RPF route. The outgoing interface in the corresponding routing entry is the RPF interface and the next hop is the RPF neighbor. The router considers the path along which the IPv6 multicast packet from the RPF neighbor arrived on the RPF interface to be the shortest path that leads back to the source.
 - The router automatically chooses an optimal IPv6 MBGP route by searching its MBGP routing table, and using the IPv6 address of the packet source as the destination address. The outgoing interface in the corresponding routing entry is the RPF interface and the next hop is the RPF neighbor.
2. The router selects one of these optimal routes as the RPF route. The selection process is as follows:
 - If configured to use the longest match principle, the router selects the longest match route from these optimal routes. If these routes have the same prefix length, the router selects the route with a higher priority. If these routes have the same priority, the router selects the IPv6 MBGP route as the RPF route.
 - If not configured to use the longest match principle, the router selects the route with a higher priority. If these routes have the same priority, the router selects the IPv6 MBGP route as the RPF route.

The term "packet source" can mean different things in different situations:

- For a packet that traveling along the shortest path tree (SPT) from the multicast source to the receivers or the rendezvous point (RP), the packet source for RPF check is the multicast source.
- For a packet that traveling along the rendezvous point tree (RPT) from the RP to the receivers, or along the source-side RPT from the multicast source to the RP, the packet source for RPF check is the RP.
- For a bootstrap message from the bootstrap router (BSR), the packet source for RPF check is the BSR.

For more information about the concepts of SPT, RPT, source-side RPT, RP, and BSR, see "[Configuring IPv6 PIM \(available only on the HP 5500 EI\)](#)."

RPF check implementation in IPv6 multicast

Implementing an RPF check on each received IPv6 multicast data packet would heavily burden the router. The use of an IPv6 multicast forwarding table is the solution to this issue. When creating an IPv6 multicast routing entry and an IPv6 multicast forwarding entry for an IPv6 multicast packet, the router sets the RPF interface of the packet as the incoming interface of the (S, G) entry. After receiving an (S, G) IPv6 multicast packet, the router first searches its IPv6 multicast forwarding table:

1. If the corresponding (S, G) entry does not exist in the IPv6 multicast forwarding table, the packet undergoes an RPF check. The router creates an IPv6 multicast routing entry based on the relevant routing information and installs the entry into the IPv6 multicast forwarding table, with the RPF interface as the incoming interface.
 - If the interface that received the packet is the RPF interface, the RPF check succeeds and the router forwards the packet to all the outgoing interfaces.
 - If the interface that received the packet is not the RPF interface, the RPF check fails and the router discards the packet.
2. If the corresponding (S, G) entry exists, and the interface that received the packet is the incoming interface, the router forwards the packet to all the outgoing interfaces.
3. If the corresponding (S, G) entry exists, but the interface that received the packet is not the incoming interface in the IPv6 multicast forwarding table, the IPv6 multicast packet undergoes an RPF check.

- If the RPF interface is the incoming interface of the (S, G) entry, this means the (S, G) entry is correct but the packet arrived from a wrong path. The packet will be discarded.
- If the RPF interface is not the incoming interface, this means that the (S, G) entry has expired, and the router replaces the incoming interface with the RPF interface. If the interface on which the packet arrived is the RPF interface, the router forwards the packet to all the outgoing interfaces. Otherwise it discards the packet.

Assume that IPv6 unicast routes are available in the network, IPv6 MBGP is not configured, and IPv6 multicast packets travel along the SPT from the multicast source to the receivers, as shown in Figure 80. The IPv6 multicast forwarding table on Router C contains the (S, G) entry, with VLAN-interface 20 as the RPF interface.

Figure 80 RPF check process

- When an IPv6 multicast packet arrives on VLAN-interface 20 of Router C, because the interface is the incoming interface of the (S, G) entry, the router forwards the packet to all outgoing interfaces.
- When an IPv6 multicast packet arrives on VLAN-interface 10 of Router C, because the interface is not the incoming interface of the (S, G) entry, the router performs an RPF check on the packet. The router searches its IPv6 unicast routing table and finds that the outgoing interface to Source (the RPF interface) is VLAN-interface 20. This means that the (S, G) entry is correct and the packet arrived along a wrong path. The RPF check fails and the packet is discarded.

Configuration task list

Task	Remarks	
Enabling IPv6 multicast routing	Required	
Configuring IPv6 multicast routing and forwarding	Configuring an IPv6 multicast routing policy	Optional
	Configuring an IPv6 multicast forwarding range	Optional
	Configuring the IPv6 multicast forwarding table size	Optional

Enabling IPv6 multicast routing

Before you configure any Layer 3 IPv6 multicast functionality, you must enable IPv6 multicast routing.

To enable IPv6 multicast routing:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6 multicast routing.	multicast ipv6 routing-enable	Disabled by default.

Configuring IPv6 multicast routing and forwarding

Configuration prerequisites

Before you configure IPv6 multicast routing and forwarding, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Configure IPv6 PIM-DM or IPv6 PIM-SM.
- Determine the maximum number of downstream nodes for a single entry in the IPv6 multicast forwarding table.
- Determine the maximum number of entries in the IPv6 multicast forwarding table.

Configuring an IPv6 multicast routing policy

You can configure the router to determine the RPF route based on the longest match principle. For more information about RPF route selection, see "[RPF check process](#)."

By configuring per-source or per-source-and-group load splitting, you can optimize the traffic delivery when multiple IPv6 multicast data streams are handled.

To configure an IPv6 multicast routing policy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the device to select the RPF route based on the longest match.	multicast ipv6 longest-match	Optional. The route with the highest priority is selected as the RPF route by default.
3. Configure IPv6 multicast load splitting.	multicast ipv6 load-splitting { source source-group }	Optional. Disabled by default.

Configuring an IPv6 multicast forwarding range

IPv6 multicast packets do not travel infinitely in a network. The IPv6 multicast data of each IPv6 multicast group must be transmitted within a definite scope.

You can configure the forwarding boundary for a specific IPv6 multicast group or an IPv6 multicast group with the scope field in its group address being specified on all interfaces that support IPv6 multicast forwarding. A multicast forwarding boundary sets the boundary condition for the IPv6 multicast groups in the specified range or scope. If the destination address of an IPv6 multicast packet matches the set boundary condition, the packet will not be forwarded. Once an IPv6 multicast boundary is configured on an interface, this interface can no longer forward IPv6 multicast packets (including those sent from the local device) or receive IPv6 multicast packets.

To configure an IPv6 multicast forwarding range:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an IPv6 multicast forwarding boundary.	multicast ipv6 boundary { <i>ipv6-group-address prefix-length</i> scope { <i>scope-id</i> admin-local global organization-local site-local } }	No forwarding boundary by default.

Configuring the IPv6 multicast forwarding table size

The switch maintains the corresponding forwarding entry for each IPv6 multicast packet that it receives. Excessive IPv6 multicast routing entries, however, can exhaust the switch's memory and cause lower performance. You can set a limit on the number of entries in the IPv6 multicast forwarding table based on the actual networking situation and the performance requirements. If the configured maximum number of IPv6 multicast forwarding table entries is smaller than the current value, the entries in excess are not immediately deleted. Instead, the IPv6 multicast routing protocol that runs on the switch deletes them. The switch no longer adds new IPv6 multicast forwarding entries until the number of existing IPv6 multicast forwarding entries comes down below the configured value.

When the switch forwards IPv6 multicast traffic, it replicates a copy of the IPv6 multicast traffic for each downstream node and forwards the traffic. Each of these downstream nodes forms a branch of the IPv6 multicast distribution tree. You can configure the maximum number of downstream nodes (the maximum number of outgoing interfaces) for a single entry in the IPv6 multicast forwarding table to lessen the burden on the switch for replicating IPv6 multicast traffic. If the configured maximum number of downstream nodes for a single IPv6 multicast forwarding entry is smaller than the current number, the downstream nodes in excess are not deleted immediately. Instead, the IPv6 multicast routing protocol deletes them. The switch no longer adds new IPv6 multicast forwarding entries for newly added downstream nodes until the number of existing downstream nodes comes down below the configured value.

To configure the IPv6 multicast forwarding table size:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the maximum number of entries in the IPv6 multicast forwarding table.	multicast ipv6 forwarding-table route-limit <i>limit</i>	Optional. 1000 by default.

Step	Command	Remarks
3. Configure the maximum number of downstream nodes for a single IPv6 multicast forwarding entry.	multicast ipv6 forwarding-table downstream-limit <i>limit</i>	Optional. 128 by default.

Displaying and maintaining IPv6 multicast routing and forwarding

Task	Command	Remarks
Display the IPv6 multicast boundary information.	display multicast ipv6 boundary { group [<i>ipv6-group-address</i> [<i>prefix-length</i>]] scope [<i>scope-id</i>] } [interface <i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information of the IPv6 multicast forwarding table.	display multicast ipv6 forwarding-table [<i>ipv6-source-address</i> [<i>prefix-length</i>] <i>ipv6-group-address</i> [<i>prefix-length</i>] incoming-interface { <i>interface-type interface-number</i> register } outgoing-interface { exclude include match } { <i>interface-type interface-number</i> register } statistics slot <i>slot-number</i>] * [port-info] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the DF information of the IPv6 multicast forwarding table.	display multicast ipv6 forwarding-table df-info [<i>rp-address</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information of the IPv6 multicast routing table.	display multicast ipv6 routing-table [<i>ipv6-source-address</i> [<i>prefix-length</i>] <i>ipv6-group-address</i> [<i>prefix-length</i>] incoming-interface { <i>interface-type interface-number</i> register } outgoing-interface { exclude include match } { <i>interface-type interface-number</i> register }] * [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the RPF route information of the specified IPv6 multicast source.	display multicast ipv6 rpf-info <i>ipv6-source-address</i> [<i>ipv6-group-address</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear forwarding entries from the IPv6 multicast forwarding table.	reset multicast ipv6 forwarding-table { { <i>ipv6-source-address</i> [<i>prefix-length</i>] <i>ipv6-group-address</i> [<i>prefix-length</i>] incoming-interface { <i>interface-type interface-number</i> register } } * all }	Available in user view

Task	Command	Remarks
Clear routing entries from the IPv6 multicast routing table.	reset multicast ipv6 routing-table { { <i>ipv6-source-address</i> [<i>prefix-length</i>] <i>ipv6-group-address</i> [<i>prefix-length</i>] incoming-interface { <i>interface-type</i> <i>interface-number</i> register } } * all }	Available in user view

For more information about designated forwarder (DF), see "[Configuring IPv6 PIM \(available only on the HP 5500 EI\)](#)."

ⓘ IMPORTANT:

The **reset** command clears the information in the IPv6 multicast routing table or the multicast forwarding table and might cause transmission failure of IPv6 multicast information.

When a routing entry is deleted from the IPv6 multicast routing table, the corresponding forwarding entry is also deleted from the IPv6 multicast forwarding table.

When a forwarding entry is deleted from the IPv6 multicast forwarding table, the corresponding routing entry is also deleted from the IPv6 multicast routing table.

Troubleshooting IPv6 multicast policy configuration

Abnormal termination of IPv6 multicast data

Symptom

- A host sends an MLD report announcing its joining an IPv6 multicast group (G). However, no member information about the IPv6 multicast group (G) exists on the intermediate router. The intermediate router can receive IPv6 multicast packets successfully, but the packets cannot reach the stub network.
- The interface of the intermediate router receives the IPv6 multicast packets, but no corresponding (S, G) entry exists in the IPv6 PIM routing table.

Analysis

- The **multicast ipv6 boundary** command filters IPv6 multicast packets received on an interface. If an IPv6 multicast packet fails to match the IPv6 ACL rule of this command, IPv6 PIM will create no routing entry.
- In addition, the **source-policy** command in IPv6 PIM filters received IPv6 multicast packets. If an IPv6 multicast packet fails to match the IPv6 ACL rule of this command, IPv6 PIM will not create a routing entry, either.

Solution

1. Use the **display current-configuration** command to display the IPv6 ACL rule configured on the multicast forwarding boundary. Change the IPv6 ACL rule used in the **multicast ipv6 boundary** command so that the source IP address of the IPv6 multicast packets and the IPv6 multicast group address can both match the IPv6 ACL rule.
2. View the configuration of the multicast filter. Use the **display current-configuration** command to display the configuration of the IPv6 multicast filter. Change the IPv6 ACL rule used in the

source-policy command so that the source IP address of the IPv6 multicast packets and the IPv6 multicast group address can both match the IPv6 ACL rule.

Configuring MLD (available only on the HP 5500 EI)

Overview

An IPv6 router uses the Multicast Listener Discovery (MLD) protocol to discover the presence of multicast listeners on the directly attached subnets. Multicast listeners are nodes that want to receive IPv6 multicast packets.

Through MLD, the router can determine whether any IPv6 multicast listeners exist on the directly connected subnets, put corresponding records in the database, and maintain timers related to IPv6 multicast addresses.

Routers running MLD use an IPv6 unicast link-local address as the source address to send MLD messages. MLD messages are Internet Control Message Protocol for IPv6 (ICMPv6) messages. All MLD messages are confined to the local subnet, with a hop count of 1.

The term "router" in this document refers to both routers and Layer 3 switches.

The term "interface" in the MLD features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

MLD versions

- MLDv1 (defined in RFC 2710), which is derived from IGMPv2.
- MLDv2 (defined in RFC 3810), which is derived from IGMPv3.

All MLD versions support the Any-Source Multicast (ASM) model. In addition, MLDv2 can directly implement the Source-Specific Multicast (SSM) model, but MLDv1 must work with the MLD SSM mapping function to implement SSM service.

For more information about the ASM and SSM models, see "[Multicast overview](#)."

How MLDv1 works

MLDv1 implements IPv6 multicast listener management based on the query/response mechanism.

MLD querier election

All IPv6 multicast routers on the same subnet can monitor MLD listener report messages (often called "reports") from hosts, but only one router is needed for sending MLD query messages (often called "queries"). A querier election mechanism determines which router will act as the MLD querier on the subnet.

1. Initially, every MLD router assumes itself as the querier and sends MLD general query messages (often called "general queries") to all hosts and routers on the local subnet. The destination address is FF02::1.

2. After receiving a general query, every MLD router compares the source IPv6 address of the query message with its own interface address. After comparison, the router with the lowest IPv6 address wins the querier election and all other routers become non-queriers.
3. All the non-queriers start a timer called the "other querier present timer." If a router receives an MLD query from the querier before the timer expires, it resets this timer. Otherwise, it assumes that the querier has timed out and initiates a new querier election process.

Joining an IPv6 multicast group

Figure 81 MLD queries and reports

Assume that Host B and Host C will receive IPv6 multicast data addressed to IPv6 multicast group G1, and Host A will receive IPv6 multicast data addressed to G2, as shown in Figure 81. The following process describes how the hosts join the IPv6 multicast groups and how the MLD querier (Router B in the figure) maintains the IPv6 multicast group memberships:

1. The hosts send unsolicited MLD reports to the addresses of the IPv6 multicast groups that they will join, without having to wait for the MLD queries from the MLD querier.
2. The MLD querier periodically multicasts MLD queries (with the destination address of FF02::1) to all hosts and routers on the local subnet.
3. After receiving a query message, Host B or Host C (the delay timer of whichever expires first) sends an MLD report to the IPv6 multicast group address of G1, to announce its membership for G1. Assume that Host B sends the report message. After hearing the report from Host B, Host C, which is on the same subnet as Host B, suppresses its own report for G1, because the MLD routers (Router A and Router B) have already known that at least one host on the local subnet is interested in G1. This mechanism, known as the "MLD report suppression", helps reduce traffic on the local subnet.
4. At the same time, because Host A is interested in G2, it sends a report to the IPv6 multicast group address of G2.
5. Through the query/report process, the MLD routers learn that members of G1 and G2 are attached to the local subnet, and the IPv6 multicast routing protocol (for example, IPv6 PIM) that is running on the routers generates (*, G1) and (*, G2) multicast forwarding entries. These entries will be the basis for subsequent IPv6 multicast forwarding, where * represents any IPv6 multicast source.

6. When the IPv6 multicast data addressed to G1 or G2 reaches an MLD router, because the (*, G1) and (*, G2) multicast forwarding entries exist on the MLD router, the router forwards the IPv6 multicast data to the local subnet, and then the receivers on the subnet receive the data.

Leaving an IPv6 multicast group

When a host leaves a multicast group, the following occur:

1. The host sends an MLD done message to all IPv6 multicast routers on the local subnet. The destination address is FF02::2.
2. After receiving the MLD done message, the querier sends a configurable number of multicast-address-specific queries to the group that the host is leaving. The destination address field and group address field of the message are both filled with the address of the IPv6 multicast group that is being queried.
3. One of the remaining members (if any on the subnet) of the group being queried should send a report within the time of the maximum response delay set in the query messages.
4. If the querier receives a report for the group within the maximum response delay time, it will maintain the memberships of the IPv6 multicast group. Otherwise, the querier will assume that no hosts on the subnet are still interested in IPv6 multicast traffic addressed to that group and will stop maintaining the memberships of the group.

How MLDv2 works

Compared with MLDv1, MLDv2 provides the following new features:

IPv6 multicast group filtering

MLDv2 has introduced IPv6 multicast source filtering modes (Include and Exclude), so that a host not only can join a designated IPv6 multicast group, but also can specify to receive or reject multicast data from designated IPv6 multicast sources. When a host joins an IPv6 multicast group, one of the following situation occurs:

- If it expects IPv6 multicast data from specific IPv6 multicast sources like S1, S2, ..., it sends a report with Filter-Mode denoted as "Include Sources (S1, S2, ...)."
- If it does not expect IPv6 multicast data from specific IPv6 multicast sources like S1, S2, ..., it sends a report with Filter-Mode denoted as "Exclude Sources (S1, S2, ...)."

As shown in [Figure 82](#), the network comprises two IPv6 multicast sources, Source 1 (S1) and Source 2 (S2), both of which can send IPv6 multicast data to IPv6 multicast group G. Host B is interested only in the IPv6 multicast data that Source 1 sends to G but not in the data from Source 2.

Figure 82 Flow paths of multicast-address-and-source-specific multicast traffic

In the case of MLDv1, Host B cannot select IPv6 multicast sources when it joins IPv6 multicast group G. Therefore, IPv6 multicast streams from both Source 1 and Source 2 will flow to Host B whether it needs them or not.

When MLDv2 is running on the hosts and routers, Host B can explicitly express its interest in the IPv6 multicast data that Source 1 sends to G (denoted as (S1, G)), rather than the IPv6 multicast data that Source 2 sends to G (denoted as (S2, G)). Thus, only IPv6 multicast data from Source 1 will be delivered to Host B.

MLD state

A multicast router that is running MLDv2 maintains the multicast address state per multicast address per attached subnet. The multicast address state consists of the following information:

- **Filter mode**—The router keeps tracing the Include or Exclude state.
- **List of sources**—The router keeps tracing the newly added or deleted IPv6 multicast source.
- **Timers**—Filter timers, including the time that the router waits before switching to the Include mode after an IPv6 multicast address times out, the source timer for source recording, and so on.

Receiver host state listening

By listening to the state of receiver hosts, a multicast router running MLDv2 records and maintains information of hosts joining the source group on the attached subnet.

MLD messages

The following descriptions are based on MLDv2 messages.

MLD query message

An MLD querier learns the multicast listening state of neighbor interfaces by sending MLD query messages. The dark area in Figure 83 shows the MLDv1 message format.

Figure 83 MLDv2 query message format

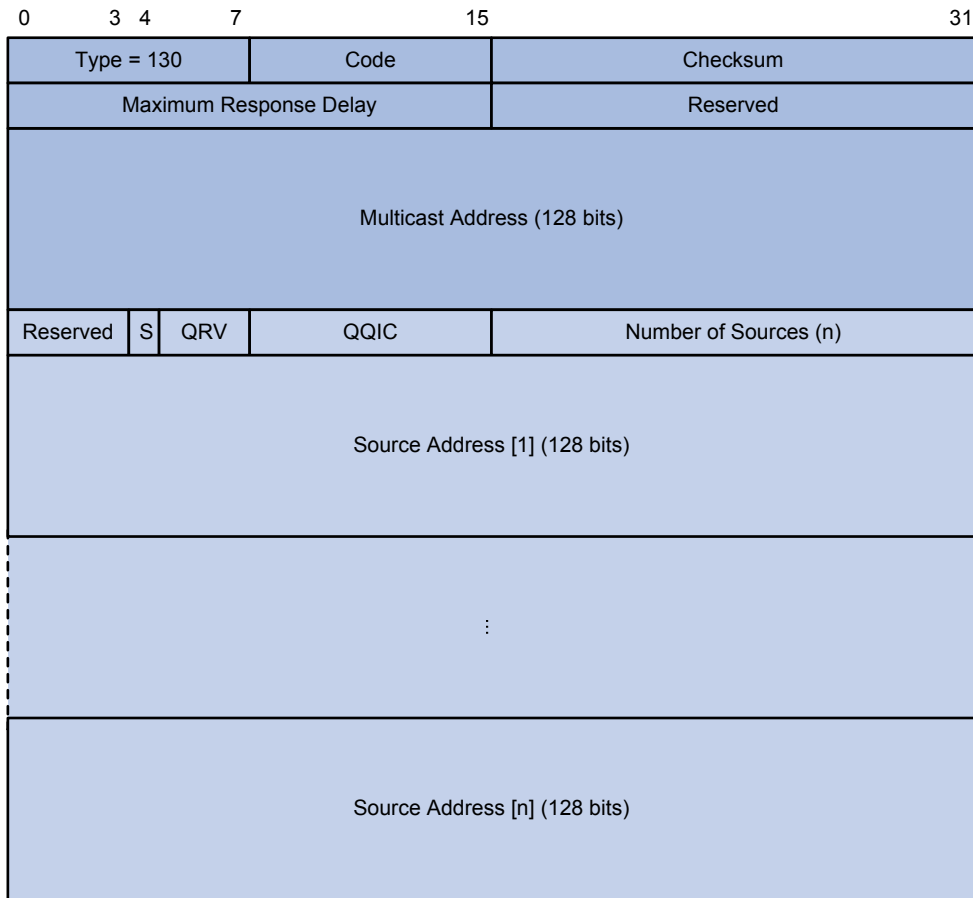

Table 9 MLDv2 query message field description

Field	Description
Type = 130	Message type. For a query message, this field is set to 130.
Code	Initialized to zero.
Checksum	Standard IPv6 checksum.
Maximum Response Delay	Maximum response delay allowed before a host sends a report message.
Reserved	Reserved field and initialized to zero.
Multicast Address	<ul style="list-style-type: none"> This field is set to 0 in a general query message. It is set to a specific IPv6 multicast address in a multicast-address-specific query message or multicast-address-and-source-specific query message.
S	Flag indicating whether a router updates the timer for suppression after receiving a query message.
QRV	Querier's Robustness Variable.
QQIC	Querier's Query Interval Code.

Field	Description
Number of Sources	<ul style="list-style-type: none"> This field is set to 0 in a general query message or a multicast-address-specific query message. This field represents the number of source addresses in a multicast-address-and-source-specific query message.
Source Address(i)	IPv6 multicast source address in a multicast-address-specific query message (i = 1, 2, ..., n, where n represents the number of multicast source addresses.)

MLD report message

A host sends an MLD report message to report the current multicast listening state. Figure 84 shows the MLD report message format.

Figure 84 MLDv2 report message format

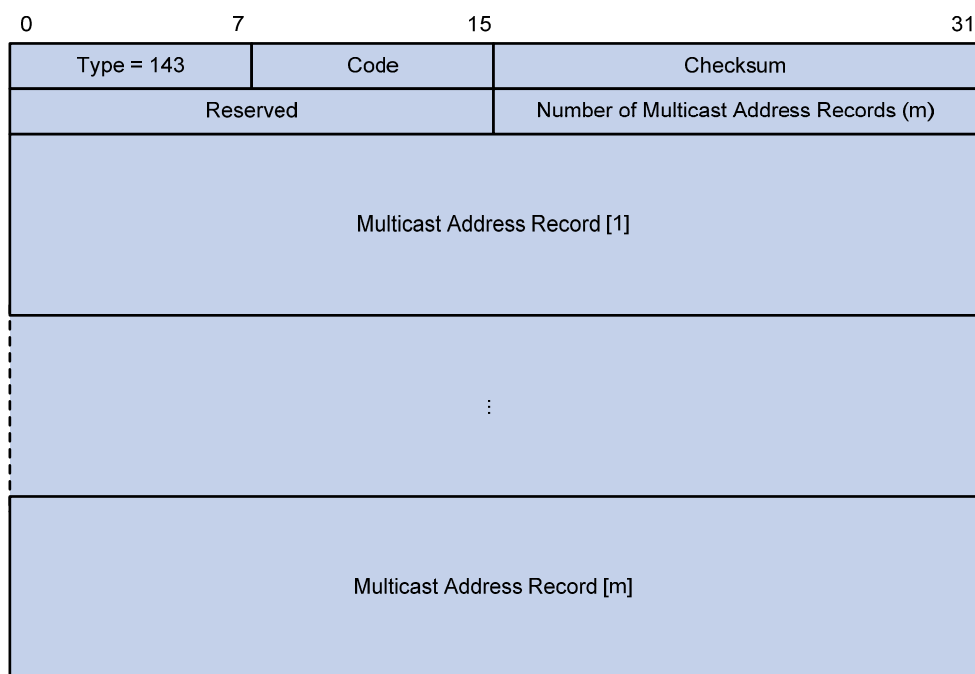

Table 10 MLDv2 report message field description

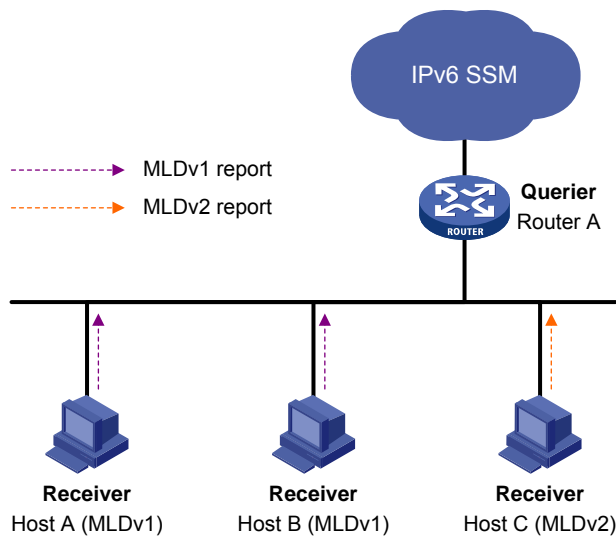

Field	Description
Type = 143	Message type. For a report message, this field is set to 143.
Reserved	The Reserved fields are set to 0 on transmission and ignored on reception.
Checksum	Standard IPv6 checksum.
Number of Multicast Address Records	This field indicates how many IPv6 multicast address records are present in this report message.
Multicast Address Record(i)	This field represents information of each IPv6 multicast address the host listens to on the interface from which the report message is sent, including record type, IPv6 multicast address, and IPv6 multicast source address on the sender (i= 1, 2, ... m, where m represents the number of IPv6 multicast address records).

MLD SSM mapping

The MLD SSM mapping feature enables you to configure static MLD SSM mappings on the last hop router to provide SSM support for receiver hosts that are running MLDv1. The SSM model assumes that the last hop router has identified the desired IPv6 multicast sources when receivers join IPv6 multicast groups.

- When an MLDv2 enabled host joins a multicast group, it can explicitly specify one or more multicast sources in its MLDv2 report.
- An MLDv1-enabled host, however, cannot specify multicast source addresses in its MLDv1 report. You must configure the MLD SSM mapping feature to translate the (*, G) information in the MLDv1 report into (G, INCLUDE, (S1, S2...)) information.

Figure 85 Network diagram

On the IPv6 SSM network in [Figure 85](#), Host A and Host B are running MLDv1 and Host C is running MLDv2. To provide SSM service for Host A and Host B, you must configure the MLD SSM mapping feature on Router A.

With the MLD SSM mapping feature configured, when Router A receives an MLDv1 report, it checks the IPv6 multicast group address G carried in the message.

- If G is not in the IPv6 SSM group range, Router A cannot provide the SSM service but can provide the ASM service.
- If G is in the IPv6 SSM group range but no MLD SSM mappings have been configured for the IPv6 multicast group G on Router A, Router A cannot provide SSM service and drops the packet.
- If G is in the IPv6 SSM group range, and the MLD SSM mappings have been configured on Router A for multicast group G, Router A translates the (*, G) information in the MLD report into (G, INCLUDE, (S1, S2...)) information based on the configured MLD SSM mappings and provides SSM service accordingly.

NOTE:

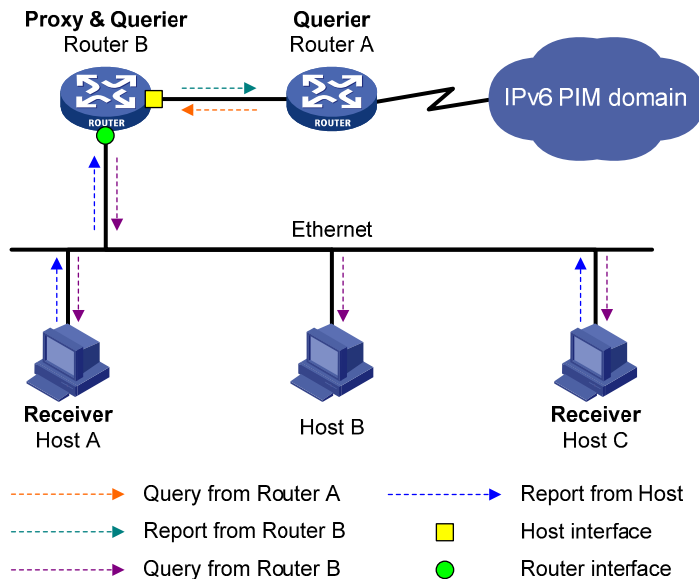

The MLD SSM mapping feature does not process MLDv2 reports.

For more information about the IPv6 SSM group range, see "[Configuring IPv6 PIM \(available only on the HP 5500 EI\)](#)."

MLD proxying

In some simple tree-shaped topologies, you do not need to configure complex IPv6 multicast routing protocols, such as IPv6 PIM, on the boundary devices. Instead, you can configure MLD proxying on these devices. With MLD proxying configured, the device serves as a proxy for the downstream hosts to send MLD messages, maintain group memberships, and implement IPv6 multicast forwarding based on the memberships. In this case, the MLD proxy device is a host but no longer an IPv6 PIM neighbor to the upstream device.

Figure 86 Network diagram

As shown in [Figure 86](#), an MLD proxy device has the following types of interfaces:

- **Upstream interface**—Also called the "proxy interface." A proxy interface is an interface on which MLD proxying is configured. It is in the direction toward the root of the multicast forwarding tree. An upstream interface acts as a host that is running MLD, and is also called a "host interface."
- **Downstream interface**—An interface that is running MLD and not in the direction toward the root of the multicast forwarding tree. A downstream interface acts as a router that is running MLD, and is also called a "router interface."

A device with MLD proxying configured maintains a group membership database, which stores the group memberships on all the downstream interfaces in this database. Each entry comprises the multicast address, filter mode, and source list. Such an entry is a collection of members in the same multicast group on each downstream interface.

A proxy device performs host functions on the upstream interface based on the database. It responds to the queries according to the information in the database or sends join/leave messages when the database changes. The proxy device performs router functions on the downstream interfaces by participating in the querier election, sending queries, and maintaining memberships based on the reports.

Protocols and standards

- RFC 2710, *Multicast Listener Discovery (MLD) for IPv6*
- RFC 3810, *Multicast Listener Discovery Version 2 (MLDv2) for IPv6*

- RFC 4605, *Internet Group Management Protocol (IGMP)/Multicast Listener Discovery (MLD)-Based Multicast Forwarding ("IGMP/MLD Proxying")*

MLD configuration task list

Task	Remarks	
	Enabling MLD	Required
Configuring basic MLD functions	Configuring the MLD version	Option
	Configuring static joining	Optional
	Configuring an IPv6 multicast group filter	Optional
	Setting the maximum number of IPv6 multicast groups that an interface can join	Optional
	Configuring MLD message options	Optional
Adjusting MLD performance	Configuring MLD query and response parameters	Optional
	Configuring MLD fast-leave processing	Optional
	Enabling the MLD host tracking function	Optional
	Setting the DSCP value for MLD messages	Optional
Configuring MLD SSM mapping	Enabling MLD SSM mapping	Optional
	Configuring MLD SSM mappings	Optional
Configuring MLD proxying	Enabling MLD proxying	Optional
	Configuring IPv6 multicast forwarding on a downstream interface	Optional

NOTE:

- In MLD view, the configuration is effective globally. In interface view, the configuration is effective on only the current interface.
- If no configuration is performed in interface view, the global configuration in MLD view will apply to that interface. Configurations performed in interface view take precedence over those performed in MLD view.

Configuring basic MLD functions

Configuration prerequisites

Before you configure basic MLD functions, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain can be interoperable at the network layer.
- Configure IPv6 PIM-DM or IPv6 PIM-SM.
- Determine the MLD version.

- Determine the IPv6 multicast group address and IPv6 multicast source address for static group member configuration.
- Determine the ACL rule for IPv6 multicast group filtering.
- Determine the maximum number of IPv6 multicast groups that an interface can join.

Enabling MLD

Enable MLD on the interface on which IPv6 multicast group memberships will be created and maintained.

To enable MLD:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6 multicast routing.	multicast ipv6 routing-enable	Disable by default
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable MLD.	mld enable	Disabled by default

For more information about the **multicast ipv6 routing-enable** command, see *IP Multicast Command Reference*.

Configuring the MLD version

Because MLD message types and formats vary with MLD versions, the same MLD version should be configured for all routers on the same subnet before MLD can work properly.

Configuring an MLD version globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD view.	mld	N/A
3. Configure an MLD version globally.	version <i>version-number</i>	MLDv1 by default

Configuring an MLD version on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an MLD version on the interface.	mld version <i>version-number</i>	MLDv1 by default

Configuring static joining

After an interface is configured as a static member of an IPv6 multicast group or an IPv6 multicast source and group, it will act as a virtual member of the IPv6 multicast group to receive IPv6 multicast data addressed to that IPv6 multicast group for the purpose of testing IPv6 multicast data forwarding.

Configuration guidelines

Before you can configure an interface of an IPv6 PIM-SM device as a static member of an IPv6 multicast group or an IPv6 multicast source and group, if the interface is IPv6 PIM-SM enabled, it must be an IPv6 PIM-SM DR. If this interface is MLD enabled but not IPv6 PIM-SM enabled, it must be an MLD querier. For more information about IPv6 PIM-SM and a DR, see "[Configuring IPv6 PIM \(available only on the HP 5500 EI\)](#)."

A static member port does not respond to queries from the MLD querier. When you configure an interface as a static member port or remove this configuration on the interface, the interface does not unsolicitedly send any MLD report or an MLD done message. In other words, the interface is not a real member of the IPv6 multicast group or the IPv6 multicast and source group.

Configuration procedure

To configure a static member of an IPv6 multicast group or an IPv6 multicast source and group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure a static member of an IPv6 multicast group or an IPv6 multicast source and group.	mld static-group <i>ipv6-group-address</i> [source <i>ipv6-source-address</i>]	By default, an interface is not a static member of any IPv6 multicast group or IPv6 multicast source and group.

Configuring an IPv6 multicast group filter

To restrict the hosts on the network attached to an interface from joining certain IPv6 multicast groups, you can set an IPv6 ACL rule on the interface so that the interface maintains only the IPv6 multicast groups matching the criteria.

To configure an IPv6 multicast group filter:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an IPv6 multicast group filter.	mld group-policy <i>acl6-number</i> [<i>version-number</i>]	By default, no IPv6 group filter is configured on the interface. That is, hosts on the current interface can join any valid multicast group.

Setting the maximum number of IPv6 multicast groups that an interface can join

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the maximum number of IPv6 multicast groups that the interface can join.	mld group-limit <i>limit</i>	1000 by default.

NOTE:

This configuration takes effect for dynamically joined IPv6 multicast groups but not the statically configured multicast groups.

Adjusting MLD performance

For the configuration tasks in this section:

- In MLD view, the configuration is effective globally. In interface view, the configuration is effective only on the current interface.
- If the same function or parameter is configured in both MLD view and interface view, the configuration performed in interface view is given priority, regardless of the configuration order.

Configuration prerequisites

Before adjusting MLD performance, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain can be interoperable at the network layer.
- Configure basic MLD functions.
- Determine the startup query interval.
- Determine the startup query count.
- Determine the MLD query interval.
- Determine the MLD querier's robustness variable.
- Determine the maximum response delay of MLD general query messages.
- Determine the MLD last listener query interval.
- Determine the MLD other querier present interval.
- Determine the DSCP value for MLD messages.

Configuring MLD message options

MLD queries include multicast-address-specific queries and multicast-address-and-source-specific queries, and IPv6 multicast groups change dynamically, so a device cannot maintain the information for all IPv6 multicast sources and groups. Therefore, a router might receive IPv6 multicast packets addressed to IPv6

multicast groups that have no members on the local subnet. In this case, the Router-Alert option carried in the IPv6 multicast packets is useful for the router to determine whether to deliver the IPv6 multicast packets to the upper-layer protocol for processing. For more information about the Router-Alert option, see RFC 2113.

An MLD message is processed differently depending on whether it carries the Router-Alert option in the IPv6 header, as follows:

- For compatibility, the device by default ignores the Router-Alert option and processes all received MLD messages, no matter whether the MLD messages carry the Router-Alert option or not.
- To enhance device performance, avoid unnecessary costs, and ensure protocol security, configure the device to discard MLD messages that do not carry the Router-Alert option.

Configuring the Router-Alert option for MLD messages globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD view.	mld	N/A
3. Configure the interface to discard any MLD message without the Router-Alert option.	require-router-alert	By default, the device does not check MLD messages for the Router-Alert option.
4. Enable the insertion of the Router-Alert option into MLD messages.	send-router-alert	By default, MLD messages carry the Router-Alert option.

Configuring the Router-Alert option on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the interface to discard any MLD message without the Router-Alert option.	mld require-router-alert	By default, the device does not check MLD messages for the Router-Alert option.
4. Enable the insertion of the Router-Alert option into MLD messages.	mld send-router-alert	By default, MLD messages carry the Router-Alert option.

Configuring MLD query and response parameters

MLD query and response parameters

On startup, the MLD querier sends MLD general queries at the startup query interval, which is one-quarter of the MLD query interval. The number of queries, or the startup query count, is user configurable.

After startup, the MLD querier periodically sends MLD general queries at the MLD query interval to check for IPv6 multicast group members on the network. You can modify the query interval based on the actual condition of the network.

The MLDv1 querier sends MLD multicast-address-specific queries at the MLD last listener query interval when it receives an MLD done message. The MLDv2 querier sends MLD multicast-address-and-source-specific queries at the MLD last listener query interval when it receives a multicast group and multicast source mapping change report. The number of queries, or the last listener query count, equals the robustness variable (the maximum number of packet retransmissions).

A multicast listening host starts a timer for each IPv6 multicast group that it has joined when it receives an MLD query (general query, multicast-address-specific query, or multicast-address-and-source-specific query). The timer is initialized to a random value in the range of 0 to the maximum response delay advertised in the MLD query message. When the timer decreases to 0, the host sends an MLD membership report message to the IPv6 multicast group.

Configuration guidelines

To speed up the response of hosts to MLD queries and avoid simultaneous timer expirations causing MLD report traffic bursts, you must properly set the maximum response delay.

- For MLD general queries, the maximum response delay is set by the **max-response-time** command.
- For MLD multicast-address-specific query and multicast-address-and-source-specific query messages, the maximum response delay equals the last listener query interval.

When multiple multicast routers exist on the same subnet, the MLD querier is responsible for sending MLD query messages. If a non-querier router receives no MLD query from the querier when the other querier present interval expires, it considers the querier as having failed and starts a new querier election. Otherwise, the non-querier resets the other querier present timer.

To avoid frequent MLD querier changes, set the other querier present interval greater than the MLD query interval.

To avoid incorrect multicast group member removals, set the MLD query interval greater than the maximum response delay for MLD general queries.

Configuration procedure

To configure MLD query and response parameters globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD view.	mld	N/A
3. Configure the MLD querier's robustness variable.	robust-count <i>robust-value</i>	2 times by default. A higher robustness variable makes the MLD querier more robust but results in a longer IPv6 multicast group timeout time.
4. Configure the startup query interval.	startup-query-interval <i>interval</i>	By default, the startup query interval is 1/4 of the "MLD query interval".
5. Configure the startup query count.	startup-query-count <i>value</i>	By default, the startup query count is set to the MLD querier's robustness variable.

Step	Command	Remarks
6. Configure the MLD query interval.	timer query <i>interval</i>	125 seconds by default.
7. Configure the maximum response delay for MLD general query messages.	max-response-time <i>interval</i>	10 seconds by default.
8. Configure the MLD last listener query interval.	last-listener-query-interval <i>interval</i>	1 second by default.
9. Configure the MLD other querier present interval.	timer other-querier-present <i>interval</i>	By default, the other querier present interval is determined by the formula "Other querier present interval (in seconds) = [MLD query interval] × [MLD querier's robustness variable] + [maximum response delay for MLD general query] / 2".

To configure MLD query and response parameters on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the MLD querier's robustness variable.	mld robust-count <i>robust-value</i>	2 times by default.
4. Configure the startup query interval.	mld startup-query-interval <i>interval</i>	By default, the startup query interval is 1/4 of the "MLD query interval".
5. Configure the startup query count.	mld startup-query-count <i>value</i>	By default, the startup query count is the same as the robustness variable.
6. Configure the MLD query interval.	mld timer query <i>interval</i>	125 seconds by default.
7. Configure the maximum response delay for MLD general query messages.	mld max-response-time <i>interval</i>	10 seconds by default.
8. Configure the MLD last listener query interval.	mld last-listener-query-interval <i>interval</i>	1 second by default.
9. Configure the MLD other querier present interval.	mld timer other-querier-present <i>interval</i>	By default, the other querier present interval is determined by the formula "Other querier present interval (in seconds) = [MLD query interval] × [MLD querier's robustness variable] + [maximum response delay for MLD general query] / 2".

Configuring MLD fast-leave processing

In some applications, such as ADSL dial-up networking, only one multicast receiver host is attached to a port of the MLD querier. To allow fast response to the MLD done messages of the host when it switches frequently from one IPv6 multicast group to another, you can enable MLD fast-leave processing on the MLD querier.

With fast-leave processing enabled, after receiving an MLD done message from a host, the MLD querier sends a leave notification to the upstream immediately without first sending MLD multicast-address-specific queries. In this way, the leave latency is reduced on one hand, and the network bandwidth is saved on the other hand.

Configuring MLD fast-leave processing globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD view.	mld	N/A
3. Configure MLD fast-leave processing.	fast-leave [group-policy <i>acl6-number</i>]	Disabled by default.

Configuring MLD fast-leave processing on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure MLD fast-leave processing.	mld fast-leave [group-policy <i>acl6-number</i>]	Disabled by default.

NOTE:

The MLD fast-leave processing configuration is effective on Layer 3 interfaces other than VLAN interfaces, including Layer 3 Ethernet ports, Layer 3 aggregate interfaces, and Tunnel interfaces.

Enabling the MLD host tracking function

With the MLD host tracking function, the switch can record the information of the member hosts that are receiving IPv6 multicast traffic, including the host IPv6 address, running duration, and timeout time. You can monitor and manage the member hosts according to the recorded information.

Enabling the MLD host tracking function globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD view.	mld	N/A
3. Configure the MLD host tracking function globally.	host-tracking	Disabled by default

Enabling the MLD host tracking function on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Enable the MLD host tracking function on the interface.	mld host-tracking	Disabled by default

Setting the DSCP value for MLD messages

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD view.	mld	N/A
3. Set the DSCP value for MLD messages.	dscp <i>dscp-value</i>	Optional. By default, the DSCP value in MLD messages is 48.

Configuring MLD SSM mapping

Because of some possible restrictions, some receiver hosts on an SSM network might run MLDv1. To provide SSM service support for these receiver hosts, you need to configure the MLD SSM mapping feature on the last hop router.

Configuration prerequisites

Before you configure the MLD SSM mapping feature, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain can be interoperable at the network layer.
- Configure basic MLD functions.

Enabling MLD SSM mapping

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Enable the MLD SSM mapping feature.	mld ssm-mapping enable	Disabled by default

NOTE:

To ensure SSM service for all hosts on a subnet, regardless of the MLD version running on the hosts, enable MLDv2 on the interface that forwards IPv6 multicast traffic onto the subnet.

Configuring MLD SSM mappings

By performing this configuration multiple times, you can map an IPv6 multicast group to different IPv6 multicast sources.

If MLDv2 is enabled on a VLAN interface of a switch, and if a port in that VLAN is configured as a simulated host, the simulated host will send MLDv2 reports even if you did not specify an IPv6 multicast source when you configure simulated joining with the **mld-snooping host-join** command. In this case, the corresponding IPv6 multicast group will not be created based on the configured MLD SSM mappings. For more information about the **mld-snooping host-join** command, see *IP Multicast Command Reference*.

To configure an MLD SSM mapping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter MLD view.	mld	N/A
3. Configure an MLD SSM mapping.	ssm-mapping <i>ipv6-group-address</i> <i>prefix-length</i> <i>ipv6-source-address</i>	No MLD mappings are configured by default.

Configuring MLD proxying

Configuration prerequisites

Before you configure the MLD proxying feature, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Enable IPv6 multicast routing.

Enabling MLD proxying

You can enable MLD proxying on the interface in the direction toward the root of the multicast forwarding tree to make the device serve as an MLD proxy.

Configuration guidelines

- Each device can have only one interface serving as the MLD proxy interface.
- You cannot enable MLD on interfaces with MLD proxying enabled. Moreover, only the **mld require-router-alert**, **mld send-router-alert**, and **mld version** commands can take effect on such interfaces.
- You cannot enable other IPv6 multicast routing protocols (such as IPv6 PIM-DM or IPv6 PIM-SM) on interfaces with MLD proxying enabled, or vice versa. However, the **source-lifetime**, **source-policy**, and **ssm-policy** commands configured in IPv6 PIM view can still take effect.
- You cannot enable MLD proxying on a VLAN interface with MLD snooping enabled, or vice versa.

Configuration procedure

To enable MLD proxying:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the MLD proxying feature.	mld proxying enable	Disabled by default

Configuring IPv6 multicast forwarding on a downstream interface

Typically, to avoid duplicate multicast flows, only queriers can forward IPv6 multicast traffic. On MLD proxy devices, a downstream interface must be a querier in order to forward IPv6 multicast traffic to downstream hosts. If the interface has failed in the querier election, you must manually enable IPv6 multicast forwarding on this interface.

ⓘ IMPORTANT:

On a multi-access network with more than one MLD proxy devices, you cannot enable IPv6 multicast forwarding on any other non-querier downstream interface after one of the downstream interfaces of these MLD proxy devices has been elected as the querier. Otherwise, duplicate multicast flows might be received on the multi-access network.

To enable IPv6 multicast forwarding on a downstream interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable IPv6 multicast forwarding on a non-querier downstream interface.	mld proxying forwarding	Disabled by default

Displaying and maintaining MLD

Task	Command	Remarks
Display MLD group information.	display mld group [<i>ipv6-group-address</i> interface <i>interface-type interface-number</i>] [static verbose] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display Layer 2 port information about MLD groups.	display mld group port-info [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [verbose] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display information about the hosts tracked by MLD on an interface.	display mld host interface <i>interface-type interface-number</i> group <i>ipv6-group-address</i> [source <i>ipv6-source-address</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the hosts tracked by MLD on the Layer 2 ports.	display mld host port-info vlan <i>vlan-id</i> group <i>ipv6-group-address</i> [source <i>ipv6-source-address</i>] [vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MLD configuration and running information on the specified interface or all MLD-enabled interfaces.	display mld interface [<i>interface-type interface-number</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information of the MLD proxying groups.	display mld proxying group [<i>group-address</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the information of the MLD routing table.	display mld routing-table [<i>ipv6-source-address</i> [<i>prefix-length</i>] <i>ipv6-group-address</i> [<i>prefix-length</i>] flags { act suc }] * [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display MLD SSM mappings.	display mld ssm-mapping <i>ipv6-group-address</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the IPv6 multicast group information created based on the configured MLD SSM mappings.	display mld ssm-mapping group [<i>ipv6-group-address</i> interface <i>interface-type interface-number</i>] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the hosts that join based on the MLD SSM mappings on an interface.	display mld ssm-mapping host interface <i>interface-type</i> <i>interface-number</i> group <i>ipv6-group-address</i> source <i>ipv6-source-address</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Remove the dynamic group entries of a specified MLD group or all MLD groups.	reset mld group { all interface <i>interface-type interface-number</i> { all <i>ipv6-group-address</i> [<i>prefix-length</i>] [<i>ipv6-source-address</i> [<i>prefix-length</i>]] } }	Available in user view

Task	Command	Remarks
Remove the dynamic Layer 2 port entries of a specified MLD group or all MLD groups.	reset mld group port-info { all <i>ipv6-group-address</i> } [vlan <i>vlan-id</i>]	Available in user view
Clear MLD SSM mappings.	reset mld ssm-mapping group { all interface <i>interface-type</i> <i>interface-number</i> { all <i>ipv6-group-address</i> [<i>prefix-length</i>] [<i>ipv6-source-address</i> [<i>prefix-length</i>]] } }	Available in user view

! **IMPORTANT:**

The **reset mld group** command might cause an interruption of receivers' reception of multicast data.

The **reset mld group** command cannot remove dynamic MLD group entries.

The **reset mld group port-info** command cannot remove the Layer 2 port entries of MLD groups.

The **display mld host interface** command can display information about the hosts tracked by MLD on Layer 3 interfaces other than VLAN interfaces.

The **display mld ssm-mapping host interface** command can display information about the hosts that join the group based on MLD SSM mappings on Layer 3 interfaces other than VLAN interfaces.

MLD configuration examples

Basic MLD functions configuration example

Network requirements

As shown in [Figure 87](#), receivers receive VOD information in the multicast mode. Receivers of different organizations form stub networks N1 and N2, and Host A and Host C are multicast receivers in N1 and N2 respectively.

MLDv1 runs between Switch A and N1. MLDv1 runs between the other two switches (Switch B and Switch C) and N2. Switch B acts as the MLD querier because it has a lower IPv6 address.

The hosts in N1 can join only IPv6 multicast group FF1E::101, and the hosts in N2 can join any IPv6 multicast groups.

Figure 87 Network diagram

Configuration procedure

1. Enable IPv6 forwarding and configure IPv6 addresses and IPv6 unicast routing:

Enable IPv6 forwarding on each switch and configure an IP address and prefix length for each interface as shown in [Figure 87](#). (Details not shown.)

Configure OSPFv3 for interoperation between the switches. Ensure the network-layer interoperation among the switches on the IPv6 PIM network and dynamic update of routing information between the switches through a unicast routing protocol. (Details not shown.)
2. Enable the IPv6 multicast routing, and enable IPv6 PIM-DM and MLD:

Enable IPv6 multicast routing on Switch A, enable IPv6 PIM-DM on each interface, and enable MLD on VLAN-interface 100.

```
<SwitchA> system-view
[SwitchA] multicast ipv6 routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] mld enable
[SwitchA-Vlan-interface100] pim ipv6 dm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim ipv6 dm
[SwitchA-Vlan-interface101] quit
```

Enable IPv6 multicast routing on Switch B, enable IPv6 PIM-DM on each interface, and enable MLD on VLAN-interface 200.

```
<SwitchB> system-view
[SwitchB] multicast ipv6 routing-enable
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] mld enable
[SwitchB-Vlan-interface200] pim ipv6 dm
[SwitchB-Vlan-interface200] quit
```

```
[SwitchB] interface vlan-interface 201
[SwitchB-Vlan-interface201] pim ipv6 dm
[SwitchB-Vlan-interface201] quit
```

Enable IPv6 multicast routing on Switch C, enable IPv6 PIM-DM on each interface, and enable MLD on VLAN-interface 200.

```
<SwitchC> system-view
[SwitchC] multicast ipv6 routing-enable
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] mld enable
[SwitchC-Vlan-interface200] pim ipv6 dm
[SwitchC-Vlan-interface200] quit
[SwitchC] interface vlan-interface 202
[SwitchC-Vlan-interface202] pim ipv6 dm
[SwitchC-Vlan-interface202] quit
```

3. Configure an IPv6 multicast group filter:

Configure an IPv6 multicast group filter on Switch A, so that the hosts connected to VLAN-interface 100 can join IPv6 multicast group FF1E::101 only.

```
[SwitchA] acl ipv6 number 2001
[SwitchA-acl6-basic-2001] rule permit source ffe::101 128
[SwitchA-acl6-basic-2001] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] mld group-policy 2001
[SwitchA-Vlan-interface100] quit
```

4. Verify the configuration:

Use the **display mld interface** command to display the MLD configuration and running information on each switch interface. Example:

Display MLD information on VLAN-interface 200 of Switch B.

```
[SwitchB] display mld interface vlan-interface 200
Vlan-interface200(FE80::200:5EFF:FE66:5100):
  MLD is enabled
  Current MLD version is 1
  Value of query interval for MLD(in seconds): 125
  Value of other querier present interval for MLD(in seconds): 255
  Value of maximum query response time for MLD(in seconds): 10
  Querier for MLD: FE80::200:5EFF:FE66:5100 (this router)
Total 1 MLD Group reported
```

MLD SSM mapping configuration example

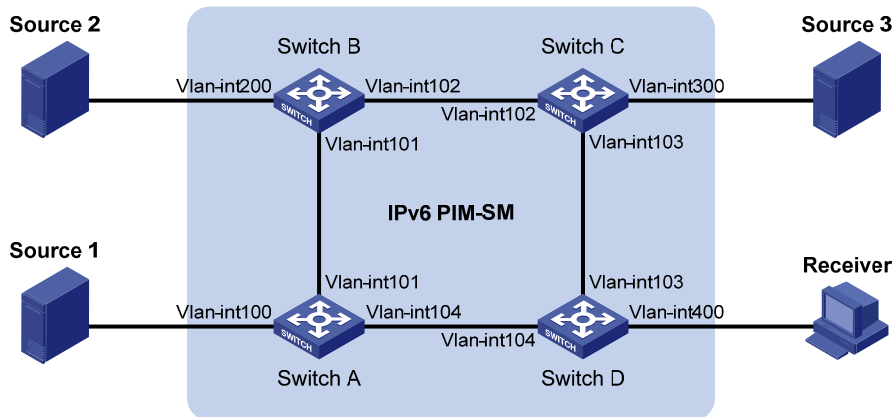

Network requirements

As shown in [Figure 88](#), the IPv6 PIM-SM domain applies both the ASM model and SSM model for IPv6 multicast delivery. Switch D's VLAN-interface 104 serves as the C-BSR and C-RP. The SSM group range is FF3E::/64.

MLDv2 runs on Switch D's VLAN-interface 400. The receiver host runs MLDv1, and does not support MLDv2. Therefore, the Receiver host cannot specify expected multicast sources in its membership reports.

Source 1, Source 2, and Source 3 send IPv6 multicast packets to multicast groups in the IPv6 SSM group range. You can configure the MLD SSM mapping feature on Switch D so that the receiver host will receive IPv6 multicast data from Source 1 and Source 3 only.

Figure 88 Network diagram

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Source 1	—	1001::1/64	Source 3	—	3001::1/64
Source 2	—	2001::1/64	Receiver	—	4001::1/64
Switch A	Vlan-int100	1001::2/64	Switch C	Vlan-int300	3001::2/64
	Vlan-int101	1002::1/64		Vlan-int103	3002::1/64
	Vlan-int104	1003::1/64		Vlan-int102	2002::2/64
Switch B	Vlan-int200	2001::2/64	Switch D	Vlan-int400	4001::2/64
	Vlan-int101	1002::2/64		Vlan-int103	3002::2/64
	Vlan-int102	2002::1/64		Vlan-int104	1003::2/64

Configuration procedure

1. Enable IPv6 forwarding and configure IPv6 addresses and IPv6 unicast routing:
 Enable IPv6 forwarding on each switch and configure an IPv6 address and prefix length for each interface as shown in [Figure 88](#). (Details not shown.)
 Configure OSPFv3 for interoperability among the switches. Ensure the network-layer interoperation on the IPv6 PIM-SM domain and dynamic update of routing information among the switches through an IPv6 unicast routing protocol. (Details not shown.)
2. Enable IPv6 multicast routing, enable IPv6 PIM-SM on each interface and enable MLD and MLD SSM mapping on the host-side interface:

Enable IPv6 multicast routing on Switch D, enable IPv6 PIM-SM on each interface, and enable MLD (version 2) and MLD SSM mapping on VLAN-interface 400.

```
<SwitchD> system-view
[SwitchD] multicast ipv6 routing-enable
[SwitchD] interface vlan-interface 400
[SwitchD-Vlan-interface400] mld enable
[SwitchD-Vlan-interface400] mld version 2
[SwitchD-Vlan-interface400] mld ssm-mapping enable
[SwitchD-Vlan-interface400] pim ipv6 sm
[SwitchD-Vlan-interface400] quit
```

```
[SwitchD] interface vlan-interface 103
[SwitchD-Vlan-interface103] pim ipv6 sm
[SwitchD-Vlan-interface103] quit
[SwitchD] interface vlan-interface 104
[SwitchD-Vlan-interface104] pim ipv6 sm
[SwitchD-Vlan-interface104] quit
```

Enable IPv6 multicast routing on Switch A, and enable IPv6 PIM-SM on each interface.

```
<SwitchA> system-view
[SwitchA] multicast ipv6 routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] pim ipv6 sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim ipv6 sm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface vlan-interface 104
[SwitchA-Vlan-interface104] pim ipv6 sm
[SwitchA-Vlan-interface104] quit
```

The configuration on Switch B and Switch C is similar to that on Switch A.

3. Configure a C-BSR and a C-RP:

Configure C-BSR and C-RP interfaces on Switch D.

```
[SwitchD] pim ipv6
[SwitchD-pim6] c-bsr 1003::2
[SwitchD-pim6] c-rp 1003::2
[SwitchD-pim6] quit
```

4. Configure the IPv6 SSM group range:

Configure the IPv6 SSM group range FF3E::/64 on Switch D.

```
[SwitchD] acl ipv6 number 2000
[SwitchD-acl6-basic-2000] rule permit source ff3e:: 64
[SwitchD-acl6-basic-2000] quit
[SwitchD] pim ipv6
[SwitchD-pim6] ssm-policy 2000
[SwitchD-pim6] quit
```

The configuration on Switch A, Switch B and Switch C is similar to that on Switch D.

5. Configure MLD SSM mappings:

Configure MLD SSM mappings on Switch D.

```
[SwitchD] mld
[SwitchD-mld] ssm-mapping ff3e:: 64 1001::1
[SwitchD-mld] ssm-mapping ff3e:: 64 3001::1
[SwitchD-mld] quit
```

6. Verify the configuration:

Display MLD SSM mapping information about the IPv6 multicast group FF3E::101 on Switch D.

```
[SwitchD] display mld ssm-mapping ff3e::101
Group: FF3E::101
Source list:
    1001::1
```

```

3001::1
# Display the IPv6 multicast group information created based on the configured MLD SSM
mappings on Switch D.
[SwitchD] display mld ssm-mapping group
Total 1 MLD SSM-mapping Group(s).
Interface group report information

```

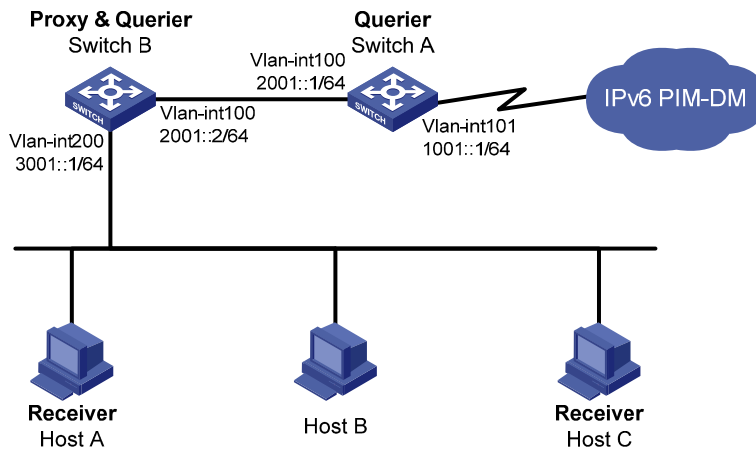

MLD proxying configuration example

Network requirements

As shown in [Figure 89](#), IPv6 PIM-DM runs on the core network. Host A and Host C in the stub network receive VOD information destined to multicast group FF3E::101.

Configure the MLD proxying feature on Switch B so that Switch B can maintain group memberships and forward IPv6 multicast traffic without running IPv6 PIM-DM.

Figure 89 Network diagram

Configuration procedure

1. Enable IPv6 forwarding and configure the IPv6 addresses:
Enable IPv6 forwarding on each switch and configure the IPv6 address and prefix length of each interface as per [Figure 89](#). (Details not shown.)
2. Enable IPv6 multicast routing, IPv6 PIM-DM, MLD, and MLD proxying:
Enable IPv6 multicast routing on Switch A, IPv6 PIM-DM on VLAN-interface 101, and MLD on VLAN-interface 100.

```
<SwitchA> system-view
[SwitchA] multicast ipv6 routing-enable
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim ipv6 dm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] mld enable
[SwitchA-Vlan-interface100] pim ipv6 dm
[SwitchA-Vlan-interface100] quit
```

Enable IPv6 multicast routing on Switch B, MLD proxying on VLAN-interface 100, and MLD on VLAN-interface 200.

```
<SwitchB> system-view
[SwitchB] multicast ipv6 routing-enable
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] mld proxying enable
[SwitchB-Vlan-interface100] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] mld enable
[SwitchB-Vlan-interface200] quit
```

3. Verify the configuration:
Display MLD configuration and operation information on VLAN-interface 100 of Switch B.

```
[SwitchB] display mld interface vlan-interface 100 verbose
Vlan-interface100(2001::2):
  MLD proxy is enabled
  Current MLD version is 1
  Multicast routing on this interface: enabled
```

```

Require-router-alert: disabled
# Display MLD group information on Switch A.
[SwitchA] display mld group
Total 1 MLD Group(s).
Interface group report information
Vlan-interface100(2001::1):
  Total 1 MLD Groups reported
  Group Address      Last Reporter      Uptime           Expires
  ff3e::101          2001::2            00:02:04         00:01:15

```

The output shows that the MLD reports sent from the hosts are forwarded to Switch A through the proxy interface, VLAN-interface 100 of Switch B.

Troubleshooting MLD

No member information on the receiver-side router

Symptom

When a host sends a message to announce its joining IPv6 multicast group G, no member information of multicast group G exists on the immediate router.

Analysis

- The correctness of networking and interface connections and whether the protocol layer of the interface is up directly affect the generation of IPv6 group member information.
- IPv6 multicast routing must be enabled on the router and MLD must be enabled on the interface connecting to the host.
- If the MLD version on the router interface is lower than that on the host, the router will not be able to recognize the MLD report from the host.
- If the **mld group-policy** command has been configured on an interface, the interface cannot receive report messages that fail to pass filtering.

Solution

1. Check that the networking, interface connections, and IP address configuration are correct. Check the interface information with the **display mld interface** command. If no information is output, the interface is in an abnormal state. This is usually because you have configured the **shutdown** command on the interface, the interface is not properly connected, or the IPv6 address configuration is not correctly done.
2. Use the **display current-configuration** command to verify that the IPv6 multicast routing is enabled. If not, carry out the **multicast ipv6 routing-enable** command in system view to enable IPv6 multicast routing. In addition, enable MLD on the corresponding interface.
3. You can use the **display mld interface** command to verify that the MLD version on the interface is lower than that on the host.
4. Use the **display current-configuration interface** command to verify that no ACL rule has been configured to restrict the host from joining IPv6 multicast group G. If an IPv6 ACL is configured to restrict the host from joining IPv6 multicast group G, the ACL must be modified to allow IPv6 multicast group G to receive report messages.

Inconsistent memberships on routers on the same subnet

Symptom

Different memberships are maintained on different MLD routers on the same subnet.

Analysis

- A router running MLD maintains multiple parameters for each interface, and these parameters influence one another, forming very complicated relationships. Inconsistent MLD interface parameter configurations for routers on the same subnet will surely result in inconsistent MLD memberships.
- Two MLD versions are available. Although routers running different MLD versions are compatible with hosts, all routers on the same subnet must run the same MLD version. Inconsistent MLD versions running on routers on the same subnet will also lead to inconsistent MLD memberships.

Solution

1. Use the **display current-configuration** command to verify the MLD configuration information on the interface.
2. Use the **display mld interface** command on all routers on the same subnet to check the MLD timers for inconsistent configuration.
3. Use the **display mld interface** command to verify that the routers are running the same MLD version.

Configuring IPv6 PIM (available only on the HP 5500 EI)

Overview

Protocol Independent Multicast for IPv6 (IPv6 PIM) provides IPv6 multicast forwarding by leveraging IPv6 unicast static routes or IPv6 unicast routing tables generated by any IPv6 unicast routing protocol, such as RIPng, OSPFv3, IS-ISv6, or BGP4+. IPv6 PIM uses an IPv6 unicast routing table to perform reverse path forwarding (RPF) check to implement IPv6 multicast forwarding. Independent of the IPv6 unicast routing protocols running on the device, IPv6 multicast routing can be implemented as long as the corresponding IPv6 multicast routing entries are created through IPv6 unicast routes. IPv6 PIM uses the reverse path forwarding (RPF) mechanism to implement IPv6 multicast forwarding. When an IPv6 multicast packet arrives on an interface of the device, RPF check is performed on it. If the RPF check succeeds, the device creates the corresponding routing entry and forwards the packet. If the RPF check fails, the device discards the packet. For more information about RPF, see "[Configuring IPv6 multicast routing and forwarding \(available only on the HP 5500 EI\)](#)."

Based on the implementation mechanism, IPv6 PIM supports the following types:

- Protocol Independent Multicast–Dense Mode for IPv6 (IPv6 PIM-DM)
- Protocol Independent Multicast–Sparse Mode for IPv6 (IPv6 PIM-SM)
- Bidirectional Protocol Independent Multicast for IPv6 (IPv6 BIDIR-PIM)
- Protocol Independent Multicast Source-Specific Multicast for IPv6 (IPv6 PIM-SSM)

To facilitate description, a network comprising IPv6 PIM–supporting routers is referred to as an "IPv6 PIM domain" in this document.

The term "router" in this document refers to both routers and Layer 3 switches.

The term "interface" in the IPv6 PIM features refers to Layer 3 interfaces, including VLAN interfaces and route-mode (or Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*).

IPv6 PIM-DM overview

IPv6 PIM-DM is a type of dense mode IPv6 multicast protocol. It uses the push mode for IPv6 multicast forwarding, and is suitable for small-sized networks with densely distributed IPv6 multicast members.

The basic implementation of IPv6 PIM-DM is as follows:

- IPv6 PIM-DM assumes that at least one IPv6 multicast group member exists on each subnet of a network. Therefore, IPv6 multicast data is flooded to all nodes on the network. Then, branches without IPv6 multicast forwarding are pruned from the forwarding tree, leaving only those branches that contain receivers. This flood-and-prune process takes place periodically. That is, pruned branches resume IPv6 multicast forwarding when the pruned state times out and then data is flooded again down these branches, and then the branches are pruned again.
- When a new receiver on a previously pruned branch joins an IPv6 multicast group, to reduce the join latency, IPv6 PIM-DM uses the graft mechanism to resume IPv6 multicast data forwarding to that branch.

In general, the IPv6 multicast forwarding path is a source tree. That is, it is a forwarding tree with the IPv6 multicast source as its "root" and IPv6 multicast group members as its "leaves." Because the source tree is the shortest path from the IPv6 multicast source to the receivers, it is also called "shortest path tree (SPT)."

The working mechanism of IPv6 PIM-DM is summarized as follows:

- Neighbor discovery
- SPT establishment
- Graft
- Assert

Neighbor discovery

In an IPv6 PIM domain, a PIM router discovers IPv6 PIM neighbors, maintains IPv6 PIM neighboring relationships with other routers, and builds and maintains SPTs by periodically multicasting IPv6 PIM hello messages to all other IPv6 PIM routers on the local subnet.

NOTE:

Every IPv6 PIM enabled interface on a router sends hello messages periodically and, therefore, learns the IPv6 PIM neighboring information pertinent to the interface.

SPT establishment

The process of constructing an SPT is the flood and prune process.

1. In an IPv6 PIM-DM domain, an IPv6 multicast source first floods IPv6 multicast packets when it sends IPv6 multicast data to IPv6 multicast group *G*. The packet undergoes an RPF check. If the packet passes the RPF check, the router creates an (*S*, *G*) entry and forwards the packet to all downstream nodes in the network. In the flooding process, an (*S*, *G*) entry is created on all the routers in the IPv6 PIM-DM domain.
2. The nodes without downstream receivers are pruned. A router that has no downstream receivers sends a prune message to the upstream node to notify the upstream node to delete the corresponding interface from the outgoing interface list in the (*S*, *G*) entry and stop forwarding subsequent packets addressed to that IPv6 multicast group down to this node.

An (*S*, *G*) entry contains the multicast source address *S*, IPv6 multicast group address *G*, outgoing interface list, and incoming interface.

For a given IPv6 multicast stream, the interface that receives the IPv6 multicast stream is referred to as "upstream," and the interfaces that forward the IPv6 multicast stream are referred to as "downstream."

A leaf router first initiates a prune process. As shown in [Figure 90](#), a router without any receiver attached to it (the router connected with Host A, for example) sends a prune message, and this prune process continues until only necessary branches remain in the IPv6 PIM-DM domain. These branches constitute the SPT.

Figure 90 SPT establishment in an IPv6 PIM-DM domain

The flood-and-prune process takes place periodically. A pruned state timeout mechanism is provided. A pruned branch restarts multicast forwarding when the pruned state times out and then is pruned again when it no longer has any multicast receiver.

NOTE:

Pruning has a similar implementation in IPv6 PIM-SM.

Graft

When a host attached to a pruned node joins an IPv6 multicast group, to reduce the join latency, IPv6 PIM-DM uses the graft mechanism to resume IPv6 multicast data forwarding to that branch. The process is as follows:

1. The node that needs to receive IPv6 multicast data sends a graft message toward its upstream node as a request to join the SPT again.
2. After receiving this graft message, the upstream node puts the interface on which the graft was received into the forwarding state and responds with a graft-ack message to the graft sender.
3. If the node that sent a graft message does not receive a graft-ack message from its upstream node, it keeps sending graft messages at a configurable interval until it receives an acknowledgment from its upstream node.

Assert

Where more than one multicast routers exists, the assert mechanism shuts off duplicate IPv6 multicast flows onto the same multi-access network. It does this by electing a unique IPv6 multicast forwarder on the multi-access network.

Figure 91 Assert mechanism

As shown in Figure 91, after Router A and Router B receive an (S, G) IPv6 multicast packet from the upstream node, they both forward the packet to the local subnet. As a result, the downstream node Router C receives two identical multicast packets, and both Router A and Router B, on their own local interface, receive a duplicate IPv6 multicast packet that the other has forwarded. After detecting this condition, both routers send an assert message to all IPv6 PIM routers on the local subnet through the interface that received the packet. The assert message contains the multicast source address (S), the multicast group address (G), and the preference and metric of the IPv6 unicast route/IPv6 MBGP route/IPv6 multicast static route to the source. By comparing these parameters, either Router A or Router B becomes the unique forwarder of the subsequent (S, G) IPv6 multicast packets on the multi-access subnet. The comparison process is as follows:

1. The router with a higher preference to the source wins.
2. If both routers have the same preference to the source, the router with a smaller metric to the source wins.
3. If a tie exists in the route metric to the source, the router with a higher IPv6 link-local address wins.

IPv6 PIM-SM overview

IPv6 PIM-DM uses the flood-and-prune principle to build SPTs for IPv6 multicast data distribution. Although an SPT has the shortest path, it is built with a low efficiency. Therefore the PIM-DM mode is not suitable for large-sized and medium-sized networks.

IPv6 PIM-SM is a type of sparse-mode IPv6 multicast protocol. It uses the pull mode for IPv6 multicast forwarding, and is suitable for large-sized and medium-sized networks with sparsely and widely distributed IPv6 multicast group members.

The basic implementation of IPv6 PIM-SM is as follows:

- IPv6 PIM-SM assumes that no hosts need to receive IPv6 multicast data. In the IPv6 PIM-SM mode, routers must specifically request a particular IPv6 multicast stream before the data is forwarded to them. The core task for IPv6 PIM-SM to implement IPv6 multicast forwarding will build and maintain rendezvous point trees (RPTs). An RPT is rooted at a router in the IPv6 PIM domain as the common node, or rendezvous point (RP), through which the IPv6 multicast data travels along the RPT and reaches the receivers.
- When a receiver is interested in the IPv6 multicast data addressed to a specific IPv6 multicast group, the router connected to this receiver sends a join message to the RP corresponding to that IPv6 multicast group. The path along which the message goes hop by hop to the RP forms a branch of the RPT.

- When an IPv6 multicast source sends IPv6 multicast streams to an IPv6 multicast group, the source-side designated router (DR) first registers the multicast source with the RP by sending register messages to the RP by unicast until it receives a register-stop message from the RP. The arrival of a register message at the RP triggers the establishment of an SPT. The IPv6 multicast source sends subsequent IPv6 multicast packets along the SPT to the RP. After reaching the RP, the IPv6 multicast packet is duplicated and delivered to the receivers along the RPT.

NOTE:

IPv6 multicast traffic is duplicated only where the distribution tree branches, and this process automatically repeats until the IPv6 multicast traffic reaches the receivers.

The working mechanism of IPv6 PIM-SM is summarized as follows:

- Neighbor discovery
- DR election
- RP discovery
- Embedded RP
- RPT establishment
- IPv6 Multicast source registration
- Switchover to SPT
- Assert

Neighbor discovery

IPv6 PIM-SM uses the similar neighbor discovery mechanism as IPv6 PIM-DM does. For more information, see "[Neighbor discovery](#)."

DR election

IPv6 PIM-SM also uses hello messages to elect a DR for a multi-access network (such as a LAN). The elected DR will be the only IPv6 multicast forwarder on this multi-access network.

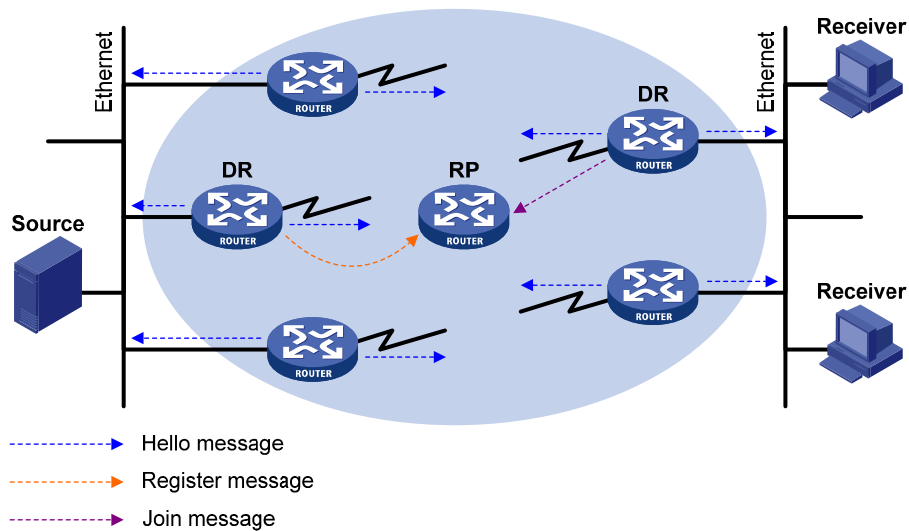

In the case of a multi-access network, a DR must be elected, no matter this network connects to IPv6 multicast sources or to receivers. The DR at the receiver side sends join messages to the RP; the DR at the IPv6 multicast source side sends register messages to the RP.

A DR is elected on a multi-access subnet by means of comparison of the priorities and IPv6 link-local addresses carried in hello messages.

MLD must be enabled on a device that acts as a receiver-side DR before receivers attached to this device can join IPv6 multicast groups through this DR.

For more information about MLD, see "[Configuring MLD \(available only on the HP 5500 EI\)](#)."

Figure 92 DR election

As shown in Figure 92, the DR election process is as follows:

1. Routers on the multi-access network send hello messages to one another. The hello messages contain the router priority for DR election. The router with the highest DR priority will become the DR.
2. In the case of a tie in the router priority, or if any router in the network does not support carrying the DR-election priority in hello messages, the router with the highest IPv6 link-local address will win the DR election.

When the DR works abnormally, a timeout in receiving hello message triggers a new DR election process among the other routers.

RP discovery

The RP is the core of an IPv6 PIM-SM domain. For a small-sized, simple network, one RP is enough for forwarding IPv6 multicast information throughout the network, and the position of the RP can be statically specified on each router in the IPv6 PIM-SM domain. In most cases, however, an IPv6 PIM-SM network covers a wide area and a huge amount of IPv6 multicast traffic must be forwarded through the RP. To lessen the RP burden and optimize the topological structure of the RPT, you can configure multiple candidate-RPs (C-RPs) in an IPv6 PIM-SM domain. Among them, an RP is dynamically elected through the bootstrap mechanism. Each elected RP serves a different multicast group range. For this purpose, you must configure a bootstrap router (BSR). The BSR serves as the administrative core of the IPv6 PIM-SM domain. An IPv6 PIM-SM domain can have only one BSR, but can have multiple candidate-BSRs (C-BSRs). If the BSR fails, a new BSR is automatically elected from the C-BSRs to avoid service interruption.

NOTE:

- An RP can serve IPv6 multiple multicast groups or all IPv6 multicast groups. Only one RP can serve a given IPv6 multicast group at a time.
 - A device can serve as a C-RP and a C-BSR at the same time.
-

As shown in Figure 93, each C-RP periodically unicasts its advertisement messages (C-RP-Adv messages) to the BSR. A C-RP-Adv message contains the address of the advertising C-RP and the IPv6 multicast group range it serves. The BSR collects these advertisement messages and chooses the appropriate C-RP information for each multicast group to form an RP-set, which is a database of mappings between IPv6

multicast groups and RPs. The BSR then encapsulates the RP-set in the bootstrap messages it periodically originates and floods the bootstrap messages (BSMs) to the entire IPv6 PIM-SM domain.

Figure 93 BSR and C-RPs

Based on the information in the RP-sets, all routers in the network can calculate the location of the corresponding RPs based on the following rules:

1. The C-RP with the highest priority wins.
2. If all the C-RPs have the same priority, their hash values are calculated through the hashing algorithm. The C-RP with the largest hash value wins.
3. If all the C-RPs have the same priority and hash value, the C-RP that has the highest IP address wins.

The hashing algorithm used for RP calculation is "Value (G, M, C_i) = (1103515245 * ((1103515245 * (G & M) + 12345) XOR C_i) + 12345) mod 2³¹."

Table 11 Values in the hashing algorithm

Value	Description
Value	Hash value.
G	The digest from the exclusive-or (XOR) operation between the 32-bit segments of the IPv6 multicast group address. For example, if the IPv6 multicast address is FFOE:C20:1A3:63::101, G = 0xFF0E0C20 XOR 0x01A30063 XOR 0x00000000 XOR 0x00000101.
M	Hash mask length.
C _i	The digest from the exclusive-or (XOR) operation between the 32-bit segments of the C-RP IPv6 address. For example, if the IPv6 address of the C-RP is 3FFE:B00:C18:1::10, C _i = 0x3FFE0B00 XOR 0x0C180001 XOR 0x00000000 XOR 0x00000010.
&	Logical operator of "and."
XOR	Logical operator of "exclusive-or."
mod	Modulo operator, which gives the remainder of an integer division.

Embedded RP

The embedded RP mechanism enables a router to resolve the RP address from an IPv6 multicast address so that the IPv6 multicast group is mapped to an RP. This RP can take the place of the statically configured RP or the RP dynamically calculated based on the BSR mechanism. The DR does not need to identify the RP address beforehand. The specific process is as follows.

At the receiver side, the following occur:

1. A receiver host initiates an MLD report to announce that it is joining an IPv6 multicast group.
2. After receiving the MLD report, the receiver-side DR resolves the RP address embedded in the IPv6 multicast address and sends a join message to the RP.

At the IPv6 multicast source side, the following occur:

1. The IPv6 multicast source sends IPv6 multicast traffic to the IPv6 multicast group.
2. The source-side DR resolves the RP address embedded in the IPv6 multicast address, and sends a register message to the RP.

RPT establishment

Figure 94 RPT establishment in an IPv6 PIM-SM domain

As shown in Figure 94, the process of building an RPT is as follows:

1. When a receiver joins IPv6 multicast group G, it uses an MLD report message to inform the directly connected DR.
2. After getting the IPv6 multicast group G's receiver information, the DR sends a join message, which is forwarded hop by hop to the RP that corresponds to the multicast group.
3. The routers along the path from the DR to the RP form an RPT branch. Each router on this branch generates a (*, G) entry in its forwarding table. The asterisk means any IPv6 multicast source. The RP is the root of the RPT, and the DRs are the leaves of the RPT.

The IPv6 multicast data addressed to the IPv6 multicast group G flows through the RP, reaches the corresponding DR along the established RPT, and finally is delivered to the receiver.

When a receiver is no longer interested in the IPv6 multicast data addressed to a multicast group G, the directly connected DR sends a prune message, which goes hop by hop along the RPT to the RP. After receiving the prune message, the upstream node deletes the interface connected with this downstream

node from the outgoing interface list and determines whether it has receivers for that IPv6 multicast group. If not, the router continues to forward the prune message to its upstream router.

Multicast source registration

The purpose of IPv6 multicast source registration will inform the RP about the existence of the IPv6 multicast source.

Figure 95 IPv6 multicast source registration

As shown in [Figure 95](#), the IPv6 multicast source registers with the RP as follows:

1. The IPv6 multicast source S sends the first IPv6 multicast packet to IPv6 multicast group G . After receiving the multicast packet, the DR that directly connects to the multicast source encapsulates the packet in a register message. Then it sends the message to the corresponding RP by unicast.
2. When the RP receives the register message, it extracts the multicast packet from the register message and forwards the multicast IPv6 multicast packet down the RPT, and sends an (S, G) join message hop by hop toward the IPv6 multicast source. The routers along the path from the RP to the IPv6 multicast source form an SPT branch. Each router on this branch generates an (S, G) entry in its forwarding table. The source-side DR is the root of the SPT, and the RP is the leaf of the SPT.
3. The subsequent IPv6 multicast data from the IPv6 multicast source travels along the established SPT to the RP, and then the RP forwards the data along the RPT to the receivers. When the IPv6 multicast traffic arrives at the RP along the SPT, the RP sends a register-stop message to the source-side DR by unicast to stop the source registration process.

NOTE:

The RP is configured to initiate an SPT switchover as described in this section. Otherwise, the DR at the IPv6 multicast source side keeps encapsulating multicast data in register messages and the registration process will not stop unless no outgoing interfaces exist in the (S, G) entry on the RP.

Switchover to SPT

In an IPv6 PIM-SM domain, an IPv6 multicast group corresponds to one RP and one RPT. Before the SPT switchover occurs, the DR at the IPv6 multicast source side encapsulates all multicast data destined to the multicast group in register messages and sends these messages to the RP. After receiving these register messages, the RP extracts the multicast data and sends the multicast data down the RPT to the DRs at the

receiver side. The RP acts as a transfer station for all IPv6 multicast packets. The whole process involves the following issues:

- The DR at the source side and the RP need to implement complicated encapsulation and de-encapsulation of IPv6 multicast packets.
- IPv6 multicast packets are delivered along a path that might not be the shortest one.
- An increase in IPv6 multicast traffic heavily burdens the RP, increasing the risk of failure.

To solve the issues, IPv6 PIM-SM allows an RP or the DR at the receiver side to initiate an SPT switchover process:

1. The RP initiates an SPT switchover process.

The RP can periodically check the passing-by IPv6 multicast packets. If it finds that the traffic rate exceeds a configurable threshold, the RP sends an (S, G) join message hop by hop toward the IPv6 multicast source to establish an SPT between the DR at the source side and the RP. Subsequent IPv6 multicast data travels along the established SPT to the RP.

For more information about the SPT switchover initiated by the RP, see "[Multicast source registration](#)."

2. The receiver-side DR initiates an SPT switchover process

After receiving the first IPv6 multicast packet, the receiver-side DR initiates an SPT switchover process, as follows:

- The receiver-side DR sends an (S, G) join message hop by hop toward the IPv6 multicast source. When the join message reaches the source-side DR, all the routers on the path have installed the (S, G) entry in their forwarding table, and thus an SPT branch is established.
- When the IPv6 multicast packets travel to the router where the RPT and the SPT deviate, the router drops the multicast packets received from the RPT and sends an RP-bit prune message hop by hop to the RP. After receiving this prune message, the RP sends a prune message toward the IPv6 multicast source (suppose only one receiver exists) to implement SPT switchover.
- IPv6 multicast data is directly sent from the source to the receivers along the SPT.

IPv6 PIM-SM builds SPTs through SPT switchover more economically than IPv6 PIM-DM does through the flood-and-prune mechanism.

Assert

IPv6 PIM-SM uses a similar assert mechanism as IPv6 PIM-DM does. For more information, see "[Assert](#)."

IPv6 BIDIR-PIM overview

In some many-to-many applications, such as multi-side video conference, there might be multiple receivers interested in multiple IPv6 multicast sources simultaneously. With IPv6 PIM-DM or IPv6 PIM-SM, each router along the SPT must create an (S, G) entry for each IPv6 multicast source, consuming a lot of system resources. IPv6 BIDIR-PIM is introduced to address this problem. Derived from IPv6 PIM-SM, IPv6 BIDIR-PIM builds and maintains bidirectional RPTs, each of which is rooted at an RP and connects IPv6 multiple multicast sources with multiple receivers. Traffic from the IPv6 multicast sources is forwarded through the RP to the receivers along the bidirectional RPT. In this case, each router needs to maintain only a (*, G) multicast routing entry, saving system resources.

IPv6 BIDIR-PIM is suitable for networks with dense multicast sources and dense receivers.

The working mechanism of IPv6 BIDIR-PIM is summarized as follows:

- Neighbor discovery

- RP discovery
- DF election
- Bidirectional RPT building

Neighbor discovery

IPv6 BIDIR-PIM uses the same neighbor discovery mechanism as IPv6 PIM-SM does. For more information, see "[Neighbor discovery](#)."

RP discovery

IPv6 BIDIR-PIM uses the same RP discovery mechanism as IPv6 PIM-SM does. For more information, see "[RP discovery](#)."

In IPv6 PIM-SM, an RP must be specified with a real IPv6 address. In IPv6 BIDIR-PIM, however, an RP can be specified with a virtual IPv6 address, which is called the rendezvous point address (RPA). The link corresponding to the RPA's subnet is called the rendezvous point link (RPL). All interfaces connected to the RPL can act as RPs, which back up one another.

In IPv6 BIDIR-PIM, an RPF interface is the interface pointing to an RP, and an RPF neighbor is the address of the next hop to the RP.

DF election

On a network segment with multiple multicast routers, the same multicast packets might be forwarded to the RP repeatedly. To address this issue, IPv6 BIDIR-PIM uses a DF election mechanism to elect a unique designated forwarder (DF) for each RP on every network segment within the IPv6 BIDIR-PIM domain, and allows only the DF to forward multicast data to the RP.

NOTE:

DF election is not necessary for an RPL.

Figure 96 DF election

As shown in [Figure 96](#), without the DF election mechanism, both Router B and Router C can receive multicast packets from Router A, and they might both forward the packets to downstream routers on the local subnet. As a result, the RP (Router E) receives duplicate multicast packets. With the DF election mechanism, once receiving the RP information, Router B and Router C initiate a DF election process for the RP:

1. Router B and Router C multicast DF election messages to all PIM routers (224.0.0.13). The election messages carry the RP's address, and the priority and metric of the unicast route, MBGP route, or multicast static route to the RP.
2. The router with a route of the highest priority becomes the DF.
3. In the case of a tie, the router with the route with the lowest metric wins the DF election.
4. In the case of a tie in the metric, the router with the highest link-local IPv6 address wins.

Bidirectional RPT building

A bidirectional RPT comprises a receiver-side RPT and a source-side RPT. The receiver-side RPT is rooted at the RP and takes the routers directly connected with the receivers as leaves. The source-side RPT is also rooted at the RP but takes the routers directly connected with the IPv6 multicast sources as leaves. The processes for building these two parts are different.

Figure 97 RPT building at the receiver side

As shown in [Figure 97](#), the process for building a receiver-side RPT is similar to that for building an RPT in IPv6 PIM-SM:

1. When a receiver joins IPv6 multicast group G , it uses an MLD message to inform the directly connected router.
2. After getting the receiver information, the router sends a join message, which is forwarded hop by hop to the RP of the IPv6 multicast group.
3. The routers along the path from the receiver's directly connected router to the RP form an RPT branch, and each router on this branch adds a $(*, G)$ entry to its forwarding table. The $*$ means any IPv6 multicast source.

When a receiver is no longer interested in the multicast data addressed to IPv6 multicast group G , the directly connected router sends a prune message, which goes hop by hop along the reverse direction of the RPT to the RP. After receiving the prune message, each upstream node deletes the interface connected with the downstream node from the outgoing interface list and checks whether it has receivers in that IPv6 multicast group. If not, the router continues to forward the prune message to its upstream router.

Figure 98 RPT building at the multicast source side

As shown in Figure 98, the process of building a source-side RPT is relatively simple:

1. When an IPv6 multicast source sends IPv6 multicast packets to IPv6 multicast group G, the DF in each network segment unconditionally forwards the packets to the RP.
2. The routers along the path from the source's directly connected router to the RP form an RPT branch. Each router on this branch adds a (*, G) entry to its forwarding table. The * means any IPv6 multicast source.

After a bidirectional RPT is built, multicast traffic is forwarded along the source-side RPT and receiver-side RPT from IPv6 multicast sources to receivers.

NOTE:

If a receiver and an IPv6 multicast source are at the same side of the RP, the source-side RPT and the receiver-side RPT might meet at a node before reaching the RP. In this case, IPv6 multicast packets from the IPv6 multicast source to the receiver are directly forwarded by the node to the receiver, instead of by the RP.

IPv6 administrative scoping overview

Division of IPv6 PIM-SM domains

Typically, an IPv6 PIM-SM/IPv6 BIDIR-PIM domain contains only one BSR, which is responsible for advertising RP-set information within the entire IPv6 PIM-SM/IPv6 BIDIR-PIM domain. The information for all multicast groups is forwarded within the network scope administered by the BSR. We call this IPv6 non-scoped BSR mechanism.

To implement refined management, an IPv6 PIM-SM/IPv6 BIDIR-PIM domain can be divided into one IPv6 global scope zone and multiple IPv6 administratively scoped zones (IPv6 admin-scope zones). We call this IPv6 administrative scoping mechanism.

The IPv6 administrative scoping mechanism effectively releases stress on the management in a single-BSR domain and enables provision of zone-specific services using private group addresses.

IPv6 admin-scope zones correspond to IPv6 multicast groups with different scope values in their group addresses. The boundary of the IPv6 admin-scope zone is formed by zone border routers (ZBRs). Each IPv6 admin-scope zone maintains one BSR, which serves multicast groups within a specific scope. IPv6 multicast protocol packets, such as assert messages and bootstrap messages, for a specific group range cannot cross the IPv6 admin-scope zone boundary. IPv6 multicast group ranges served by different IPv6 admin-scope zones can overlap. An IPv6 multicast group is valid only within its local IPv6 admin-scope zone, functioning as a private group address.

The IPv6 global scope zone maintains a BSR, which serves the IPv6 multicast groups with the Scope field in their group addresses being 14.

Relationship between IPv6 admin-scope zones and the IPv6 global scope zone

The IPv6 global scope zone and each IPv6 admin-scope zone have their own C-RPs and BSRs. These devices are effective only in their respective IPv6 admin-scope zones. That is, BSR election and RP election are implemented independently within each IPv6 admin-scope zone. Each IPv6 admin-scope zone has its own boundary. The multicast information cannot cross this border in either direction. A better understanding of the IPv6 global scope zone and IPv6 admin-scope zones should be based on geographical space and group address range.

- Geographical space

IPv6 admin-scope zones are logical zones specific to particular multicast groups. The multicast packets of these multicast groups are confined within the local IPv6 admin-scope zone and cannot cross the boundary of the zone.

Figure 99 Relationship between admin-scope zones and the global scope zone in geographic space

As shown in Figure 99, for multicast groups with the same Scope field in their group addresses, IPv6 admin-scope zones must be geographically separated from one another. Namely, a router must not serve different admin-scope zones. In other words, different admin-scope zones contain different routers, whereas the global scope zone covers all routers in the IPv6 PIM-SM/IPv6 BIDIR-PIM domain. Multicast packets that do not belong to any admin-scope zones can be transmitted in the entire IPv6 PIM-SM/IPv6 BIDIR-PIM domain.

- Multicast group address Scope field

As shown in Figure 100, the Scope field in each IPv6 multicast group address indicates the admin-scope zone the corresponding multicast group belongs to.

Figure 100 IPv6 multicast address format

The admin-scope zone range increases with the value of the Scope field. For example, value E indicates IPv6 global scope, which contains other admin-scope zones with the Scope field values smaller than E. Possible values of the Scope field are given in [Table 2](#).

Table 2 Values of the Scope field

Value	Meaning	Remarks
0, F	Reserved	N/A
1	Interface-local scope	N/A
2	Link-local scope	N/A
3	Subnet-local scope	IPv6 admin-scope zone
4	Admin-local scope	IPv6 admin-scope zone
5	Site-local scope	IPv6 admin-scope zone
6, 7, 9 through D	Unassigned	IPv6 admin-scope zone
8	Organization-local scope	IPv6 admin-scope zone
E	Global scope	IPv6 global-scope zone

IPv6 PIM-SSM overview

The source-specific multicast (SSM) model and the any-source multicast (ASM) model are opposites. The ASM model includes the IPv6 PIM-DM and IPv6 PIM-SM modes. You can implement the SSM model by leveraging part of the IPv6 PIM-SM technique. It is also called "IPv6 PIM-SSM."

The SSM model provides a solution for source-specific multicast. It maintains the relationships between hosts and routers through MLDv2.

In actual application, MLDv2 and part of IPv6 PIM-SM technique is adopted to implement the SSM model. In the SSM model, receivers know exactly where an IPv6 multicast source is located by using advertisements, consultancy, and so on. This model does not require RP or RPT, and it does not require a source registration process for the purpose of discovering IPv6 multicast sources in other IPv6 PIM domains.

In IPv6 PIM-SSM, the term "channel " refers to an IPv6 multicast group, and the term "channel subscription" refers to a join message.

The working mechanism of IPv6 PIM-SSM is summarized as follows:

- Neighbor discovery
- DR election
- SPT building

Neighbor discovery

IPv6 PIM-SSM uses the same neighbor discovery mechanism as in IPv6 PIM-SM. For more information, see "[Neighbor discovery](#)."

DR election

IPv6 PIM-SSM uses the same DR election mechanism as in IPv6 PIM-SM. For more information, see "[DR election](#)."

SPT building

The decision to build an RPT for IPv6 PIM-SM or an SPT for IPv6 PIM-SSM depends on whether the IPv6 multicast group that the receiver will join falls into the IPv6 SSM group range. The IPv6 SSM group range that IANA has reserved is FF3x::/32, where x represents any legal address scope.

Figure 101 Building an SPT in IPv6 PIM-SSM

As shown in [Figure 101](#), Hosts B and C are IPv6 multicast information receivers. They send an MLDv2 report message to the respective DRs to announce that they are interested in the information about the specific IPv6 multicast source S and that sent to the IPv6 multicast group G.

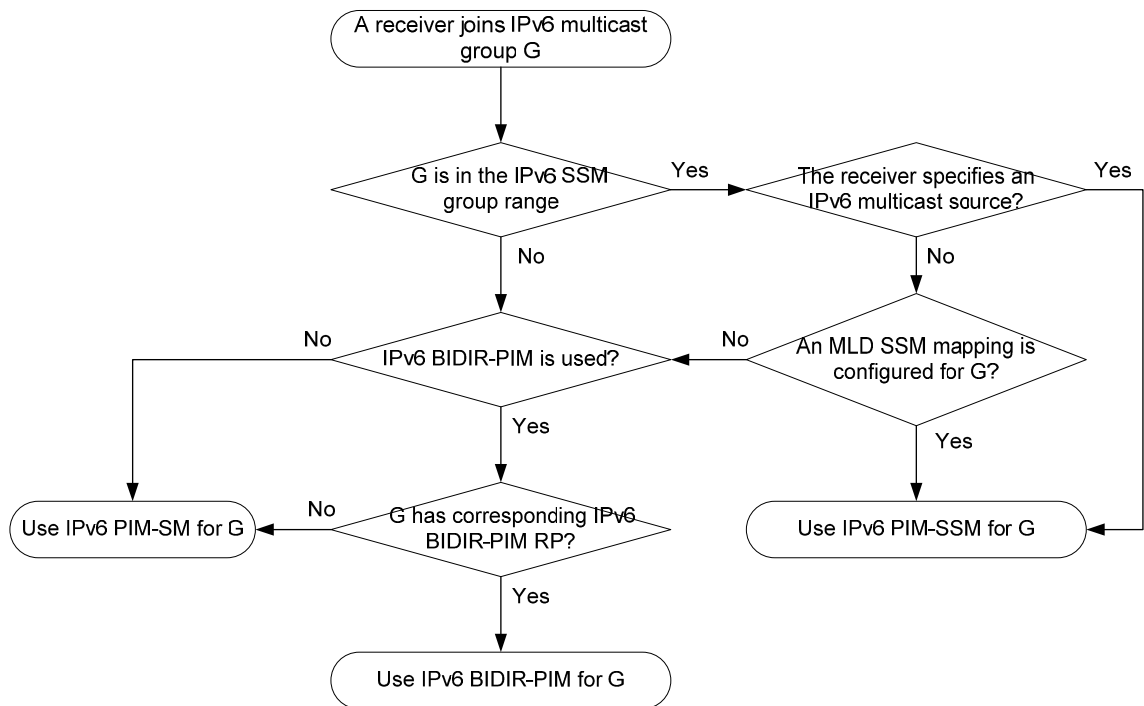

The DR that has received the report first determines whether the IPv6 group address in this message falls into the IPv6 SSM group range and then does the following:

- If the IPv6 group address in the message does fall into the IPv6 SSM group range, the IPv6 PIM-SSM model is built. The DR sends a channel subscription message hop by hop toward the IPv6 multicast source S. An (S, G) entry is created on all routers on the path from the DR to the source. Thus, an SPT is built in the network, with the source S as its root and receivers as its leaves. This SPT is the transmission channel in IPv6 PIM-SSM.
- If the IPv6 group address in the message does not fall into the IPv6 SSM group range, the DR follows the IPv6 PIM-SM process. The receiver-side DR sends a (*, G) join message to the RP, and the source-side DR registers the IPv6 multicast source.

Relationships among IPv6 PIM protocols

In an IPv6 PIM network, IPv6 PIM-DM cannot work with IPv6 PIM-SM, IPv6 BIDIR-PIM, or IPv6 PIM-SSM. However, IPv6 PIM-SM, IPv6 BIDIR-PIM, and IPv6 PIM-SSM can work together. When they work together, which one is chosen for a receiver trying to join a group depends, as shown in [Figure 102](#).

Figure 102 Relationships among IPv6 PIM protocols

For more information about MLD SSM mapping, see "[Configuring MLD \(available only on the HP 5500 EI\)](#)."

Configuring IPv6 PIM-DM

IPv6 PIM-DM configuration task list

Task	Remarks
Enabling IPv6 PIM-DM	Required
Enabling state-refresh capability	Optional
Configuring state refresh parameters	Optional
Configuring IPv6 PIM-DM graft retry period	Optional
Configuring IPv6 PIM common features	Optional

Configuration prerequisites

Before you configure IPv6 PIM-DM, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Determine the interval between state refresh messages.
- Determine the minimum time to wait before receiving a new refresh message.
- Determine the hop limit value of state-refresh messages.
- Determine the graft retry period.

Enabling IPv6 PIM-DM

With IPv6 PIM-DM enabled, a router sends hello messages periodically to discover IPv6 PIM neighbors and processes messages from the IPv6 PIM neighbors. When you deploy an IPv6 PIM-DM domain, enable IPv6 PIM-DM on all non-border interfaces of routers.

! IMPORTANT:

- All the interfaces of the same device must operate in the same IPv6 PIM mode.
- IPv6 PIM-DM cannot be used for IPv6 multicast groups in the IPv6 SSM group range.

To enable IPv6 PIM-DM:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6 multicast routing.	multicast ipv6 routing-enable	Disabled by default.
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable IPv6 PIM-DM.	pim ipv6 dm	Disabled by default.

For more information about the **multicast ipv6 routing-enable** command, see *IP Multicast Command Reference*.

Enabling state-refresh capability

Pruned interfaces resume multicast forwarding when the pruned state times out. To prevent this, the router directly connected with the IPv6 multicast source periodically sends an (S, G) state-refresh message, which is forwarded hop by hop along the initial flooding path of the IPv6 PIM-DM domain, to refresh the

prune timer state of all the routers on the path. A multi-access subnet can have the state-refresh capability only if the state-refresh capability is enabled on all IPv6 PIM routers on the subnet.

To enable the state-refresh capability:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Enable the state-refresh capability.	pim ipv6 state-refresh-capable	Optional. Enabled by default.

Configuring state refresh parameters

The router directly connected with the multicast source periodically sends state-refresh messages. You can configure the interval for sending such messages.

A router might receive multiple state-refresh messages within a short time. Some messages might be duplicated messages. To keep a router from receiving such duplicated messages, you can configure the time that the router must wait before receiving the next state-refresh message. If the router receives a new state-refresh message within the waiting time, it discards it. If this timer times out, the router will accept a new state-refresh message, refresh its own IPv6 PIM-DM state, and reset the waiting timer.

The hop limit value of a state-refresh message decrements by 1 whenever it passes a router before it is forwarded to the downstream node until the hop limit value comes down to 0. In a small network, a state-refresh message might cycle in the network. To control the propagation scope of state-refresh messages, you must configure an appropriate hop limit value based on the network size.

Perform the following configurations on all routers in the IPv6 PIM domain.

To configure state-refresh parameters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the interval between state-refresh messages.	state-refresh-interval <i>interval</i>	Optional. 60 seconds by default.
4. Configure the time to wait before receiving a new state-refresh message.	state-refresh-rate-limit <i>interval</i>	Optional. 30 seconds by default.
5. Configure the hop limit value of state-refresh messages.	state-refresh-hoplimit <i>hoplimit-value</i>	Optional. 255 by default.

Configuring IPv6 PIM-DM graft retry period

In IPv6 PIM-DM, graft is the only type of message that uses the acknowledgment mechanism. In an IPv6 PIM-DM domain, if a router does not receive a graft-ack message from the upstream router within the specified time after it sends a graft message, the router keeps sending new graft messages at a

configurable interval (namely, graft retry period) until it receives a graft-ack message from the upstream router.

To configure the IPv6 PIM-DM graft retry period:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the graft retry period.	pim ipv6 timer graft-retry <i>interval</i>	Optional. 3 seconds by default.

For more information about the configuration of other timers in IPv6 PIM-DM, see "[Configuring IPv6 PIM common timers](#)."

Configuring IPv6 PIM-SM

IPv6 PIM-SM configuration task list

Task	Remarks	
Enabling IPv6 PIM-SM	Required.	
Configuring an RP	Configuring a static RP	Required.
	Configuring a C-RP	Use any approach.
	Enabling embedded RP	
Configuring a BSR	Configuring C-RP timers globally	Optional.
	Configuring a C-BSR	Required.
	Configuring an IPv6 PIM domain border	Optional.
	Configuring C-BSR parameters globally	Optional.
	Configuring C-BSR timers	Optional.
Configuring IPv6 administrative scoping	Disabling BSM semantic fragmentation	Optional.
	Enabling IPv6 administrative scoping	Optional.
	Configuring an IPv6 admin-scope zone boundary	Optional.
Configuring IPv6 multicast source registration	Optional.	
Configuring C-BSRs for IPv6 admin-scope zones	Optional.	
Disabling SPT switchover	Optional.	
Configuring IPv6 PIM common features	Optional.	

Configuration prerequisites

Before you configure IPv6 PIM-SM, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Determine the IP address of a static RP and the ACL rule defining the range of IPv6 multicast groups to be served by the static RP.
- Determine the C-RP priority and the ACL rule defining the range of IPv6 multicast groups to be served by each C-RP.
- Determine the legal C-RP address range and the ACL rule defining the range of IPv6 multicast groups to be served.
- Determine the C-RP-Adv interval.
- Determine the C-RP timeout.
- Determine the C-BSR priority.
- Determine the hash mask length.
- Determine the IPv6 ACL rule defining a legal BSR address range.
- Determine the BS period.
- Determine the BS timeout.
- Determine the IPv6 ACL rule for register message filtering.
- Determine the register suppression time.
- Determine the register probe time.
- Determine the IPv6 ACL rule and sequencing rule for disabling an SPT switchover.

Enabling IPv6 PIM-SM

With IPv6 PIM-SM enabled, a router sends hello messages periodically to discover IPv6 PIM neighbors and processes messages from the IPv6 PIM neighbors. When you deploy an IPv6 PIM-SM domain, enable IPv6 PIM-SM on all non-border interfaces of the routers.

ⓘ IMPORTANT:

All the interfaces of the same device must operate in the same IPv6 PIM mode.

To enable IPv6 PIM-SM:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6 multicast routing.	multicast ipv6 routing-enable	Disabled by default.
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable IPv6 PIM-SM.	pim ipv6 sm	Disabled by default.

For more information about the **multicast ipv6 routing-enable** command, see *IP Multicast Command Reference*.

Configuring an RP

An RP can be manually configured or dynamically elected through the BSR mechanism. For a large IPv6 PIM network, static RP configuration is a tedious job. Generally, static RP configuration is just a backup

method for the dynamic RP election mechanism to enhance the robustness and operation manageability of a multicast network.

! **IMPORTANT:**

In an IPv6 PIM network, if both IPv6 PIM-SM and IPv6 BIDIR-PIM are enabled, do not configure the same RP to serve IPv6 PIM-SM and IPv6 BIDIR-PIM simultaneously to avoid IPv6 PIM routing table errors.

Configuring a static RP

If only one dynamic RP exists in a network, manually configuring a static RP can avoid communication interruption because of single-point failures. It can also avoid frequent message exchange between C-RPs and the BSR.

! **IMPORTANT:**

To enable a static RP to work normally, you must perform this configuration on all routers in the IPv6 PIM-SM domain and specify the same RP address.

Perform the following configuration on all the routers in the IPv6 PIM-SM domain.

To configure a static RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure a static RP for IPv6 PIM-SM.	static-rp <i>ipv6-rp-address</i> [<i>acl6-number</i>] [preferred]	No static RP by default.

Configuring a C-RP

In an IPv6 PIM-SM domain, you can configure routers that intend to become the RP as C-RPs. The BSR collects the C-RP information by receiving the C-RP-Adv messages from C-RPs or auto-RP announcements from other routers and organizes the information into an RP-set, which is flooded throughout the entire network. Then, the other routers in the network calculate the mappings between specific group ranges and the corresponding RPs based on the RP-set. HP recommends that you configure C-RPs on backbone routers.

To guard against C-RP spoofing, you need to configure a legal C-RP address range and the range of IPv6 multicast groups to be served on the BSR. In addition, because every C-BSR has a chance to become the BSR, you need to configure the same filtering policy on all C-BSRs in the IPv6 PIM-SM domain.

When you configure a C-RP, ensure a relatively large bandwidth between this C-RP and the other devices in the IPv6 PIM-SM domain.

An RP can serve multiple IPv6 multicast groups or all IPv6 multicast groups. Only one RP can forward IPv6 multicast traffic for an IPv6 multicast group at a moment.

To configure a C-RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A

Step	Command	Remarks
3. Configure an interface to be a C-RP for IPv6 PIM-SM.	c-rp <i>ipv6-address</i> [{ group-policy <i>acl6-number</i> scope <i>scope-id</i> } priority <i>priority</i> holdtime <i>hold-interval</i> advertisement-interval <i>adv-interval</i>] *	No C-RPs are configured by default.
4. Configure a legal C-RP address range and the range of IPv6 multicast groups to be served.	crp-policy <i>acl6-number</i>	Optional. No restrictions by default.

Enabling embedded RP

With the embedded RP feature enabled, the router can resolve the RP address directly from the IPv6 multicast group address of an IPv6 multicast packets. This RP can replace the statically configured RP or the RP dynamically calculated based on the BSR mechanism. Therefore, the DR does not need to identify the RP address beforehand.

Perform this configuration on all routers in the IPv6 PIM-SM domain.

To enable embedded RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Enable embedded RP.	embedded-rp [<i>acl6-number</i>]	Optional. By default, embedded RP is enabled for IPv6 multicast groups in the default embedded RP address scopes.

NOTE:

The default embedded RP address scopes are FF7x::/12 and FFFx::/12. Here "x" refers to any legal address scope. For more information about the Scope field, see "[Multicast overview](#)."

Configuring C-RP timers globally

To enable the BSR to distribute the RP-set information within the IPv6 PIM-SM domain, C-RPs must periodically send C-RP-Adv messages to the BSR. The BSR obtains the RP-set information from the received messages, and encapsulates its own IPv6 address together with the RP-set information in its bootstrap messages. The BSR then floods the bootstrap messages to all IPv6 routers in the network.

Each C-RP encapsulates a timeout value in its C-RP-Adv messages. After receiving a C-RP-Adv message, the BSR obtains this timeout value and starts a C-RP timeout timer. If the BSR fails to obtain a subsequent C-RP-Adv message from the C-RP when the timer times out, the BSR assumes the C-RP to have expired or become unreachable.

You must configure the C-RP timers on C-RP routers.

To configure C-RP timers globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A

Step	Command	Remarks
3. Configure the C-RP-Adv interval.	c-rp advertisement-interval <i>interval</i>	Optional. 60 seconds by default.
4. Configure C-RP timeout time.	c-rp holdtime <i>interval</i>	Optional. 150 seconds by default.

For more information about the configuration of other timers in IPv6 PIM-SM, see "[Configuring IPv6 PIM common timers.](#)"

Configuring a BSR

Configuration guidelines

Before you configure a BSR, make sure that you are familiar with BSR election process, BSR legal address against BSR spoofing, IPv6 PIM domain border, global C-BSR parameters, C-BSR timers, and bootstrap message fragments (BSMFs).

- BSR election process

An IPv6 PIM-SM domain can have only one BSR, but must have at least one C-BSR. Any router can be configured as a C-BSR. Elected from C-BSRs, the BSR is responsible for collecting and advertising RP information in the IPv6 PIM-SM domain.

You should configure C-BSRs on routers in the backbone network. When you configure a router as a C-BSR, be sure to specify the IPv6 address of an IPv6 PIM-SM-enabled interface on the router. The BSR election process is as follows:

- a. Initially, every C-BSR assumes itself to be the BSR of this IPv6 PIM-SM domain and uses its interface IPv6 address as the BSR address to send bootstrap messages.
 - b. When a C-BSR receives the bootstrap message of another C-BSR, it first compares its own priority with the other C-BSR's priority carried in the message. The C-BSR with a higher priority wins. If a tie exists in the priority, the C-BSR with a higher IPv6 address wins. The loser uses the winner's BSR address to replace its own BSR address and no longer assumes itself to be the BSR, and the winner keeps its own BSR address and continues assuming itself to be the BSR.
- BSR legal address against BSR spoofing

Configuring a legal range of BSR addresses enables filtering of bootstrap messages based on the address range, thereby preventing a maliciously configured host from masquerading as a BSR. You must make the same configuration on all routers in the IPv6 PIM-SM domain. Typical BSR spoofing cases and the corresponding preventive measures are as follows:

- Some maliciously configured hosts can forge bootstrap messages to fool routers and change RP mappings. Such attacks often occur on border routers. Because a BSR is inside the network whereas hosts are outside the network, you can protect a BSR against attacks from external hosts by enabling the border routers to perform neighbor checks and RPF checks on bootstrap messages and to discard unwanted messages.
- If an attacker controls a router in the network or if the network contains an illegal router, the attacker can configure this router as a C-BSR and make it win BSR election to control the right of advertising RP information in the network. After you configure a router as a C-BSR, the router automatically floods the network with bootstrap messages. Because a bootstrap message has a hop limit value of 1, the whole network will not be affected as long as the neighbor router discards these bootstrap messages. Therefore, with a legal BSR address range configured on

all routers in the entire network, all these routers will discard bootstrap messages from out of the legal address range.

These preventive measures can partially protect the security of BSRs in a network. However, if an attacker controls a legal BSR, the problem will still occur.

Because a large amount of information needs to be exchanged between a BSR and the other devices in the IPv6 PIM-SM domain, a relatively large bandwidth should be provided between the C-BSR and the other devices in the IPv6 PIM-SM domain.

- IPv6 PIM domain border

As the administrative core of an IPv6 PIM-SM domain, the BSR sends the collected RP-set information in the form of bootstrap messages to all routers in the IPv6 PIM-SM domain.

An IPv6 PIM domain border is a bootstrap message boundary. Each BSR has its specific service scope. IPv6 PIM domain border interfaces partition a network into different IPv6 PIM-SM domains. Bootstrap messages cannot cross a domain border in either direction.

- C-BSR parameters

In each IPv6 PIM-SM domain, a unique BSR is elected from C-BSRs. The C-RPs in the IPv6 PIM-SM domain send advertisement messages to the BSR. The BSR summarizes the advertisement messages to form an RP-set and advertises it to all routers in the IPv6 PIM-SM domain. All the routers use the same hash algorithm to get the RP address that corresponds to specific IPv6 multicast groups.

- C-BSR timers

The BSR election winner multicasts its own IPv6 address and RP-Set information throughout the region that it serves through bootstrap messages. The BSR floods bootstrap messages throughout the network at the interval of the BS (BSR state) period. Any C-BSR that receives a bootstrap message retains the RP-set for the length of BS timeout, during which no BSR election occurs. If no bootstrap message is received from the BSR before the BS timeout timer expires, a new BSR election process begins among the C-BSRs.

About the BS period:

- By default, the BS period is determined by the formula "BS period = (BS timeout – 10) / 2." The default BS timeout is 130 seconds, so the default BS period = (130 – 10) / 2 = 60 (seconds).
- If this parameter is manually configured, the system will use the configured value.

About the BS timeout timer:

- By default, the BS timeout value is determined by the formula "BS timeout timer = BS period × 2 + 10." The default BS period is 60 seconds, so the default BS timeout timer = 60 × 2 + 10 = 130 (seconds).
- If this parameter is manually configured, the system will use the configured value.

In the configuration, make sure that the BS period is smaller than the BS timeout value.

- Bootstrap message fragments (BSMFs)

Generally, a BSR periodically distributes the RP-set information in bootstrap messages within the IPv6 PIM-SM domain. It encapsulates a BSM in an IPv6 datagram and might split the datagram into fragments if the message exceeds the maximum transmission unit (MTU). In respect of such IP fragmentation, loss of a single IP fragment leads to unavailability of the entire message.

Semantic fragmentation of BSMs can solve this issue. When a BSM exceeds the MTU, it is split to multiple bootstrap message fragments (BSMFs).

- After receiving a BSMF that contains the RP-set information of one group range, a non-BSR router updates corresponding RP-set information directly.

- If the RP-set information of one group range is carried in multiple BSMFs, a non-BSR router updates corresponding RP-set information after receiving all these BSMFs.

Because the RP-set information contained in each segment is different, loss of some IP fragments will not result in dropping of the entire message.

The function of BSM semantic fragmentation is enabled by default. Devices not supporting this function might deem a fragment as an entire message and learn only part of the RP-set information. Therefore, if such devices exist in the IPv6 PIM-SM domain, you need to disable the semantic fragmentation function on the C-BSRs.

Generally, a BSR performs BSM semantic fragmentation according to the MTU of its BSR interface. However, the semantic fragmentation of BSMs originated because of learning of a new IPv6 PIM neighbor is performed according to the MTU of the outgoing interface.

Configuring a C-BSR

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure an interface as a C-BSR.	c-bsr <i>ipv6-address</i> [<i>hash-length</i> [<i>priority</i>]]	No C-BSRs are configured by default.
4. Configure a legal BSR address range.	bsr-policy <i>acl6-number</i>	Optional. No restrictions by default.

Configuring an IPv6 PIM domain border

Perform the following configuration on routers that you want to configure as an IPv6 PIM domain border.

To configure an IPv6 PIM border domain:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an IPv6 PIM domain border.	pim ipv6 bsr-boundary	No IPv6 PIM domain border is configured by default.

Configuring C-BSR parameters globally

Perform the following configuration on C-BSR routers.

To configure C-BSR parameters globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the hash mask length.	c-bsr hash-length <i>hash-length</i>	Optional. 126 by default.

Step	Command	Remarks
4. Configure the C-BSR priority.	c-bsr priority <i>priority</i>	Optional. 64 by default.

Configuring C-BSR timers

Perform the following configuration on C-BSR routers.

To configure C-BSR timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the BS period.	c-bsr interval <i>interval</i>	Optional. For the default value, see the note after this table.
4. Configure the BS timeout timer.	c-bsr holdtime <i>interval</i>	Optional. For the default value, see the note after this table.

Disabling BSM semantic fragmentation

To disable the BSM semantic fragmentation function:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Disable the BSM semantic fragmentation function.	undo bsm-fragment enable	By default, the BSM semantic fragmentation function is enabled.

Configuring IPv6 administrative scoping

With IPv6 administrative scoping disabled, an IPv6 PIM-SM domain has only one BSR. The BSR manages the whole network. To manage your network more effectively and specifically, you can partition the IPv6 PIM-SM domain into multiple IPv6 admin-scope zones. Each IPv6 admin-scope zone maintains a BSR, which serves a specific IPv6 multicast group range. The IPv6 global scope zone also maintains a BSR, which serves the IPv6 multicast groups with the Scope field in the group addresses being 14.

Enabling IPv6 administrative scoping

Before you configure an IPv6 admin-scope zone, you must enable IPv6 administrative scoping.

Perform the following configuration on all routers in the IPv6 PIM-SM domain.

To enable IPv6 administrative scoping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A

Step	Command	Remarks
3.	Enable IPv6 administrative scoping. c-bsr admin-scope	Disabled by default

Configuring an IPv6 admin-scope zone boundary

The boundary of each IPv6 admin-scope zone is formed by ZBRs. Each admin-scope zone maintains a BSR, which serves multicast groups with a specific Scope field in their group addresses. Multicast protocol packets (such as assert messages and bootstrap messages) that belong to this range cannot cross the admin-scope zone boundary.

Perform the following configuration on routers that you want to configure as a ZBR.

To configure an IPv6 admin-scope zone boundary:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter interface view. interface interface-type interface-number	N/A
3.	Configure an IPv6 multicast forwarding boundary. multicast ipv6 boundary { <i>ipv6-group-address prefix-length</i> scope { <i>scope-id</i> admin-local global organization-local site-local } }	By default, no multicast forwarding boundary is configured.

For more information about the **multicast ipv6 boundary** command, see *IP Multicast Command Reference*.

Configuring C-BSRs for IPv6 admin-scope zones

In a network with IPv6 administrative scoping enabled, BSRs are elected from C-BSRs specific to different Scope field values. The C-RPs in the network send advertisement messages to the specific BSR. The BSR summarizes the advertisement messages to form an RP-set and advertises it to all routers in the specific admin-scope zone. All the routers use the same hash algorithm to get the RP address corresponding to the specific IPv6 multicast group.

You can configure the hash mask length and C-BSR priority globally and in an IPv6 admin-scope zone.

- The values configured in the IPv6 admin-scope zone have preference over the global values.
- If you do not configure these parameters in the IPv6 admin-scope zone, the corresponding global values will be used.

For configuration of global C-BSR parameters, see "[Configuring C-BSR parameters globally.](#)"

Perform the following configuration on the routers that you want to configure as C-BSRs in IPv6 admin-scope zones.

To configure a C-BSR for an IPv6 admin-scope zone:

Step	Command	Remarks
1.	Enter system view. system-view	N/A
2.	Enter IPv6 PIM view. pim ipv6	N/A
3.	Configure a C-BSR for an IPv6 admin-scope zone. c-bsr scope { <i>scope-id</i> admin-local global organization-local site-local } [hash-length <i>hash-length</i> priority <i>priority</i>] *	No C-BSRs are configured for an IPv6 admin-scope zone by default.

Configuring IPv6 multicast source registration

Configuration guidelines

Within an IPv6 PIM-SM domain, the source-side DR sends register messages to the RP, and these register messages have different IPv6 multicast source or IPv6 multicast group addresses. You can configure a filtering rule to filter register messages so that the RP can serve specific IPv6 multicast groups. If the filtering rule denies an (S, G) entry, or if the filtering rule does not define an action for this entry, the RP will send a register-stop message to the DR to stop the registration process for the IPv6 multicast data.

In view of information integrity of register messages in the transmission process, you can configure the device to calculate the checksum based on the entire register messages. However, to reduce the workload of encapsulating data in register messages and for the sake of interoperability, HP does not recommend this method of checksum calculation.

When receivers stop receiving data addressed to a certain IPv6 multicast group through the RP (that is, the RP stops serving the receivers of that IPv6 multicast group), or when the RP starts receiving IPv6 multicast data from the IPv6 multicast source along the SPT, the RP sends a register-stop message to the source-side DR. After receiving this message, the DR stops sending register messages encapsulated with IPv6 multicast data and starts a register-stop timer. Before the register-stop timer expires, the DR sends a null register message (a register message without multicast data) to the RP. If the DR receives a register-stop message during the register probe time, it will reset its register-stop timer. Otherwise, the DR starts sending register messages with encapsulated data again when the register-stop timer expires.

The register-stop timer is set to a random value chosen uniformly from the interval (0.5 times register_suppression_time, 1.5 times register_suppression_time) minus register_probe_time.

Configure a filtering rule for register messages on all C-RP routers, and configure them to calculate the checksum based on the entire register messages. Configure the register suppression time and the register probe time on all routers that might become IPv6 source-side DRs.

Configuration procedure

To configure register-related parameters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure a filtering rule for register messages.	register-policy <i>acl6-number</i>	Optional. No register filtering rule by default.
4. Configure the device to calculate the checksum based on the entire register messages.	register-whole-checksum	Optional. Based on the header of register messages by default.
5. Configure the register suppression time.	register-suppression-timeout <i>interval</i>	Optional. 60 seconds by default.
6. Configure the register probe time.	probe-interval <i>interval</i>	Optional. 5 seconds by default.

Disabling SPT switchover

If an HP 5500 EI switch acts as an RP or the receiver-side DR, it initiates an SPT switchover process by default upon receiving the first IPv6 multicast packet along the RPT. You can disable the switchover from RPT to SPT.

! **IMPORTANT:**

For an HP 5500 EI switch, once an IPv6 multicast forwarding entry is created, subsequent IPv6 multicast data will not be encapsulated in register messages before being forwarded even if a register outgoing interface is available. Therefore, to avoid forwarding failure, do not use the **spt-switch-threshold infinity** command on a switch that might become an RP (namely, a static RP or a C-RP).

To configure SPT switchover:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Disable the SPT switchover.	spt-switch-threshold infinity [group-policy <i>acl6-number</i> [order <i>order-value</i>]]	Optional. By default, the device switches to the SPT immediately after it receives the first IPv6 multicast packet from the RPT.

Configuring IPv6 BIDIR-PIM

IPv6 BIDIR-PIM configuration task list

Task	Remarks	
Enabling IPv6 PIM-SM	Required.	
Enabling IPv6 BIDIR-PIM	Required.	
Configuring an RP	Configuring a static RP	Required.
	Configuring a C-RP	Use any approach.
	Enabling embedded RP	
	Configuring C-RP timers globally	Optional.
Configuring a BSR	Configuring a C-BSR	Required.
	Configuring an IPv6 BIDIR-PIM domain border	Optional.
	Configuring global C-BSR parameters	Optional.
	Configuring C-BSR timers	Optional.
	Disabling BSM semantic fragmentation	Optional.
Configuring IPv6 administrative scoping	Enabling IPv6 administrative scoping	Optional.
	Configuring an IPv6 admin-scope zone boundary	Optional.
	Configuring C-BSRs for each admin-scope zone	Optional.

Task	Remarks
Configuring IPv6 PIM common features	Optional.

Configuration prerequisites

Before you configure IPv6 BIDIR-PIM, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain can communicate with each other at Layer 3.
- Determine the IPv6 address of a static RP and the IPv6 ACL that defines the range of IPv6 multicast groups to be served by the static RP.
- Determine the C-RP priority and the IPv6 ACL that defines the range of IPv6 multicast groups to be served by each C-RP.
- Determine the legal C-RP address range and the IPv6 ACL that defines the range of IPv6 multicast groups to be served.
- Determine the C-RP-Adv interval.
- Determine the C-RP timeout.
- Determine the C-BSR priority.
- Determine the hash mask length.
- Determine the IPv6 ACL defining the legal BSR address range.
- Determine the BS period.
- Determine the BS timeout.

Enabling IPv6 PIM-SM

You must enable IPv6 PIM-SM before enabling IPv6 BIDIR-PIM because IPv6 BIDIR-PIM is implemented on the basis of IPv6 PIM-SM. To deploy an IPv6 BIDIR-PIM domain, enable IPv6 PIM-SM on all non-border interfaces of the domain.

ⓘ IMPORTANT:

On a router, all interfaces in the same VPN instance must operate in the same IPv6 PIM mode.

To enable IPv6 PIM-SM:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6 multicast routing.	multicast ipv6 routing-enable	Disabled by default
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable IPv6 PIM-SM.	pim ipv6 sm	Disabled by default

For more information about the **multicast ipv6 routing-enable** command, see *IP Multicast Command Reference*.

Enabling IPv6 BIDIR-PIM

Perform this configuration on all routers in the IPv6 BIDIR-PIM domain.

To enable IPv6 BIDIR-PIM:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Enable IPv6 BIDIR-PIM.	bidir-pim enable	Disabled by default

Configuring an RP

An RP can be manually configured or dynamically elected through the BSR mechanism. For a large IPv6 PIM network, static RP configuration is a tedious job. Generally, static RP configuration is just a backup means for the dynamic RP election mechanism to enhance the robustness and operation manageability of a multicast network.

! IMPORTANT:

In an IPv6 PIM network, if both IPv6 PIM-SM and IPv6 BIDIR-PIM are enabled, do not configure the same RP to serve IPv6 PIM-SM and IPv6 BIDIR-PIM simultaneously to avoid IPv6 PIM routing table errors.

Configuring a static RP

If only one dynamic RP exists in a network, manually configuring a static RP can avoid communication interruption because of single-point failures and avoid frequent message exchange between C-RPs and the BSR.

In IPv6 BIDIR-PIM, a static RP can be specified with a virtual IPv6 address. For example, if the IPv6 addresses of the interfaces at the two ends of a link are 1001::1/64 and 1001::2/64, you can specify a virtual IPv6 address, like 1001::100/64, for the static RP. As a result, the link becomes an RPL.

! IMPORTANT:

You must perform static RP configuration on all routers in the IPv6 PIM-SM domain and specify the same RP address.

Perform this configuration on all routers in the IPv6 BIDIR-PIM domain.

To configure a static RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure a static RP for IPv6 BIDIR-PIM.	static-rp <i>ipv6-rp-address</i> [<i>acl6-number</i>] [preferred] bidir	No static RP by default

Configuring a C-RP

In an IPv6 BIDIR-PIM domain, you can configure routers that intend to become the RP as C-RPs. The BSR collects the C-RP information by receiving the C-RP-Adv messages from C-RPs or auto-RP announcements

from other routers and organizes the information into an RP-set, which is flooded throughout the entire network. Then, the other routers in the network calculate the mappings between specific group ranges and the corresponding RPs based on the RP-set. HP recommends that you configure C-RPs on backbone routers.

To guard against C-RP spoofing, configure a legal C-RP address range and the range of multicast groups to be served on the BSR. In addition, because every C-BSR has a chance to become the BSR, you must configure the same filtering policy on all C-BSRs in the IPv6 BIDIR-PIM domain.

To configure a C-RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure an interface to be a C-RP for IPv6 BIDIR-PIM.	c-rp <i>ipv6-address</i> [{ group-policy <i>acl6-number</i> scope <i>scope-id</i> } priority <i>priority</i> holdtime <i>hold-interval</i> advertisement-interval <i>adv-interval</i>] * bidir	No C-RP is configured by default.

NOTE:

- When you configure a C-RP, ensure a relatively large bandwidth between this C-RP and the other devices in the IPv6 BIDIR-PIM domain.
- An RP can serve multiple IPv6 multicast groups or all IPv6 multicast groups. Only one RP can forward multicast traffic for an IPv6 multicast group at a moment.

Enabling embedded RP

With the embedded RP feature enabled, the router can resolve the RP address directly from the IPv6 multicast group address of an IPv6 multicast packets. This RP can replace the statically configured RP or the RP dynamically calculated based on the BSR mechanism. Thus, the DR does not need to know the RP address beforehand.

Perform this configuration on all routers in the IPv6 BIDIR-PIM domain.

To enable embedded RP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Enable embedded RP.	embedded-rp [<i>acl6-number</i>]	Optional. By default, embedded RP is enabled for IPv6 multicast groups in the default embedded RP address scopes.

NOTE:

The default embedded RP address scopes are FF7x::/12 and FFFx::/12, where x refers to any legal address scope. For more information about the Scope field, see "[Multicast overview](#)."

Configuring C-RP timers globally

To enable the BSR to distribute the RP-Set information within the IPv6 BIDIR-PIM domain, C-RPs must periodically send C-RP-Adv messages to the BSR. The BSR learns the RP-Set information from the received messages, and encapsulates its own IPv6 address together with the RP-Set information in its bootstrap messages. The BSR then floods the bootstrap messages to all IPv6 routers in the network.

Each C-RP encapsulates a timeout value in its C-RP-Adv messages. After receiving a C-RP-Adv message, the BSR obtains this timeout value and starts a C-RP timeout timer. If the BSR fails to hear a subsequent C-RP-Adv message from the C-RP when the timer times out, the BSR assumes the C-RP to have expired or become unreachable.

The C-RP timers need to be configured on C-RP routers.

To configure C-RP timers globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the C-RP-Adv interval.	c-rp advertisement-interval <i>interval</i>	Optional. 60 seconds by default.
4. Configure C-RP timeout time.	c-rp holdtime <i>interval</i>	Optional. 150 seconds by default.

For more information about the configuration of other timers in IPv6 PIM-SM, see "[Configuring IPv6 PIM common timers.](#)"

Configuring a BSR

Configuration guidelines

Before you configure a BSR, make sure that you are familiar with BSR election process, BSR legal address against BSR spoofing, IPv6 PIM domain border, global C-BSR parameters, C-BSR timers, and bootstrap message fragments (BSMFs). They operate the same way as in the PIM-SM domain. For more information, see "[Configuration guidelines.](#)"

Configuring a C-BSR

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure an interface as a C-BSR.	c-bsr <i>ipv6-address</i> [<i>hash-length</i> [<i>priority</i>]]	No C-BSRs are configured by default.
4. Configure a legal BSR address range.	bsr-policy <i>acl6-number</i>	Optional. No restrictions on BSR address range by default.

Configuring an IPv6 BIDIR-PIM domain border

Perform the following configuration on routers that you want to configure as the IPv6 BIDIR-PIM domain border.

To configure an IPv6 BIDIR-PIM domain border:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an IPv6 BIDIR-PIM domain border.	pim ipv6 bsr-boundary	By default, no IPv6 BIDIR-PIM domain border is configured.

Configuring global C-BSR parameters

Perform the following configuration on C-BSR routers.

To configure global C-BSR parameters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the hash mask length.	c-bsr hash-length <i>hash-length</i>	Optional. 126 by default.
4. Configure the C-BSR priority.	c-bsr priority <i>priority</i>	Optional. 64 by default.

Configuring C-BSR timers

Perform the following configuration on C-BSR routers.

To configure C-BSR timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the BS period.	c-bsr interval <i>interval</i>	Optional. For the default value, see the note after this table.
4. Configure the BS timeout timer.	c-bsr holdtime <i>interval</i>	Optional. For the default value, see the note after this table.

Disabling BSM semantic fragmentation

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Disable the BSM semantic fragmentation function.	undo bsm-fragment enable	By default, the BSM semantic fragmentation function is enabled.

Configuring IPv6 administrative scoping

With administrative scoping disabled, an IPv6 BIDIR-PIM domain has only one BSR. The BSR manages the whole network. To manage your network more effectively and specifically, you can partition the IPv6 BIDIR-PIM domain into multiple admin-scope zones. Each admin-scope zone maintains a BSR, which serves a specific multicast group range. The global scope zone also maintains a BSR, which serves all the rest multicast groups.

Enabling IPv6 administrative scoping

Before you configure an IPv6 admin-scope zone, you must enable IPv6 administrative scoping first.

Perform the following configuration on all routers in the IPv6 PIM-SM domain.

To enable IPv6 administrative scoping:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Enable IPv6 administrative scoping.	c-bsr admin-scope	Disabled by default

Configuring an IPv6 admin-scope zone boundary

The boundary of each IPv6 admin-scope zone is formed by ZBRs. Each admin-scope zone maintains a BSR, which serves a specific IPv6 multicast group range. IPv6 multicast packets (such as assert messages and bootstrap messages) that belong to this range cannot cross the admin-scope zone boundary.

Perform the following configuration on routers that you want to configure as a ZBR.

To configure an admin-scope zone boundary:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an IPv6 multicast forwarding boundary.	multicast ipv6 boundary { <i>ipv6-group-address prefix-length</i> scope { <i>scope-id</i> admin-local global organization-local site-local } }	By default, no IPv6 multicast forwarding boundary is configured.

For more information about the **multicast ipv6 boundary** command, see *IP Multicast Command Reference*.

Configuring C-BSRs for each admin-scope zone

In a network with administrative scoping enabled, group-range-specific BSRs are elected from C-BSRs. C-RPs in the network send advertisement messages to the specific BSR. The BSR summarizes the advertisement messages to form an RP-set and advertises it to all routers in the specific admin-scope zone. All the routers use the same hash algorithm to get the RP address corresponding to the specific multicast group.

You can configure the hash mask length and C-BSR priority globally, only in an IPv6 admin-scope zone, or both globally and in an IPv6 admin-scope zone.

- The values configured in the IPv6 admin-scope zone have preference over the global values.
- If you do not configure these parameters in the IPv6 admin-scope zone, the corresponding global values will be used.

For configuration of global C-BSR parameters, see "[Configuring global C-BSR parameters](#)."

Perform the following configuration on the routers that you want to configure as C-BSRs in admin-scope zones.

To configure a C-BSR for an admin-scope zone:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure a C-BSR for an admin-scope zone.	c-bsr scope { <i>scope-id</i> admin-local global organization-local site-local } [hash-length <i>hash-length</i> priority <i>priority</i>] *	No C-BSRs are configured for an admin-scope zone by default.

Configuring IPv6 PIM-SSM

ⓘ IMPORTANT:

The IPv6 PIM-SSM model needs the support of MLDv2. Be sure to enable MLDv2 on IPv6 PIM routers with receivers attached to them.

IPv6 PIM-SSM configuration task list

Task	Remarks
Enabling IPv6 PIM-SSM	Required
Configuring the IPv6 SSM group range	Optional
Configuring IPv6 PIM common features	Optional

Configuration prerequisites

Before you configure IPv6 PIM-SSM, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain are interoperable at the network layer.

- Determine the IPv6 SSM group range.

Enabling IPv6 PIM-SM

Configuration guidelines

The SSM model is implemented based on some subsets of IPv6 PIM-SM. Therefore, you must enable IPv6 PIM-SM before configuring IPv6 PIM-SSM.

When you deploy an IPv6 PIM-SSM domain, enable IPv6 PIM-SM on all non-border interfaces of routers.

All the interfaces of the same device must operate in the same IPv6 PIM mode.

Configuration procedure

To enable IPv6 PIM-SSM:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable IPv6 multicast routing.	multicast ipv6 routing-enable	Disabled by default
3. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable IPv6 PIM-SM.	pim ipv6 sm	Disabled by default

For more information about the **multicast ipv6 routing-enable** command, see *IP Multicast Command Reference*.

Configuring the IPv6 SSM group range

Configuration guidelines

Whether the information from an IPv6 multicast source is delivered to the receivers based on the IPv6 PIM-SSM model or the IPv6 PIM-SM model depends on whether the group address in the (S, G) channel subscribed by the receivers falls into the IPv6 SSM group range. All IPv6 PIM-SM-enabled interfaces assume that IPv6 multicast groups within this address range are using the IPv6 SSM model.

Make sure that the same IPv6 SSM group range is configured on all routers in the entire domain. Otherwise, IPv6 multicast data cannot be delivered through the IPv6 SSM model.

When a member of an IPv6 multicast group in the IPv6 SSM group range sends an MLDv1 report message, the device does not trigger a (*, G) join.

Configuration procedure

Perform the following configuration on all routers in the IPv6 PIM-SSM domain.

To configure the IPv6 SSM group range:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A

Step	Command	Remarks
3. Configure the IPv6 SSM group range.	<code>ssm-policy acl6-number</code>	Optional. FF3x::/32 by default, here "x" refers to any legal group scope.

Configuring IPv6 PIM common features

For the configuration tasks in this section:

- In IPv6 PIM view, the configuration is effective on all interfaces. In interface view, the configuration is effective on only the current interface.
- If the same function or parameter is configured in both IPv6 PIM view and interface view, the configuration in interface view has preference over the configuration in PIM view, regardless of the configuration sequence.

IPv6 PIM common feature configuration task list

Task	Remarks
Configuring an IPv6 multicast data filter	Optional
Configuring a hello message filter	Optional
Configuring IPv6 PIM hello options	Optional
Configuring the prune delay	Optional
Configuring IPv6 PIM common timers	Optional
Configuring join/prune message sizes	Optional
Configuring IPv6 PIM to work with BFD	Optional
Setting the DSCP value for IPv6 PIM messages	Optional

Configuration prerequisites

Before you configure IPv6 PIM common features, complete the following tasks:

- Enable IPv6 forwarding and configure an IPv6 unicast routing protocol so that all devices in the domain are interoperable at the network layer.
- Configure IPv6 PIM-DM (or IPv6 PIM-SM or IPv6 PIM-SSM).
- Determine the IPv6 ACL rule for filtering IPv6 multicast data.
- Determine the IPv6 ACL rule defining a legal source address range for hello messages.
- Determine the priority for DR election (global value/interface level value).
- Determine the IPv6 PIM neighbor timeout time (global value/interface value).
- Determine the prune message delay (global value/interface level value).
- Determine the prune override interval (global value/interface level value).
- Determine the prune delay.
- Determine the hello interval (global value/interface level value).
- Determine the maximum delay between hello message (interface level value).

- Determine the assert timeout time (global value/interface value).
- Determine the join/prune interval (global value/interface level value).
- Determine the join/prune timeout (global value/interface value).
- Determine the IPv6 multicast source lifetime.
- Determine the maximum size of join/prune messages.
- Determine the maximum number of (S, G) entries in a join/prune message.
- Determine the DSCP value for IPv6 PIM messages.

Configuring an IPv6 multicast data filter

Configuration guidelines

In either an IPv6 PIM-DM domain or an IPv6 PIM-SM domain, routers can check passing-by IPv6 multicast data based on the configured filtering rules and determine whether to continue forwarding the IPv6 multicast data. In other words, IPv6 PIM routers can act as IPv6 multicast data filters. These filters can help implement traffic control on one hand, and control the information available to downstream receivers to enhance data security on the other hand.

Generally, a smaller distance from the filter to the IPv6 multicast source results in a more remarkable filtering effect.

This filter works not only on independent IPv6 multicast data but also on IPv6 multicast data encapsulated in register messages.

Configuration procedure

To configure an IPv6 multicast data filter:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure an IPv6 multicast group filter.	source-policy <i>acl6-number</i>	No IPv6 multicast data filter by default

Configuring a hello message filter

Along with the wide applications of IPv6 PIM, the security requirement for the protocol is becoming increasingly demanding. The establishment of correct IPv6 PIM neighboring relationships is a prerequisite for secure application of IPv6 PIM. To guide against IPv6 PIM message attacks, you can configure a legal source address range for hello messages on interfaces of routers to ensure the correct IPv6 PIM neighboring relationships.

To configure a hello message filter:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
3. Configure a hello message filter.	<code>pim ipv6 neighbor-policy acl6-number</code>	No hello message filter by default

NOTE:

With the hello message filter configured, if hello messages of an existing IPv6 PIM neighbor fail to pass the filter, the IPv6 PIM neighbor will be removed automatically when it times out.

Configuring IPv6 PIM hello options

IPv6 PIM hello options

In either an IPv6 PIM-DM domain or an IPv6 PIM-SM domain, the hello messages sent among routers contain the following configurable options:

- **DR_Priority** (for IPv6 PIM-SM only)—Priority for DR election. The higher the priority is, the easier it is for the router to win DR election. You can configure this parameter on all the routers in a multi-access network directly connected to IPv6 multicast sources or receivers.
- **Holdtime**—The timeout time of IPv6 PIM neighbor reachability state. When this timer times out, if the router has received no hello message from an IPv6 PIM neighbor, it assumes that this neighbor has expired or become unreachable.
- **LAN_Prune_Delay**—The delay of prune messages on a multi-access network. This option consists of LAN-delay (namely, prune message delay), override-interval, and neighbor tracking flag. If the LAN-delay or override-interval values of different IPv6 PIM routers on a multi-access subnet are different, the largest value takes effect. If you want to enable neighbor tracking, be sure to enable the neighbor tracking feature on all IPv6 PIM routers on a multi-access subnet.

The LAN-delay setting will cause the upstream routers to delay forwarding received prune messages. The override-interval sets the length of time that a downstream router can wait before sending a prune override message. When a router receives a prune message from a downstream router, it does not perform the prune action immediately. Instead, it maintains the current forwarding state for a period of LAN-delay plus override-interval. If the downstream router needs to continue receiving IPv6 multicast data, it must send a join message within the prune override interval. Otherwise, the upstream route will perform the prune action when the period of LAN-delay plus override-interval times out.

A hello message sent from an IPv6 PIM router contains a generation ID option. The generation ID is a random value for the interface on which the hello message is sent. Normally, the generation ID of an IPv6 PIM router does not change unless the status of the router changes (for example, when IPv6 PIM is just enabled on the interface or the device is restarted). When the router starts or restarts sending hello messages, it generates a new generation ID. If an IPv6 PIM router finds that the generation ID in a hello message from the upstream router has changed, it assumes that the status of the upstream neighbor is lost or that the upstream neighbor has changed. In this case, it triggers a join message for state update.

If you disable join suppression (namely, enable neighbor tracking), be sure to disable the join suppression feature on all IPv6 PIM routers on a multi-access subnet. Otherwise, the upstream router will fail to explicitly track join messages from downstream routers.

Configuring hello options globally

Step	Command	Remarks
1. Enter system view.	<code>system-view</code>	N/A

Step	Command	Remarks
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the priority for DR election.	hello-option dr-priority <i>priority</i>	Optional. 1 by default.
4. Configure IPv6 PIM neighbor timeout time.	hello-option holdtime <i>interval</i>	Optional. 105 seconds by default.
5. Configure the prune message delay time (LAN-delay).	hello-option lan-delay <i>interval</i>	Optional. 500 milliseconds by default.
6. Configure the prune override interval.	hello-option override-interval <i>interval</i>	Optional. 2,500 milliseconds by default.
7. Disable join suppression.	hello-option neighbor-tracking	Enabled by default.

Configuring hello options on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the priority for DR election.	pim ipv6 hello-option dr-priority <i>priority</i>	Optional. 1 by default.
4. Configure IPv6 PIM neighbor timeout time.	pim ipv6 hello-option holdtime <i>interval</i>	Optional. 105 seconds by default.
5. Configure the prune message delay time (LAN-delay).	pim ipv6 hello-option lan-delay <i>interval</i>	Optional. 500 milliseconds by default.
6. Configure the prune override interval.	pim ipv6 hello-option override-interval <i>interval</i>	Optional. 2500 milliseconds by default.
7. Disable join suppression.	pim ipv6 hello-option neighbor-tracking	Enabled by default.
8. Configure the interface to reject hello messages without a generation ID.	pim ipv6 require-genid	By default, hello messages without Generation_ID are accepted.

Configuring the prune delay

Configuring the prune delay interval on an upstream router in a shared network segment can make the upstream router not perform the prune action immediately after receiving the prune message from its downstream router. Instead, the upstream router maintains the current forwarding state for a period of time that the prune delay interval defines. In this period, if the upstream router receives a join message from the downstream router, it cancels the prune action. Otherwise, it performs the prune action.

To configure the prune delay time

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the prune delay interval.	prune delay <i>interval</i>	Optional. 3 seconds by default, which equals the prune pending time.

Configuring IPv6 PIM common timers

IPv6 PIM common timers

IPv6 PIM routers discover IPv6 PIM neighbors and maintain IPv6 PIM neighboring relationships with other routers by periodically sending hello messages.

After receiving a hello message, an IPv6 PIM router waits a random period, which is smaller than the maximum delay between hello messages, before sending a hello message. This avoids collisions that occur when multiple IPv6 PIM routers send hello messages simultaneously.

An IPv6 PIM router periodically sends join/prune messages to its upstream for state update. A join/prune message contains the join/prune timeout time. The upstream router sets a join/prune timeout timer for each pruned downstream interface.

Any router that has lost assert election will prune its downstream interface and maintain the assert state for a period of time. When the assert state times out, the assert loser will resume IPv6 multicast forwarding.

When a router fails to receive subsequent IPv6 multicast data from the IPv6 multicast source S, the router does not immediately delete the corresponding (S, G) entry. Instead, it maintains the (S, G) entry for a period of time—namely, the IPv6 multicast source lifetime—before deleting the (S, G) entry.

Configuring IPv6 PIM common timers globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the hello interval.	timer hello <i>interval</i>	Optional. 30 seconds by default.
4. Configure the join/prune interval.	timer join-prune <i>interval</i>	Optional. 60 seconds by default.
5. Configure the join/prune timeout time.	holdtime join-prune <i>interval</i>	Optional. 210 seconds by default.
6. Configure assert timeout time.	holdtime assert <i>interval</i>	Optional. 180 seconds by default.
7. Configure the IPv6 multicast source lifetime.	source-lifetime <i>interval</i>	Optional. 210 seconds by default.

Configuring IPv6 PIM common timers on an interface

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the hello interval.	pim ipv6 timer hello <i>interval</i>	Optional. 30 seconds by default.
4. Configure the maximum delay between hello messages.	pim ipv6 triggered-hello-delay <i>interval</i>	Optional. 5 seconds by default.
5. Configure the join/prune interval.	pim ipv6 timer join-prune <i>interval</i>	Optional. 60 seconds by default.
6. Configure the join/prune timeout time.	pim ipv6 holdtime join-prune <i>interval</i>	Optional. 210 seconds by default.
7. Configure assert timeout time.	pim ipv6 holdtime assert <i>interval</i>	Optional 180 seconds by default.

NOTE:

If no special networking requirements are raised, use the default settings.

Configuring join/prune message sizes

A large size of a join/prune message might result in loss of a larger amount of information if a message is lost. You can set a small value for the size of each join/prune message to reduce the impact in case of the loss of a message.

By controlling the maximum number of (S, G) entries in a join/prune message, you can effectively reduce the number of (S, G) entries sent per unit of time.

! IMPORTANT:

If IPv6 PIM snooping-enabled switches are deployed in the IPv6 PIM network, be sure to set a value no greater than the IPv6 path MTU for the maximum size of each join/prune message on the receiver-side edge IPv6 PIM devices.

To configure join/prune message sizes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Configure the maximum size of each join/prune message.	jp-pkt-size <i>packet-size</i>	Optional. 8100 bytes by default.
4. Configure the maximum number of (S, G) entries in a join/prune message.	jp-queue-size <i>queue-size</i>	Optional. 1020 by default.

Configuring IPv6 PIM to work with BFD

IPv6 PIM uses hello messages to elect a DR for a multi-access network. The elected DR will be the only multicast forwarder on the multi-access network.

If the DR fails, a new DR election process will start after the DR is aged out. However, it might take a long period of time. To start a new DR election process immediately after the original DR fails, you can enable IPv6 PIM to work with Bidirectional Forwarding Detection (BFD) on a multi-access network to detect failures of the links among IPv6 PIM neighbors. You must enable IPv6 PIM to work with BFD on all IPv6 PIM-capable routers on a multi-access network, so that the IPv6 PIM neighbors can fast detect DR failures and start a new DR election process.

Before you configure this feature on an interface, be sure to enable IPv6 PIM-DM or IPv6 PIM-SM on the interface.

To enable IPv6 PIM to work with BFD:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type interface-number</i>	N/A
3. Enable IPv6 PIM to work with BFD.	pim ipv6 bfd enable	Disabled by default

For more information about BFD, see *High Availability Configuration Guide*.

Setting the DSCP value for IPv6 PIM messages

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter IPv6 PIM view.	pim ipv6	N/A
3. Set the DSCP value for IPv6 PIM messages.	dscp <i>dscp-value</i>	Optional. By default, the DSCP value in IPv6 PIM messages is 48.

Displaying and maintaining IPv6 PIM

Task	Command	Remarks
Display the BSR information in the IPv6 PIM-SM domain and locally configured C-RP information in effect.	display pim ipv6 bsr-info [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about IPv6 unicast routes used by IPv6 PIM.	display pim ipv6 claimed-route [<i>ipv6-source-address</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display the number of IPv6 PIM control messages.	display pim ipv6 control-message counters [message-type { probe register register-stop }] [interface <i>interface-type interface-number</i> message-type { assert bsr crp graft graft-ack hello join-prune state-refresh }] * [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the DF information of IPv6 BIDIR-PIM.	display pim ipv6 df-info [<i>rp-address</i>] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about unacknowledged graft messages.	display pim ipv6 grafts [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the IPv6 PIM information on an interface or all interfaces.	display pim ipv6 interface [<i>interface-type interface-number</i>] [verbose] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about join/prune messages to send.	display pim ipv6 join-prune mode { sm [flags <i>flag-value</i>] ssm } [interface <i>interface-type interface-number</i> neighbor <i>ipv6-neighbor-address</i>] * [verbose] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 PIM neighboring information.	display pim ipv6 neighbor [interface <i>interface-type interface-number</i> <i>ipv6-neighbor-address</i> verbose] * [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about the IPv6 PIM routing table.	display pim ipv6 routing-table [<i>ipv6-group-address</i> [<i>prefix-length</i>] <i>ipv6-source-address</i> [<i>prefix-length</i>] incoming-interface [<i>interface-type interface-number</i> register] outgoing-interface { include exclude match } { <i>interface-type interface-number</i> register } mode <i>mode-type</i> flags <i>flag-value</i> fsm] * [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the RP information.	display pim ipv6 rp-info [<i>ipv6-group-address</i>] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Reset IPv6 PIM control message counters.	reset pim ipv6 control-message counters [interface <i>interface-type</i> <i>interface-number</i>]	Available in user view

IPv6 PIM configuration examples

IPv6 PIM-DM configuration example

Network requirements

Receivers receive VOD information through multicast. The receiver groups of different organizations form stub networks, and one or more receiver hosts exist in each stub network. The entire IPv6 PIM domain is operating in the dense mode.

Host A and Host C are multicast receivers in two stub networks N1 and N2.

MLDv1 runs between Switch A and N1 and between Switch B/Switch C and N2.

Figure 103 Network diagram

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Switch A	Vlan-int100	1001::1/64	Switch D	Vlan-int300	4001::1/64
	Vlan-int103	1002::1/64		Vlan-int103	1002::2/64
Switch B	Vlan-int200	2001::1/64	Switch D	Vlan-int101	2002::2/64
	Vlan-int101	2002::1/64		Vlan-int102	3001::2/64
Switch C	Vlan-int200	2001::2/64			
	Vlan-int102	3001::1/64			

Configuration procedure

1. Enable IPv6 forwarding and configure IPv6 addresses and IPv6 unicast routing:
Enable IPv6 forwarding on each switch and configure the IPv6 address and prefix length for each interface as per [Figure 103](#). (Details not shown.)
Configure OSPFv3 on the switches in the IPv6 PIM-DM domain to ensure network-layer reachability among them. (Details not shown.)

2. Enable IPv6 multicast routing, and enable IPv6 PIM-DM and MLD:

Enable IPv6 multicast routing on Switch A, enable IPv6 PIM-DM on each interface, and enable MLD on VLAN-interface 100, which connects Switch A to N1.

```
<SwitchA> system-view
[SwitchA] multicast ipv6 routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] mld enable
[SwitchA-Vlan-interface100] pim ipv6 dm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 103
[SwitchA-Vlan-interface103] pim ipv6 dm
[SwitchA-Vlan-interface103] quit
```

The configuration on Switch B and Switch C is similar to that on Switch A.

Enable IPv6 multicast routing on Switch D, and enable IPv6 PIM-DM on each interface.

```
<SwitchD> system-view
[SwitchD] multicast ipv6 routing-enable
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] pim ipv6 dm
[SwitchD-Vlan-interface300] quit
[SwitchD] interface vlan-interface 103
[SwitchD-Vlan-interface103] pim ipv6 dm
[SwitchD-Vlan-interface103] quit
[SwitchD] interface vlan-interface 101
[SwitchD-Vlan-interface101] pim ipv6 dm
[SwitchD-Vlan-interface101] quit
[SwitchD] interface vlan-interface 102
[SwitchD-Vlan-interface102] pim ipv6 dm
[SwitchD-Vlan-interface102] quit
```

3. Verify the configuration:

Use the **display pim ipv6 interface** command to view the IPv6 PIM configuration and running status on each interface. For example:

Display IPv6 PIM information on Switch D.

```
[SwitchD] display pim ipv6 interface
```

Interface	NbrCnt	HelloInt	DR-Pri	DR-Address
Vlan300	0	30	1	4001::1 (local)
Vlan103	0	30	1	1002::2 (local)
Vlan101	1	30	1	2002::2 (local)

```
Vlan102          1          30          1          3001::2
                (local)
```

Use the **display pim ipv6 neighbor** command to view the IPv6 PIM neighboring relationships among the switches. For example:

Display IPv6 PIM neighboring relationships on Switch D.

```
[SwitchD] display pim ipv6 neighbor
Total Number of Neighbors = 3
```

Neighbor	Interface	Uptime	Expires	Dr-Priority
1002::1	Vlan103	00:04:00	00:01:29	1
2002::1	Vlan101	00:04:16	00:01:29	3
3001::1	Vlan102	00:03:54	00:01:17	5

Assume that Host A needs to receive the information addressed to IPv6 multicast group G (FF0E::101). After IPv6 multicast source S (4001::100/64) sends IPv6 multicast packets to the IPv6 multicast group G, an SPT is established through traffic flooding. Switches on the SPT path (Switch A and Switch D) have their (S, G) entries. Host A sends an MLD report to Switch A to join IPv6 multicast group G, and a (*, G) entry is generated on Switch A. You can use the **display pim IPv6 routing-table** command to view the IPv6 PIM routing table information on each switch. For example:

Display IPv6 PIM multicast routing table information on Switch A.

```
[SwitchA] display pim ipv6 routing-table
Total 1 (*, G) entry; 1 (S, G) entry
```

```
(*, FF0E::101)

    2: Vlan-interface102
      Protocol: pim-dm, UpTime: 00:02:19, Expires: never
```

IPv6 PIM-SM non-scoped zone configuration example

Network requirements

Receivers receive VOD information through multicast. The receiver groups of different organizations form stub networks, and one or more receiver hosts exist in each stub network. The entire PIM domain is operating in the sparse mode.

Host A and Host C are IPv6 multicast receivers in two stub networks, N1 and N2.

VLAN-interface 105 on Switch D and VLAN-interface 102 on Switch E act as C-BSRs and C-RPs. The C-BSR on Switch E has a higher priority. The IPv6 multicast group range served by the C-RP is FFOE::101/64. Modify the hash mask length to map a certain number of consecutive IPv6 group addresses within the range to the two C-RPs.

MLDv1 runs between Switch A and N1 and between Switch B/Switch C and N2.

Figure 104 Network diagram

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Switch A	Vlan-int100	1001::1/64	Switch D	Vlan-int300	4001::1/64
	Vlan-int101	1002::1/64		Vlan-int101	1002::2/64
	Vlan-int102	1003::1/64		Vlan-int105	4002::1/64
Switch B	Vlan-int200	2001::1/64	Switch E	Vlan-int104	3001::2/64
	Vlan-int103	2002::1/64		Vlan-int103	2002::2/64
Switch C	Vlan-int200	2001::2/64		Vlan-int102	1003::2/64
	Vlan-int104	3001::1/64		Vlan-int105	4002::2/64

Configuration procedure

1. Enable IPv6 forwarding and configure IPv6 addresses and IPv6 unicast routing:
Enable IPv6 forwarding on each switch and configure the IPv6 address and prefix length for each interface as per Figure 104. (Details not shown.)

Configure OSPFv3 on the switches in the IPv6 PIM-DM domain to ensure network-layer reachability among them. (Details not shown.)

2. Enable IPv6 multicast routing, and enable IPv6 PIM-SM and MLD:

Enable IPv6 multicast routing on Switch A, enable IPv6 PIM-SM on each interface, and enable MLD on VLAN-interface 300, which connects Switch A to N1.

```
<SwitchA> system-view
[SwitchA] multicast ipv6 routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] mld enable
[SwitchA-Vlan-interface100] pim ipv6 sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
```

```
[SwitchA-Vlan-interface101] pim ipv6 sm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface vlan-interface 102
[SwitchA-Vlan-interface102] pim ipv6 sm
[SwitchA-Vlan-interface102] quit
```

The configuration on Switch B and Switch C is similar to that on Switch A. The configuration on Switch D and Switch E is also similar to that on Switch A except that it is not necessary to enable MLD on the corresponding interfaces on these two switches.

3. Configure a C-BSR and a C-RP:

On Switch D, configure the service scope of RP advertisements, specify a C-BSR and a C-RP, and set the hash mask length to 128 and the priority of the C-BSR to 10.

```
<SwitchD> system-view
[SwitchD] acl ipv6 number 2005
[SwitchD-acl6-basic-2005] rule permit source ff0e::101 64
[SwitchD-acl6-basic-2005] quit
[SwitchD] pim ipv6
[SwitchD-pim6] c-bsr 4002::1 128 10
[SwitchD-pim6] c-rp 4002::1 group-policy 2005
[SwitchD-pim6] quit
```

On Switch E, configure the service scope of RP advertisements, specify a C-BSR and a C-RP, and set the hash mask length to 128 and the priority of the C-BSR to 20.

```
<SwitchE> system-view
[SwitchE] acl ipv6 number 2005
[SwitchE-acl6-basic-2005] rule permit source ff0e::101 64
[SwitchE-acl6-basic-2005] quit
[SwitchE] pim ipv6
[SwitchE-pim6] c-bsr 1003::2 128 20
[SwitchE-pim6] c-rp 1003::2 group-policy 2005
[SwitchE-pim6] quit
```

4. Verify the configuration:

Use the **display pim ipv6 interface** command to view the IPv6 PIM configuration and running status on each interface. For example:

Display IPv6 PIM information on all interfaces of Switch A.

```
[SwitchA] display pim ipv6 interface
Interface           NbrCnt  HelloInt  DR-Pri  DR-Address
Vlan100             0        30        1       1001::1
                   (local)
Vlan101             1        30        1       1002::2
Vlan102             1        30        1       1003::2
```

To view the BSR election information and the locally configured C-RP information in effect on a switch, use the **display pim ipv6 bsr-info** command. For example:

Display BSR information and the locally configured C-RP information in effect on Switch A.

```
[SwitchA] display pim ipv6 bsr-info
Elected BSR Address: 1003::2
Priority: 20
Hash mask length: 128
State: Accept Preferred
```

```
Uptime: 00:04:22
Expires: 00:01:46
```

Display BSR information and the locally configured C-RP information in effect on Switch D.

```
[SwitchD] display pim ipv6 bsr-info
```

```
Elected BSR Address: 1003::2
  Priority: 20
  Hash mask length: 128
  State: Elected
  Uptime: 00:05:26
  Expires: 00:01:45
Candidate BSR Address: 4002::1
  Priority: 10
  Hash mask length: 128
  State: Candidate
```

```
Candidate RP: 4002::1(Vlan-interface105)
  Priority: 192
  HoldTime: 130
  Advertisement Interval: 60
  Next advertisement scheduled at: 00:00:48
```

Display BSR information and the locally configured C-RP information in effect on Switch E.

```
[SwitchE] display pim ipv6 bsr-info
```

```
Elected BSR Address: 1003::2
  Priority: 20
  Hash mask length: 128
  State: Elected
  Uptime: 00:01:10
  Next BSR message scheduled at: 00:01:48
Candidate BSR Address: 1003::2
  Priority: 20
  Hash mask length: 128
  State: Elected
```

```
Candidate RP: 1003::2(Vlan-interface102)
  Priority: 192
  HoldTime: 130
  Advertisement Interval: 60
  Next advertisement scheduled at: 00:00:48
```

To view the RP information discovered on a switch, use the **display pim ipv6 rp-info** command. For example:

Display RP information on Switch A.

```
[SwitchA] display pim ipv6 rp-info
```

```
PIM-SM BSR RP information:
prefix/prefix length: FF0E::101/64
  RP: 4002::1
  Priority: 192
  HoldTime: 130
  Uptime: 00:05:19
```

```
Expires: 00:02:11
```

```
RP: 1003::2
```

```
Priority: 192
```

```
HoldTime: 130
```

```
Uptime: 00:05:19
```

```
Expires: 00:02:11
```

Assume that Host A needs to receive information addressed to the IPv6 multicast group G (FF0E::100). The RP corresponding to the multicast group G is Switch E as a result of hash calculation, so an RPT will be built between Switch A and Switch E. When the IPv6 multicast source S (4001::100/64) registers with the RP, an SPT will be built between Switch D and Switch E. After receiving IPv6 multicast data, Switch A immediately switches from the RPT to the SPT. The switches on the RPT path (Switch A and Switch E) have a (*, G) entry, and the switches on the SPT path (Switch A and Switch D) have an (S, G) entry. You can use the **display pim ipv6 routing-table** command to view the PIM routing table information on the switches. For example:

```
# Display IPv6 PIM multicast routing table information on Switch A.
```

```
[SwitchA] display pim ipv6 routing-table
```

```
Total 1 (*, G) entry; 1 (S, G) entry
```

```
(*, FF0E::100)

IPv6 PIM-SM admin-scope zone configuration example

Network requirements

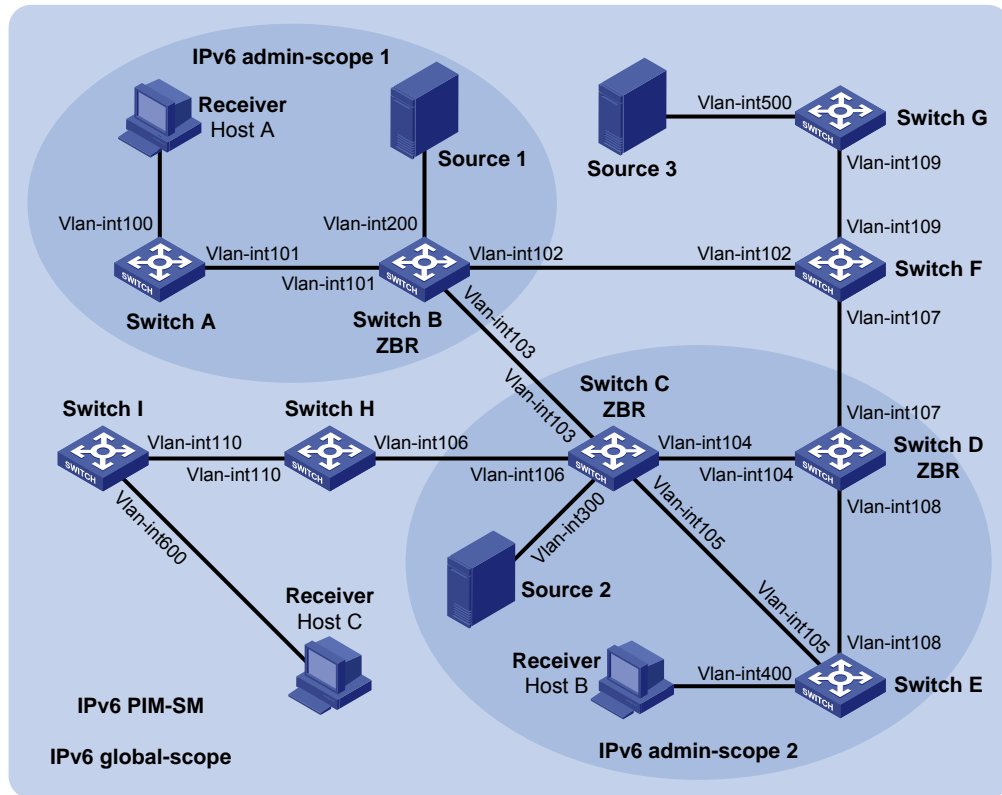

Receivers receive VOD information through multicast. The entire IPv6 PIM-SM domain is divided into IPv6 admin-scope zone 1, IPv6 admin-scope zone 2, and the IPv6 global zone. Switch B, Switch C, and Switch D are ZBRs of these three domains respectively.

Source 1 and Source 2 send different multicast information to FF14::101. Host A receives the multicast information only from Source 1, and Host B receives the multicast information only from Source 2. Source 3 sends multicast information to multicast group FF1E::202. Host C is a multicast receiver for this multicast group.

VLAN-interface 101 of Switch B acts as a C-BSR and C-RP of admin-scope zone 1, which serves the IPv6 multicast groups with the Scope field value in their group addresses being 4. VLAN-interface 104 of Switch D acts as a C-BSR and C-RP of admin-scope zone 2, which also serves the IPv6 multicast groups with the Scope field value in their group addresses being 4. VLAN-interface 109 of Switch F acts as C-BSRs and C-RPs of the global scope zone, which serves IPv6 multicast groups with the Scope field value in their group addresses being 14.

MLDv1 runs between Switch A, Switch E, Switch I, and their respective receivers.

Figure 105 Network diagram

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Switch A	Vlan-int100	1001::1/64	Switch D	Vlan-int104	3002::2/64
	Vlan-int101	1002::1/64		Vlan-int108	6001::1/64
Switch B	Vlan-int200	2001::1/64		Vlan-int107	6002::1/64
	Vlan-int101	1002::2/64	Switch E	Vlan-int400	7001::1/64
	Vlan-int103	2002::1/64		Vlan-int105	3003::2/64
	Vlan-int102	2003::1/64		Vlan-int108	6001::2/64
Switch C	Vlan-int300	3001::1/64	Switch F	Vlan-int109	8001::1/64
	Vlan-int104	3002::1/64		Vlan-int107	6002::2/64
	Vlan-int105	3003::1/64		Vlan-int102	2003::2/64
	Vlan-int103	2002::2/64	Switch G	Vlan-int500	9001::1/64
	Vlan-int106	3004::1/64		Vlan-int109	8001::2/64
Switch H	Vlan-int110	4001::1/64	Source 1	—	2001::100/64
	Vlan-int106	3004::2/64	Source 2	—	3001::100/64
Switch I	Vlan-int600	5001::1/64	Source 3	—	9001::100/64
	Vlan-int110	4001::2/64			

Configuration procedure

1. Configure IPv6 addresses and unicast routing:

Configure the IPv6 address and prefix length for each interface as per Figure 105. (Details not shown.)

Configure OSPFv3 on the switches in the IPv6 PIM-SM domain to ensure network-layer reachability among them. (Details not shown.)

2. Enable IPv6 multicast routing and IPv6 administrative scoping, and enable IPv6 PIM-SM and MLD:
Enable IPv6 multicast routing and administrative scoping on Switch A, enable IPv6 PIM-SM on each interface, and enable MLD on the host-side interface VLAN-interface 100.

```
<SwitchA> system-view
[SwitchA] multicast ipv6 routing-enable
[SwitchA] pim ipv6
[SwitchA-pim6] c-bsr admin-scope
[SwitchA-pim6] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] mld enable
[SwitchA-Vlan-interface100] pim ipv6 sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim ipv6 sm
[SwitchA-Vlan-interface101] quit
```

The configuration on Switch E and Switch I is similar to the configuration on Switch A.

- # On Switch B, enable IPv6 multicast routing and IPv6 administrative scoping, and enable IPv6 PIM-SM on each interface.

```
<SwitchB> system-view
[SwitchB] multicast ipv6 routing-enable
[SwitchB] pim ipv6
[SwitchB-pim6] c-bsr admin-scope
[SwitchB-pim6] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] pim ipv6 sm
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] pim ipv6 sm
[SwitchB-Vlan-interface101] quit
[SwitchB] interface vlan-interface 102
[SwitchB-Vlan-interface102] pim ipv6 sm
[SwitchB-Vlan-interface102] quit
[SwitchB] interface vlan-interface 103
[SwitchB-Vlan-interface103] pim ipv6 sm
[SwitchB-Vlan-interface103] quit
```

The configuration on Switch C, Switch D, Switch F, Switch G, and Switch H is similar to the configuration on Switch B. (Details not shown.)

3. Configure an admin-scope zone boundary:

- # On Switch B, configure VLAN-interface 102 and VLAN-interface 103 to be the boundary of admin-scope zone 1.

```
[SwitchB] interface vlan-interface 102
[SwitchB-Vlan-interface102] multicast ipv6 boundary scope 4
[SwitchB-Vlan-interface102] quit
[SwitchB] interface vlan-interface 103
[SwitchB-Vlan-interface103] multicast ipv6 boundary scope 4
[SwitchB-Vlan-interface103] quit
```

On Switch C, configure VLAN-interface 103 and VLAN-interface 106 to be the boundary of admin-scope zone 2.

```
<SwitchC> system-view
[SwitchC] interface vlan-interface 103
[SwitchC-Vlan-interface103] multicast ipv6 boundary scope 4
[SwitchC-Vlan-interface103] quit
[SwitchC] interface vlan-interface 106
[SwitchC-Vlan-interface106] multicast ipv6 boundary scope 4
[SwitchC-Vlan-interface106] quit
```

On Switch D, configure VLAN-interface 107 to be the boundary of admin-scope zone 2.

```
<SwitchD> system-view
[SwitchD] interface vlan-interface 107
[SwitchD-Vlan-interface107] multicast ipv6 boundary scope 4
[SwitchD-Vlan-interface107] quit
```

4. Configure C-BSRs and C-RPs:

On Switch B, configure the service scope of RP advertisements, and configure VLAN-interface 101 as a C-BSR and C-RP of admin-scope zone 1.

```
[SwitchB] pim ipv6
[SwitchB-pim6] c-bsr scope 4
[SwitchB-pim6] c-bsr 1002::2
[SwitchB-pim6] c-rp 1002::2 scope 4
[SwitchB-pim6] quit
```

On Switch D, configure the service scope of RP advertisements, and configure VLAN-interface 104 as a C-BSR and C-RP of admin-scope zone 2.

```
[SwitchD] pim ipv6
[SwitchD-pim6] c-bsr scope 4
[SwitchD-pim6] c-bsr 3002::2
[SwitchD-pim6] c-rp 3002::2 scope 4
[SwitchD-pim6] quit
```

On Switch F, configure VLAN-interface 109 as a C-BSR and C-RP in the global scope zone.

```
<SwitchF> system-view
[SwitchF] pim ipv6
[SwitchF-pim6] c-bsr scope global
[SwitchF-pim6] c-bsr 8001::1
[SwitchF-pim6] c-rp 8001::1
[SwitchF-pim6] quit
```

5. Verify the configuration:

To view the BSR election information and the C-RP information on a switch, use the **display pim ipv6 bsr-info** command. For example:

Display BSR information and the locally configured C-RP information on Switch B.

```
[SwitchB] display pim ipv6 bsr-info
Elected BSR Address: 8001::1
    Priority: 64
    Hash mask length: 126
    State: Accept Preferred
    Scope: 14
    Uptime: 00:01:45
```

```
Expires: 00:01:25
Elected BSR Address: 1002::2
  Priority: 64
  Hash mask length: 126
  State: Elected
  Scope: 4
  Uptime: 00:04:54
  Next BSR message scheduled at: 00:00:06
```

```
Candidate BSR Address: 1002::2
  Priority: 64
  Hash mask length: 126
  State: Elected
  Scope: 4
```

```
Candidate RP: 1002::2(Vlan-interface101)
  Priority: 192
  HoldTime: 130
  Advertisement Interval: 60
  Next advertisement scheduled at: 00:00:15
```

Display BSR information and the locally configured C-RP information on Switch D.

```
[SwitchD] display pim ipv6 bsr-info
```

```
Elected BSR Address: 8001::1
  Priority: 64
  Hash mask length: 126
  State: Accept Preferred
  Scope: 14
  Uptime: 00:01:45
  Expires: 00:01:25
```

```
Elected BSR Address: 3002::2
  Priority: 64
  Hash mask length: 126
  State: Elected
  Scope: 4
  Uptime: 00:03:48
  Next BSR message scheduled at: 00:01:12
```

```
Candidate BSR Address: 3002::2
  Priority: 64
  Hash mask length: 126
  State: Elected
  Scope: 4
```

```
Candidate RP: 3002::2(Vlan-interface104)
  Priority: 192
  HoldTime: 130
  Advertisement Interval: 60
  Next advertisement scheduled at: 00:00:10
```

Display BSR information and the locally configured C-RP information on Switch F.

```
[SwitchF] display pim ipv6 bsr-info
```

```
Elected BSR Address: 8001::1
  Priority: 64
  Hash mask length: 126
  State: Elected
  Scope: 14
  Uptime: 00:01:11
  Next BSR message scheduled at: 00:00:49
```

```
Candidate BSR Address: 8001::1
  Priority: 64
  Hash mask length: 126
  State: Elected
  Scope: 14
```

```
Candidate RP: 8001::1(Vlan-interface109)
  Priority: 192
  HoldTime: 130
  Advertisement Interval: 60
  Next advertisement scheduled at: 00:00:55
```

To view the RP information learned on a switch, use the **display pim ipv6 rp-info** command. For example:

```
# Display RP information on Switch B.
```

```
[SwitchB] display pim ipv6 rp-info
```

```
PIM-SM BSR RP information:
```

```

IPv6 BIDIR-PIM configuration example

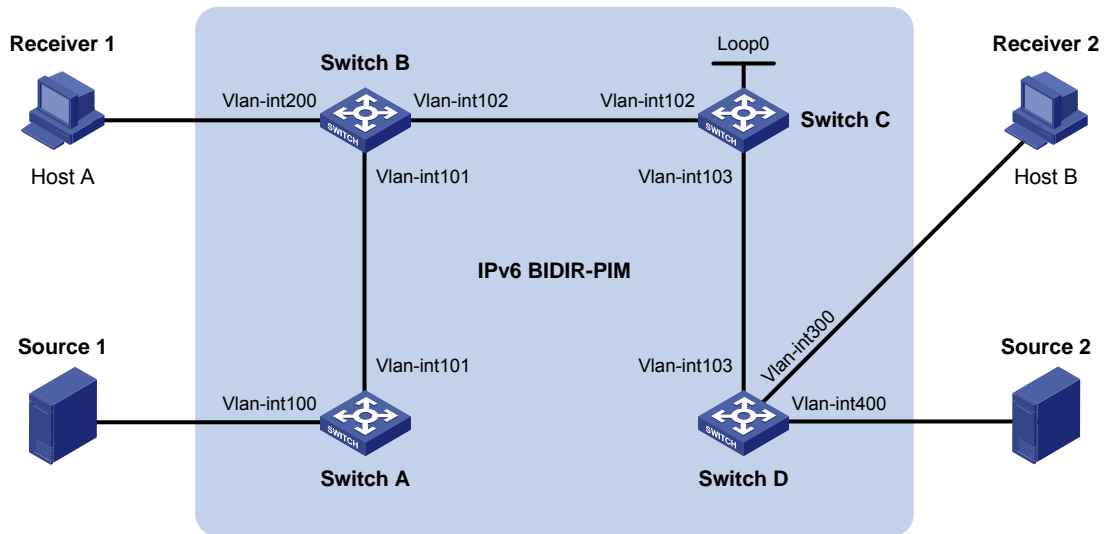

Network requirements

In the IPv6 BIDIR-PIM domain shown in [Figure 106](#). Source 1 and Source 2 send different IPv6 multicast information to IPv6 multicast group FF14::101. Host A and Host B receive IPv6 multicast information from the two sources.

VLAN interface 102 of Switch C acts as a C-BSR, and loopback interface 0 acts as a C-RP of the IPv6 BIDIR-PIM domain.

MLDv1 runs between Switch B and Host A and between Switch D and Host B.

Figure 106 Network diagram

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Switch A	Vlan-int100	1001::1/64	Switch D	Vlan-int300	4001::1/64
	Vlan-int101	1002::1/64		Vlan-int400	5001::1/64
Switch B	Vlan-int200	2001::1/64	Source 1	-	1001::2/64
	Vlan-int101	1002::2/64		Source 2	-
Switch C	Vlan-int102	2002::1/64	Receiver 1	-	2001::2/64
	Vlan-int103	3001::1/64	Receiver 2	-	4001::2/64
	Loop0	6001::1/128			

Configuration procedure

1. Configure IPv6 forwarding, IPv6 addresses and the IPv6 unicast routing protocol:
 Enable IPv6 forwarding on each switch, and configure the IPv6 address and prefix length for each interface as per Figure 106. (Details not shown.)
 Configure OSPFv3 on the switches in the IPv6 BIDIR-PIM domain to ensure network-layer reachability among them. (Details not shown.)
2. Enable IPv6 multicast routing, IPv6 PIM-SM, IPv6 BIDIR-PIM, and MLD:
 # On Switch A, enable IPv6 multicast routing, enable IPv6 PIM-SM on each interface, and enable IPv6 BIDIR-PIM.

```

<SwitchA> system-view
[SwitchA] multicast ipv6 routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] pim ipv6 sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim ipv6 sm
[SwitchA-Vlan-interface101] quit
[SwitchA] pim ipv6
[SwitchA-pim6] bidir-pim enable
[SwitchA-pim6] quit
    
```

On Switch B, enable IPv6 multicast routing, enable IPv6 PIM-SM on each interface, enable MLD in VLAN interface 200, and enable IPv6 BIDIR-PIM.

```
<SwitchB> system-view
[SwitchB] multicast ipv6 routing-enable
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] mld enable
[SwitchB-Vlan-interface200] pim ipv6 sm
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] pim ipv6 sm
[SwitchB-Vlan-interface101] quit
[SwitchB] interface vlan-interface 102
[SwitchB-Vlan-interface102] pim ipv6 sm
[SwitchB-Vlan-interface102] quit
[SwitchB] pim ipv6
[SwitchB-pim6] bidir-pim enable
[SwitchB-pim6] quit
```

On Switch C, enable IPv6 multicast routing, enable IPv6 PIM-SM on each interface, and enable IPv6 BIDIR-PIM.

```
<SwitchC> system-view
[SwitchC] multicast ipv6 routing-enable
[SwitchC] interface vlan-interface 102
[SwitchC-Vlan-interface102] pim ipv6 sm
[SwitchC-Vlan-interface102] quit
[SwitchC] interface vlan-interface 103
[SwitchC-Vlan-interface103] pim ipv6 sm
[SwitchC-Vlan-interface103] quit
[SwitchC] interface loopback 0
[SwitchC-LoopBack0] pim ipv6 sm
[SwitchC-LoopBack0] quit
[SwitchC] pim ipv6
[SwitchC-pim6] bidir-pim enable
```

On Switch D, enable IPv6 multicast routing, enable IPv6 PIM-SM on each interface, enable MLD in VLAN interface 300, and enable IPv6 BIDIR-PIM.

```
<SwitchD> system-view
[SwitchD] multicast ipv6 routing-enable
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] mld enable
[SwitchD-Vlan-interface300] pim ipv6 sm
[SwitchD-Vlan-interface300] quit
[SwitchD] interface vlan-interface 400
[SwitchD-Vlan-interface400] pim ipv6 sm
[SwitchD-Vlan-interface400] quit
[SwitchD] interface vlan-interface 103
[SwitchD-Vlan-interface103] pim ipv6 sm
[SwitchD-Vlan-interface103] quit
[SwitchD] pim ipv6
[SwitchD-pim6] bidir-pim enable
```

```
[SwitchD-pim6] quit
```

3. Configure C-BSR and C-RP:

On Switch C, configure VLAN interface 102 as a C-BSR, and loopback interface 0 as a C-RP for the entire IPv6 BIDIR-PIM domain.

```
[SwitchC-pim6] c-bsr 2002::2
```

```
[SwitchC-pim6] c-rp 6001::1 bidir
```

```
[SwitchC-pim6] quit
```

4. Verify the configuration:

To view the DF information of IPv6 BIDIR-PIM on a switch, use the **display pim ipv6 df-info** command:

Display the DF information of IPv6 BIDIR-PIM on Switch A.

```
[SwitchA] display pim ipv6 df-info
```

```
RP Address: 6001::1
```

Interface	State	DF-Pref	DF-Metric	DF-Uptime	DF-Address
Vlan100	Win	100	2	01:08:50	FE80::200:5EFF: FE71:2800 (local)

IPv6 PIM-SSM configuration example

Network requirements

Receivers receive VOD information through multicast. The receiver groups of different organizations form stub networks, and one or more receiver hosts exist in each stub network. The entire PIM domain is operating in the SSM mode.

Host A and Host C are IPv6 multicast receivers in two stub networks, N1 and N2.

The SSM group range is FF3E::/64.

MLDv2 runs between Switch A and N1 and between Switch B/Switch C and N2.

Figure 107 Network diagram

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Switch A	Vlan-int100	1001::1/64	Switch D	Vlan-int300	4001::1/64
	Vlan-int101	1002::1/64		Vlan-int101	1002::2/64
	Vlan-int102	1003::1/64		Vlan-int105	4002::1/64

Switch B	Vlan-int200	2001::1/64	Switch E	Vlan-int104	3001::2/64
	Vlan-int103	2002::1/64		Vlan-int103	2002::2/64
Switch C	Vlan-int200	2001::2/64		Vlan-int102	1003::2/64
	Vlan-int104	3001::1/64		Vlan-int105	4002::2/64

Configuration procedure

1. Enable IPv6 forwarding and configure IPv6 addresses and IPv6 unicast routing:
Enable IPv6 forwarding on each switch and configure the IPv6 address and prefix length for each interface as per [Figure 107](#). (Details not shown.)

Configure OSPFv3 on the switches in the IPv6 PIM-SSM domain to ensure network-layer reachability among them. (Details not shown.)

2. Enable IPv6 multicast routing, and enable IPv6 PIM-SM and MLD:

Enable IPv6 multicast routing on Switch A, enable IPv6 PIM-SM on each interface, and run MLDv2 on VLAN-interface 100, which connects Switch A to N1.

```
<SwitchA> system-view
[SwitchA] multicast ipv6 routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] mld enable
[SwitchA-Vlan-interface100] mld version 2
[SwitchA-Vlan-interface100] pim ipv6 sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim ipv6 sm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface vlan-interface 102
[SwitchA-Vlan-interface102] pim ipv6 sm
[SwitchA-Vlan-interface102] quit
```

The configuration on Switch B and Switch C is similar to that on Switch A. The configuration on Switch D and Switch E is also similar to that on Switch A except that it is not necessary to enable MLD on the corresponding interfaces on these two switches.

3. Configure the IPv6 SSM group range:

Configure the IPv6 SSM group range to be FF3E::/64 on Switch A.

```
[SwitchA] acl ipv6 number 2000
[SwitchA-acl6-basic-2000] rule permit source ff3e:: 64
[SwitchA-acl6-basic-2000] quit
[SwitchA] pim ipv6
[SwitchA-pim6] ssm-policy 2000
[SwitchA-pim6] quit
```

The configuration on Switch B, Switch C, Switch D, and Switch E is similar to that on Switch A.

4. Verify the configuration:

Use the **display pim ipv6 interface** command to view the IPv6 PIM configuration and running status on each interface. For example:

Display IPv6 PIM configuration information on Switch A.

```
[SwitchA] display pim ipv6 interface
Interface          NbrCnt HelloInt   DR-Pri   DR-Address
Vlan100            0         30        1        1001::1
```

				(local)
Vlan101	1	30	1	1002::2
Vlan102	1	30	1	1003::2

Assume that Host A needs to receive the information a specific IPv6 multicast source S (4001::100/64) sends to IPv6 multicast group G (FF3E::101). Switch A builds an SPT toward the IPv6 multicast source. Switches on the SPT path (Switch A and Switch D) have generated an (S, G) entry, but Switch E, which is not on the SPT path, does not have IPv6 multicast routing entries. You can use the **display pim ipv6 routing-table** command to view the IPv6 PIM routing table information on each switch. For example:

Display IPv6 PIM multicast routing table information on Switch A.

```
[SwitchA] display pim ipv6 routing-table
Total 0 (*, G) entry; 1 (S, G) entry

(4001::100, FF3E::101)
  Protocol: pim-ssm, Flag:
  UpTime: 00:00:11
  Upstream interface: Vlan-interface101
    Upstream neighbor: 1002::2
    RPF prime neighbor: 1002::2
  Downstream interface(s) information:
  Total number of downstreams: 1
    1: Vlan-interface100
      Protocol: mld, UpTime: 00:00:11, Expires: 00:03:25
```

Display IPv6 PIM multicast routing table information on Switch B.

```
[SwitchD] display pim ipv6 routing-table
Total 0 (*, G) entry; 1 (S, G) entry

(4001::100, FF3E::101)
  Protocol: pim-ssm, Flag: LOC
  UpTime: 00:08:02
  Upstream interface: Vlan-interface300
    Upstream neighbor: NULL
    RPF prime neighbor: NULL
  Downstream interface(s) information:
  Total number of downstreams: 1
    1: Vlan-interface105
      Protocol: pim-ssm, UpTime: 00:08:02, Expires: 00:03:25
```

Troubleshooting IPv6 PIM configuration

Failure to build a multicast distribution tree correctly

Symptom

None of the routers in the network (including routers directly connected with IPv6 multicast sources and receivers) have IPv6 multicast forwarding entries. That is, a multicast distribution tree cannot be built correctly and clients cannot receive IPv6 multicast data.

Analysis

- An IPv6 PIM routing entry is created based on an IPv6 unicast route, whichever IPv6 PIM mode is running. Multicast works only when unicast does.
- IPv6 PIM must be enabled on the RPF interface. An RPF neighbor must be an IPv6 PIM neighbor as well. If IPv6 PIM is not enabled on the RPF interface or the RPF neighbor, the establishment of a multicast distribution tree will fail, resulting in abnormal multicast forwarding.
- IPv6 PIM requires that the same IPv6 PIM mode (namely, DM or SM) must run on the entire network. Otherwise, the establishment of a multicast distribution tree will fail, resulting in abnormal multicast forwarding.

Solution

1. Use the **display ipv6 routing-table** command to verify that a unicast route exists to the IPv6 multicast source or the RP.
2. Use the **display pim ipv6 interface** command to verify that the RPF interface is IPv6 PIM enabled. If IPv6 PIM is not enabled on the interface, use the **pim ipv6 dm** or **pim ipv6 sm** command to enable IPv6 PIM.
3. Use the **display pim ipv6 neighbor** command to verify that the RPF neighbor is an IPv6 PIM neighbor.
4. Verify that IPv6 PIM and MLD are enabled on the interfaces that are directly connected to the IPv6 multicast source and to the receiver.
5. Use the **display pim ipv6 interface verbose** command to verify that the same PIM mode is enabled on the RPF interface and the corresponding interface of the RPF neighbor router.
6. Use the **display current-configuration** command to verify that the same IPv6 PIM mode is enabled on all the routers in the entire network. Make sure that the same IPv6 PIM mode is enabled on all the routers: IPv6 PIM-SM on all routers, or IPv6 PIM-DM on all routers.

IPv6 multicast data abnormally terminated on an intermediate router

Symptom

An intermediate router can receive IPv6 multicast data successfully, but the data cannot reach the last hop router. An interface on the intermediate router receives data, but no corresponding (S, G) entry is created in the IPv6 PIM routing table.

Analysis

- If an IPv6 multicast forwarding boundary has been configured through the **multicast ipv6 boundary** command, any IPv6 multicast packet will be kept from crossing the boundary, and no routing entry can be created in the IPv6 PIM routing table.
- In addition, the **source-policy** command filters received IPv6 multicast packets. If the IPv6 multicast data fails to pass the IPv6 ACL rule defined in this command, IPv6 PIM cannot create the route entry either.

Solution

1. Use the **display current-configuration** command to verify the IPv6 multicast forwarding boundary settings. Use the **multicast ipv6 boundary** command to change the IPv6 multicast forwarding boundary settings.

2. Use the **display current-configuration** command to verify the IPv6 multicast filter configuration. Change the IPv6 ACL rule defined in the **source-policy** command so that the source/group address of the IPv6 multicast data can pass ACL filtering.

RPS cannot join SPT in IPv6 PIM-SM

Symptom

An RPT cannot be established correctly, or the RPs cannot join the SPT to the IPv6 multicast source.

Analysis

- As the core of an IPv6 PIM-SM domain, the RPs serves specific IPv6 multicast groups. Multiple RPs can coexist in a network. Make sure that the RP information on all routers is exactly the same and that a specific group is mapped to the same RP. Otherwise, IPv6 multicast will fail.
- In the case of the static RP mechanism, the same RP address must be configured on all the routers in the entire network, including static RPs, by means of the static RP command. Otherwise, IPv6 multicast will fail.

Solution

1. Use the **display ipv6 routing-table** command to verify that a route is available on each router to the RP.
2. Use the **display pim ipv6 rp-info** command to verify that the RP information is consistent on all routers. In the case of inconsistent RP information, configure consistent RP address on all the routers.
3. Use the **display pim ipv6 rp-info** command to verify that the same RP address has been configured on all the routers throughout the network.

RPT establishment failure or source registration failure in IPv6 PIM-SM

Symptom

C-RPs cannot unicast advertise messages to the BSR. The BSR does not advertise bootstrap messages containing C-RP information and has no unicast route to any C-RP. An RPT cannot be established correctly, or the DR cannot perform source registration with the RP.

Analysis

- C-RPs periodically send advertisement messages to the BSR by unicast. If a C-RP does not have a route to the BSR, the BSR cannot receive the advertisements from the C-RP, and the bootstrap messages of the BSR will not contain the information about that C-RP.
- The RP is the core of an IPv6 PIM-SM domain. Make sure that the RP information on all routers is exactly the same, a specific group is mapped to the same RP, and a unicast route is available to the RP.

Solution

1. Use the **display ipv6 routing-table** command to verify that routes are available on each router to the RP and the BSR, and whether a route is available between the RP and the BSR. Make sure that each C-RP has a unicast route to the BSR, the BSR has a unicast route to each C-RP, and all the routers in the entire network have a unicast route to the RP.

2. IPv6 PIM-SM needs the support of the RP and BSR. Use the **display pim ipv6 bsr-info** command to verify that the BSR information is available on each router, and then use the **display pim ipv6 rp-info** command to check whether the RP information is correct.
3. Use the **display pim ipv6 neighbor** command to verify that normal neighboring relationships have been established among the routers.

Configuring IPv6 MBGP (available only on the HP 5500 EI)

IPv6 MBGP overview

This chapter covers configuration tasks related to multiprotocol BGP for IPv6 multicast. For information about BGP and IPv6 BGP, see *Layer 3—IP Routing Configuration Guide*. The term "router" in this chapter refers to both routers and Layer 3 switches.

IETF defined Multiprotocol BGP (MP-BGP) to carry routing information for multiple network-layer protocols.

For an IPv6 network, the topology for IPv6 multicast might be different from that for IPv6 unicast. To distinguish them, the MP-BGP enables BGP to carry the IPv6 unicast Network Layer Reachability Information (NLRI) and IPv6 multicast NLRI separately, and the multicast NLRI performs reverse path forwarding (RPF) exclusively. In this way, route selection for a destination through the IPv6 unicast routing table and through the IPv6 multicast routing table have different results, ensuring consistent unicast forwarding and normal multicast between domains. For information about RPF, see "[Configuring multicast routing and forwarding \(available only on the HP 5500 EI\)](#)."

MP-BGP is defined in RFC 2858 (Multiprotocol Extensions for BGP-4). The application of MP-BGP on IPv6 multicast is called IPv6 Multicast BGP (IPv6 MBGP).

IPv6 MBGP configuration task list

Task	Remarks
Configuring basic IPv6 MBGP functions	Configuring an IPv6 MBGP peer Required
	Configuring a preferred value for routes from a peer or a peer group Optional
Controlling route distribution and reception	Injecting a local IPv6 MBGP route Optional
	Configuring IPv6 MBGP route redistribution Optional
	Configuring IPv6 MBGP route summarization Optional
	Advertising a default route to a peer or peer group Optional
	Configuring outbound IPv6 MBGP route filtering Optional
	Configuring inbound IPv6 MBGP route filtering Optional
	Configuring IPv6 MBGP route dampening Optional
Configuring IPv6 MBGP route attributes	Configuring IPv6 MBGP route preferences Optional
	Configuring the default local preference Optional
	Configuring the MED attribute Optional
	Configuring the next hop attribute Optional
Tuning and	Configuring the as_path attribute Optional
	Configuring IPv6 MBGP soft reset Optional

Task		Remarks
optimizing IPv6 MBGP networks	Enabling the IPv6 MBGP orf capability	Optional
	Configuring the maximum number of equal-cost routes for load-balancing	Optional
Configuring a large scale IPv6 MBGP network	Configuring an IPv6 MBGP peer group	Optional
	Configuring IPv6 MBGP community	Optional
	Configuring an IPv6 MBGP route reflector	Optional

Configuring basic IPv6 MBGP functions

Configuration prerequisites

IPv6 MBGP is an application of multiprotocol BGP. Before you configure IPv6 MBGP, complete the following tasks:

- Enable IPv6.
- Configure network layer addresses for interfaces.
- Complete BGP basic configuration.

Configuring an IPv6 MBGP peer

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable BGP and enter BGP view.	bgp <i>as-number</i>	Not enabled by default.
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Specify an IPv6 BGP peer and its AS number.	peer <i>ipv6-address</i> as-number <i>as-number</i>	Not configured by default.
5. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
6. Enable the IPv6 MBGP peer.	peer <i>ipv6-address</i> enable	Not enabled by default.

Configuring a preferred value for routes from a peer or a peer group

If you both reference a routing policy and use the command **peer** { *ipv6-group-name* | *ipv6-address* } **preferred-value** *value* to set a preferred value for routes from a peer or a peer group, the routing policy sets the specified preferred value for the routes that match it. Other routes that do not match the routing policy use the value set through the command. If the preferred value in the routing policy is 0, the routes that match it will also use the value set through the **peer** { *ipv6-group-name* | *ipv6-address* } **preferred-value** *value* command. To learn how to use a routing policy to set a preferred value, see the **peer** { *ipv6-group-name* | *ipv6-address* } **route-policy** *route-policy-name* { **import** | **export** } command and the **apply preferred-value** *preferred-value* command. For more information about these commands, see *Layer 3—IP Routing Command Reference*.

To configure a preferred value for routes from a peer or a peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Specify a preferred value for routes received from the IPv6 MBGP peer or the peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } preferred-value <i>value</i>	Optional. The preferred value defaults to 0.

Controlling route distribution and reception

Configuration prerequisites

Before you configure this task, complete the following tasks:

- Enable IPv6.
- Configure basic IPv6 MBGP functions.

Injecting a local IPv6 MBGP route

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Inject a network into the IPv6 MBGP routing table.	network <i>ipv6-address prefix-length</i> [route-policy <i>route-policy-name</i> short-cut]	Not injected by default.

Configuring IPv6 MBGP route redistribution

Step	Command	Description
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP multicast address family view.	ipv6-family multicast	N/A

Step	Command	Description
4. Enable default route redistribution into the IPv6 MBGP routing table.	default-route imported	Optional. By default, default route redistribution is not allowed. If the default-route imported command is not configured, using the import-route command cannot redistribute any IGP default route.
5. Enable route redistribution from another routing protocol.	import-route <i>protocol</i> [<i>process-id</i> [med <i>med-value</i> route-policy <i>route-policy-name</i>] *]	Not enabled by default.

Configuring IPv6 MBGP route summarization

To reduce the routing table size on medium and large BGP networks, you must configure route summarization on IPv6 MBGP routers. BGP supports only manual summarization of IPv6 multicast routes.

To configure IPv6 MBGP route summarization:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Configure manual route summarization.	aggregate <i>ipv6-address prefix-length</i> [as-set attribute-policy <i>route-policy-name</i> detail-suppressed origin-policy <i>route-policy-name</i> suppress-policy <i>route-policy-name</i>]*	Not configured by default.

Advertising a default route to a peer or peer group

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Advertise a default route to an IPv6 MBGP peer or peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } default-route-advertise [route-policy <i>route-policy-name</i>]	Not advertised by default. With the peer default-route-advertise command executed, the router sends a default route with the next hop as itself to the specified IPv6 MBGP peer or the specified peer group, regardless of whether the default route is available in the routing table.

Configuring outbound IPv6 MBGP route filtering

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Configure outbound IPv6 MBGP route filtering.	<ul style="list-style-type: none"> Configure the filtering of outgoing routes: filter-policy { acl6-number ipv6-prefix ipv6-prefix-name } export [protocol process-id] Specify an IPv6 ACL to filter routes advertised to a peer or a peer group: peer { ipv6-group-name ipv6-address } filter-policy acl6-number export Specify an AS path ACL to filter IPv6 MBGP routing information advertised to a peer or a peer group: peer { ipv6-group-name ipv6-address } as-path-acl as-path-acl-number export Specify an IPv6 prefix list to filter routes advertised to a peer or a peer group: peer { ipv6-group-name ipv6-address } ipv6-prefix ipv6-prefix-name export Apply a routing policy to routes advertised to a peer or a peer group: peer { ipv6-group-name ipv6-address } route-policy route-policy-name export 	<p>Use any of the commands. No filtering is configured by default.</p> <p>You can configure filter policies as required. If you configure multiple filter policies, they are applied in the following order:</p> <ol style="list-style-type: none"> filter-policy export peer filter-policy export peer as-path-acl export peer ipv6-prefix export peer route-policy export <p>A filter policy can be applied only after the previous one is passed. Routing information can be advertised only after passing all the configured filter policies.</p>

NOTE:

- Members of an IPv6 MBGP peer group must have the same outbound route filtering policy as the peer group.
- IPv6 BGP advertises the redistributed routes that pass the specified policy to the IPv6 MBGP peer.

Configuring inbound IPv6 MBGP route filtering

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A

Step	Command	Remarks
4. Configure IPv6 MBGP inbound route filtering.	<ul style="list-style-type: none"> Configure inbound route filtering: filter-policy { <i>acl6-number</i> ipv6-prefix <i>ipv6-prefix-name</i> } import Apply a routing policy to routes from a peer or a peer group: peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } route-policy <i>route-policy-name</i> import Specify an IPv6 ACL to filter routes from a peer or a peer group: peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } filter-policy <i>acl6-number</i> import Specify an AS path ACL to filter IPv6 BGP routing information from a peer or a peer group: peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } as-path-acl <i>as-path-acl-number</i> import Specify an IPv6 prefix list to filter routes from a peer or a peer group: peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } ipv6-prefix <i>ipv6-prefix-name</i> import 	<p>Use any of the commands</p> <p>By default, advertised routes are not filtered.</p> <p>You can configure a filtering policy as required.</p> <p>If you configure several filtering policies, they are applied in the following sequence:</p> <ol style="list-style-type: none"> filter-policy import peer filter-policy import peer as-path-acl import peer ip-prefix import peer route-policy import <p>A filter policy can be applied only after the previous one is passed. Routing information can be received only after passing all the configured filter policies.</p>
10. Specify the upper limit of prefixes that can be imported from a peer or a peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } route-limit <i>limit</i> [<i>percentage</i>]	<p>Optional.</p> <p>The number is unlimited by default.</p>

NOTE:

A peer can have an inbound route filtering policy that is different from the policy of the peer group that it belongs to. That is, peer group members can have different inbound route filtering policies.

Configuring IPv6 MBGP route dampening

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Configure IPv6 MBGP route dampening parameters.	dampening [<i>half-life-reachable</i> <i>half-life-unreachable</i> <i>reuse</i> <i>suppress ceiling</i> route-policy <i>route-policy-name</i>]*	<p>Optional.</p> <p>Not configured by default.</p>

Configuring IPv6 MBGP route attributes

This section describes how to use IPv6 MBGP route attributes to affect IPv6 MBGP route selection. IPv6 MBGP route attributes involve:

- IPv6 MBGP protocol preference
- Default LOCAL_PREF attribute
- MED attribute
- NEXT_HOP attribute
- AS_PATH attribute

Configuration prerequisites

Before you configure IPv6 MBGP route attributes, complete the following tasks:

- Enable IPv6.
- Configure basic IPv6 MBGP functions.

Configuring IPv6 MBGP route preferences

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Configure preferences for external, internal, and local IPv6 MBGP routes.	preference { <i>external-preference</i> <i>internal-preference</i> <i>local-preference</i> route-policy <i>route-policy-name</i> }	Optional. The default preference values of external, internal, and local routes are 255, 255, and 130, respectively.

Configuring the default local preference

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Set the default local preference.	default local-preference <i>value</i>	Optional. By default, the default local preference is 100.

Configuring the MED attribute

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A

Step	Command	Remarks
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Configure a default MED value.	default med <i>med-value</i>	Optional. By default, the default <i>med-value</i> is 0.
5. Enable the comparison of the MED for routes from different ASs.	compare-different-as-med	Optional. Not enabled by default.
6. Enable the comparison of the MED for routes from each AS.	bestroute compare-med	Optional. Disabled by default.
7. Enable the comparison of the MED for routes from confederation peers.	bestroute med-confederation	Optional. Disabled by default.

Configuring the next hop attribute

You can use the **peer next-hop-local** command to specify the local router as the next hop of routes sent to an IPv6 multicast IBGP peer or a peer group. If load balancing is configured, the router specifies itself as the next hop of routes sent to the IPv6 multicast IBGP peer or the peer group regardless of whether the **peer next-hop-local** command is configured.

In a third-party next-hop network, that is, the local router has two IPv6 multicast EBGP peers in a broadcast network, the router does not specify itself as the next hop of routes sent to the EBGP peers by default.

To specify the router as the next hop of routes sent to a peer or a peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Configure the router as the next hop of routes sent to the peer or the peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } next-hop-local	Optional. By default, IPv6 MBGP specifies the local router as the next hop for routes sent to an EBGP peer or a peer group, but not for routes sent to an IBGP peer or a peer group.

Configuring the as_path attribute

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A

Step	Command	Remarks
4. Allow the local AS number to appear in the as-path of routes from a peer or a peer group and specify the number of times that the local AS number can appear in the as-path of routes from the peer or the peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } allow-as-loop [<i>number</i>]	Optional. Not allowed by default.
5. Disable IPv6 MBGP from considering the as_path during best route selection.	bestroute as-path-neglect	Optional. Enabled by default.
6. Configure updates to a peer or a peer group to carry only the public AS number.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } public-as-only	Optional. By default, outbound IPv6 MBGP updates can carry private AS numbers.

Tuning and optimizing IPv6 MBGP networks

Configuration prerequisites

Before you tune and optimize an OSPF network, complete the following tasks:

- Enable IPv6.
- Configure basic IPv6 MBGP functions.

Configuring IPv6 MBGP soft reset

After you modify a route selection policy, you must reset IPv6 MBGP connections to make the new one take effect.

The current IPv6 MBGP implementation supports the route-refresh feature that enables dynamic route refresh without terminating IPv6 MBGP connections.

If a peer that does not support route refresh exists in the network, you must configure the **peer keep-all-routes** command to save all routes from the peer. When the routing policy is changed, the system will update the IPv6 MBGP routing table and apply the new policy.

Performing soft reset through route refresh

If the peer is enabled with route refresh, when the IPv6 MBGP route selection policy is modified on a router, the router advertises a route-refresh message to its IPv6 MBGP peers, which resend their routing information to the router after they receive the message. Therefore, the local router can perform dynamic route update and apply the new policy without terminating IPv6 MBGP connections.

To configure IPv6 MBGP soft reset through route refresh:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A

Step	Command	Remarks
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Enable IPv6 BGP route refresh for a peer or a peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } capability-advertise route-refresh	Optional. Enabled by default.

Performing soft reset manually

If the peer does not support route refresh, you can use the **peer keep-all-routes** command to save all the route updates from the peer, and then use the **refresh bgp ipv6 multicast** command to soft-reset IPv6 MBGP connections to refresh the IPv6 MBGP routing table and apply the new policy without terminating IPv6 MBGP connections.

To perform soft reset manually:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
5. Keep all routes from a peer or a peer group regardless of whether they pass the inbound filtering policy.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } keep-all-routes	Not kept by default.
6. Perform soft reset manually.	refresh bgp ipv6 multicast { all <i>ipv6-address</i> group <i>ipv6-group-name</i> external internal } { export import }	Optional.

Enabling the IPv6 MBGP orf capability

The BGP Outbound Route Filter (ORF) feature enables a BGP speaker to send a set of ORFs to its BGP peer through route-refresh messages. The peer then applies the ORFs, in addition to its local routing policies (if any), to filter updates to the BGP speaker, thus reducing the number of exchanged update messages and saving network resources.

After you enable the ORF capability, the local BGP router negotiates the ORF capability with the BGP peer through open messages. That is, the router determines whether to carry ORF information in messages, and if yes, whether to carry non-standard ORF information in the packets. After completing the negotiation process and establishing the neighboring relationship, the BGP router and its BGP peer can exchange ORF information through specific route-refresh messages.

For the parameters configured on both sides for ORF capability negotiation, see [Table 12](#).

To enable the IPv6 MBGP ORF capability:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A

Step	Command	Remarks
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Enable BGP route refresh for a peer or a peer group.	peer { group-name ipv6-address } capability-advertise route-refresh	Optional. Enabled by default. If this feature is not enabled, you must configure this command.
5. Enable the non-standard ORF capability for a BGP peer or a peer group.	peer { group-name ipv6-address } capability-advertise orf non-standard	Optional. By default, standard BGP ORF capability defined in RFC 5291 and RFC 5292 is supported. If this feature is not enabled, you must configure this command.
6. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
7. Enable the ORF IP prefix negotiation capability for a BGP peer or a peer group.	peer { group-name ipv6-address } capability-advertise orf ip-prefix { both receive send }	Not enabled by default.

Table 12 Description of the send, receive, and both parameters and the negotiation result

Local parameter	Peer parameter	Negotiation result
send	<ul style="list-style-type: none"> • receive • both 	The ORF sending capability is enabled locally and the ORF receiving capability is enabled on the peer.
receive	<ul style="list-style-type: none"> • send • both 	The ORF receiving capability is enabled locally and the ORF sending capability is enabled on the peer.
both	both	Both the ORF sending and receiving capabilities are enabled locally and on the peer, respectively.

Configuring the maximum number of equal-cost routes for load-balancing

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp as-number	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Configure the maximum number of equal-cost routes for load balancing.	balance number	By default, load balancing is disabled.

Configuring a large scale IPv6 MBGP network

Configuration prerequisites

Before you configure the following tasks, you must configure basic IPv6 MBGP functions.

Configuring an IPv6 MBGP peer group

For easy management and configuration, you can organize some IPv6 MBGP peers that have the same route update policy into a peer group. A policy configured for a peer group applies to all the members in the group.

To create an IPv6 MBGP peer group, you must enable an existing IPv6 unicast peer group in IPv6 MBGP address family view.

Before adding an IPv6 MBGP peer to the IPv6 MBGP peer group, you must add the corresponding IPv6 BGP unicast peer to the corresponding IPv6 BGP unicast peer group.

To configure an IPv6 MBGP peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 address family view.	ipv6-family	N/A
4. Create an IPv6 BGP peer group.	group <i>ipv6-group-name</i> [external internal]	N/A
5. Add a peer to the peer group.	peer <i>ipv6-address</i> group <i>ipv6-group-name</i> [as-number <i>as-number</i>]	By default, no peer is added.
6. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
7. Enable the configured IPv6 unicast BGP peer group to create the IPv6 MBGP peer group.	peer <i>ipv6-group-name</i> enable	N/A
8. Add the IPv6 MBGP peer into the peer group.	peer <i>ipv6-address</i> group <i>ipv6-group-name</i>	By default, no peer is added.

Configuring IPv6 MBGP community

A peer group enables a group of peers to share the same policy, and a community enables a group of IPv6 MBGP routers in multiple ASs to share the same policy. The community attribute is propagated among IPv6 MBGP peers and not restricted to AS boundaries.

You can reference a routing policy to modify the community attribute for routes sent to a peer. In addition, you can define extended community attributes as required.

For more information about routing policy configuration, see *Layer 3—IP Routing Configuration Guide*.

To advertise the community attribute to an IPv6 MBGP peer or a peer group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Advertise the community attribute to an IPv6 MBGP peer or a peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } advertise-community	By default, no community attribute is advertised to any peer group/peer.
5. Advertise the extended community attribute to an IPv6 MBGP peer or a peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } advertise-ext-community	By default, no extended community attribute is advertised to any peer or peer group.
6. Apply a routing policy to routes sent to an IPv6 MBGP peer or a peer group.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } route-policy <i>route-policy-name</i> export	Not configured by default.

NOTE:

You must configure a routing policy to define the community attribute, and apply the policy to outgoing routes.

Configuring an IPv6 MBGP route reflector

To guarantee connectivity between IPv6 multicast IBGP peers, you must make them fully meshed. However, this becomes unpractical when too many IPv6 multicast IBGP peers exist. Using route reflectors can solve the problem.

The clients of a route reflector should not be fully meshed, and the route reflector reflects the routes of a client to the other clients. If the clients are fully meshed, you must disable route reflection between clients to reduce routing costs.

If a cluster has multiple route reflectors, you must specify the same cluster ID for these route reflectors to avoid routing loops.

To configure an IPv6 BGP route reflector:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter BGP view.	bgp <i>as-number</i>	N/A
3. Enter IPv6 MBGP address family view.	ipv6-family multicast	N/A
4. Configure the router as a route reflector and specify an IPv6 MBGP peer or a peer group as its client.	peer { <i>ipv6-group-name</i> <i>ipv6-address</i> } reflect-client	Not configured by default.
5. Enable route reflection between clients.	reflect between-clients	Optional. Enabled by default.

Step	Command	Remarks
6. Configure the cluster ID of the route reflector.	reflector cluster-id <i>cluster-id</i>	Optional. By default, a route reflector uses its router ID as the cluster ID.

Displaying and maintaining IPv6 MBGP

Displaying IPv6 MBGP

Task	Command	Remarks
Display IPv6 MBGP peer group information.	display bgp ipv6 multicast group [<i>ipv6-group-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 MBGP routing information injected with the network command.	display bgp ipv6 multicast network [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the IPv6 MBGP AS path information of routes.	display bgp ipv6 multicast paths [<i>as-regular-expression</i> { begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 MBGP peer information or peer group information.	display bgp ipv6 multicast peer [[<i>ipv6-address</i>] verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the prefix entries in the ORF information of the specified BGP peer.	display bgp ipv6 multicast peer <i>ipv6-address</i> received ipv6-prefix [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 MBGP routing table information.	display bgp ipv6 multicast routing-table [<i>ipv6-address prefix-length</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 MBGP routing information that matches an AS path ACL.	display bgp ipv6 multicast routing-table as-path-acl <i>as-path-acl-number</i> [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 MBGP routing information with the specified community attribute.	display bgp ipv6 multicast routing-table community [<i>aa:nn<1-13></i>] [no-advertise no-export no-export-subconfed]* [whole-match] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display routing information matching an IPv6 MBGP community list.	display bgp ipv6 multicast routing-table community-list { { <i>basic-community-list-number</i> <i>comm-list-name</i> } [whole-match] <i>adv-community-list-number</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 MBGP dampened routing information.	display bgp ipv6 multicast routing-table dampened [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 MBGP dampening parameter information.	display bgp ipv6 multicast routing-table dampening parameter [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 MBGP routing information originated from different ASs.	display bgp ipv6 multicast routing-table different-origin-as [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display IPv6 MBGP routing flap statistics.	display bgp ipv6 multicast routing-table flap-info [regular-expression <i>as-regular-expression</i> [as-path-acl <i>as-path-acl-number</i> <i>ipv6-address</i> <i>prefix-length</i> [longer-match]] [{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display the IPv6 MBGP routes received from or advertised to the IPv6 MBGP peer or peer group.	display bgp ipv6 multicast routing-table peer <i>ipv6-address</i> { advertised-routes received-routes } [<i>network-address</i> <i>prefix-length</i> statistic] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display IPv6 multicast routing information matching an AS regular expression.	display bgp ipv6 multicast routing-table regular-expression <i>as-regular-expression</i>	Available in any view
Display IPv6 MBGP routing statistics.	display bgp ipv6 multicast routing-table statistic [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the IPv6 MBGP routing table information.	display ipv6 multicast routing-table [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the multicast routing information of the specified destination address.	display ipv6 multicast routing-table <i>ipv6-address</i> <i>prefix-length</i> [longer-match] [verbose] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Resetting IPv6 MBGP connections

When you change an IPv6 MBGP routing policy, you can make the new configuration effective by resetting the IPv6 MBGP connections.

Task	Command	Remarks
Reset the specified IPv6 MBGP connections.	reset bgp ipv6 multicast { <i>as-number</i> <i>ipv6-address</i> all group <i>ipv6-group-name</i> external internal }	Available in user view

Clearing IPv6 MBGP information

Task	Command	Remarks
Clear dampened IPv6 MBGP routing information and release suppressed routes.	reset bgp ipv6 multicast dampening [<i>ipv6-address</i> <i>prefix-length</i>]	Available in user view
Clear IPv6 MBGP route flap statistics.	reset bgp ipv6 multicast flap-info [<i>ipv6-address/prefix-length</i> regex <i>as-path-regex</i> as-path-acl <i>as-path-acl-number</i>]	Available in user view

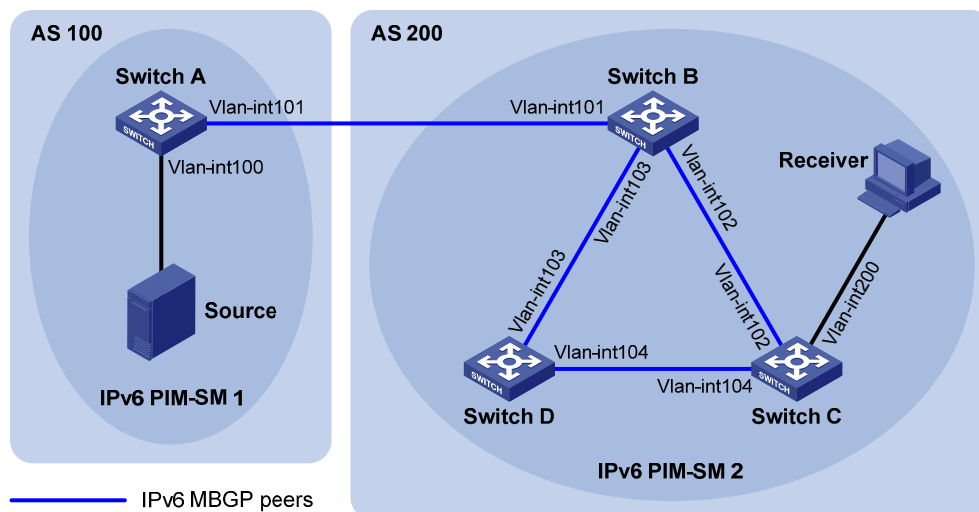

IPv6 MBGP configuration example

Network requirements

As shown in the following figure:

- IPv6 PIM-SM 1 is in AS 100, and IPv6 PIM-SM 2 is in AS 200. OSPFv3 is the IGP in the two ASs, and IPv6 MBGP runs between the two ASs to exchange IPv6 multicast route information.
- The IPv6 multicast source belongs to IPv6 PIM-SM 1 and the receiver belongs to IPv6 PIM-SM 2.
- The VLAN-interface 101 of Switch A and Switch B must be configured as the C-BSR and C-RP of the IPv6 PIM-SM domains, respectively.

Figure 108 Network diagram

Device	Interface	IP address	Device	Interface	IP address
Source	N/A	1002::100/64	Switch C	Vlan-int200	3002::1/64
Switch A	Vlan-int100	1002::1/64	Switch B	Vlan-int102	2001::2/64
	Vlan-int101	1001::1/64		Vlan-int104	3001::1/64
Switch B	Vlan-int101	1001::2/64	Switch D	Vlan-int103	2002::2/64
	Vlan-int102	2001::1/64		Vlan-int104	3001::2/64
	Vlan-int103	2002::1/64			

Configuration procedure

1. Configure IPv6 addresses for interfaces as shown in Figure 108. (Details not shown.)
2. Configure OSPFv3. (Details not shown.)
3. Enable IPv6 multicast routing, IPv6 PIM-SM and MLD, and configure an IPv6 PIM-SM domain border:

Enable IPv6 multicast routing on Switch A, and enable IPv6 PIM-SM on each interface.

```
<SwitchA> system-view
[SwitchA] multicast ipv6 routing-enable
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] pim ipv6 sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
```

```
[SwitchA-Vlan-interface101] pim ipv6 sm
[SwitchA-Vlan-interface101] quit
```

The configuration on Switch B and Switch D is similar to the configuration on Switch A.

Enable IPv6 multicast routing on Switch C, enable IPv6 PIM-SM on each interface, and enable MLD on the host-side interface VLAN-interface 200.

```
<SwitchC> system-view
[SwitchC] multicast ipv6 routing-enable
[SwitchC] interface vlan-interface 102
[SwitchC-Vlan-interface102] pim ipv6 sm
[SwitchC-Vlan-interface102] quit
[SwitchC] interface vlan-interface 104
[SwitchC-Vlan-interface104] pim ipv6 sm
[SwitchC-Vlan-interface104] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] pim ipv6 sm
[SwitchC-Vlan-interface200] mld enable
[SwitchC-Vlan-interface200] quit
```

Configure an IPv6 PIM domain border on Switch A.

```
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim ipv6 bsr-boundary
[SwitchA-Vlan-interface101] quit
```

Configure an IPv6 PIM domain border on Switch B.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] pim ipv6 bsr-boundary
[SwitchB-Vlan-interface101] quit
```

4. Configure the position of C-BSR and C-RP:

Configure the position of C-BSR and C-RP on Switch A.

```
[SwitchA] pim ipv6
[SwitchA-pim6] c-bsr 1001::1
[SwitchA-pim6] c-rp 1001::1
[SwitchA-pim6] quit
```

Configure the position of C-BSR and C-RP on Switch B.

```
[SwitchB] pim ipv6
[SwitchB-pim6] c-bsr 1001::2
[SwitchB-pim6] c-rp 1001::2
[SwitchB-pim6] quit
```

5. Configure BGP, specify the IPv6 MBGP peer and enable direct route redistribution:

On Switch A, configure the IPv6 MBGP peer and enable direct route redistribution.

```
[SwitchA] ipv6
[SwitchA] bgp 100
[SwitchA-bgp] router-id 1.1.1.1
[SwitchA-bgp] ipv6-family
[SwitchA-bgp-af-ipv6] peer 1001::2 as-number 200
[SwitchA-bgp-af-ipv6] import-route direct
[SwitchA-bgp-af-ipv6] quit
[SwitchA-bgp] ipv6-family multicast
```

```
[SwitchA-bgp-af-ipv6-mul] peer 1001::2 enable
[SwitchA-bgp-af-ipv6-mul] import-route direct
[SwitchA-bgp-af-ipv6-mul] quit
[SwitchA-bgp] quit
```

On Switch B, configure the IPv6 MBGP peers and redistribute OSPF routes.

```
[SwitchB] ipv6
[SwitchB] bgp 200
[SwitchB-bgp] router-id 2.2.2.2
[SwitchB-bgp] ipv6-family
[SwitchB-bgp-af-ipv6] peer 1001::1 as-number 100
[SwitchB-bgp-af-ipv6] import-route ospfv3 1
[SwitchB-bgp-af-ipv6] quit
[SwitchB-bgp] ipv6-family multicast
[SwitchB-bgp-af-ipv6-mul] peer 1001::1 enable
[SwitchB-bgp-af-ipv6-mul] import-route ospfv3 1
[SwitchB-bgp-af-ipv6-mul] quit
[SwitchB-bgp] quit
```

6. Verify the configuration:

You can use the **display bgp ipv6 multicast peer** command to display IPv6 MBGP peers on a switch. For example, display IPv6 MBGP peers on Switch B.

```
[SwitchB] display bgp ipv6 multicast peer
```

```
BGP local router ID : 2.2.2.2
Local AS number : 200
Total number of peers : 3                Peers in established state : 3
```

Peer	AS	MsgRcvd	MsgSent	OutQ	PrefRcv	Up/Down	State
1001::1	100	56	56	0	0	00:40:54	Established

Configuring ACLs

- Unless otherwise stated, ACLs refer to both IPv4 and IPv6 ACLs throughout this document.
- The term *interface* in the routing features refers to VLAN interfaces, bridge mode (Layer 2) and route mode (Layer 3) Ethernet ports. You can set an Ethernet port to operate in route mode by using the **port link-mode route** command (see *Layer 2—LAN Switching Configuration Guide*). 5500 SI Switch Series does not support Layer 3 Ethernet ports.

Overview

An access control list (ACL) is a set of rules (or permit or deny statements) for identifying traffic based on criteria such as source IP address, destination IP address, and port number.

ACLs are primarily used for packet filtering. A packet filter drops packets that match a deny rule and permits packets that match a permit rule. ACLs are also used by many modules, QoS and IP routing for example, for traffic classification and identification.

Applications on the switch

An ACL is implemented in hardware or software, depending on the module that uses it. If the module, the packet filter or QoS module for example, is implemented in hardware, the ACL is applied to hardware to process traffic. If the module, the routing or user interface access control module (Telnet, SNMP, or web) for example, is implemented in software, the ACL is applied to software to process traffic.

The user interface access control module denies packets that do not match any ACL. Some modules, QoS for example, ignore the permit or deny action in ACL rules and do not base their drop or forwarding decisions on the action set in ACL rules. See the specified module for information about ACL application.

ACL categories

Category	ACL number	IP version	Match criteria
Basic ACLs	2000 to 2999	IPv4	Source IPv4 address
		IPv6	Source IPv6 address
Advanced ACLs	3000 to 3999	IPv4	Source IPv4 address, destination IPv4 address, packet priority, protocols over IPv4, and other Layer 3 and Layer 4 header fields
		IPv6	Source IPv6 address, destination IPv6 address, packet priority, protocols over IPv6, and other Layer 3 and Layer 4 header fields
Ethernet frame header ACLs	4000 to 4999	IPv4 and IPv6	Layer 2 header fields, such as source and destination MAC addresses, 802.1p priority, and link layer protocol type

Numbering and naming ACLs

Each ACL category has a unique range of ACL numbers. When creating an ACL, you must assign it a number. In addition, you can assign the ACL a name for ease of identification. After creating an ACL with a name, you cannot rename it or delete its name.

For an Ethernet frame header ACL, the ACL number and name must be globally unique. For an IPv4 basic or advanced ACLs, its ACL number and name must be unique among all IPv4 ACLs, and for an IPv6 basic or advanced ACL, its ACL number and name must be unique among all IPv6 ACLs. You can assign an IPv4 ACL and an IPv6 ACL the same number and name.

Match order

The rules in an ACL are sorted in a specific order. When a packet matches a rule, the device stops the match process and performs the action defined in the rule. If an ACL contains overlapping or conflicting rules, the matching result and action to take depend on the rule order.

The following ACL match orders are available:

- **config**—Sorts ACL rules in ascending order of rule ID. A rule with a lower ID is matched before a rule with a higher ID. If you use this approach, carefully check the rules and their order.
- **auto**—Sorts ACL rules in depth-first order. Depth-first ordering guarantees that any subset of a rule is always matched before the rule. [Table 1](#) lists the sequence of tie breakers that depth-first ordering uses to sort rules for each type of ACL.

Table 1 Sort ACL rules in depth-first order

ACL category	Sequence of tie breakers
IPv4 basic ACL	<ol style="list-style-type: none">1. VPN instance2. More 0s in the source IP address wildcard (more 0s means a narrower IP address range)3. Rule configured earlier
IPv4 advanced ACL	<ol style="list-style-type: none">1. VPN instance2. Specific protocol type rather than IP (IP represents any protocol over IP)3. More 0s in the source IP address wildcard mask4. More 0s in the destination IP address wildcard5. Narrower TCP/UDP service port number range6. Rule configured earlier
IPv6 basic ACL	<ol style="list-style-type: none">1. VPN instance2. Longer prefix for the source IP address (a longer prefix means a narrower IP address range)3. Rule configured earlier
IPv6 advanced ACL	<ol style="list-style-type: none">1. VPN instance2. Specific protocol type rather than IP (IP represents any protocol over IPv6)3. Longer prefix for the source IPv6 address4. Longer prefix for the destination IPv6 address5. Narrower TCP/UDP service port number range6. Rule configured earlier

ACL category	Sequence of tie breakers
Ethernet frame header ACL	7. More 1s in the source MAC address mask (more 1s means a smaller MAC address)
	8. More 1s in the destination MAC address mask
	9. Rule configured earlier

A wildcard mask, also called an inverse mask, is a 32-bit binary and represented in dotted decimal notation. In contrast to a network mask, the 0 bits in a wildcard mask represent "do care" bits, and the 1 bits represent "don't care" bits. If the "do care" bits in an IP address are identical to the "do care" bits in an IP address criterion, the IP address matches the criterion. All "don't care" bits are ignored. The 0s and 1s in a wildcard mask can be noncontiguous. For example, 0.255.0.255 is a valid wildcard mask

NOTE:

Only 5500 EI Switch Series supports VPN instance configuration in an ACL rule. .

ACL rule comments and rule range remarks

You can add a comment about an ACL rule to make it easy to understand. The rule comment appears below the rule statement.

You can also add a rule range remark to indicate the start or end of a range of rules created for the same purpose. A rule range remark always appears above the specified ACL rule. If the specified rule has not been created yet, the position of the comment in the ACL is as follows:

- If the match order is config, the remark is inserted into the ACL in descending order of rule ID.
- If the match order is auto, the remark is placed at the end of the ACL. After you create the rule, the remark appears above the rule.

For more information about how to use rule range remarks, see the **rule remark** command in *ACL and QoS Command Reference* for your device.

ACL rule numbering

What is the ACL rule numbering step

If you do not assign an ID to the rule you are creating, the system automatically assigns it a rule ID. The rule numbering step sets the increment by which the system automatically numbers rules. For example, the default ACL rule numbering step is 5. If you do not assign IDs to rules you are creating, they are automatically numbered 0, 5, 10, 15, and so on. The wider the numbering step, the more rules you can insert between two rules.

By introducing a gap between rules rather than contiguously numbering rules, you have the flexibility of inserting rules in an ACL. This feature is important for a config order ACL, where ACL rules are matched in ascending order of rule ID.

Automatic rule numbering and renumbering

The ID automatically assigned to an ACL rule takes the nearest higher multiple of the numbering step to the current highest rule ID, starting with 0.

For example, if the numbering step is 5 (the default), and there are five ACL rules numbered 0, 5, 9, 10, and 12, the newly defined rule is numbered 15. If the ACL does not contain any rule, the first rule is numbered 0.

Whenever the step changes, the rules are renumbered, starting from 0. For example, if there are five rules numbered 5, 10, 13, 15, and 20, changing the step from 5 to 2 causes the rules to be renumbered 0, 2, 4, 6, and 8.

Fragments filtering with ACLs

Traditional packet filtering matches only first fragments of packets, and allows all subsequent non-first fragments to pass through. Attackers can fabricate non-first fragments to attack networks.

To avoid the risks, the HP ACL implementation:

- Filters all fragments by default, including non-first fragments.
- Allows for matching criteria modification, for example, filters non-first fragments only.

ACL configuration task list

Task	Remarks
Configuring a time range	Optional Applicable to IPv4 and IPv6 ACLs.
Configuring a basic ACL	Required
Configuring an advanced ACL	Configure at least one task.
Configuring an Ethernet frame header ACL	Applicable to IPv4 and IPv6 except that simple ACLs are for IPv6.
Copying an ACL	Optional Applicable to IPv4 and IPv6.
Packet filtering with ACLs	Optional Applicable to IPv4 and IPv6.

Configuring a time range

You can implement ACL rules based on the time of day by applying a time range to them. A time-based ACL rule only takes effect in any time periods specified by the time range.

The following basic types of time range are available:

- **Periodic time range**—Recurrs periodically on a day or days of the week.
- **Absolute time range**—Represents only a period of time and does not recur.

You can create a maximum of 256 time ranges, each with a maximum of 32 periodic statements and 12 absolute statements. The active period of a time range is calculated as follows:

1. Combining all periodic statements.
2. Combining all absolute statements.
3. Taking the intersection of the two statement sets as the active period of the time range.

To configure a time range:

Step	Command	Remarks
1. Enter system view.	<code>system-view</code>	N/A

Step	Command	Remarks
2. Configure a time range.	time-range <i>time-range-name</i> { <i>start-time to end-time days</i> [from <i>time1 date1</i>] [to <i>time2 date2</i>] from <i>time1 date1</i> [to <i>time2 date2</i>] to <i>time2 date2</i> }	By default, no time range exists. Repeat this command with the same time range name to create multiple statements for a time range.

Configuring a basic ACL

Configuring an IPv4 basic ACL

IPv4 basic ACLs match packets based only on source IP addresses.

To configure an IPv4 basic ACL:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an IPv4 basic ACL and enter its view.	acl number <i>acl-number</i> [name <i>acl-name</i>] [match-order { auto config }]	By default, no ACL exists. IPv4 basic ACLs are numbered in the range of 2000 to 2999. You can use the acl name <i>acl-name</i> command to enter the view of a named IPv4 ACL.
3. Configure a description for the IPv4 basic ACL.	description <i>text</i>	Optional. By default, an IPv4 basic ACL has no ACL description.
4. Set the rule numbering step.	step <i>step-value</i>	Optional. The default setting is 5.
5. Create or edit a rule.	rule [<i>rule-id</i>] { deny permit } [counting fragment logging source { <i>sour-addr</i> <i>sour-wildcard</i> any } time-range <i>time-range-name</i> vpn-instance <i>vpn-instance-name</i>] *	By default, an IPv4 basic ACL does not contain any rule. The vpn-instance <i>vpn-instanced-name</i> option is not available on a 5500 SI switch. If the ACL is for QoS traffic classification or packet filtering, do not specify the vpn-instance keyword. This keyword can cause ACL application failure. The logging and counting keywords (even if specified) do not take effect for QoS policies.
6. Add or edit a rule comment.	rule <i>rule-id</i> comment <i>text</i>	Optional. By default, no rule comments are configured.
7. Add or edit a rule range remark.	rule [<i>rule-id</i>] remark <i>text</i>	Optional. By default, no rule range remarks are configured.
8. Enable counting ACL rule matches performed in hardware.	hardware-count enable	Optional. Disabled by default. When the ACL is referenced by a QoS policy, this command does not take effect.

Configuring an IPv6 basic ACL

To configure an IPv6 basic ACL:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an IPv6 basic ACL view and enter its view.	acl ipv6 number <i>acl6-number</i> [name <i>acl6-name</i>] [match-order { auto config }]	By default, no ACL exists. IPv6 basic ACLs are numbered in the range of 2000 to 2999. You can use the acl ipv6 name <i>acl6-name</i> command to enter the view of a named IPv6 ACL.
3. Configure a description for the IPv6 basic ACL.	description <i>text</i>	Optional. By default, an IPv6 basic ACL has no ACL description.
4. Set the rule numbering step.	step <i>step-value</i>	Optional. The default setting is 5.
5. Create or edit a rule.	rule [<i>rule-id</i>] { deny permit } [counting fragment logging routing [type <i>routing-type</i>] source { <i>ipv6-address</i> <i>prefix-length</i> <i>ipv6-address/prefix-length</i> any } time-range <i>time-range-name</i> vpn-instance <i>vpn-instance-name</i>] *	By default, an IPv6 basic ACL does not contain any rule. The vpn-instance <i>vpn-instance-name</i> option is not available on a 5500 SI switch. If the ACL is for QoS traffic classification or packet filtering, do not specify the fragment , routing , and vpn-instance keywords. The keywords can cause ACL application failure. The logging and counting keywords (even if specified) do not take effect for QoS.
6. Add or edit a rule comment.	rule <i>rule-id</i> comment <i>text</i>	Optional. By default, no rule comments are configured.
7. Add or edit a rule range remark.	rule [<i>rule-id</i>] remark <i>text</i>	Optional. By default, no rule range remarks are configured.
8. Enable counting ACL rule matches performed in hardware.	hardware-count enable	Optional. Disabled by default. When the ACL is referenced by a QoS policy, this command does not take effect.

Configuring an advanced ACL

Configuring an IPv4 advanced ACL

IPv4 advanced ACLs match packets based on source IP addresses, destination IP addresses, packet priorities, protocols over IP, and other protocol header information, such as TCP/UDP source and destination port numbers, TCP flags, ICMP message types, and ICMP message codes.

Compared to IPv4 basic ACLs, IPv4 advanced ACLs allow more flexible and accurate filtering.

To configure an IPv4 advanced ACL:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an IPv4 advanced ACL and enter its view.	acl number <i>acl-number</i> [name <i>acl-name</i>] [match-order { auto config }]	By default, no ACL exists. IPv4 advanced ACLs are numbered in the range of 3000 to 3999. You can use the acl name <i>acl-name</i> command to enter the view of a named IPv4 ACL.
3. Configure a description for the IPv4 advanced ACL.	description <i>text</i>	Optional. By default, an IPv4 advanced ACL has no ACL description.
4. Set the rule numbering step.	step <i>step-value</i>	Optional. The default setting is 5.
5. Create or edit a rule.	rule [<i>rule-id</i>] { deny permit } protocol [{ { ack <i>ack-value</i> fin <i>fin-value</i> psh <i>psh-value</i> rst <i>rst-value</i> syn <i>syn-value</i> urg <i>urg-value</i> } * established } counting destination { <i>dest-addr</i> <i>dest-wildcard</i> any } destination-port <i>operator</i> <i>port1</i> [<i>port2</i>] dscp <i>dscp</i> fragment icmp-type { <i>icmp-type</i> [<i>icmp-code</i>] <i>icmp-message</i> } logging precedence <i>precedence</i> source { <i>sour-addr</i> <i>sour-wildcard</i> any } source-port <i>operator</i> <i>port1</i> [<i>port2</i>] time-range <i>time-range-name</i> tos <i>tos</i> vpn-instance <i>vpn-instance-name</i>] *	By default, an IPv4 advanced ACL does not contain any rule. The vpn-instance <i>vpn-instance-name</i> option is not available on a 5500 SI switch. If an IPv4 advanced ACL is for QoS traffic classification or packet filtering, do not specify the vpn-instance keyword or specify neg for the <i>operator</i> argument. The logging and counting keywords (even if specified) do not take effect for QoS traffic classification.
6. Add or edit a rule comment.	rule <i>rule-id</i> comment <i>text</i>	Optional. By default, no rule comments are configured.
7. Add or edit a rule range remark.	rule [<i>rule-id</i>] remark <i>text</i>	Optional. By default, no rule range remarks are configured.
8. Enable counting ACL rule matches performed in hardware.	hardware-count enable	Optional. Disabled by default. When the ACL is referenced by a QoS policy, this command does not take effect.

Configuring an IPv6 advanced ACL

IPv6 advanced ACLs match packets based on the source IPv6 addresses, destination IPv6 addresses, packet priorities, protocols carried over IPv6, and other protocol header fields such as the TCP/UDP source port number, TCP/UDP destination port number, ICMPv6 message type, and ICMPv6 message code.

Compared to IPv6 basic ACLs, IPv6 advanced ACLs allow more flexible and accurate filtering.

To configure an IPv6 advanced ACL:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an IPv6 advanced ACL and enter its view.	acl ipv6 number <i>acl6-number</i> [name <i>acl6-name</i>] [match-order { auto config }]	By default, no ACL exists. IPv6 advanced ACLs are numbered in the range of 3000 to 3999. You can use the acl ipv6 name <i>acl6-name</i> command to enter the view of a named IPv6 ACL.
3. Configure a description for the IPv6 advanced ACL.	description <i>text</i>	Optional. By default, an IPv6 advanced ACL has no ACL description.
4. Set the rule numbering step.	step <i>step-value</i>	Optional. 5 by default.
5. Create or edit a rule.	rule [<i>rule-id</i>] { deny permit } <i>protocol</i> [{ { ack <i>ack-value</i> fin <i>fin-value</i> psh <i>psh-value</i> rst <i>rst-value</i> syn <i>syn-value</i> urg <i>urg-value</i> } * established } counting destination { <i>dest</i> <i>dest-prefix</i> <i>dest/dest-prefix</i> any } destination-port <i>operator port1</i> [<i>port2</i>] dscp <i>dscp</i> flow-label <i>flow-label-value</i> fragment icmp6-type { <i>icmp6-type</i> <i>icmp6-code</i> <i>icmp6-message</i> } logging routing [<i>type</i> <i>routing-type</i>] source { <i>source</i> <i>source-prefix</i> <i>source/source-prefix</i> any } source-port <i>operator port1</i> [<i>port2</i>] time-range <i>time-range-name</i> vpn-instance <i>vpn-instance-name</i>] *	By default IPv6 advanced ACL does not contain any rule. The vpn-instance <i>vpn-instance-name</i> option is not available on a 5500 SI switch. If an IPv6 advanced ACL is for QoS traffic classification or packet filtering: <ul style="list-style-type: none"> Do not specify the fragment, routing, or vpn-instance keyword, or specify neg for the <i>operator</i> argument. Do not specify the flow-label keyword if the ACL is for outbound QoS traffic classification or outbound packet filtering on a 5500 EI switch. The logging and counting keywords (even if specified) do not take effect for QoS traffic classification.
6. Add or edit a rule comment.	rule <i>rule-id</i> comment <i>text</i>	Optional. By default, no rule comments are configured.
7. Add or edit a rule range remark.	rule [<i>rule-id</i>] remark <i>text</i>	Optional. By default, no rule range remarks are configured.
8. Enable counting ACL rule matches performed in hardware.	hardware-count enable	Optional. Disabled by default. When the ACL is referenced by a QoS policy, this command does not take effect.

Configuring an Ethernet frame header ACL

Ethernet frame header ACLs, also called "Layer 2 ACLs," match packets based on Layer 2 protocol header fields, such as source MAC address, destination MAC address, 802.1p priority (VLAN priority), and link layer protocol type.

To configure an Ethernet frame header ACL:

Step	Command	Remarks
1. Enter system view.	<code>system-view</code>	N/A
2. Create an Ethernet frame header ACL and enter its view.	<code>acl number <i>acl-number</i></code> [<code>name <i>acl-name</i></code>] [<code>match-order { auto config }</code>]	By default, no ACL exists. Ethernet frame header ACLs are numbered in the range of 4000 to 4999. You can use the <code>acl name <i>acl-name</i></code> command to enter the view of a named Ethernet frame header ACL.
3. Configure a description for the Ethernet frame header ACL.	<code>description <i>text</i></code>	Optional. By default, an Ethernet frame header ACL has no ACL description.
4. Set the rule numbering step.	<code>step <i>step-value</i></code>	Optional. The default setting is 5.
5. Create or edit a rule.	<code>rule [<i>rule-id</i>] { deny permit } [cos <i>vlan-pri</i> counting dest-mac <i>dest-addr dest-mask</i> { isap <i>isap-type isap-type-mask</i> type <i>protocol-type protocol-type-mask</i> } source-mac <i>sour-addr source-mask</i> time-range <i>time-range-name</i>] *</code>	By default, an Ethernet frame header ACL does not contain any rule. If the ACL is for QoS traffic classification or packet filtering, to use the <code>isap</code> keyword, the <code>isap-type</code> argument must be AAAA, and the <code>isap-type-mask</code> argument must be FFFF. Otherwise, the ACL cannot be function normally.
6. Add or edit a rule comment.	<code>rule <i>rule-id</i> comment <i>text</i></code>	Optional. By default, no rule comments are configured.
7. Add or edit a rule range remark.	<code>rule [<i>rule-id</i>] remark <i>text</i></code>	Optional. By default, no rule range remarks are configured.
8. Enable counting ACL rule matches performed in hardware.	<code>hardware-count enable</code>	Optional. Disabled by default. When the ACL is referenced by a QoS policy, this command does not take effect.

Copying an ACL

You can create an ACL by copying an existing ACL (source ACL). The new ACL (destination ACL) has the same properties and content as the source ACL, but not the same ACL number and name.

To successfully copy an ACL, make sure that:

- The destination ACL number is from the same category as the source ACL number.
- The source ACL already exists but the destination ACL does not.

Copying an IPv4 ACL

Step	Command
1. Enter system view.	system-view
2. Copy an existing IPv4 ACL to create a new IPv4 ACL.	acl copy { <i>source-acl-number</i> name <i>source-acl-name</i> } to { <i>dest-acl-number</i> name <i>dest-acl-name</i> }

Copying an IPv6 ACL

Step	Command
1. Enter system view.	system-view
2. Copy an existing IPv6 ACL to generate a new one of the same category.	acl ipv6 copy { <i>source-acl6-number</i> name <i>source-acl6-name</i> } to { <i>dest-acl6-number</i> name <i>dest-acl6-name</i> }

Packet filtering with ACLs

You can use an ACL to filter incoming or outgoing IPv4 or IPv6 packets. You can apply one IPv4 ACL, one IPv6 ACL, and one Ethernet frame header ACL most to filter packets in the same direction of an interface.

With a basic or advanced ACL, you can log filtering events by specifying the **logging** keyword in the ACL rules and enabling the counting function. To enable counting for rule matches performed in hardware, configure the **hardware-count enable** command for the ACL or specify the **counting** keyword in the ACL rules.

You can set the packet filter to periodically send packet filtering logs to the information center as informational messages. The interval for generating and outputting packet filtering logs is configurable. The log information includes the number of matching packets and the ACL rules used in an interval. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

NOTE:

ACLs on VLAN interfaces filter only packets forwarded at Layer 3.

Applying an IPv4 or Ethernet frame header ACL for packet filtering

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Apply an IPv4 basic, IPv4 advanced, or Ethernet frame header ACL to the interface to filter packets.	packet-filter { <i>acl-number</i> name <i>acl-name</i> } { inbound outbound }	By default, no ACL is applied to any interface.
4. Exit to system view.	quit	N/A
5. Set the interval for generating and outputting IPv4 packet filtering logs.	acl logging frequency <i>frequency</i>	By default, the interval is 0. No IPv4 packet filtering logs are generated.

Applying an IPv6 ACL for packet filtering

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Apply an IPv6 basic or IPv6 advanced ACL to the interface to filter IPv6 packets.	packet-filter ipv6 { <i>acl6-number</i> name <i>acl6-name</i> } { inbound outbound }	By default, no IPv6 ACL is applied to the interface.
4. Exit to system view.	quit	N/A
5. Set the interval for generating and outputting IPv6 packet filtering logs.	acl ipv6 logging frequency <i>frequency</i>	The default interval is 0. No IPv6 packet filtering logs are generated.

Displaying and maintaining ACLs

Task	Command	Remarks
Display configuration and match statistics for one or all IPv4 ACLs.	display acl { <i>acl-number</i> all name <i>acl-name</i> } [<i>slot slot-number</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display configuration and match statistics for one or all IPv6 ACLs.	display acl ipv6 { <i>acl6-number</i> all name <i>acl6-name</i> } [<i>slot slot-number</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display the usage of ACL rules.	display acl resource [<i>slot slot-number</i>] [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view
Display the application status of packet filtering ACLs on interfaces.	display packet-filter { { all interface <i>interface-type interface-number</i> } [inbound outbound] interface vlan-interface <i>vlan-interface-number</i> [inbound outbound] } [<i>slot slot-number</i>] } [[{ begin exclude include } <i>regular-expression</i>]]	Available in any view

Task	Command	Remarks
Display the configuration and status of one or all time ranges.	display time-range { <i>time-range-name</i> all } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear statistics for one or all IPv4 ACLs.	reset acl counter { <i>acl-number</i> all name <i>acl-name</i> }	Available in user view
Clear statistics for one or all IPv6 basic and advanced ACLs.	reset acl ipv6 counter { <i>acl6-number</i> all name <i>acl6-name</i> }	Available in user view

Configuration example of using ACL for device management

Network requirements

As shown in [Figure 1](#), configure ACLs so that:

- Host A can telnet to the switch only during the working time (8:30 to 18:00 of every working day).
- As a TFTP client, the switch can get files from only the server 11.1.1.100. This makes sure that the switch saves only authorized files.
- As an FTP server, the switch accepts the login requests from only the NMS.

Figure 1 Network diagram

Configuration procedure

1. Limit the telnet login requests.

Create a time range named **telnet** to cover 8:30 to 18:00 of every working day.

```
<Switch> system-view
```

```
[Switch] time-range telnet 8:30 to 18:00 working-day
# Create IPv4 basic ACL 2000, and configure a rule for the ACL to permit the packets sourced
from 10.1.3.1 during only the time specified by time range telnet.
[Switch] acl number 2000
[Switch-acl-basic-2000] rule permit source 10.1.3.1 0 time-range telnet
[Switch-acl-basic-2000] quit
# Apply ACL 2000 to the inbound traffic of all telnet user interfaces to limit the telnet login
requests.
[Switch] user-interface vty 0 4
[Switch-ui-vty0-4] acl 2000 inbound
```

2. Limit the access to the TFTP server.

Create IPv4 basic ACL 2001, and configure a rule for the ACL to permit only the packets sourced from 11.1.1.100.

```
[Switch] acl number 2001
[Switch-acl-basic-2001] rule permit source 11.1.1.100 0
[Switch-acl-basic-2001] quit
```

Use ACL 2001 to control the switch's access to a specific TFTP server.

```
[Switch] tftp-server acl 2001
```

3. Limit the FTP login requests.

Create IPv4 basic ACL 2002, and configure a rule for the ACL to permit only the packets sourced from 10.1.3.1.

```
[Switch] acl number 2002
[Switch-acl-basic-2001] rule permit source 10.1.3.1 0
[Switch-acl-basic-2001] quit
```

Enable the FTP server on the switch.

```
[Switch] ftp server enable
```

Use ACL 2001 to control FTP clients' access to the FTP server.

```
[Switch] ftp server acl 2002
```

IPv4 packet filtering configuration example

Network requirements

As shown in [Figure 2](#), apply an ACL to the inbound direction of interface GigabitEthernet 1/0/1 on Device A so that every day from 08:00 to 18:00 the interface allows only packets sourced from Host A to pass. Configure Device A to output IPv4 packet filtering logs to the console at 10-minute intervals.

Figure 2 Network diagram

Configuration procedure

Create a time range from 08:00 to 18:00 every day.

```
<DeviceA> system-view
[DeviceA] time-range study 8:00 to 18:00 daily
```

Create IPv4 ACL 2009, and configure two rules in the ACL. One rule permits packets sourced from Host A and the other denies packets sourced from any other host during the time range **study**. Enable logging for the permit rule.

```
[DeviceA] acl number 2009
[DeviceA-acl-basic-2009] rule permit source 192.168.1.2 0 time-range study logging
[DeviceA-acl-basic-2009] rule deny source any time-range study
[DeviceA-acl-basic-2009] quit
```

Enable the device to generate and output IPv4 packet filtering logs at 10-minute intervals.

```
[DeviceA] acl logging frequency 10
```

Configure the device to output informational log messages to the console.

```
[DeviceA] info-center source default channel 0 log level informational
```

Apply IPv4 ACL 2009 to filter incoming packets on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] packet-filter 2009 inbound
[DeviceA-GigabitEthernet1/0/1] quit
```

IPv6 packet filtering configuration example

Network requirements

As shown in [Figure 3](#), apply an IPv6 ACL to the incoming traffic of GigabitEthernet 1/0/1 on Device A so that every day from 08:00 to 18:00 the interface allows only packets from Host A to pass through. Configure Device A to output IPv4 packet filtering logs to the console at 10-minute intervals.

Figure 3 Network diagram

Configuration procedure

Create a time range from 08:00 to 18:00 every day.

```
<DeviceA> system-view
[DeviceA] time-range study 8:0 to 18:0 daily
```

Create IPv6 ACL 2009, and configure two rules for the ACL. One permits packets sourced from Host A and the other denies packets sourced from any other host during the time range **study**. Enable logging for the permit rule.

```
[DeviceA] acl ipv6 number 2009
[DeviceA-acl6-basic-2009] rule permit source 1001::2 128 time-range study logging
[DeviceA-acl6-basic-2009] rule deny source any time-range study
[DeviceA-acl6-basic-2009] quit
```

Configure the device to collect and output IPv6 packet filtering logs at 10-minute intervals.

```
[DeviceA] acl ipv6 logging frequency 10
```

Configure the device to output informational log messages to the console.

```
[DeviceA] info-center source default channel 0 log level informational
```

Apply IPv6 ACL 2009 to filter incoming packets on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] packet-filter ipv6 2009 inbound
[DeviceA-GigabitEthernet1/0/1] quit
```

QoS overview

In data communications, Quality of Service (QoS) is a network's ability to provide differentiated service guarantees for diversified traffic in terms of bandwidth, delay, jitter, and drop rate.

Network resources are scarce. The contention for resources requires that QoS prioritize important traffic flows over trivial ones. For example, in the case of fixed bandwidth, if a traffic flow gets more bandwidth, the other traffic flows will get less bandwidth and may be affected. When making a QoS scheme, you must consider the characteristics of various applications to balance the interests of diversified users and to utilize network resources.

The following section describes some typical QoS service models and widely used, mature QoS techniques.

QoS service models

Best-effort service model

The best-effort model is a single-service model and also the simplest service model. In this service model, the network does its best to deliver packets, but does not guarantee delivery or control delay.

The best-effort service model is the default model in the Internet and applies to most network applications. It uses the first in first out (FIFO) queuing mechanism.

IntServ model

The integrated service (IntServ) model is a multiple-service model that can accommodate diverse QoS requirements. This service model provides the most granularly differentiated QoS by identifying and guaranteeing definite QoS for each data flow.

In the IntServ model, an application must request service from the network before it sends data. IntServ signals the service request with the Resource Reservation Protocol (RSVP). All nodes receiving the request reserve resources as requested and maintain state information for the application flow.

The IntServ model demands high storage and processing capabilities because it requires all nodes along the transmission path to maintain resource state information for each flow. This model is suitable for small-sized or edge networks, but not large-sized networks, for example, the core layer of the Internet, where billions of flows are present.

DiffServ model

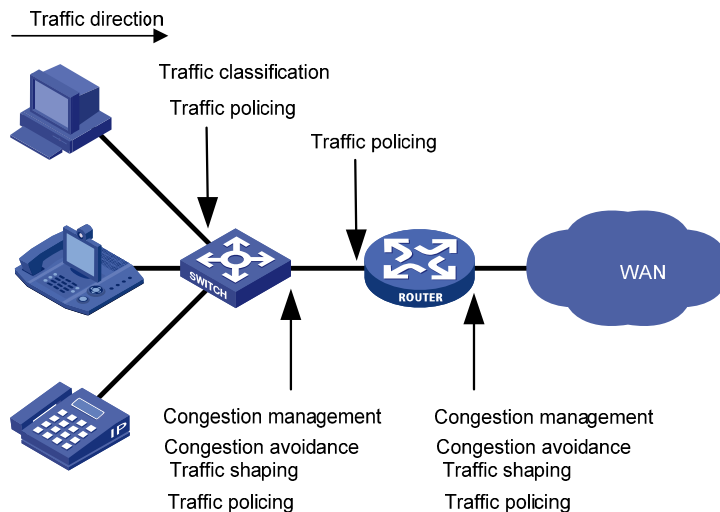

The differentiated service (DiffServ) model is a multiple-service model that can satisfy diverse QoS requirements. It is easy to implement and extend. DiffServ does not signal the network to reserve resources before sending data, as IntServ does.

All QoS techniques in this document are based on the DiffServ model.

QoS techniques

The QoS techniques include traffic classification, traffic policing, traffic shaping, line rate, congestion management, and congestion avoidance. They address problems that arise at different positions of a network.

Figure 4 Placement of the QoS techniques in a network

As shown in [Figure 4](#), traffic classification, traffic shaping, traffic policing, congestion management, and congestion avoidance mainly implement the following functions:

- **Traffic classification**—Uses certain match criteria to assign packets with the same characteristics to a class. Based on classes, you can provide differentiated services.
- **Traffic policing**—Policies flows entering or leaving a device, and imposes penalties on traffic flows that exceed the pre-set threshold to prevent aggressive use of network resources. You can apply traffic policing to both incoming and outgoing traffic of a port.
- **Traffic shaping**—Proactively adapts the output rate of traffic to the network resources available on the downstream device to eliminate packet drops. Traffic shaping usually applies to the outgoing traffic of a port.
- **Congestion management**—Provides a resource scheduling policy to determine the packet forwarding sequence when congestion occurs. Congestion management usually applies to the outgoing traffic of a port.
- **Congestion avoidance**—Monitors the network resource usage, and is usually applied to the outgoing traffic of a port. When congestion worsens, congestion avoidance reduces the queue length by dropping packets.

QoS configuration approaches

You can configure QoS in these approaches:

- [MQC approach](#)
- [Non-MQC approach](#)

Some features support both approaches, but some support only one.

MQC approach

In modular QoS configuration (MQC) approach, you configure QoS service parameters by using QoS policies (see "[Configuring a QoS policy](#)").

Non-MQC approach

In non-MQC approach, you configure QoS service parameters without using a QoS policy. For example, you can use the line rate feature to set a rate limit on an interface without using a QoS policy.

Configuring a QoS policy

Overview

A QoS policy is a set of class-behavior associations and defines the shaping, policing, or other QoS actions to take on different classes of traffic.

A class is a set of match criteria for identifying traffic and it uses the AND or OR operator:

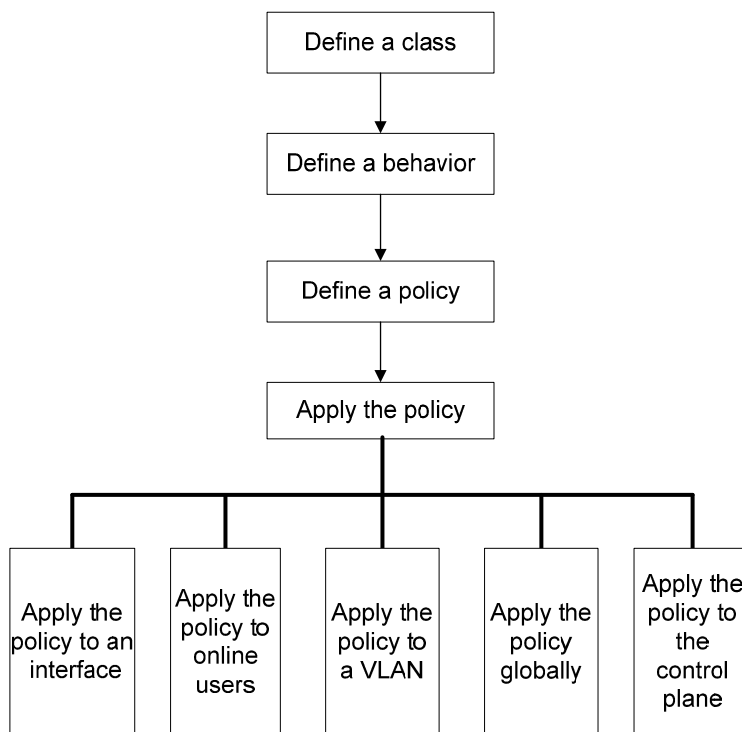

- **AND**—A packet must match all the criteria to match the class.
- **OR**—A packet matches the class if it matches any of the criteria in the class.

A traffic behavior defines a set of QoS actions to take on packets, such as priority marking and redirect.

By associating a traffic behavior with a class in a QoS policy, you apply the specific set of QoS actions to the class of traffic.

Figure 5 shows how to configure a QoS policy.

Figure 5 QoS policy configuration procedure

Defining a class

To define a class, specify its name and then configure the match criteria in class view.

Configuration restrictions and guidelines

- If a class that uses the AND operator has multiple **if-match acl**, **if-match acl ipv6**, **if-match customer-vlan-id** or **if-match service-vlan-id** clauses, a packet that matches any of the clauses matches the class.
- To successfully execute the traffic behavior associated with a traffic class that uses the AND operator, define only one **if-match** clause for any of the following match criteria and input only one value for any of the following *list* arguments. To create multiple **if-match** clauses for these match criteria or specify multiple values for the *list* arguments, specify the operator of the class as OR and use the **if-match** command multiple times.
 - **customer-dot1p** *8021p-list*
 - **destination-mac** *mac-address*
 - **dscp** *dscp-list*
 - **ip-precedence** *ip-precedence-list*
 - **service-dot1p** *8021p-list*
 - **source-mac** *mac-address*
 - **system-index** *index-value-list*

Configuration procedure

To define a class:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator { and or }]	<p>By default, the operator of a class is AND.</p> <p>The operator of a class can be AND or OR:</p> <ul style="list-style-type: none"> • AND—A packet is assigned to a class only when the packet matches all the criteria in the class. • OR—A packet is assigned to a class if it matches any of the criteria in the class.
3. Configure match criteria.	if-match <i>match-criteria</i>	N/A

match-criteria: Match criterion.

Table 2 The value range for the *match-criteria* argument

Option	Description
acl [ipv6] { <i>acl-number</i> name <i>acl-name</i> }	<p>Matches an ACL.</p> <p>The <i>acl-number</i> argument ranges from 2000 to 3999 for an IPv4 ACL, 2000 to 3999 for an IPv6 ACL, and 4000 to 4999 for an Ethernet frame header ACL.</p> <p>The <i>acl-name</i> argument is a case-insensitive string of 1 to 63 characters, which must start with an alphabetic letter from a to z (or A to Z), and to avoid confusion, cannot be all.</p>
any	Matches all packets.

Option	Description
dscp <i>dscp-list</i>	Matches DSCP values. The <i>dscp-list</i> argument is a list of up to eight DSCP values. A DSCP value can be a number from 0 to 63 or any keyword in Table 9 .
destination-mac <i>mac-address</i>	Matches a destination MAC address.
customer-dot1p <i>8021p-list</i>	Matches the 802.1p priority of the customer network. The <i>8021p-list</i> argument is a list of up to eight 802.1p priority values. An 802.1p priority ranges from 0 to 7.
service-dot1p <i>8021p-list</i>	Matches the 802.1p priority of the service provider network. The <i>8021p-list</i> argument is a list of up to eight 802.1p priority values. An 802.1p priority ranges from 0 to 7.
ip-precedence <i>ip-precedence-list</i>	Matches IP precedence. The <i>ip-precedence-list</i> argument is a list of up to eight IP precedence values. An IP precedence ranges from 0 to 7.
protocol <i>protocol-name</i>	Matches a protocol. The <i>protocol-name</i> argument can be IP or IPv6.
source-mac <i>mac-address</i>	Matches a source MAC address.
customer-vlan-id { <i>vlan-id-list</i> <i>vlan-id1 to vlan-id2</i> }	Matches the VLAN IDs of customer networks. The <i>vlan-id-list</i> argument is a list of up to eight VLAN IDs. The <i>vlan-id1 to vlan-id2</i> specifies a VLAN ID range, where the <i>vlan-id1</i> must be smaller than the <i>vlan-id2</i> . A VLAN ID ranges from 1 to 4094.
service-vlan-id { <i>vlan-id-list</i> <i>vlan-id1 to vlan-id2</i> }	Matches the VLAN IDs of ISP networks. The <i>vlan-id-list</i> is a list of up to eight VLAN IDs. The <i>vlan-id1 to vlan-id2</i> specifies a VLAN ID range, where the <i>vlan-id1</i> must be smaller than the <i>vlan-id2</i> . A VLAN ID ranges from 1 to 4094.
system-index <i>index-value-list</i>	Matches a pre-defined match criterion (system-index) for packets sent to the control plane. The <i>index-value-list</i> argument specifies a list of up to eight system indexes. The system index ranges from 1 to 128.

Defining a traffic behavior

A traffic behavior is a set of QoS actions (such as traffic filtering, shaping, policing, and priority marking) to take on a class of traffic. To define a traffic behavior, first create it and then configure QoS actions, such as priority marking and traffic redirecting, in traffic behavior view.

To define a traffic behavior:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a traffic behavior and enter traffic behavior view.	traffic behavior <i>behavior-name</i>	N/A
3. Configure actions in the traffic behavior.	See the subsequent chapters, depending on the purpose of the traffic behavior: traffic policing, traffic filtering, traffic redirecting, priority marking, traffic accounting, and so on.	

Defining a policy

You associate a behavior with a class in a QoS policy to perform the actions defined in the behavior for the class of packets.

Configuration restrictions and guidelines

- If an ACL is referenced by a QoS policy for defining traffic match criteria, packets matching the ACL are organized as a class and the behavior defined in the QoS policy applies to the class regardless of whether the action in the rule is **deny** or **permit**.
- In a QoS policy with multiple class-to-traffic-behavior associations, if the action of creating an outer VLAN tag, setting customer network VLAN ID, or setting service provider network VLAN ID is configured in a traffic behavior, do not configure any other action in this traffic behavior; otherwise, the QoS policy may not function as expected after it is applied. For more information about the action of setting customer network VLAN ID or service provider network VLAN ID, see *Layer 2—LAN Switching Configuration Guide*.

Configuration procedure

To associate a class with a behavior in a policy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a policy and enter policy view.	qos policy <i>policy-name</i>	N/A
3. Associate a class with a behavior in the policy.	classifier <i>tcl-name</i> behavior <i>behavior-name</i> [mode dot1q-tag-manipulation]	Repeat this step to create more class-behavior associations.

The **dot1q-tag-manipulation** keyword is only for VLAN mapping purposes. For more information about VLAN mapping, see *Layer 2—LAN Switching Configuration Guide*.

Applying the QoS policy

You can apply a QoS policy to the following occasions:

- **An interface**—The policy takes effect on the traffic sent or received on the interface.
- **A user profile**—The policy takes effect on the traffic sent or received by the online users of the user profile.
- **A VLAN**—The policy takes effect on the traffic sent or received on all ports in the VLAN.
- **Globally**—The policy takes effect on the traffic sent or received on all ports.
- **Control plane**—The policy takes effect on the traffic received on the control plane.

The QoS policies applied to ports, to VLANs, and globally are in the descending priority order. If the system finds a matching QoS policy for the incoming/outgoing traffic, the system stops matching the traffic against QoS policies.

You can modify classes, behaviors, and class-behavior associations in a QoS policy applied to an interface, VLAN, or inactive user profile, or globally. If a class references an ACL for traffic classification, you can delete or modify the ACL (such as add rules to, delete rules from, and modify rules of the ACL).

If a QoS policy has been applied to an active user profile, you cannot modify classes, behaviors, and class-behavior associations of the QoS policy, or delete the QoS policy.

Applying the QoS policy to an interface

Both bridge mode (Layer 2) and route mode (Layer 3) Ethernet ports support QoS policies. The term *interface* in this section collectively refers to these types of ports. You can use the **port link-mode** command to set an Ethernet port to operate in bridge or route mode (see *Layer 2—LAN Switching Configuration Guide*).

The 5500 SI Switch Series does not support Layer 3 Ethernet ports.

A policy can be applied to multiple interfaces, but only one policy can be applied in one direction (inbound or outbound) of an interface.

The QoS policy applied to the outgoing traffic of a port does not regulate local packets, which are critical protocol packets sent by the device that hosts the interface for maintaining the normal operation of the device. The most common local packets include link maintenance packets, STP, LDP, and RSVP packets.

To apply the QoS policy to an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	<p>Use either command.</p> <p>Settings in interface view take effect on the current interface.</p> <p>Settings in port group view take effect on all ports in the port group.</p>
3. Apply the policy to the interface or port group.	qos apply policy <i>policy-name</i> { inbound outbound }	The outbound keyword is not available on the 5500 SI Switch Series.

Applying the QoS policy to online users

You can apply a QoS policy to multiple online users. In one direction of each online user, only one policy can be applied. To modify a QoS policy already applied in a certain direction, remove the QoS policy application first.

Configuration restrictions and guidelines

- The QoS policy applied to a user profile supports only the **remark**, **car**, and **filter** actions.
- Do not apply a null policy to a user profile. The user profile using a null policy cannot be activated.
- The authentication methods available for online users include 802.1X and Portal.

Configuration procedure

To apply the QoS policy to online users:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter user profile view.	user-profile <i>profile-name</i>	The configuration made in user profile view takes effect when the user profile is activated and the users of the user profile are online. For more information about user profiles, see <i>Security Configuration Guide</i> .
3. Apply the QoS policy.	qos apply policy <i>policy-name</i> { inbound outbound }	Use the inbound keyword to apply the QoS policy to the incoming traffic of the device (traffic sent by the online users). Use the outbound keyword to apply the QoS policy to the outgoing traffic (traffic received by the online users). The outbound keyword is not available on the 5500 SI Switch Series.
4. Return to system view.	quit	N/A
5. Activate the user profile.	user-profile <i>profile-name</i> enable	By default, a user profile is inactive.

Applying the QoS policy to a VLAN

You can apply a QoS policy to a VLAN to regulate traffic of the VLAN.

QoS policies cannot be applied to dynamic VLANs, such as VLANs created by GVRP.

To apply the QoS policy to a VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Apply the QoS policy to VLANs.	qos vlan-policy <i>policy-name</i> vlan <i>vlan-id-list</i> { inbound outbound }	The outbound keyword is not available on the 5500 SI Switch Series.

Applying the QoS policy globally

You can apply a QoS policy globally to the inbound or outbound direction of all ports.

To apply the QoS policy globally:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Apply the QoS policy globally.	qos apply policy <i>policy-name</i> global { inbound outbound }	The outbound keyword is not available on the 5500 SI Switch Series.

Applying the QoS policy to the control plane

A device provides the data plane and the control plane.

- The data plane has units responsible for receiving, transmitting, and switching (forwarding) packets, such as various dedicated forwarding chips. They deliver super processing speeds and throughput.
- The control plane has processing units running most routing and switching protocols and responsible for protocol packet resolution and calculation, such as CPUs. Compared with data plane units, the control plane units allow for great packet processing flexibility, but have lower throughput.

When the data plane receives packets that it cannot recognize or process, it transmits them to the control plane. If the transmission rate exceeds the processing capability of the control plane, which very likely occurs at times of DoS attacks, the control plane will be busy handling undesired packets and fail to handle legitimate packets correctly or timely. As a result, protocol performance is affected.

To address this problem, apply a QoS policy to the control plane to take QoS actions, such as traffic filtering or rate limiting, on inbound traffic. This action ensures that the control plane can receive, transmit, and process packets properly.

Configuration restrictions and guidelines

- By default, devices are configured with pre-defined control plane policies, which take effect on the control planes by default. A pre-defined control plane QoS policy uses the system-index to identify the type of packets sent to the control plane. You can reference system-indexes in **if-match** commands in class view for traffic classification and then re-configure traffic behaviors for these classes as required. You can use the **display qos policy control-plane pre-defined** command to display them.
- In a QoS policy for control planes, if a system index classifier is configured, the associated traffic behavior can contain only the **car** action or the combination of **car** and **accounting packet** actions. In addition, if the CAR action is configured, only its CIR setting can be applied.
- In the QoS policy for a control plane, if a system index classifier is not configured, the associated traffic behaviors also take effect on the data traffic of the device where the control plane resides.

Configuration procedure

To apply the QoS policy to the control plane:

Step	Command
1. Enter system view.	system-view
2. Enter control plane view.	control-plane slot <i>slot-number</i>
3. Apply the QoS policy to the control plane.	qos apply policy <i>policy-name</i> inbound

Displaying and maintaining QoS policies

IMPORTANT:

The **outbound** keyword is not available on the 5500 SI Switch Series.

Task	Command	Remarks
Display traffic class configuration.	display traffic classifier user-defined [<i>tcl-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display traffic behavior configuration.	display traffic behavior user-defined [<i>behavior-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display user-defined QoS policy configuration.	display qos policy user-defined [<i>policy-name</i> [classifier <i>tcl-name</i>]] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display QoS policy configuration on the specified or all interfaces.	display qos policy interface [<i>interface-type</i> <i>interface-number</i>] [inbound outbound] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display VLAN QoS policy configuration.	display qos vlan-policy { name <i>policy-name</i> vlan <i>vlan-id</i> } [slot <i>slot-number</i>] [inbound outbound] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about QoS policies applied globally.	display qos policy global [slot <i>slot-number</i>] [inbound outbound] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about QoS policies applied to a control plane.	display qos policy control-plane slot <i>slot-number</i> [inbound] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about pre-defined QoS policies applied to a control plane.	display qos policy control-plane pre-defined [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear VLAN QoS policy statistics.	reset qos vlan-policy [vlan <i>vlan-id</i>] [inbound outbound]	Available in user view
Clear the statistics for a QoS policy applied globally.	reset qos policy global [inbound outbound]	Available in user view
Clear the statistics for the QoS policy applied to a control plane.	reset qos policy control-plane slot <i>slot-number</i> [inbound]	Available in user view

Configuring priority mapping

Both bridge mode (Layer 2) and route mode (Layer 3) Ethernet ports support the priority mapping function. The term *interface* in this chapter collectively refers to these types of ports. You can use the **port link-mode** command to set an Ethernet port to operate in bridge or route mode (see *Layer 2—LAN Switching Configuration Guide*).

The 5500 SI Switch Series does not support Layer 3 Ethernet ports.

Overview

When a packet enters a device, depending on your configuration, the device assigns a set of QoS priority parameters to the packet based on either a certain priority field carried in the packet or the port priority of the incoming port. This process is called "priority mapping". During this process, the device can modify the priority of the packet depending on device status. The set of QoS priority parameters decides the scheduling priority and forwarding priority of the packet.

Priority mapping is implemented with priority mapping tables and involves priorities such as 802.1p priority, DSCP, IP precedence, local precedence, and drop precedence.

Types of priorities

Priorities fall into the following types: priorities carried in packets, and priorities locally assigned for scheduling only.

The packet-carried priorities include 802.1p priority, DSCP precedence, IP precedence, and so on. These priorities have global significance and affect the forwarding priority of packets across the network. For more information about these priorities, see "[Appendix B Packet precedences](#)."

The locally assigned priorities only have local significance. They are assigned by the device for scheduling only. These priorities include the local precedence and drop precedence, as follows:

- **Local precedence**—Local precedence is used for queuing. A local precedence value corresponds to an output queue. A packet with higher local precedence is assigned to a higher priority output queue to be preferentially scheduled.
- **Drop precedence**—Drop precedence is used for making packet drop decisions. Packets with the highest drop precedence are dropped preferentially.

Priority mapping tables

Priority mapping is implemented with priority mapping tables. By looking up a priority mapping table, the device decides which priority value to assign to a packet for subsequent packet processing. The switch provides the following priority mapping tables:

- **dot1p-dp**—802.1p-to-drop priority mapping table.
- **dot1p-lp**—802.1p-to-local priority mapping table.
- **dscp-dot1p**—DSCP-to-802.1p priority mapping table, which is applicable to only IP packets.
- **dscp-dp**—DSCP-to-drop priority mapping table, which is applicable to only IP packets.
- **dscp-dscp**—DSCP-to-DSCP priority mapping table, which is applicable to only IP packets.

The default priority mapping tables (see "[Appendix A Default priority mapping tables](#)") are available for priority mapping. In most cases, they are adequate for priority mapping. If a default priority mapping table cannot meet your requirements, you can modify the priority mapping table as required.

Priority trust mode on a port

The priority trust mode on a port decides which priority is used for priority mapping table lookup. Port priority was introduced to use for priority mapping in addition to priority fields carried in packets. The HP 5500 EI and 5500 SI Switch Series provides the following priority trust modes:

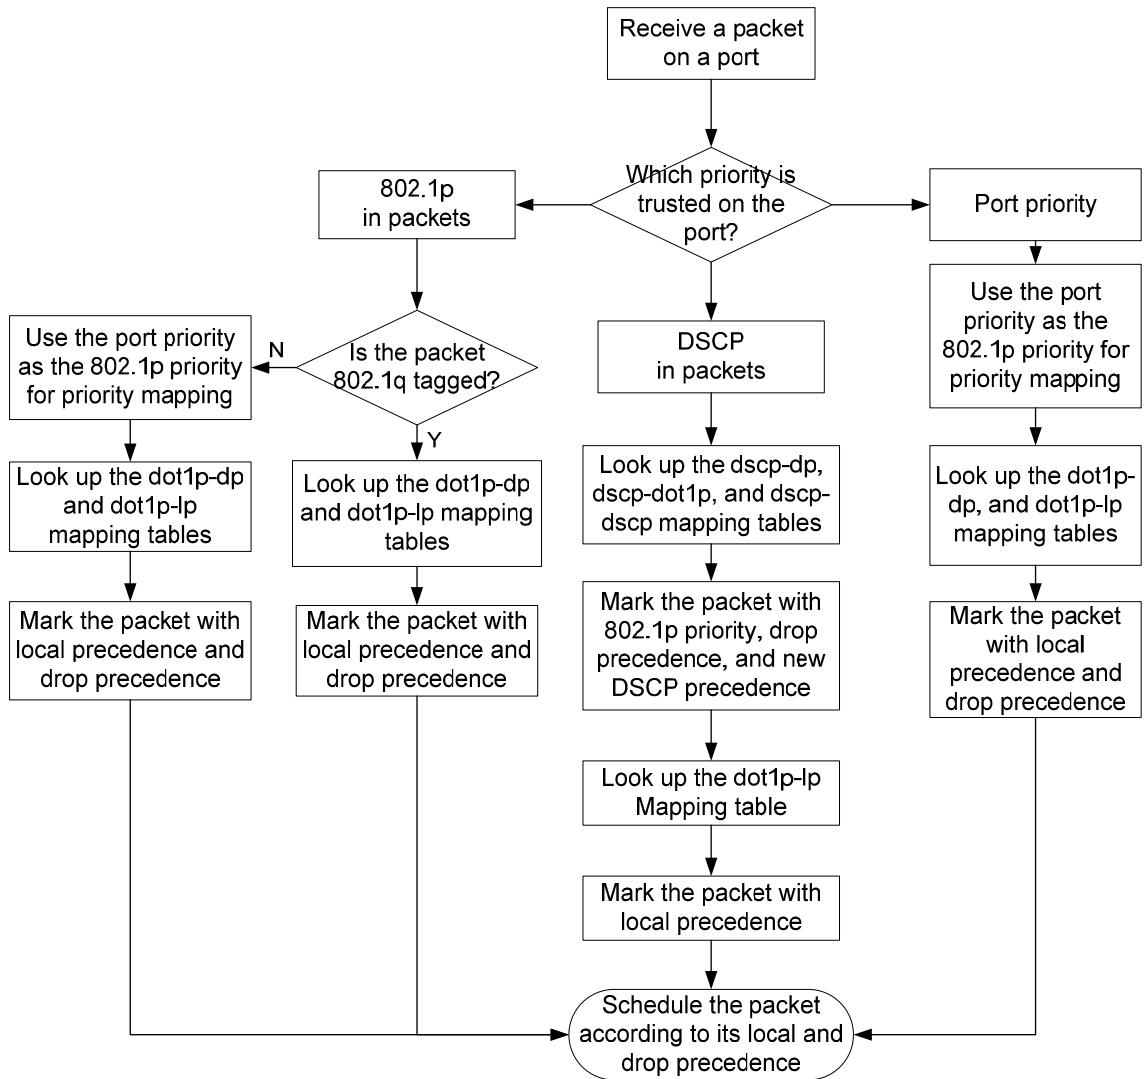

- Using the 802.1p priority carried in packets for priority mapping.
- Using the DSCP carried in packets for priority mapping.
- Using the port priority as the 802.1p priority for priority mapping. The port priority is user configurable.

The priority mapping procedure varies with the priority modes. For more information, see the subsequent section.

Priority mapping procedure

On receiving an Ethernet packet on a port, the switch marks the scheduling priorities (local precedence and drop precedence) for the Ethernet packet. This procedure is done according to the priority trust mode of the receiving port and the 802.1q tagging status of the packet, as shown in [Figure 6](#).

Figure 6 Priority mapping procedure for an Ethernet packet

The priority mapping procedure shown in Figure 6 applies in the absence of priority marking. If priority marking is configured, the switch performs priority marking before priority mapping. The switch then uses the re-marked packet-carried priority for priority mapping or directly uses the re-marked scheduling priority for traffic scheduling depending on your configuration. Neither priority trust mode configuration on the port nor port priority configuration takes effect.

Configuration guidelines

You can modify priority mappings by modifying priority mapping tables, priority trust mode on a port, and port priority.

HP recommends planning QoS throughout the network before making your QoS configuration.

Configuring a priority mapping table

To configure a priority mapping table:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter priority mapping table view.	qos map-table { dot1p-dp dot1p-lp dscp-dot1p dscp-dp dscp-dscp }	N/A
3. Configure the priority mapping table.	import <i>import-value-list</i> export <i>export-value</i>	Newly configured mappings overwrite the old ones.

Configuring a port to trust packet priority for priority mapping

When you configure the trusted packet priority type on an interface or port group, use the following priority trust modes:

- **dot1p**—Uses the 802.1p priority of received packets for mapping.
- **dscp**—Uses the DSCP precedence of received IP packets for mapping.
- **untrust**—Uses port priority as the 802.1p priority for priority mapping.

To configure the trusted packet priority type on an interface or port group:

Step	Command	Remarks
1. Enter system view	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> • Enter interface view: interface <i>interface-type</i> <i>interface-number</i> • Enter port group view: port-group manual <i>port-group-name</i> 	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
3. Configure the trusted packet priority type for the interface.	<ul style="list-style-type: none"> • Trust the DSCP priority in packets: qos trust dscp • Trust the 802.1p priority in packets: qos trust dot1p • Trust the port priority: undo qos trust 	Use either command. By default, the device trusts the port priority.

Changing the port priority of an interface

To change the port priority of an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
3. Set the port priority of the interface.	qos priority <i>priority-value</i>	The default port priority is 0.

Displaying priority mappings

Task	Command	Remarks
Display priority mapping table configuration.	display qos map-table [<i>dot1p-dp</i> <i>dot1p-lp</i> <i>dscp-dot1p</i> <i>dscp-dp</i> <i>dscp-dscp</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the trusted packet priority type on a port.	display qos trust interface [<i>interface-type</i> <i>interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Priority trust mode configuration example

Network requirements

As shown in Figure 7, Device A is connected to GigabitEthernet 1/0/1 of Device C, Device B is connected to GigabitEthernet 1/0/2 of Device C, and the packets from Device A and Device B to Device C are not VLAN tagged.

Make configurations to have Device C preferentially process packets from Device A to Server when GigabitEthernet 1/0/3 of Device C is congested.

Figure 7 Network diagram

Configuration procedure

Assign port priority to GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. Make sure that the priority of GigabitEthernet 1/0/1 is higher than that of GigabitEthernet 1/0/2, and no trusted packet priority type is configured on GigabitEthernet 1/0/1 or GigabitEthernet 1/0/2.

```
<DeviceC> system-view
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] qos priority 3
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] qos priority 1
[DeviceC-GigabitEthernet1/0/2] quit
```

Priority mapping table and priority marking configuration example

Network requirements

As shown in [Figure 8](#), the company's enterprise network interconnects all departments through Device. The network is described as follows:

- The marketing department connects to GigabitEthernet 1/0/1 of Device, which sets the 802.1p priority of traffic from the marketing department to 3.
- The R&D department connects to GigabitEthernet 1/0/2 of Device, which sets the 802.1p priority of traffic from the R&D department to 4.
- The management department connects to GigabitEthernet 1/0/3 of Device, which sets the 802.1p priority of traffic from the management department to 5.

Configure port priority, 802.1p-to-local mapping table, and priority marking to implement the plan as described in [Table 3](#).

Table 3 Configuration plan

Traffic destination	Traffic priority order	Queuing plan		
		Traffic source	Output queue	Queue priority
Public servers	R&D department > management department > marketing department	R&D department	6	High
		Management department	4	Medium
		Marketing department	2	Low
Internet	Management department > marketing department > R&D department	R&D department	2	Low
		Management department	6	High
		Marketing department	4	Medium

Figure 8 Network diagram

Configuration procedure

1. Configure trusting port priority:

Set the port priority of GigabitEthernet 1/0/1 to 3.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] qos priority 3
[Device-GigabitEthernet1/0/1] quit
```

Set the port priority of GigabitEthernet 1/0/2 to 4.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] qos priority 4
[Device-GigabitEthernet1/0/2] quit
```

Set the port priority of GigabitEthernet 1/0/3 to 5.

```
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] qos priority 5
[Device-GigabitEthernet1/0/3] quit
```

2. Configure the priority mapping table:

Configure the 802.1p-to-local mapping table to map 802.1p priority values 3, 4, and 5 to local precedence values 2, 6, and 4. This guarantees the R&D department, management department, and marketing department decreased priorities to access the public server.

```
[Device] qos map-table dot1p-lp
[Device-maptbl-dot1p-lp] import 3 export 2
[Device-maptbl-dot1p-lp] import 4 export 6
```

```
[Device-maptbl-dot1p-1p] import 5 export 4
[Device-maptbl-dot1p-1p] quit
```

3. Configure priority marking:

Mark the HTTP traffic of the management department, marketing department, and R&D department to the Internet with 802.1p priorities 4, 5, and 3, respectively. Use the priority mapping table you have configured to map the 802.1p priorities to local precedence values 6, 4, and 2, respectively, for differentiated traffic treatment.

Create ACL 3000 to match HTTP traffic.

```
[Device] acl number 3000
[Device-acl-adv-3000] rule permit tcp destination-port eq 80
[Device-acl-adv-3000] quit
```

Create class **http** and reference ACL 3000 in the class.

```
[Device] traffic classifier http
[Device-classifier-http] if-match acl 3000
[Device-classifier-http] quit
```

Configure a priority marking policy for the management department, and apply the policy to the incoming traffic of GigabitEthernet 1/0/3.

```
[Device] traffic behavior admin
[Device-behavior-admin] remark dot1p 4
[Device-behavior-admin] quit
[Device] qos policy admin
[Device-qospolicy-admin] classifier http behavior admin
[Device-qospolicy-admin] quit
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] qos apply policy admin inbound
```

Configure a priority marking policy for the marketing department, and apply the policy to the incoming traffic of GigabitEthernet 1/0/1.

```
[Device] traffic behavior market
[Device-behavior-market] remark dot1p 5
[Device-behavior-market] quit
[Device] qos policy market
[Device-qospolicy-market] classifier http behavior market
[Device-qospolicy-market] quit
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] qos apply policy market inbound
```

Configure a priority marking policy for the R&D department, and apply the policy to the incoming traffic of GigabitEthernet 1/0/2.

```
[Device] traffic behavior rd
[Device-behavior-rd] remark dot1p 3
[Device-behavior-rd] quit
[Device] qos policy rd
[Device-qospolicy-rd] classifier http behavior rd
[Device-qospolicy-rd] quit
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] qos apply policy rd inbound
```

Configuring traffic policing, traffic shaping, and line rate

Both bridge mode (Layer 2) and route mode (Layer 3) Ethernet ports support the traffic shaping and line rate functions. The term *interface* in this chapter collectively refers to these types of ports. You can use the **port link-mode** command to set an Ethernet port to operate in bridge or route mode (see *Layer 2—LAN Switching Configuration Guide*).

The 5500 SI Switch Series does not support Layer 3 Ethernet ports.

Overview

Traffic policing, traffic shaping, and rate limit are QoS technologies that help assign network resources, such as assign bandwidth. They increase network performance and user satisfaction. For example, you can configure a flow to use only the resources committed to it in a certain time range. This avoids network congestion caused by burst traffic.

Traffic policing, generic traffic shaping (GTS), and line rate limit the traffic rate and resource usage according to traffic specifications. Once a particular flow exceeds its specifications, such as assigned bandwidth, the flow is shaped or policed to make sure that it is under the specifications. You can use token buckets for evaluating traffic specifications.

Traffic evaluation and token buckets

A token bucket is analogous to a container that holds a certain number of tokens. Each token represents a certain forwarding capacity. The system puts tokens into the bucket at a constant rate. When the token bucket is full, the extra tokens cause the token bucket to overflow.

Evaluating traffic with the token bucket

A token bucket mechanism evaluates traffic by looking at the number of tokens in the bucket. If the number of tokens in the bucket is enough for forwarding the packets, the traffic conforms to the specification, and is called "conforming traffic". Otherwise, the traffic does not conform to the specification, and is called "excess traffic".

A token bucket has the following configurable parameters:

- Mean rate at which tokens are put into the bucket, which is the permitted average rate of traffic. It is usually set to the committed information rate (CIR).
- Burst size or the capacity of the token bucket. It is the maximum traffic size permitted in each burst. It is usually set to the committed burst size (CBS). The set burst size must be greater than the maximum packet size.

Each arriving packet is evaluated. In each evaluation, if the number of tokens in the bucket is enough, the traffic conforms to the specification and the tokens for forwarding the packet are taken away; if the number of tokens in the bucket is not enough, the traffic is excessive.

Complicated evaluation

You can set two token buckets, bucket C and bucket E, to evaluate traffic in a more complicated environment and achieve more policing flexibility. For example, traffic policing uses the following parameters:

- **CIR**—Rate at which tokens are put into bucket C. It sets the average packet transmission or forwarding rate allowed by bucket C.
- **CBS**—Size of bucket C, which specifies the transient burst of traffic that bucket C can forward.
- **Peak information rate (PIR)**—Rate at which tokens are put into bucket E, which specifies the average packet transmission or forwarding rate allowed by bucket E.
- **Excess burst size (EBS)**—Size of bucket E, which specifies the transient burst of traffic that bucket E can forward.

CBS is implemented with bucket C, and EBS with bucket E. In each evaluation, packets are measured against the following bucket scenarios:

- If bucket C has enough tokens, packets are colored green.
- If bucket C does not have enough tokens but bucket E has enough tokens, packets are colored yellow.
- If neither bucket C nor bucket E has sufficient tokens, packets are colored red.

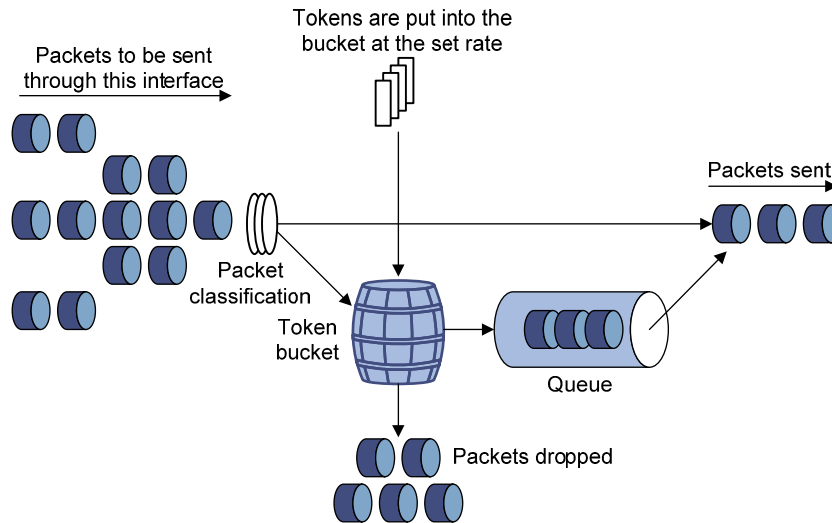

Traffic policing

ⓘ IMPORTANT:

The 5500 EI switch supports policing the inbound traffic and the outbound traffic, and the 5500 SI supports policing only the incoming traffic.

A typical application of traffic policing is to supervise the specification of certain traffic entering a network and limit it within a reasonable range, or to "discipline" the extra traffic to prevent aggressive use of network resources by a certain application. For example, you can limit bandwidth for HTTP packets to less than 50% of the total. If the traffic of a certain session exceeds the limit, traffic policing can drop the packets or reset the IP precedence of the packets. [Figure 9](#) shows an example of policing outbound traffic on an interface.

Figure 9 Traffic policing

Traffic policing is widely used in policing traffic entering the networks of internet service providers (ISPs). It can classify the policed traffic and take pre-defined policing actions on each packet depending on the evaluation result:

- Forwarding the packet if the evaluation result is "conforming"
- Dropping the packet if the evaluation result is "excess"
- Forwarding the packet with its precedence, which can be 802.1p priority (available only for green packets), DSCP, and local precedence, re-marked if the evaluation result is "conforming"

Traffic shaping

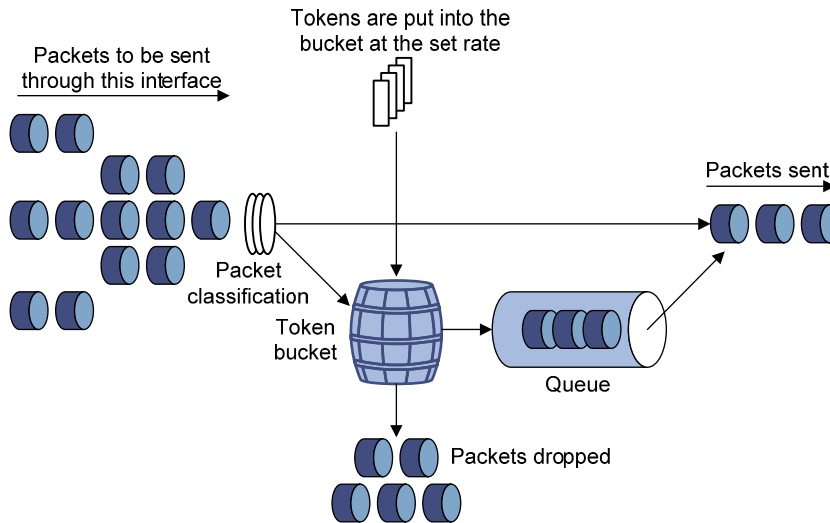

⚠ **IMPORTANT:**

Traffic shaping shapes the outbound traffic.

Traffic shaping limits the outbound traffic rate by buffering exceeding traffic. You can use traffic shaping to adapt the traffic output rate on a device to the input traffic rate of its connected device to avoid packet loss.

The difference between traffic policing and GTS is that packets to be dropped with traffic policing are retained in a buffer or queue with GTS, as shown in [Figure 10](#). When enough tokens are in the token bucket, the buffered packets are sent at an even rate. Traffic shaping can result in additional delay and traffic policing does not.

Figure 10 GTS

For example, in [Figure 11](#), Device B performs traffic policing on packets from Device A and drops packets exceeding the limit. To avoid packet loss, you can perform traffic shaping on the outgoing interface of Device A so packets exceeding the limit are cached in Device A. Once resources are released, traffic shaping takes out the cached packets and sends them out.

Figure 11 GTS application

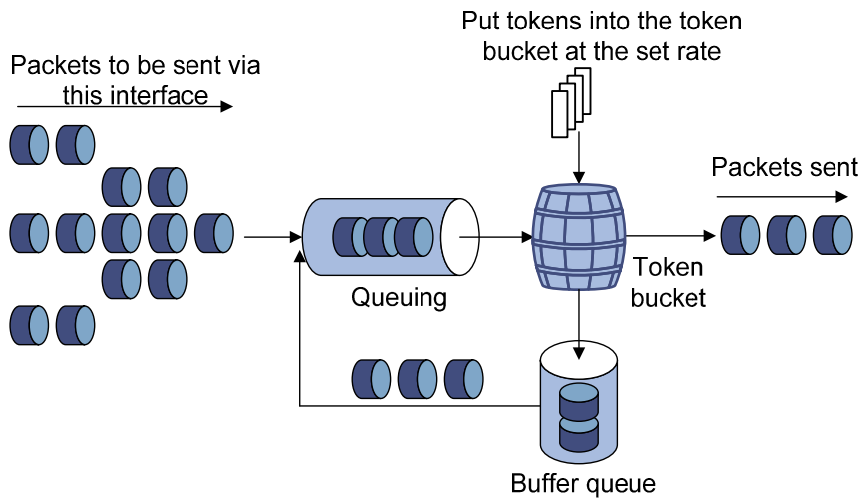

Line rate

Line rate supports rate-limiting the outbound traffic.

The line rate of a physical interface specifies the maximum rate for forwarding packets (including critical packets).

Line rate also uses token buckets for traffic control. With line rate configured on an interface, all packets to be sent through the interface are handled by the token bucket at line rate. If enough tokens are in the token bucket, packets can be forwarded. Otherwise, packets are put into QoS queues for congestion management. In this way, the traffic passing the physical interface is controlled.

Figure 12 Line rate implementation

The token bucket mechanism limits traffic rate when accommodating bursts. It allows bursty traffic to be transmitted if enough tokens are available. If tokens are scarce, packets cannot be transmitted until sufficient tokens are generated in the token bucket. It restricts the traffic rate to the rate for generating tokens.

Line rate can only limit traffic rate on a physical interface, and traffic policing can limit the rate of a flow on an interface. To limit the rate of all the packets on interfaces, using line rate is easier.

Configuring traffic policing

Configuration restrictions and guidelines

In a traffic behavior, do not configure traffic policing with any priority marking action (including local precedence, drop precedence, 802.1p priority, DSCP value, and IP precedence marking actions) in the same traffic behavior. Otherwise, you will fail to apply the QoS policy successfully.

Configuration procedure

To configure traffic policing:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator { and or }]	N/A
3. Configure match criteria.	if-match <i>match-criteria</i>	N/A
4. Return to system view.	quit	N/A
5. Create a behavior and enter behavior view.	traffic behavior <i>behavior-name</i>	N/A

Step	Command	Remarks
6. Configure a traffic policing action.	car cir <i>committed-information-rate</i> [cbs <i>committed-burst-size</i>] [ebs <i>excess-burst-size</i>] [pir <i>peak-information-rate</i>] [green action] [yellow action] [red action]	N/A
7. Return to system view.	quit	N/A
8. Create a policy and enter policy view.	qos policy <i>policy-name</i>	N/A
9. Associate the class with the traffic behavior in the QoS policy.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	N/A
10. Return to system view.	quit	N/A
11. Apply the QoS policy.	<ul style="list-style-type: none"> Applying the QoS policy to an interface Applying the QoS policy to online users Applying the QoS policy to a VLAN Applying the QoS policy globally Applying the QoS policy to the control plane 	Choose one application destination as needed.

Configuring GTS

The Switch Series supports queue-based GTS, which shapes traffic of a specific queue.

To configure GTS:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
3. Configure GTS for a queue.	qos gts queue <i>queue-number</i> cir <i>committed-information-rate</i> [cbs <i>committed-burst-size</i>]	N/A

Configuring the line rate

The line rate of a physical interface specifies the maximum rate of outgoing packets.

To configure the line rate:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
3. Configure the line rate for the interface or port group.	qos lr outbound cir <i>committed-information-rate</i> [cbs <i>committed-burst-size</i>]	N/A

Displaying and maintaining traffic policing, GTS, and line rate

On the 5500 EI and 5500 SI Switch Series, you can configure traffic policing in MQC approach. For more information about the displaying and maintaining commands, see "[Displaying and maintaining QoS policies.](#)"

Task	Command	Remarks
Display interface GTS configuration information.	display qos gts interface [<i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display interface line rate configuration information.	display qos lr interface [<i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Traffic policing configuration example

Network requirements

As shown in [Figure 13](#):

- GigabitEthernet 1/0/3 of Device A is connected to GigabitEthernet1/0/1 of Device B.
- Server, Host A, and Host B can access the Internet through Device A and Device B.

Perform traffic control on GigabitEthernet 1/0/1 of Device A for traffic received from Server and Host A, respectively, to satisfy the following requirements:

- Limit the rate of traffic from Server to 1024 kbps: transmit the conforming traffic normally, and mark the excess traffic with DSCP value 0 and then transmit the traffic.
- Limit the rate of traffic from Host A to 256 kbps: transmit the conforming traffic normally, and drop the excess traffic.

Perform traffic control on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 of Device B to satisfy the following requirements:

- Limit the total incoming traffic rate of GigabitEthernet 1/0/1 to 2048 kbps, and drop the excess traffic.

- Limit the outgoing HTTP traffic (traffic accessing the Internet) rate of GigabitEthernet 1/0/2 to 1024 kbps, and drop the excess traffic.

Figure 13 Network diagram

Configuration procedures

1. Configure Device A:

Configure ACL 2001 and ACL 2002 to match traffic from Server and Host A, respectively.

```
<DeviceA> system-view
[DeviceA] acl number 2001
[DeviceA-acl-basic-2001] rule permit source 1.1.1.1 0
[DeviceA-acl-basic-2001] quit
[DeviceA] acl number 2002
[DeviceA-acl-basic-2002] rule permit source 1.1.1.2 0
[DeviceA-acl-basic-2002] quit
```

Create a class named **server**, and use ACL 2001 as the match criterion. Create a class named **host**, and use ACL 2002 as the match criterion.

```
[DeviceA] traffic classifier server
[DeviceA-classifier-server] if-match acl 2001
[DeviceA-classifier-server] quit
[DeviceA] traffic classifier host
[DeviceA-classifier-host] if-match acl 2002
[DeviceA-classifier-host] quit
```

Create a behavior named **server**, and configure the CAR action for the behavior as follows: set the CIR to 1024 kbps, and mark the excess packets (red packets) with DSCP value 0 and transmit them.

```
[DeviceA] traffic behavior server
[DeviceA-behavior-server] car cir 1024 red remark-dscp-pass 0
[DeviceA-behavior-server] quit
```

Create a behavior named **host**, and configure the CAR action for the behavior as follows: set the CIR to 256 kbps.

```
[DeviceA] traffic behavior host
[DeviceA-behavior-host] car cir 256
[DeviceA-behavior-host] quit
```

Create a QoS policy named **car**, and associate class **server** with behavior **server** and class **host** with behavior **host**.

```
[DeviceA] qos policy car
```

```
[DeviceA-qospolicy-car] classifier server behavior server
[DeviceA-qospolicy-car] classifier host behavior host
[DeviceA-qospolicy-car] quit
# Apply QoS policy car to the incoming traffic of port GigabitEthernet 1/0/1.
[DeviceA] interface GigabitEthernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] qos apply policy car inbound
```

2. Configure Device B:

```
# Configure advanced ACL 3001 to match HTTP traffic.
<DeviceB> system-view
[DeviceB] acl number 3001
[DeviceB-acl-adv-3001] rule permit tcp destination-port eq 80
[DeviceB-acl-adv-3001] quit

# Create a class named http, and use ACL 3001 as the match criterion.
[DeviceB] traffic classifier http
[DeviceB-classifier-http] if-match acl 3001
[DeviceB-classifier-http] quit

# Create a class named class, and configure the class to match all packets.
[DeviceB] traffic classifier class
[DeviceB-classifier-class] if-match any
[DeviceB-classifier-class] quit

# Create a behavior named car_inbound, and configure the CAR action for the behavior as follows: set the CIR to 2048 kbps.
[DeviceB] traffic behavior car_inbound
[DeviceB-behavior-car_inbound] car cir 2048
[DeviceB-behavior-car_inbound] quit

# Create a behavior named car_outbound, and configure a CAR action for the behavior as follows: set the CIR to 1024 kbps.
[DeviceB] traffic behavior car_outbound
[DeviceB-behavior-car_outbound] car cir 1024
[DeviceB-behavior-car_outbound] quit

# Create a QoS policy named car_inbound, and associate class class with traffic behavior car_inbound in the QoS policy.
[DeviceB] qos policy car_inbound
[DeviceB-qospolicy-car_inbound] classifier class behavior car_inbound
[DeviceB-qospolicy-car_inbound] quit

# Create a QoS policy named car_outbound, and associate class http with traffic behavior car_outbound in the QoS policy.
[DeviceB] qos policy car_outbound
[DeviceB-qospolicy-car_outbound] classifier http behavior car_outbound
[DeviceB-qospolicy-car_outbound] quit

# Apply QoS policy car_inbound to the incoming traffic of port GigabitEthernet 1/0/1.
[DeviceB] interface GigabitEthernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] qos apply policy car_inbound inbound

# Apply QoS policy car_outbound to the outgoing traffic of port GigabitEthernet 1/0/2.
[DeviceB] interface GigabitEthernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] qos apply policy car_outbound outbound
```

Configuring congestion management

Both bridge mode (Layer 2) and route mode (Layer 3) Ethernet ports support the congestion management function. The term *interface* in this chapter collectively refers to these types of ports. You can use the **port link-mode** command to set an Ethernet port to operate in bridge or route mode (see *Layer 2—LAN Switching Configuration Guide*).

The 5500 SI Switch Series does not support Layer 3 Ethernet ports.

Overview

Network congestion degrades service quality on a traditional network. Congestion is a situation where the forwarding rate decreases due to insufficient resources, resulting in extra delay.

Congestion is more likely to occur in complex packet switching circumstances. Figure 14 shows two common cases:

Figure 14 Traffic congestion causes

Congestion can bring the following negative results:

- Increased delay and jitter during packet transmission
- Decreased network throughput and resource use efficiency
- Network resource (memory, in particular) exhaustion and system breakdown

Congestion is unavoidable in switched networks and multi-user application environments. To improve the service performance of your network, you must take proper measures to address the congestion issues.

The key to congestion management is defining a dispatching policy for resources to decide the order of forwarding packets when congestion occurs.

Congestion management techniques

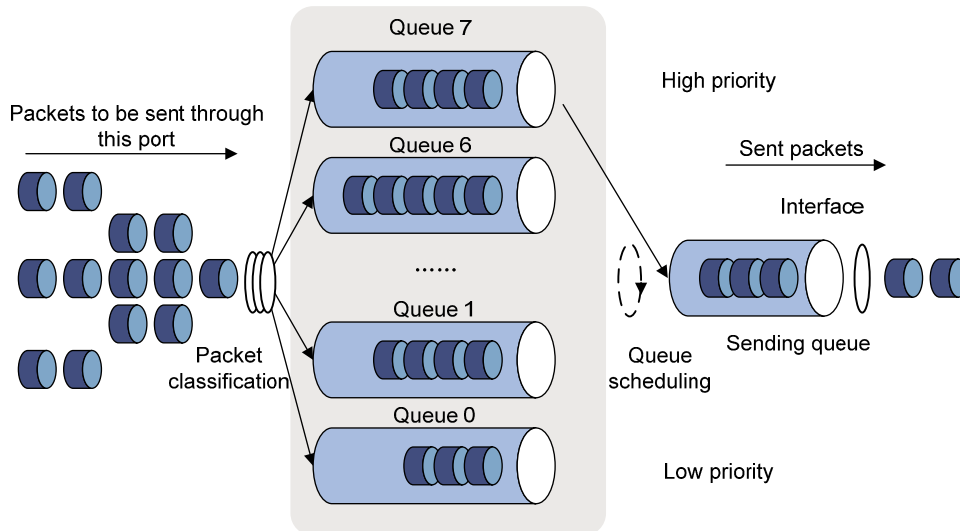

Congestion management uses queuing and scheduling algorithms to classify and sort traffic leaving a port. Each queuing algorithm addresses a particular network traffic problem, and has a different impact on bandwidth resource assignment, delay, and jitter.

Queue scheduling processes packets by their priorities, preferentially forwarding high-priority packets. The following section describes Strict Priority (SP) queuing, Weighted Fair Queuing (WFQ), Weighted Round Robin (WRR) queuing, SP+WRR queuing, and SP+WFQ queuing.

SP queuing

SP queuing is designed for mission-critical applications that require preferential service to reduce the response delay when congestion occurs.

Figure 15 SP queuing

In Figure 15, SP queuing classifies eight queues on a port into eight classes, numbered 7 to 0 in descending priority order.

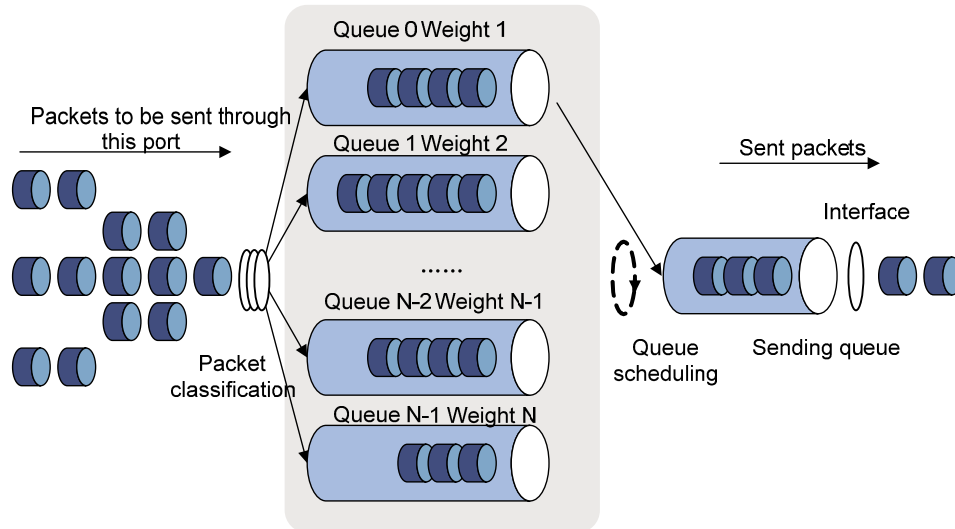

SP queuing schedules the eight queues in the descending order of priority. SP queuing sends packets in the queue with the highest priority first. When the queue with the highest priority is empty, it sends packets in the queue with the second highest priority, and so on. You can assign mission-critical packets to the high priority queue to make sure that they are always served first, and assign common service packets to the low priority queues and transmitted when the high priority queues are empty.

The disadvantage of SP queuing is that packets in the lower priority queues cannot be transmitted if packets exist in the higher priority queues. This may cause lower priority traffic to starve to death.

WRR queuing

WRR queuing schedules all the queues in turn to ensure every queue is served for a certain time, as shown in Figure 16.

Figure 16 WRR queuing

Assume a port provides eight output queues. WRR assigns each queue a weight value (represented by $w_7, w_6, w_5, w_4, w_3, w_2, w_1$, or w_0) to decide the proportion of resources assigned to the queue.

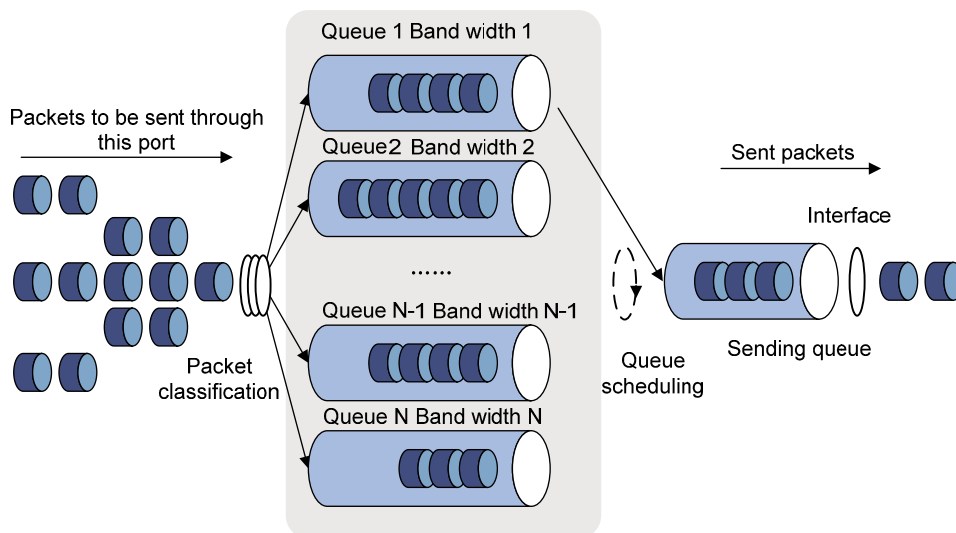

- The 5500 SI switch supports byte-count weight, which determines the weight by the number of bytes scheduled in a cycle.
- The 5500 EI switch supports byte-count weight (which determines the weight by the number of bytes scheduled in a cycle) or packet-based weight (which determines the weight by the number of packets scheduled in a cycle).

Take the byte-count weight as an example. On a 1000 Mbps port, you can configure the weight values of WRR queuing to 5, 5, 3, 3, 1, 1, 1, and 1 (corresponding to $w_7, w_6, w_5, w_4, w_3, w_2, w_1$, and w_0 , respectively). In this way, the queue with the lowest priority can get a minimum of 50 Mbps of bandwidth. WRR avoids the disadvantage of SP queuing, where packets in low-priority queues can fail to be served for a long time.

Another advantage of WRR queuing is that when the queues are scheduled in turn, the service time for each queue is not fixed. If a queue is empty, the next queue will be scheduled immediately. This improves bandwidth resource use efficiency.

WFQ queuing

Figure 17 WFQ queuing

WFQ is similar to WRR. You can use WFQ as an alternative to WRR.

Compared with WRR, WFQ can work with the minimum guaranteed bandwidth as follows:

- By setting the minimum guaranteed bandwidth, you can make sure that each WFQ queue is assured of certain bandwidth.
- The assignable bandwidth is allocated based on the priority of each queue (assignable bandwidth = total bandwidth – the sum of minimum guaranteed bandwidth of each queue).

For example, assume the total bandwidth of a port is 10 Mbps, and the port has five flows, with the precedence being 0, 1, 2, 3, and 4 and the minimum guaranteed bandwidth being 128 kbps, 128 kbps, 128 kbps, 64 kbps, and 64 kbps, respectively.

- The assignable bandwidth = 10 Mbps – (128 kbps + 128 kbps + 128 kbps + 64 kbps + and 64 kbps) = 9.5 Mbps.
- The total assignable bandwidth quota is the sum of all the (precedence value + 1)s, 1 + 2 + 3 + 4 + 5 = 15.
- The bandwidth percentage assigned to each flow is (precedence value of the flow + 1)/total assignable bandwidth quota. The bandwidth percentages for the flows are 1/15, 2/15, 3/15, 4/15, and 5/15, respectively.
- The bandwidth assigned to a queue = the minimum guaranteed bandwidth + the bandwidth allocated to the queue from the assignable bandwidth.

SP+WRR queuing

You can assign some queues on a port to the SP scheduling group and the others to the WRR scheduling group (group 1) to implement SP + WRR queue scheduling. The switch schedules packets in the SP scheduling group preferentially, and when the SP scheduling group is empty, schedules the packets in the WRR scheduling group. Queues in the SP scheduling group are scheduled with the SP queue scheduling algorithm. Queues in the WRR scheduling group are scheduled with WRR.

SP+WFQ queuing

SP+WFQ queuing is similar to SP+WRR queuing. You can assign some queues on a port to the SP scheduling group and the others to the WFQ scheduling group to implement SP + WFQ queue scheduling. The switch schedules packets of queues in the WFQ group based on their minimum guaranteed bandwidth settings, then uses SP queuing to schedule the queues in the SP scheduling group, and at last uses WFQ to schedule the queues in the WFQ scheduling group in a round robin fashion according to their weights

Configuring SP queuing

Configuration procedure

To configure SP queuing:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none">Enter interface view: interface <i>interface-type</i> <i>interface-number</i>Enter port group view: port-group manual <i>port-group-name</i>	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
3. Configure SP queuing.	qos sp	The default queuing algorithm on an interface is WRR queuing.
4. Display SP queuing configuration.	display qos sp interface [<i>interface-type interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Optional. Available in any view

Configuration example

Network requirements

Configure GigabitEthernet 1/0/1 to use SP queuing.

Configuration procedure

```
# Enter system view
<Sysname> system-view

# Configure GigabitEthernet1/0/1 to use SP queuing.
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos sp
```

Configuring WRR queuing

Configuration procedure

To configure WRR queuing:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none">Enter interface view: interface <i>interface-type</i> <i>interface-number</i>Enter port group view: port-group manual <i>port-group-name</i>	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
3. Enable byte-count or packet-based WRR queuing.	qos wrr [byte-count weight]	Optional. The default queuing algorithm on an interface is WRR. Only the 5500 EI switch supports the byte-count and weight keywords.
4. Configure the scheduling weight for a queue.	<ul style="list-style-type: none">For a byte-count WRR queue: qos wrr <i>queue-id</i> group <i>group-id</i> byte-count <i>schedule-value</i>For a packet-based WRR queue: qos wrr <i>queue-id</i> group <i>group-id</i> weight <i>schedule-value</i>	Select an approach according to the WRR queuing type. The 5500 SI switch supports only packet-based WRR queue configuration. By default, packet-based WRR is used, and the weights of queues 0 through 7 are 1, 2, 3, 4, 5, 9, 13, and 15.
5. Display WRR queuing configuration information on interfaces.	display qos wrr interface [<i>interface-type</i> <i>interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Optional. Available in any view

NOTE:

To guarantee successful WRR configuration, make sure that the scheduling weight type (byte-count or packet-based) is the same as the WRR queuing type (byte-count or packet-based) when you configure the scheduling weight for a WRR queue.

Configuration example

WRR queuing configuration example on a 5500 EI switch

- Network requirements
 - Configure byte-count WRR on GigabitEthernet 1/0/1.
 - Assign all queues to the WRR group, with the weights of 1, 2, 4, 6, 8, 10, 12, and 14.

2. Configuration procedures

Enter system view.

```
<Sysname> system-view
```

Configure WRR queuing on port GigabitEthernet 1/0/1.

```
[Sysname] interface GigabitEthernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos wrr byte-count
[Sysname-GigabitEthernet1/0/1] qos wrr 0 group 1 byte-count 1
[Sysname-GigabitEthernet1/0/1] qos wrr 1 group 1 byte-count 2
[Sysname-GigabitEthernet1/0/1] qos wrr 2 group 1 byte-count 4
[Sysname-GigabitEthernet1/0/1] qos wrr 3 group 1 byte-count 6
[Sysname-GigabitEthernet1/0/1] qos wrr 4 group 1 byte-count 8
[Sysname-GigabitEthernet1/0/1] qos wrr 5 group 1 byte-count 10
[Sysname-GigabitEthernet1/0/1] qos wrr 6 group 1 byte-count 12
[Sysname-GigabitEthernet1/0/1] qos wrr 7 group 1 byte-count 14
```

WRR queuing configuration example on a 5500 SI switch

1. Network requirements

- Configure WRR queuing on port GigabitEthernet 1/0/1.
- Assign all queues to the WRR group, with the weights of 1, 2, 4, 6, 8, 10, 12, and 14.

2. Configuration procedures

Enter system view.

```
<Sysname> system-view
```

Configure WRR queuing on port GigabitEthernet 1/0/1.

```
[Sysname] interface GigabitEthernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos wrr
[Sysname-GigabitEthernet1/0/1] qos wrr 0 group 1 weight 1
[Sysname-GigabitEthernet1/0/1] qos wrr 1 group 1 weight 2
[Sysname-GigabitEthernet1/0/1] qos wrr 2 group 1 weight 4
[Sysname-GigabitEthernet1/0/1] qos wrr 3 group 1 weight 6
[Sysname-GigabitEthernet1/0/1] qos wrr 4 group 1 weight 8
[Sysname-GigabitEthernet1/0/1] qos wrr 5 group 1 weight 10
[Sysname-GigabitEthernet1/0/1] qos wrr 6 group 1 weight 12
[Sysname-GigabitEthernet1/0/1] qos wrr 7 group 1 weight 14
```

Configuring WFQ queuing

Configuration procedure

To configure WFQ queuing:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
3. Enable byte-count or packet-based WFQ queuing.	qos wfq [byte-count weight]	The default queuing algorithm on an interface is WRR.
4. Configure the scheduling weight for a queue.	<ul style="list-style-type: none"> For a byte-count WFQ queue: qos wfq <i>queue-id</i> group <i>group-id</i> byte-count <i>schedule-value</i> For a packet-based WFQ queue: qos wfq <i>queue-id</i> group <i>group-id</i> weight <i>schedule-value</i> 	Select a command according to the WFQ type (byte-count or packet-based) you have enabled. If you have enabled WFQ on the port, byte-count WRR applies by default, and the default scheduling weight is 1 for each queue.
5. Configure the minimum guaranteed bandwidth for a WFQ queue.	qos bandwidth queue <i>queue-id</i> min <i>bandwidth-value</i>	Optional. 64 kbps by default for each queue.
6. Display WFQ queuing configuration.	display qos wfq interface [<i>interface-type</i> <i>interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Optional. Available in any view

NOTE:

To guarantee successful WFQ configuration, make sure that the scheduling weight type (byte-count or packet-based) is the same as the WFQ queuing type (byte-count or packet-based) when you configure the scheduling weight for a WFQ queue.

Configuration example

Network requirements

Configure WFQ queues on an interface and assign the scheduling weight 2, 5, 10, and 10 to queue 1, queue 3, queue 4, queue 5, and queue 6, respectively.

Configuration procedure

```
# Enter system view.
<Sysname> system-view

# Configure WFQ queues on GigabitEthernet 1/0/1.
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos wfq
[Sysname-GigabitEthernet1/0/1] qos wfq 1 weight 2
[Sysname-GigabitEthernet1/0/1] qos wfq 3 weight 5
[Sysname-GigabitEthernet1/0/1] qos wfq 4 weight 10
[Sysname-GigabitEthernet1/0/1] qos wfq 5 weight 10
[Sysname-GigabitEthernet1/0/1] qos wfq 6 weight 10
```

Configuring SP+WRR queuing

Configuration procedure

To configure SP + WRR queuing:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none">Enter interface view: interface <i>interface-type</i> <i>interface-number</i>Enter port group view: port-group manual <i>port-group-name</i>	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
3. Enable byte-count or packet-based WRR queuing.	qos wrr [byte-count weight]	Optional. By default, all ports use WRR queuing. Only the 5500 EI switch supports the byte-count and weight keywords.
4. Configure SP queue scheduling.	qos wrr queue-id group sp	By default, all the queues of a WRR-enabled port use the WRR queue scheduling algorithm.
5. Assign a queue to a WRR group and configure the scheduling weight for the queue.	qos wrr queue-id group <i>group-id</i> { weight byte-count } <i>schedule-value</i>	By default, on a WRR-enabled port, packet-based WRR is enabled, and the weights of queues 0 through 7 are 1, 2, 3, 4, 5, 9, 13, and 15. The 5500 SI switch supports only the weight keyword.

NOTE:

To guarantee successful WRR configuration, make sure that the scheduling weight type (byte-count or packet-based) is the same as the WRR queuing type (byte-count or packet-based) when you configure the scheduling weight for a WRR queue.

Configuration example

Network requirements

- Configure SP+WRR queue scheduling algorithm on GigabitEthernet 1/0/1, and use packet-based WRR.
- Configure queue 0, queue 1, queue 2, and queue 3 on GigabitEthernet 1/0/1 to be in SP queue scheduling group.
- Configure queue 4, queue 5, queue 6, and queue 7 on GigabitEthernet 1/0/1 to use WRR queuing, with the weight 2, 4, 6, and 8, respectively.

Configuration procedure

```
# Enter system view.
<Sysname> system-view

# Enable the SP+WRR queue scheduling algorithm on GigabitEthernet1/0/1.
[Sysname] interface GigabitEthernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos wrr weight
[Sysname-GigabitEthernet1/0/1] qos wrr 0 group sp
[Sysname-GigabitEthernet1/0/1] qos wrr 1 group sp
[Sysname-GigabitEthernet1/0/1] qos wrr 2 group sp
[Sysname-GigabitEthernet1/0/1] qos wrr 3 group sp
[Sysname-GigabitEthernet1/0/1] qos wrr 4 group 1 weight 2
[Sysname-GigabitEthernet1/0/1] qos wrr 5 group 1 weight 4
[Sysname-GigabitEthernet1/0/1] qos wrr 6 group 1 weight 6
[Sysname-GigabitEthernet1/0/1] qos wrr 7 group 1 weight 8
```

Configuring SP+WFQ queuing

Configuration procedure

To configure SP + WFQ queuing:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view or port group view.	<ul style="list-style-type: none">Enter interface view: interface <i>interface-type</i> <i>interface-number</i>Enter port group view: port-group manual <i>port-group-name</i>	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
3. Enable byte-count or packet-based WFQ queuing.	qos wfq [byte-count weight]	By default, WRR queuing is enabled.
4. Configure SP queue scheduling.	qos wfq <i>queue-id</i> group sp	By default, all the queues of a WFQ-enabled port are in the WFQ group.
5. Configure the scheduling weight for a queue.	qos wfq <i>queue-id</i> group <i>group-id</i> { weight byte-count } <i>schedule-value</i>	By default, the scheduling weight is 1 for each queue of a WFQ-enabled port.
6. Configure the minimum guaranteed bandwidth for a queue.	qos bandwidth queue <i>queue-id</i> min <i>bandwidth-value</i>	Optional. 64 kbps for each queue by default.

NOTE:

To guarantee successful WFQ configuration, make sure that the scheduling weight type (byte-count or packet-based) is the same as the WFQ queuing type (byte-count or packet-based) when you configure the scheduling weight for a WFQ queue.

Configuration example

Network requirements

- Configure SP+WFQ queuing on GigabitEthernet 1/0/1, and use packet-based WFQ scheduling weights.
- Configure queue 0, queue 1, queue 2, and queue 3 on GigabitEthernet 1/0/1 to be in SP queue scheduling group.
- Configure queue 4, queue 5, queue 6, and queue 7 on GigabitEthernet 1/0/1 to use WFQ queuing, with the weight 2, 4, 6, and 8 and the minimum guaranteed bandwidth 128 kbps.

Configuration procedure

Enter system view.

```
<Sysname> system-view
```

Enable the SP+WFQ queue scheduling algorithm on GigabitEthernet1/0/1.

```
[Sysname] interface GigabitEthernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos wfq weight
[Sysname-GigabitEthernet1/0/1] qos wfq 0 group sp
[Sysname-GigabitEthernet1/0/1] qos wfq 1 group sp
[Sysname-GigabitEthernet1/0/1] qos wfq 2 group sp
[Sysname-GigabitEthernet1/0/1] qos wfq 3 group sp
[Sysname-GigabitEthernet1/0/1] qos wfq 4 group 1 weight 2
[Sysname-GigabitEthernet1/0/1] qos bandwidth queue 4 min 128
[Sysname-GigabitEthernet1/0/1] qos wfq 5 group 1 weight 4
[Sysname-GigabitEthernet1/0/1] qos bandwidth queue 5 min 128
[Sysname-GigabitEthernet1/0/1] qos wfq 6 group 1 weight 6
[Sysname-GigabitEthernet1/0/1] qos bandwidth queue 6 min 128
[Sysname-GigabitEthernet1/0/1] qos wfq 7 group 1 weight 8
[Sysname-GigabitEthernet1/0/1] qos bandwidth queue 7 min 128
```

Configuring congestion avoidance (available only on the 5500 EI)

Both bridge mode (Layer 2) and route mode (Layer 3) Ethernet ports support the congestion avoidance function. The term *interface* in this chapter collectively refers to these types of ports. You can use the **port link-mode** command to set an Ethernet port to operate in bridge or route mode (see *Layer 2—LAN Switching Configuration Guide*).

Overview

Avoiding congestion before it occurs is a proactive approach to improving network performance. As a flow control mechanism, congestion avoidance actively monitors network resources (such as queues and memory buffers), and drops packets when congestion is expected to occur or deteriorate.

Compared with end-to-end flow control, this flow control mechanism controls the load of more flows in a device. When dropping packets from a source end, it cooperates with the flow control mechanism (such as TCP flow control) at the source end to regulate the network traffic size. The combination of the local packet drop policy and the source-end flow control mechanism helps maximize throughput and network use efficiency and minimize packet loss and delay.

Tail drop

Congestion management techniques drop all packets that are arriving at a full queue. This tail drop mechanism results in global TCP synchronization. If packets from multiple TCP connections are dropped, these TCP connections go into the state of congestion avoidance and slow start to reduce traffic, but traffic peak occurs later. Consequently, the network traffic jitters all the time.

RED and WRED

You can use random early detection (RED) or weighted random early detection (WRED) to avoid global TCP synchronization.

Both RED and WRED avoid global TCP synchronization by randomly dropping packets. When the sending rates of some TCP sessions slow down after their packets are dropped, other TCP sessions remain at high sending rates. Link bandwidth is efficiently used, because TCP sessions at high sending rates always exist.

The RED or WRED algorithm sets an upper threshold and lower threshold for each queue, and processes the packets in a queue as follows:

- When the queue size is shorter than the lower threshold, no packet is dropped;
- When the queue size reaches the upper threshold, all subsequent packets are dropped;
- When the queue size is between the lower threshold and the upper threshold, the received packets are dropped at random. The drop probability in a queue increases along with the queue size under the maximum drop probability.

NOTE:

The Switch Series does not support the upper threshold configuration.

Introduction to WRED configuration

On the 5500 EI Switch Series, WRED is implemented with WRED tables. WRED tables are created globally in system view and then applied to interfaces.

Before configuring WRED, determine the following parameters:

- **Lower threshold**—When the average queue length is below the lower threshold, no packet is dropped. When the average queue length exceeds the lower threshold, the switch drops packets at the user-configured drop probability.
- **Drop precedence**—A parameter used in packet drop. Value 0 represents green packets, 1 represents yellow packets, and 2 represents red packets. Red packets are preferentially dropped.
- **Denominator**—Denominator for drop probability calculation. A greater denominator means a lower drop probability. Table 4 shows the denominator and the drop probability dependencies.

Table 4 Denominator and the drop probability dependencies

Denominator	Drop probability
0	100%
1 to 8	1/8
9 to 16	1/16
17 to 32	1/32
33 to 64	1/64
65 to 128	1/128

In a WRED table, drop parameters are configured on a per queue basis because WRED regulates packets on a per queue basis.

A WRED table can be applied to multiple interfaces. For a WRED table already applied to an interface, you can modify the values of the WRED table, but you cannot remove the WRED table.

Configuration procedure

To configure and apply a queue-based WRED table:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a WRED table and enter its view.	qos wred queue table <i>table-name</i>	N/A
3. Configure the other WRED parameters.	queue <i>queue-value</i> [drop-level <i>drop-level</i>] low-limit <i>low-limit</i> [discard-probability <i>discard-prob</i>]	Optional. By default, <i>low-limit</i> is 10, and <i>discard-prob</i> is 10.

Step	Command	Remarks
4. Enter interface view or port group view.	<ul style="list-style-type: none"> Enter interface view: interface <i>interface-type</i> <i>interface-number</i> Enter port group view: port-group manual <i>port-group-name</i> 	Use either command. Settings in interface view take effect on the current interface. Settings in port group view take effect on all ports in the port group.
5. Apply the WRED table to the interface or port group.	qos wred apply <i>table-name</i>	N/A

Configuration examples

Apply a WRED table to Layer 2 port GigabitEthernet 1/0/1. Set the *low-limit* to 30 and *discard-prob* to 20 for queue 1.

Enter system view.

```
<Sysname> system-view
```

Create a queue-based WRED table named **queue-table1**, and configure the drop parameters.

```
[Sysname] qos wred queue table queue-table1
```

```
[Sysname-wred-table-queue-table1] queue 1 low-limit 30 discard-probability 20
```

```
[Sysname-wred-table-queue-table1] quit
```

Enter port view.

```
[Sysname] interface gigabitethernet 1/0/1
```

Apply the WRED table to GigabitEthernet 1/0/1.

```
[Sysname-GigabitEthernet1/0/1] qos wred apply queue-table1
```

Displaying and maintaining WRED

Task	Command	Remarks
Display WRED configuration information on the interface or all interfaces.	display qos wred interface [<i>interface-type</i> <i>interface-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display configuration information about a WRED table or all WRED tables.	display qos wred table [<i>table-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Configuring traffic filtering

Traffic filtering filters traffic matching certain criteria. For example, you can filter packets sourced from a specific IP address according to network status.

Configuration procedure

To configure traffic filtering:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator { and or }]	N/A
3. Configure match criteria.	if-match <i>match-criteria</i>	N/A
4. Return to system view.	quit	N/A
5. Create a behavior and enter behavior view.	traffic behavior <i>behavior-name</i>	N/A
6. Configure the traffic filtering action.	filter { deny permit }	<ul style="list-style-type: none">• deny—Drops packets.• permit—Permits packets to pass through.
7. Return to system view.	quit	N/A
8. Create a policy and enter policy view.	qos policy <i>policy-name</i>	N/A
9. Associate the class with the traffic behavior in the QoS policy.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	N/A
10. Return to system view.	quit	N/A
11. Apply the QoS policy.	<ul style="list-style-type: none">• Applying the QoS policy to an interface• Applying the QoS policy to online users• Applying the QoS policy to a VLAN• Applying the QoS policy globally• Applying the QoS policy to the control plane	Choose one application destination as needed.
12. Display the traffic filtering configuration.	display traffic behavior user-defined [<i>behavior-name</i>] [[{ begin exclude include } <i>regular-expression</i>]	Optional. Available in any view

NOTE:

With **filter deny** configured for a traffic behavior, the other actions (except class-based accounting and traffic mirroring) in the traffic behavior do not take effect.

Traffic filtering configuration example

Network requirements

As shown in [Figure 18](#), Host is connected to GigabitEthernet 1/0/1 of Device.

Configure traffic filtering to filter the packets with source port being 21, and received on GigabitEthernet 1/0/1.

Figure 18 Network diagram

Configuration procedure

Create advanced ACL 3000, and configure a rule to match packets whose source port number is 21.

```
<DeviceA> system-view
[DeviceA] acl number 3000
[DeviceA-acl-adv-3000] rule 0 permit tcp source-port eq 21
[DeviceA-acl-adv-3000] quit
```

Create a class named **classifier_1**, and use ACL 3000 as the match criterion in the class.

```
[DeviceA] traffic classifier classifier_1
[DeviceA-classifier-classifier_1] if-match acl 3000
[DeviceA-classifier-classifier_1] quit
```

Create a behavior named **behavior_1**, and configure the traffic filtering action to drop packets.

```
[DeviceA] traffic behavior behavior_1
[DeviceA-behavior-behavior_1] filter deny
[DeviceA-behavior-behavior_1] quit
```

Create a policy named **policy**, and associate class **classifier_1** with behavior **behavior_1** in the policy.

```
[DeviceA] qos policy policy
[DeviceA-qospolicy-policy] classifier classifier_1 behavior behavior_1
[DeviceA-qospolicy-policy] quit
```

Apply the policy named **policy** to the incoming traffic of GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] qos apply policy policy inbound
```

Configuring priority marking

Priority marking sets the priority fields or flag bits of packets to modify the priority of traffic. For example, you can use priority marking to set IP precedence or DSCP for a class of IP traffic to change its transmission priority in the network.

Priority marking can be used together with priority mapping. For more information about priority mapping, see "[Configuring priority mapping](#)."

Color-based priority marking

Coloring a packet

The switch colors a packet to indicate its transmission priority after evaluating the status of processing resources and the priority of the packet.

The switch can color a packet by using one of the following approaches:

- Uses the token bucket mechanism (bucket C and bucket E) of traffic policing:
 - If bucket C has enough tokens, the packet is colored green.
 - If bucket C does not have enough tokens but bucket E has enough tokens, the packet is colored yellow.
 - If neither bucket C nor bucket E has enough tokens, the packet is colored red.
- If traffic policing is not configured, looks up the 802.1p priority of a packet in the 802.1p-to-drop priority mapping table, allocates drop precedence to the packet, and colors the packet according to the drop precedence.
 - Drop precedence 0 represents green packets.
 - Drop precedence 1 represents yellow packets.
 - Drop precedence 2 represents red packets.

For more information about traffic policing, see "[Configuring traffic policing, traffic shaping, and line rate](#)." For more information about priority mapping tables, see "[Configuring priority mapping](#)."

Marking packets based on their colors

Color-based priority marking supports re-marking DSCP precedence.

You can configure color-based marking in the following ways:

- To mark packets based on a color set during traffic policing, configure a priority marking action for the color in the traffic policing action **car**. For more information, see "[Configuring traffic policing](#)."
- To mark packets based on their drop precedence, configure a priority marking action for a color by using the **remark** command as described in the subsequent section.

ⓘ IMPORTANT:

Do not use the **remark** command together with the **car** command in a traffic behavior to perform color-based marking.

Configuration procedure

To configure priority marking:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator { and or }]	N/A
3. Configure match criteria.	if-match <i>match-criteria</i>	N/A
4. Return to system view.	quit	N/A
5. Create a behavior and enter behavior view.	traffic behavior <i>behavior-name</i>	N/A
6. Set the DSCP value for packets.	remark [green red yellow] dscp <i>dscp-value</i>	Optional.
7. Set the 802.1p priority for packets or configure the inner-to-outer tag priority copying function.	remark dot1p { <i>8021p</i> customer-dot1p-trust }	Optional.
8. Set the drop precedence for packets.	remark drop-precedence <i>drop-precedence-value</i>	Optional. Applicable to only the outbound direction.
9. Set the IP precedence for packets.	remark ip-precedence <i>ip-precedence-value</i>	Optional.
10. Set the local precedence for packets.	remark local-precedence <i>local-precedence</i>	Optional.
11. Return to system view.	quit	N/A
12. Create a policy and enter policy view.	qos policy <i>policy-name</i>	N/A
13. Associate the class with the traffic behavior in the QoS policy.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	N/A
14. Return to system view.	quit	N/A
15. Apply the QoS policy.	<ul style="list-style-type: none"> • Applying the QoS policy to an interface • Applying the QoS policy to online users • Applying the QoS policy to a VLAN • Applying the QoS policy globally • Applying the QoS policy to the control plane 	Choose one application destination as needed.
16. Display the priority marking configuration.	display traffic behavior user-defined [<i>behavior-name</i>] [[{ begin exclude include } <i>regular-expression</i>]	Optional. Available in any view

The following table shows the support for priority marking actions in the inbound and outbound directions.

Table 5 Support for priority marking actions in the inbound and outbound directions

Action	inbound	outbound
802.1p priority marking	Yes	Yes
Drop precedence marking	Yes	No
DSCP marking	Yes	Yes
IP precedence marking	Yes	Yes
Local precedence marking	Yes	No

Local precedence re-marking configuration example

Network requirements

As shown in [Figure 19](#), the company's enterprise network interconnects hosts with servers through Device. The network is described as follows:

- Host A and Host B are connected to GigabitEthernet 1/0/1 of Device.
- The data server, mail server, and file server are connected to GigabitEthernet 1/0/2 of Device.

Configure priority marking on Device to satisfy the following requirements:

Traffic source	Destination	Processing priority
Host A, B	Data server	High
Host A, B	Mail server	Medium
Host A, B	File server	Low

Figure 19 Network diagram

Configuration procedure

Create advanced ACL 3000, and configure a rule to match packets with destination IP address 192.168.0.1.

```

<Device> system-view
[Device] acl number 3000
[Device-acl-adv-3000] rule permit ip destination 192.168.0.1 0
[Device-acl-adv-3000] quit

# Create advanced ACL 3001, and configure a rule to match packets with destination IP address
192.168.0.2.
[Device] acl number 3001
[Device-acl-adv-3001] rule permit ip destination 192.168.0.2 0
[Device-acl-adv-3001] quit

# Create advanced ACL 3002, and configure a rule to match packets with destination IP address
192.168.0.3.
[Device] acl number 3002
[Device-acl-adv-3002] rule permit ip destination 192.168.0.3 0
[Device-acl-adv-3002] quit

# Create a class named classifier_dbserver, and use ACL 3000 as the match criterion in the class.
[Device] traffic classifier classifier_dbserver
[Device-classifier-classifier_dbserver] if-match acl 3000
[Device-classifier-classifier_dbserver] quit

# Create a class named classifier_mserver, and use ACL 3001 as the match criterion in the class.
[Device] traffic classifier classifier_mserver
[Device-classifier-classifier_mserver] if-match acl 3001
[Device-classifier-classifier_mserver] quit

# Create a class named classifier_fserver, and use ACL 3002 as the match criterion in the class.
[Device] traffic classifier classifier_fserver
[Device-classifier-classifier_fserver] if-match acl 3002
[Device-classifier-classifier_fserver] quit

# Create a behavior named behavior_dbserver, and configure the action of setting the local precedence
value to 4.
[Device] traffic behavior behavior_dbserver
[Device-behavior-behavior_dbserver] remark local-precedence 4
[Device-behavior-behavior_dbserver] quit

# Create a behavior named behavior_mserver, and configure the action of setting the local precedence
value to 3.
[Device] traffic behavior behavior_mserver
[Device-behavior-behavior_mserver] remark local-precedence 3
[Device-behavior-behavior_mserver] quit

# Create a behavior named behavior_fserver, and configure the action of setting the local precedence
value to 2.
[Device] traffic behavior behavior_fserver
[Device-behavior-behavior_fserver] remark local-precedence 2
[Device-behavior-behavior_fserver] quit

# Create a policy named policy_server, and associate classes with behaviors in the policy.
[Device] qos policy policy_server
[Device-qospolicy-policy_server] classifier classifier_dbserver behavior
behavior_dbserver

```

```
[Device-qospolicy-policy_server] classifier classifier_mserver behavior
behavior_mserver
[Device-qospolicy-policy_server] classifier classifier_fserver behavior
behavior_fserver
[Device-qospolicy-policy_server] quit
# Apply the policy named policy_server to the incoming traffic of GigabitEthernet 1/0/1.
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] qos apply policy policy_server inbound
[Device-GigabitEthernet1/0/1] quit
```

Configuring traffic redirecting

Traffic redirecting is the action of redirecting the packets matching the specific match criteria to a certain location for processing.

The following redirect actions are supported:

- **Redirecting traffic to the CPU**—redirects packets that require processing by the CPU to the CPU.
- **Redirecting traffic to an interface**—redirects packets that require processing by an interface to the interface. Note that this action applies to only Layer 2 packets, and the target interface must be a Layer 2 interface.
- **Redirecting traffic to the next hop**—redirects packets that require processing by an interface to the interface. This action only applies to Layer 3 packets.

❗ **IMPORTANT:**

The 5500 SI switch does not support redirecting traffic to the next hop.

Configuration restrictions and guidelines

- The actions of redirecting traffic to the CPU, redirecting traffic to an interface, and redirecting traffic to the next hop are mutually exclusive with each other in the same traffic behavior.
- A QoS policy with traffic redirecting actions can be applied to only the inbound direction of a port, VLAN, or all ports.
- The default of the **fail-action** keyword is **forward**.
- You can use the **display traffic behavior user-defined** command to view the traffic redirecting configuration.

Configuration procedure

To configure traffic redirecting:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator { and or }]	N/A
3. Configure match criteria.	if-match <i>match-criteria</i>	N/A
4. Return to system view.	quit	N/A
5. Create a behavior and enter behavior view.	traffic behavior <i>behavior-name</i>	N/A

Step	Command	Remarks
6. Configure a traffic redirecting action.	redirect { cpu interface <i>interface-type interface-number</i> next-hop { <i>ipv4-add1</i> [<i>ipv4-add2</i>] <i>ipv6-add1</i> [<i>interface-type interface-number</i>] [<i>ipv6-add2</i> [<i>interface-type interface-number</i>]] } [fail-action { discard forward }] }	The 5500 SI switch does not support the next-hop or fail-action keyword.
7. Return to system view.	quit	N/A
8. Create a policy and enter policy view.	qos policy <i>policy-name</i>	N/A
9. Associate the class with the traffic behavior in the QoS policy.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	N/A
10. Return to system view.	quit	N/A
11. Apply the QoS policy.	<ul style="list-style-type: none"> • Applying the QoS policy to an interface • Applying the QoS policy to a VLAN • Applying the QoS policy globally • Applying the QoS policy to the control plane 	Choose one application destination as needed.

Redirect-to-next hop configuration example

Network requirements

As shown in [Figure 20](#), the network is described as follows:

- Device A is connected to Device through two links. At the same time, Device A and Device B are each connected to other devices.
- GigabitEthernet 1/0/2 of Device A and GigabitEthernet 1/0/2 of Device B belong to VLAN 200.
- Ethernet 1/3 of Device A and Ethernet 1/3 of Device B belong to VLAN 201.
- On Device A, the IP address of VLAN-interface 200 is 200.1.1.1/24, and that of VLAN-interface 201 is 201.1.1.1/24.
- On Device B, the IP address of VLAN-interface 200 is 200.1.1.2/24, and that of VLAN-interface 201 is 201.1.1.2/24.

Configure the actions of redirecting traffic to the next hop to implement policy-based routing and satisfy the following requirements:

- Packets with source IP address 2.1.1.1 received on GigabitEthernet 1/0/1 of Device A are forwarded to IP address 200.1.1.2.
- Packets with source IP address 2.1.1.2 received on GigabitEthernet 1/0/1 of Device A are forwarded to IP address 201.1.1.2.
- Other packets received on Ethernet 1/1 of Device A are forwarded according to the routing table.

Figure 20 Network diagram

Configuration procedure

Create basic ACL 2000, and configure a rule to match packets with source IP address 2.1.1.1.

```
<DeviceA> system-view
[DeviceA] acl number 2000
[DeviceA-acl-basic-2000] rule permit source 2.1.1.1 0
[DeviceA-acl-basic-2000] quit
```

Create basic ACL 2001, and configure a rule to match packets with source IP address 2.1.1.2.

```
[DeviceA] acl number 2001
[DeviceA-acl-basic-2001] rule permit source 2.1.1.2 0
[DeviceA-acl-basic-2001] quit
```

Create a class named **classifier_1**, and use ACL 2000 as the match criterion in the class.

```
[DeviceA] traffic classifier classifier_1
[DeviceA-classifier-classifier_1] if-match acl 2000
[DeviceA-classifier-classifier_1] quit
```

Create a class named **classifier_2**, and use ACL 2001 as the match criterion in the class.

```
[DeviceA] traffic classifier classifier_2
[DeviceA-classifier-classifier_2] if-match acl 2001
[DeviceA-classifier-classifier_2] quit
```

Create a behavior named **behavior_1**, and configure the action of redirecting traffic to the next hop 200.1.1.2.

```
[DeviceA] traffic behavior behavior_1
[DeviceA-behavior-behavior_1] redirect next-hop 200.1.1.2
[DeviceA-behavior-behavior_1] quit
```

Create a behavior named **behavior_2**, and configure the action of redirecting traffic to the next hop 200.1.1.2.

```
[DeviceA] traffic behavior behavior_2
[DeviceA-behavior-behavior_2] redirect next-hop 201.1.1.2
[DeviceA-behavior-behavior_2] quit
```

Create a policy named **policy**, associate class **classifier_1** with behavior **behavior_1**, and associate class **classifier_2** with behavior **behavior_2** in the policy.

```
[DeviceA] qos policy policy
[DeviceA-qospolicy-policy] classifier classifier_1 behavior behavior_1
[DeviceA-qospolicy-policy] classifier classifier_2 behavior behavior_2
[DeviceA-qospolicy-policy] quit
```

Apply the policy named **policy** to the incoming traffic of GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
```

```
[DeviceA-GigabitEthernet1/0/1] qos apply policy policy inbound
```

Configuring class-based accounting

Class-based accounting collects statistics (in packets or bytes) on a per-traffic class basis. For example, you can define the action to collect statistics for traffic sourced from a certain IP address. By analyzing the statistics, you can determine whether anomalies have occurred and what action to take. The 5500 EI and 5500 SI Switch Series supports only collecting statistics in packets.

Configuration procedure

To configure class-based accounting:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a class and enter class view.	traffic classifier <i>tcl-name</i> [operator { and or }]	N/A
3. Configure match criteria.	if-match <i>match-criteria</i>	N/A
4. Return to system view.	quit	N/A
5. Create a behavior and enter behavior view.	traffic behavior <i>behavior-name</i>	N/A
6. Configure the accounting action.	accounting	N/A
7. Return to system view.	quit	N/A
8. Create a policy and enter policy view.	qos policy <i>policy-name</i>	N/A
9. Associate the class with the traffic behavior in the QoS policy.	classifier <i>tcl-name</i> behavior <i>behavior-name</i>	N/A
10. Return to system view.	quit	N/A
11. Apply the QoS policy.	<ul style="list-style-type: none">• Applying the QoS policy to an interface• Applying the QoS policy to a VLAN• Applying the QoS policy globally• Applying the QoS policy to the control plane	Choose one application destination as needed.

Displaying and maintaining traffic accounting

You can verify the configuration with the **display qos policy global**, **display qos policy interface**, or **display qos vlan-policy** command depending on the occasion where the QoS policy is applied.

Class-based accounting configuration example

Network requirements

As shown in [Figure 21](#), Host is connected to GigabitEthernet 1/0/1 of Device A.

Configure class-based accounting to collect statistics for traffic sourced from 1.1.1.1/24 and received on GigabitEthernet 1/0/1.

Figure 21 Network diagram

Configuration procedure

Create basic ACL 2000, and configure a rule to match packets with source IP address 1.1.1.1.

```
<DeviceA> system-view
[DeviceA] acl number 2000
[DeviceA-acl-basic-2000] rule permit source 1.1.1.1 0
[DeviceA-acl-basic-2000] quit
```

Create a class named **classifier_1**, and use ACL 2000 as the match criterion in the class.

```
[DeviceA] traffic classifier classifier_1
[DeviceA-classifier-classifier_1] if-match acl 2000
[DeviceA-classifier-classifier_1] quit
```

Create a behavior named **behavior_1**, and configure the traffic accounting action.

```
[DeviceA] traffic behavior behavior_1
[DeviceA-behavior-behavior_1] accounting
[DeviceA-behavior-behavior_1] quit
```

Create a policy named **policy**, and associate class **classifier_1** with behavior **behavior_1** in the policy.

```
[DeviceA] qos policy policy
[DeviceA-qospolicy-policy] classifier classifier_1 behavior behavior_1
[DeviceA-qospolicy-policy] quit
```

Apply the policy named **policy** to the incoming traffic of GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] qos apply policy policy inbound
[DeviceA-GigabitEthernet1/0/1] quit
```

Display traffic statistics to verify the configuration.

```
[DeviceA] display qos policy interface gigabitethernet 1/0/1
```

```
Interface: GigabitEthernet1/0/1
```

```
Direction: Inbound
```

```
Policy: policy
```

```
Classifier: classifier_1
```

Operator: AND

Behavior: behavior_1
Accounting Enable:
28529 (Packets)

Configuring the data buffer

Overview

Data buffer

The Switch Series provides the data buffer to buffer packets to be sent out ports to avoid packet loss when bursty traffic causes congestion.

The switch controls how a port uses the data buffer by allocating the cell resource and packet resource (called "buffer resources").

- The cell resource is the physical storage space in cells for the data buffer. The cell resource allocated to a port indicates the maximum buffer space that the port can occupy in the buffer.
- The packet resource is the logical buffering space in packets. A packet is counted as one regardless of its length. A packet in the packet resource uses a certain amount of cell resources in the cell resource, depending on its length. The packet resource allocated to a port indicates the maximum number of packets that the port can store in the buffer.

Set independently, the packet resource and the cell resource work simultaneously to regulate data buffering. A packet can be buffered only when both resources are adequate.

Data buffer allocation

Cell resource allocation

The cell resource is divided into a shared resource and a dedicated resource. You can manually set the percentage of the shared resource to the total buffer, and the remaining buffer becomes the dedicated resource automatically.

On a 5500 EI and 5500 SI switch, the cell resource is allocated as shown in [Figure 22](#).

Figure 22 Cell resource allocation on the 5500 EI and 5500 SI

The dedicated resource is allocated following these rules:

- **On a per-port basis**—As illustrated by the vertical lines in [Figure 22](#), the switch automatically divides the dedicated resource among all ports evenly.
- **On a per-queue basis**—As illustrated by the horizontal lines in [Figure 22](#), the dedicated resource of each port is proportionately allocated among the queues on it and all ports use the same allocation scheme. The percentage of the resource allocated to a queue is called the minimum guaranteed resource percentage of the queue.

The shared buffer in the cell resource can buffer the bursty traffic on ports. The shared resource is shared by all queues of all ports. When a certain queue of a port is congested because its dedicated cell resource gets full, it can use a certain portion of the shared resource of the cell resource. The maximum shared resource size available for a queue is defined as a percentage of the shared resource. After the bursty traffic is transmitted, the shared resource used by the bursty traffic is released for other ports or queues to use. For example, you can configure port 1 to use 30% of the shared buffer of the cell resource.

You can perform the following parameters for the cell resource:

- Configure the shared resource size
- Configure the minimum guaranteed resource size for a queue
- Configure the maximum shared resource size for a port

Packet resource allocation

Different from the cell resource, the packet resource does not have a shared resource, and the whole buffer is evenly allocated to ports, as shown in [Figure 23](#).

Figure 23 Packet resource allocation on the 5500 EI and 5500 SI

Like the packet resource, the cell resource is also allocated on a per-port basis and on a per-queue basis. Because the packet resource does not have the shared resource, you can adjust only the percentage of the queue buffer to the port buffer, which is called the minimum guaranteed buffer percentage.

Data buffer configuration approaches

You can configure the data buffer on the 5500 EI and 5500 SI Switch Series in one of the following approaches:

- [Using the burst function to configure the data buffer setup](#)
- [Manually configuring the data buffer setup](#)

NOTE:

The two approaches are mutually exclusive. If the data buffer setup has been configured in one approach, you must remove the present configuration first before you use the other approach.

Using the burst function to configure the data buffer setup

The burst function allows the switch to automatically determine the shared resource size, the minimum guaranteed resource size for each queue, the maximum shared resource size for each queue, and the maximum shared resource size per port.

The burst function helps optimize packet buffering to ameliorate forwarding performance in the following scenarios:

- Broadcast or multicast traffic is dense and bursts of traffic are usually large.
- High-speed traffic is forwarded over low-speed links or traffic received from multiple ports is forwarded through a port operating at the same speed.

To use the burst function to configure the data buffer:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the burst function.	burst-mode enable	By default, the burst function is disabled.

Manually configuring the data buffer setup

Data buffer configuration is complicated and has significant impacts on the forwarding performance of a device. HP does not recommend modifying the data buffer parameters unless you are sure that your device will benefit from the change. If a larger buffer is needed, HP recommends that you enable the burst function to allocate the buffer automatically.

Manually configuring the data buffer

Complete the following tasks to manually configure the data buffer:

Task	Remarks	
Configuring the cell resource	Configuring the shared resource size	Optional
	Configuring the minimum guaranteed resource size for a queue	Optional
	Configuring the maximum shared resource size for a port	Optional
Configuring the packet resource	Configuring the minimum guaranteed resource size for a queue	Optional
Applying the data buffer settings	Required	

Configuring the cell resource

Configuring the shared resource size

To configure the shared resource size:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the shared resource area of the cell resource in percentage.	buffer egress [slot <i>slot-number</i>] cell total-shared ratio <i>ratio</i>	Optional. By default, the shared resource area of the cell resource is 60%.

Configuring the minimum guaranteed resource size for a queue

When configuring the minimum guaranteed resource size for a queue, follow these guidelines:

- Modifying the minimum guaranteed resource size for a queue can affect those of the other queues, because the dedicated resource of a port is shared by eight queues. The system will automatically allocate the remaining dedicated resource space among all queues that are not manually assigned a minimum guaranteed resource space. For example, if you set the minimum guaranteed resource size to 30% for a queue, the remaining seven queues will each share 10% of the dedicated resource of the port.
- The minimum guaranteed resource settings of a queue apply to the queue with the same number on each port.

To configure the minimum guaranteed resource size for a queue:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the minimum guaranteed cell resource size for a queue as a percentage of the dedicated cell resource per port.	buffer egress [slot <i>slot-number</i>] cell queue <i>queue-id</i> guaranteed ratio <i>ratio</i>	Optional. By default, the minimum guaranteed resource size for a queue is 12% of the dedicated resource of the port in the cell resource.

Configuring the maximum shared resource size for a port

To configure the maximum shared resource size for a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the maximum shared cell resource size for a queue as a percentage of the shared cell resource.	buffer egress [slot <i>slot-number</i>] cell shared ratio <i>ratio</i>	Optional. By default, a queue can use up to 50% of the shared cell resource.

NOTE:

The maximum shared resource settings for a queue apply to the queue with the same number on each port.

Configuring the packet resource

Configuring the minimum guaranteed resource size for a queue

When configuring the minimum guaranteed resource size for a queue, follow these guidelines:

- Modifying the minimum guaranteed resource size for a queue can affect those of the other queues, because the dedicated resource of a port is shared by eight queues. The system will automatically allocate the remaining dedicated resource space among all queues that are not manually assigned a minimum guaranteed resource space. For example, if you set the minimum guaranteed resource size to 30% for a queue, the remaining seven queues will each share 10% of the dedicated resource of the port.
- The minimum guaranteed resource settings of a queue apply to the queue with the same number on each port.

To configure the minimum guaranteed resource size for a queue:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the minimum guaranteed packet resource size for a queue as a percentage of the dedicated packet resource per port.	buffer egress [slot <i>slot-number</i>] packet queue <i>queue-id</i> guaranteed ratio <i>ratio</i>	Optional. By default, the minimum guaranteed resource size for queue 2 is 51% of the dedicated resource of the port in the packet resource, and that for any other queue is 7%.

Applying the data buffer settings

After manually configuring data buffer, you should execute the following steps to make the manual data buffer configurations take effect.

To apply the data buffer settings:

Step	Command
1. Enter system view.	system-view
2. Apply the data buffer settings.	buffer apply

Appendix A Default priority mapping tables

Uncolored priority mapping tables

For the default **dscp-dscp** mapping table, an input value yields a target value equal to it.

Table 6 Default dot1p-lp and dot1p-dp priority mapping tables

Input priority value	dot1p-lp mapping	dot1p-dp mapping
802.1p priority (dot1p)	Local precedence (lp)	Drop precedence (dp)

Input priority value	dscp-dp mapping	dscp-dot1p mapping
DSCP	Drop precedence (dp)	802.1p priority (dot1p)
0 to 7	0	0
8 to 15	0	1
16 to 23	0	2
24 to 31	0	3
32 to 39	0	4
40 to 47	0	5
48 to 55	0	6
56 to 63	0	7

Appendix B Packet precedences

IP precedence and DSCP values

Figure 24 ToS and DS fields

As shown in Figure 24, the ToS field in the IPv4 header contains eight bits, where the first three bits (0 to 2) represent IP precedence from 0 to 7; the Traffic Classes field in the IPv6 header contains eight bits, where the first three bits (0 to 2) represent IP precedence from 0 to 7. According to RFC 2474, the ToS field in the IPv4 header or the Traffic Classes field in the IPv6 header is redefined as the differentiated services (DS) field, where a DSCP value is represented by the first six bits (0 to 5) and is in the range 0 to 63. The remaining two bits (6 and 7) are reserved.

Table 8 Description on IP precedence

IP precedence (decimal)	IP precedence (binary)	Description
0	000	Routine
1	001	priority
2	010	immediate

40	101000	cs5
48	110000	cs6
56	111000	cs7
0	000000	be (default)

802.1p priority

802.1p priority lies in the Layer 2 header and applies to occasions where Layer 3 header analysis is not needed and QoS must be assured at Layer 2.

Figure 25 An Ethernet frame with an 802.1Q tag header

As shown in [Figure 25](#), the four-byte 802.1Q tag header consists of the tag protocol identifier (TPID, two bytes in length), whose value is 0x8100, and the tag control information (TCI, two bytes in length). [Figure 26](#) shows the format of the 802.1Q tag header. The Priority field in the 802.1Q tag header is called the "802.1p priority", because its use is defined in IEEE 802.1p. [Table 10](#) shows the values for 802.1p priority.

Figure 26 802.1Q tag header

Table 10 Description on 802.1p priority

802.1p priority (decimal)	802.1p priority (binary)	Description
0	000	best-effort

Configuring AAA

In the HP 5500 Switch Series, only the HP 5500 EI switches support MCE and VPN configurations.

AAA overview

Authentication, Authorization, and Accounting (AAA) provides a uniform framework for implementing network access management. It can provide the following security functions:

- **Authentication**—Identifies users and determines whether a user is valid.
- **Authorization**—Grants different users different rights and controls their access to resources and services. For example, a user who has successfully logged in to the switch can be granted read and print permissions to the files on the switch.
- **Accounting**—Records all user network service usage information, including the service type, start time, and traffic. The accounting function not only provides the information required for charging, but also allows for network security surveillance.

AAA usually uses a client/server model. The client runs on the network access server (NAS), which is also referred to as the access device. The server maintains user information centrally. In an AAA network, a NAS is a server for users but a client for the AAA servers. See [Figure 1](#).

Figure 1 Network diagram

When a user tries to log in to the NAS, use network resources, or access other networks, the NAS authenticates the user. The NAS can transparently pass the user's authentication, authorization, and accounting information to the servers. The RADIUS and HWTACACS protocols define how a NAS and a remote server exchange user information between them.

In the network shown in [Figure 1](#), there is a RADIUS server and an HWTACACS server. You can choose different servers for different security functions. For example, you can use the HWTACACS server for authentication and authorization, and the RADIUS server for accounting.

You can choose the three security functions provided by AAA as needed. For example, if your company only wants employees to be authenticated before they access specific resources, configure an authentication server. If network usage information is needed, you must also configure an accounting server.

AAA can be implemented through multiple protocols. The switch supports using RADIUS and HWTACACS. RADIUS is often used in practice.

RADIUS

Remote Authentication Dial-In User Service (RADIUS) is a distributed information interaction protocol that uses a client/server model. It can protect networks against unauthorized access and is often used in network environments where both high security and remote user access are required.

RADIUS uses UDP as the transport protocol. It uses UDP port 1812 for authentication and UDP port 1813 for accounting.

RADIUS was originally designed for dial-in user access. With the addition of new access methods, RADIUS has been extended to support additional access methods, such as Ethernet and ADSL. RADIUS provides access authentication and authorization services, and its accounting function collects and records network resource usage information.

Client/server model

The RADIUS client runs on the NASs located throughout the network. It passes user information to designated RADIUS servers and acts on the responses (for example, rejects or accepts user access requests).

The RADIUS server runs on the computer or workstation at the network center and maintains information related to user authentication and network service access. It listens to connection requests, authenticates users, and returns user access control information (for example, rejecting or accepting the user access request) to the clients.

In general, the RADIUS server maintains the following databases: Users, Clients, and Dictionary.

Figure 2 RADIUS server components

- **Users**—Stores user information, such as usernames, passwords, applied protocols, and IP addresses.
- **Clients**—Stores information about RADIUS clients, such as shared keys and IP addresses.
- **Dictionary**—Stores RADIUS protocol attributes and their values.

Security and authentication mechanisms

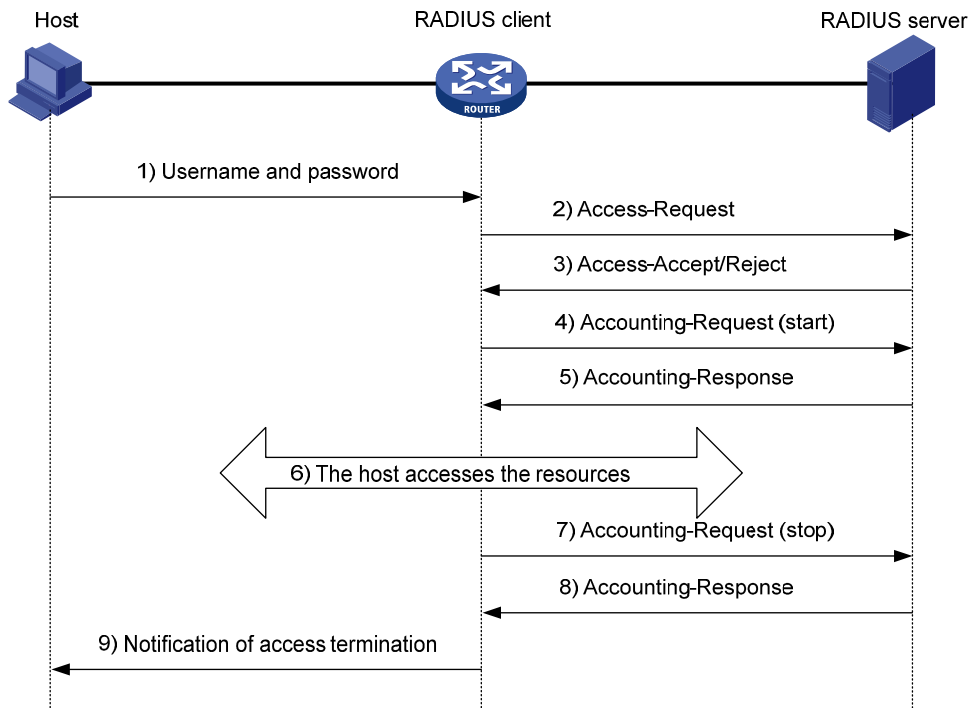

A RADIUS client and the RADIUS server use the shared key to authenticate RADIUS packets and encrypt user passwords that are exchanged between them. The keys are never transmitted over the network. This security mechanism improves the security of RADIUS communication and prevents user passwords from being intercepted on insecure networks.

A RADIUS server supports multiple user authentication methods. A RADIUS server can also act as the client of another AAA server to provide authentication proxy services.

Basic RADIUS message exchange process

Figure 3 illustrates the interactions between the host, the RADIUS client, and the RADIUS server.

Figure 3 Basic RADIUS message exchange process

RADIUS operates in the following manner:

1. The host initiates a connection request that carries the user's username and password to the RADIUS client.
2. Having received the username and password, the RADIUS client sends an authentication request (Access-Request) to the RADIUS server, with the user password encrypted by using the Message-Digest 5 (MD5) algorithm and the shared key.
3. The RADIUS server authenticates the username and password. If the authentication succeeds, the server sends back an Access-Accept message containing the user's authorization information. If the authentication fails, the server returns an Access-Reject message.
4. The RADIUS client permits or denies the user according to the returned authentication result. If it permits the user, it sends a start-accounting request (Accounting-Request) to the RADIUS server.
5. The RADIUS server returns a start-accounting response (Accounting-Response) and starts accounting.
6. The user accesses the network resources.
7. The host requests the RADIUS client to tear down the connection and the RADIUS client sends a stop-accounting request (Accounting-Request) to the RADIUS server.
8. The RADIUS server returns a stop-accounting response (Accounting-Response) and stops accounting for the user.

RADIUS packet format

RADIUS uses UDP to transmit messages. To ensure smooth message exchange between the RADIUS server and the client, RADIUS uses a series of mechanisms, including the timer management mechanism, the retransmission mechanism, and the backup server mechanism. Figure 4 shows the RADIUS packet format.

Figure 4 RADIUS packet format

Descriptions of the fields are as follows:

- The Code field (1 byte long) indicates the type of the RADIUS packet. [Table 1](#) gives the possible values and their meanings.

Table 1 Main values of the Code field

Code	Packet type	Description
1	Access-Request	From the client to the server. A packet of this type carries user information for the server to authenticate the user. It must contain the User-Name attribute and can optionally contain the attributes of NAS-IP-Address, User-Password, and NAS-Port.
2	Access-Accept	From the server to the client. If all the attribute values carried in the Access-Request are acceptable, the authentication succeeds, and the server sends an Access-Accept response.
3	Access-Reject	From the server to the client. If any attribute value carried in the Access-Request is unacceptable, the authentication fails and the server sends an Access-Reject response.
4	Accounting-Request	From the client to the server. A packet of this type carries user information for the server to start or stop accounting for the user. The Acct-Status-Type attribute in the packet indicates whether to start or stop accounting.
5	Accounting-Response	From the server to the client. The server sends a packet of this type to notify the client that it has received the Accounting-Request and has successfully recorded the accounting information.

- The Identifier field (1 byte long) is used to match request and response packets and to detect duplicate request packets. Request and response packets of the same type have the same identifier.
- The Length field (2 bytes long) indicates the length of the entire packet, including the Code, Identifier, Length, Authenticator, and Attribute fields. Bytes beyond this length are considered padding and are ignored at the receiver. If the length of a received packet is less than this length, the packet is dropped. The value of this field is in the range of 20 to 4096.
- The Authenticator field (16 bytes long) is used to authenticate replies from the RADIUS server and to encrypt user passwords. There are two types of authenticators: request authenticator and response authenticator.

- The Attributes field (variable in length) carries the specific authentication, authorization, and accounting information that defines the configuration details of the request or response. This field may contain multiple attributes, each with three sub-fields:
 - **Type**—(1 byte long) Type of the attribute. It is in the range of 1 to 255. Commonly used RADIUS attributes are defined in RFC 2865, RFC 2866, RFC 2867, and RFC 2868. [Table 2](#) shows a list of the attributes. For more information about commonly used standard RADIUS attributes, see "[Commonly used standard RADIUS attributes.](#)"
 - **Length**—(1 byte long) Length of the attribute in bytes, including the Type, Length, and Value fields.
 - **Value**—(Up to 253 bytes) Value of the attribute. Its format and content depend on the Type and Length fields.

Table 2 Commonly used RADIUS attributes

No.	Attribute	No.	Attribute
1	User-Name	45	Acct-Authentic
2	User-Password	46	Acct-Session-Time
3	CHAP-Password	47	Acct-Input-Packets
4	NAS-IP-Address	48	Acct-Output-Packets
5	NAS-Port	49	Acct-Terminate-Cause
6	Service-Type	50	Acct-Multi-Session-Id
7	Framed-Protocol	51	Acct-Link-Count
8	Framed-IP-Address	52	Acct-Input-Gigawords
9	Framed-IP-Netmask	53	Acct-Output-Gigawords
10	Framed-Routing	54	(unassigned)
11	Filter-ID	55	Event-Timestamp
12	Framed-MTU	56-59	(unassigned)
13	Framed-Compression	60	CHAP-Challenge
14	Login-IP-Host	61	NAS-Port-Type
15	Login-Service	62	Port-Limit
16	Login-TCP-Port	63	Login-LAT-Port
17	(unassigned)	64	Tunnel-Type
18	Reply-Message	65	Tunnel-Medium-Type
19	Callback-Number	66	Tunnel-Client-Endpoint
20	Callback-ID	67	Tunnel-Server-Endpoint
21	(unassigned)	68	Acct-Tunnel-Connection
22	Framed-Route	69	Tunnel-Password
23	Framed-IPX-Network	70	ARAP-Password
24	State	71	ARAP-Features
25	Class	72	ARAP-Zone-Access
26	Vendor-Specific	73	ARAP-Security

No.	Attribute	No.	Attribute
27	Session-Timeout	74	ARAP-Security-Data
28	Idle-Timeout	75	Password-Retry
29	Termination-Action	76	Prompt
30	Called-Station-Id	77	Connect-Info
31	Calling-Station-Id	78	Configuration-Token
32	NAS-Identifier	79	EAP-Message
33	Proxy-State	80	Message-Authenticator
34	Login-LAT-Service	81	Tunnel-Private-Group-id
35	Login-LAT-Node	82	Tunnel-Assignment-id
36	Login-LAT-Group	83	Tunnel-Preference
37	Framed-AppleTalk-Link	84	ARAP-Challenge-Response
38	Framed-AppleTalk-Network	85	Acct-Interim-Interval
39	Framed-AppleTalk-Zone	86	Acct-Tunnel-Packets-Lost
40	Acct-Status-Type	87	NAS-Port-Id
41	Acct-Delay-Time	88	Framed-Pool
42	Acct-Input-Octets	89	(unassigned)
43	Acct-Output-Octets	90	Tunnel-Client-Auth-id
44	Acct-Session-Id	91	Tunnel-Server-Auth-id

Extended RADIUS attributes

The RADIUS protocol features excellent extensibility. Attribute 26 (Vendor-Specific), an attribute defined by RFC 2865, allows a vendor to define extended attributes to implement functions that the standard RADIUS protocol does not provide.

A vendor can encapsulate multiple sub-attributes in the type-length-value (TLV) format in RADIUS packets for extension of applications. As shown in [Figure 5](#), a sub-attribute encapsulated in Attribute 26 consists of the following parts:

- **Vendor-ID**—Indicates the ID of the vendor. Its most significant byte is 0, and the other three bytes contains a code that is compliant to RFC 1700. For more information about the proprietary RADIUS sub-attributes of HP, see "[HP proprietary RADIUS sub-attributes](#)."
- **Vendor-Type**—Indicates the type of the sub-attribute.
- **Vendor-Length**—Indicates the length of the sub-attribute.
- **Vendor-Data**—Indicates the contents of the sub-attribute.

Figure 5 Segment of a RADIUS packet containing an extended attribute

HWTACACS

HW Terminal Access Controller Access Control System (HWTACACS) is an enhanced security protocol based on TACACS (RFC 1492). Similar to RADIUS, it uses a client/server model for information exchange between the NAS and the HWTACACS server.

HWTACACS typically provides AAA services for Point-to-Point Protocol (PPP) users, Virtual Private Dial-up Network (VPDN) users, and terminal users. In a typical HWTACACS scenario, some terminal users log in to the NAS for operations. Working as the HWTACACS client, the NAS sends the usernames and passwords of the users to the HWTACACS sever for authentication. After passing authentication and being authorized, the users log in to the switch and performs operations, and the HWTACACS server records the operations that each user performs.

Differences between HWTACACS and RADIUS

HWTACACS and RADIUS both provide authentication, authorization, and accounting services. They have many features in common, such as using a client/server model, using shared keys for user information security, and providing flexibility and extensibility.

Table 3 Primary differences between HWTACACS and RADIUS

HWTACACS	RADIUS
Uses TCP, providing more reliable network transmission.	Uses UDP, providing higher transport efficiency.
Encrypts the entire packet except for the HWTACACS header.	Encrypts only the user password field in an authentication packet.
Protocol packets are complicated and authorization is independent of authentication. Authentication and authorization can be deployed on different HWTACACS servers.	Protocol packets are simple and the authorization process is combined with the authentication process.
Supports authorization of configuration commands. Which commands a user can use depends on both the user level and the AAA authorization. A user can use only commands that are at, or lower than, the user level and authorized by the HWTACACS server.	Does not support authorization of configuration commands. Which commands a user can use solely depends on the level of the user. A user can use all the commands at, or lower than, the user level.

Basic HWTACACS message exchange process

The following example describes how HWTACACS performs user authentication, authorization, and accounting for a Telnet user.

Figure 6 Basic HWTACACS message exchange process for a Telnet user

HWTACACS operates in the following manner:

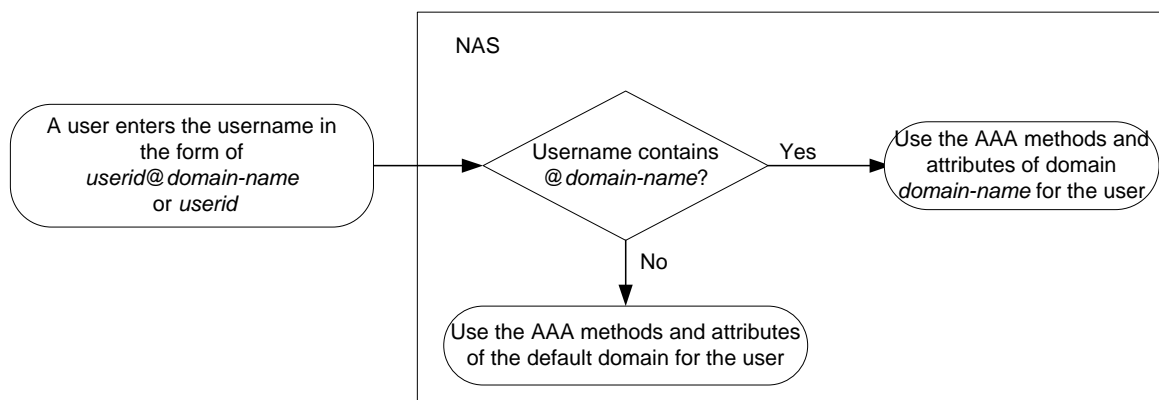

1. A Telnet user sends an access request to the HWTACACS client.
2. Upon receiving the request, the HWTACACS client sends a start-authentication packet to the HWTACACS server.
3. The HWTACACS server sends back an authentication response to request the username.
4. Upon receiving the response, the HWTACACS client asks the user for the username.
5. The user enters the username.
6. After receiving the username from the user, the HWTACACS client sends the server a continue-authentication packet that carries the username.
7. The HWTACACS server sends back an authentication response, requesting the login password.
8. Upon receipt of the response, the HWTACACS client asks the user for the login password.

9. The user enters the password.
10. After receiving the login password, the HWTACACS client sends the HWTACACS server a continue-authentication packet that carries the login password.
11. The HWTACACS server sends back an authentication response to indicate that the user has passed authentication.
12. The HWTACACS client sends the user authorization request packet to the HWTACACS server.
13. The HWTACACS server sends back the authorization response, indicating that the user is now authorized.
14. Knowing that the user is now authorized, the HWTACACS client pushes its configuration interface to the user.
15. The HWTACACS client sends a start-accounting request to the HWTACACS server.
16. The HWTACACS server sends back an accounting response, indicating that it has received the start-accounting request.
17. The user logs off.
18. The HWTACACS client sends a stop-accounting request to the HWTACACS server.
19. The HWTACACS server sends back a stop-accounting response, indicating that the stop-accounting request has been received.

Domain-based user management

A NAS manages users based on Internet service provider (ISP) domains. On a NAS, each user belongs to one ISP domain. A NAS determines the ISP domain a user belongs to by the username entered by the user at login, as shown in [Figure 7](#).

Figure 7 Determining the ISP domain of a user by the username

The authentication, authorization, and accounting of a user depends on the AAA methods configured for the domain to which the user belongs. If no specific AAA methods are configured for the domain, the default methods are used. By default, a domain uses local authentication, local authorization, and local accounting.

AAA allows you to manage users based on their access types:

- **LAN users**—Users on a LAN who must pass 802.1X or MAC address authentication to access the network.
- **Login users**—Users who want to log in to the switch, including SSH users, Telnet users, Web users, FTP users, and terminal users.

- **Portal users**—Users who must pass portal authentication to access the network.

In addition, AAA provides the following services for login users to enhance switch security:

- **Command authorization**—Enables the NAS to defer to the authorization server to determine whether a command entered by a login user is permitted for the user, making sure that login users execute only commands they are authorized to execute. For more information about command authorization, see *Fundamentals Configuration Guide*.
- **Command accounting**—Allows the accounting server to record all commands executed on the switch or all authorized commands successfully executed. For more information about command accounting, see *Fundamentals Configuration Guide*.
- **Level switching authentication**—Allows the authentication server to authenticate users who perform privilege level switching. As long as passing level switching authentication, users can switch their user privilege levels, without logging out and disconnecting current connections. For more information about user privilege level switching, see *Fundamentals Configuration Guide*.

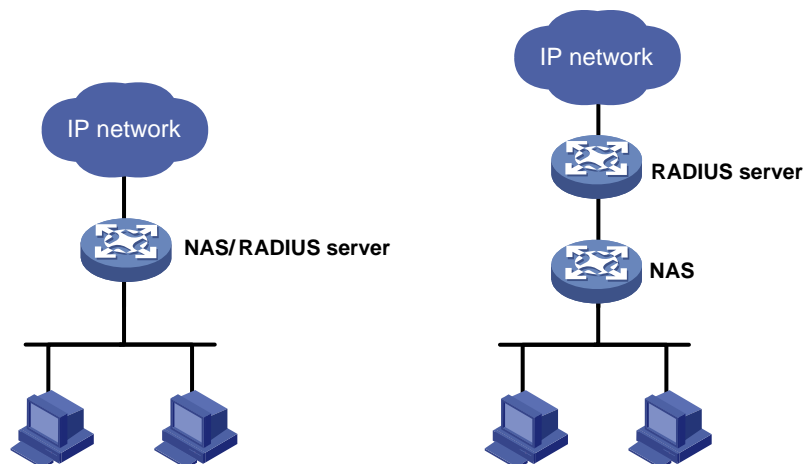

You can configure different authentication, authorization, and accounting methods for different types of users in a domain. See "[Configuring AAA methods for ISP domains](#)."

RADIUS server feature of the switch

Generally, the RADIUS server runs on a computer or workstation, and the RADIUS client runs on a NAS. A network device that supports the RADIUS server feature can also serve as the RADIUS server, working with RADIUS clients to implement user authentication, authorization, and accounting. As shown in [Figure 8](#), the RADIUS server and client can reside on the same switch or different switches.

Using a network device as the RADIUS server simplifies networking and reduces deployment costs. This implementation is usually deployed on networks by using the clustering feature. In such a scenario, configure the RADIUS server feature on a management device at the distribution layer, so that the device functions as a RADIUS server to cooperate with cluster member switches at the access layer to provide user authentication and authorization services.

Figure 8 Devices functioning as a RADIUS server

The switch can serve as a RADIUS server to provide the following functions:

- User information management
You can create, modify, and delete user information, including the username, password, authority, lifetime, and user description.
- RADIUS client information management

You can create and delete RADIUS clients, which are identified by IP addresses and configured with attributes such as a shared key. With a managed client range configured, the RADIUS server processes only the RADIUS packets from the clients within the management range. A shared key is used to ensure secure communication between a RADIUS client and the RADIUS server.

- RADIUS authentication and authorization

With the RADIUS server enabled, the switch checks whether or not the client of an incoming RADIUS packet is under its management. If yes, it verifies the packet validity by using the shared key, checks whether there is an account with the username, whether the password is correct, and whether the user attributes meet the requirements defined on the RADIUS server (for example, whether the account has expired). Then, the RADIUS server assigns the corresponding authority to the client if the authentication succeeds, or denies the client if the authentication fails.

NOTE:

A RADIUS server running the standard RADIUS protocol listens on UDP port 1812 for authentication requests, but an HP switch listens on UDP port 1645 instead when acting as the RADIUS server. Be sure to specify 1645 as the authentication port number on the RADIUS client when you use an HP switch as the RADIUS server.

AAA for MPLS L3VPNs (available only on the HP 5500 EI)

In an MPLS L3VPN scenario where clients in different VPNs are centrally authenticated, you can deploy AAA across VPNs to enable forwarding RADIUS and HWTACACS packets across MPLS VPNs. With the AAA across VPNs feature, the PE at the left side of the MPLS backbone serves as a NAS and transparently delivers the AAA packets of private users in VPN 1 and VPN 2 to the AAA servers in VPN 3 for centralized authentication, as shown in [Figure 9](#). Authentication packets of private users in different VPNs do not affect each other.

Figure 9 Network diagram

NOTE:

This feature can also help an MCE to implement portal authentication for VPNs. For more information about MCE, see *Layer 3 - IP Routing Configuration Guide*.

Protocols and standards

The following protocols and standards are related to AAA, RADIUS, and HWTACACS:

- RFC 2865, *Remote Authentication Dial In User Service (RADIUS)*
- RFC 2866, *RADIUS Accounting*
- RFC 2867, *RADIUS Accounting Modifications for Tunnel Protocol Support*
- RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*
- RFC 2869, *RADIUS Extensions*
- RFC 1492, *An Access Control Protocol, Sometimes Called TACACS*

RADIUS attributes

Commonly used standard RADIUS attributes

No.	Attribute	Description
1	User-Name	Name of the user to be authenticated.
2	User-Password	User password for PAP authentication, present only in Access-Request packets in PAP authentication mode.
3	CHAP-Password	Digest of the user password for CHAP authentication, present only in Access-Request packets in CHAP authentication mode.
4	NAS-IP-Address	IP address for the server to identify a client. Usually, a client is identified by the IP address of the access interface on the NAS, namely the NAS IP address. This attribute is present in only Access-Request packets.
5	NAS-Port	Physical port of the NAS that the user accesses.
6	Service-Type	Type of service that the user has requested or type of service to be provided.
7	Framed-Protocol	Encapsulation protocol for framed access.
8	Framed-IP-Address	IP address assigned to the user.
11	Filter-ID	Name of the filter list.
12	Framed-MTU	Maximum transmission unit (MTU) for the data link between the user and NAS. For example, with 802.1X EAP authentication, NAS uses this attribute to notify the server of the MTU for EAP packets, so as to avoid oversized EAP packets.
14	Login-IP-Host	IP address of the NAS interface that the user accesses.
15	Login-Service	Type of the service that the user uses for login.
18	Reply-Message	Text to be displayed to the user, which can be used by the server to indicate, for example, the reason of the authentication failure.
26	Vendor-Specific	Vendor specific attribute. A packet can contain one or more such proprietary attributes, each of which can contain one or more sub-attributes.
27	Session-Timeout	Maximum duration of service to be provided to the user before termination of the session.
28	Idle-Timeout	Maximum idle time permitted for the user before termination of the session.
31	Calling-Station-Id	User identification that the NAS sends to the server. For the LAN access service provided by an HP device, this attribute carries the MAC address of the user in the format HHHH-HHHH-HHHH.
32	NAS-Identifier	Identification that the NAS uses for indicating itself.

No.	Attribute	Description
40	Acct-Status-Type	Type of the Accounting-Request packet. Possible values are as follows: <ul style="list-style-type: none"> • 1—Start. • 2—Stop. • 3—Interim-Update. • 4—Reset-Charge. • 7—Accounting-On. (Defined in 3GPP, the 3rd Generation Partnership Project.) • 8—Accounting-Off. (Defined in 3GPP.) • 9 to 14—Reserved for tunnel accounting. • 15—Reserved for failed.
45	Acct-Authentic	Authentication method used by the user. Possible values are as follows: <ul style="list-style-type: none"> • 1—RADIUS. • 2—Local. • 3—Remote.
60	CHAP-Challenge	CHAP challenge generated by the NAS for MD5 calculation during CHAP authentication.
61	NAS-Port-Type	Type of the physical port of the NAS that is authenticating the user. Possible values are as follows: <ul style="list-style-type: none"> • 15—Ethernet. • 16—Any type of ADSL. • 17—Cable (with cable for cable TV). • 201—VLAN. • 202—ATM. <p>If the port is an ATM or Ethernet one and VLANs are implemented on it, the value of this attribute is 201.</p>
79	EAP-Message	Used for encapsulating EAP packets to allow the NAS to authenticate dial-in users via EAP without having to understand the EAP protocol.
80	Message-Authenticator	Used for authentication and checking of authentication packets to prevent spoofing Access-Requests. This attribute is used when RADIUS supports EAP authentication.
87	NAS-Port-Id	String for describing the port of the NAS that is authenticating the user.

HP proprietary RADIUS sub-attributes

No.	Sub-attribute	Description
1	Input-Peak-Rate	Peak rate in the direction from the user to the NAS, in bps.
2	Input-Average-Rate	Average rate in the direction from the user to the NAS, in bps.
3	Input-Basic-Rate	Basic rate in the direction from the user to the NAS, in bps.
4	Output-Peak-Rate	Peak rate in the direction from the NAS to the user, in bps.
5	Output-Average-Rate	Average rate in the direction from the NAS to the user, in bps.
6	Output-Basic-Rate	Basic rate in the direction from the NAS to the user, in bps.
15	Remanent_Volume	Remaining, available total traffic of the connection, in different units for different server types.

No.	Sub-attribute	Description
20	Command	<p>Operation for the session, used for session control. It can be:</p> <ul style="list-style-type: none"> • 1—Trigger-Request. • 2—Terminate-Request. • 3—SetPolicy. • 4—Result. • 5—PortalClear.
24	Control_Identifier	<p>Identification for retransmitted packets. For retransmitted packets of the same session, this attribute must take the same value. For retransmitted packets of different sessions, this attribute may take the same value. The client response of a retransmitted packet must also carry this attribute and the value of the attribute must be the same.</p> <p>For Accounting-Request packets of the start, stop, and interim update types, the Control-Identifier attribute, if present, makes no sense.</p>
25	Result_Code	Result of the Trigger-Request or SetPolicy operation. A value of zero means the operation succeeded. Any other value means the operation failed.
26	Connect_ID	Index of the user connection.
28	Ftp_Directory	<p>Working directory of the FTP user.</p> <p>For an FTP user, when the RADIUS client acts as the FTP server, this attribute is used to set the FTP directory on the RADIUS client.</p>
29	Exec_Privilege	Priority of the EXEC user.
59	NAS_Startup_Timestamp	Startup time of the NAS in seconds, which is represented by the time elapsed after 00:00:00 on Jan. 1, 1970 (UTC).
60	Ip_Host_Addr	User IP address and MAC address carried in authentication and accounting requests, in the format A.B.C.D hh:hh:hh:hh:hh:hh. A space is required between the IP address and the MAC address.
61	User_Notify	Information to be sent from the server to the client transparently.
62	User_HeartBeat	Hash value assigned after an 802.1X user passes authentication, which is a 32-byte string. This attribute is stored in the user list on the device and is used for verifying the handshake messages from the 802.1X user. This attribute exists in only Access-Accept and Accounting-Request packets.
140	User_Group	User groups assigned after the SSL VPN user passes authentication. A user may belong to more than one user group. In this case, the user groups are delimited by semi-colons. This attribute is used for cooperation with the SSL VPN device.
141	Security_Level	Security level assigned after the SSL VPN user passes security authentication.
201	Input-Interval-Octets	Bytes input within a real-time accounting interval.
202	Output-Interval-Octets	Bytes output within a real-time accounting interval.
203	Input-Interval-Packets	Packets input within an accounting interval, in the unit set on the device.
204	Output-Interval-Packets	Packets output within an accounting interval, in the unit set on the device.
205	Input-Interval-Gigawords	Result of bytes input within an accounting interval divided by 4G bytes.
206	Output-Interval-Gigawords	Result of bytes output within an accounting interval divided by 4G bytes.

No.	Sub-attribute	Description
207	Backup-NAS-IP	Backup source IP address for sending RADIUS packets.
255	Product_ID	Product name.

AAA configuration considerations and task list

To configure AAA, you must complete these tasks on the NAS:

1. Configure the required AAA schemes.
 - **Local authentication**—Configure local users and the related attributes, including the usernames and passwords of the users to be authenticated.
 - **Remote authentication**—Configure the required RADIUS and HWTACACS schemes. You must configure user attributes on the servers accordingly.
2. Configure AAA methods for the users' ISP domains.
 - **Authentication method**—No authentication (**none**), local authentication (**local**), or remote authentication (**scheme**)
 - **Authorization method**—No authorization (**none**), local authorization (**local**), or remote authorization (**scheme**)
 - **Accounting method**—No accounting (**none**), local accounting (**local**), or remote accounting (**scheme**)

Figure 10 AAA configuration diagram

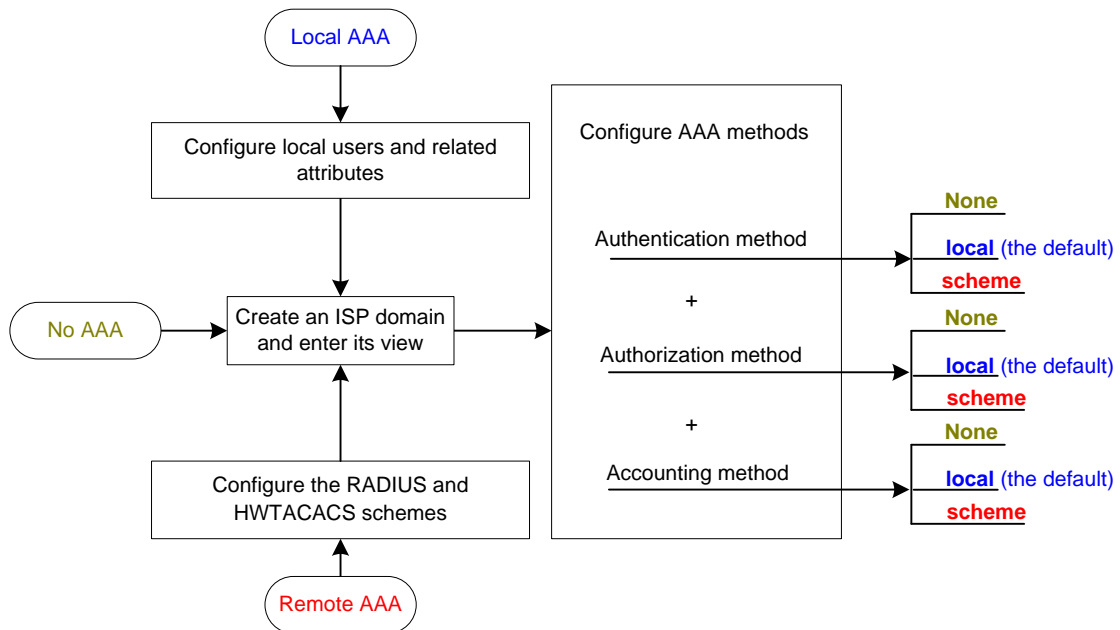

Table 4 AAA configuration task list

Task	Remarks
Configuring AAA schemes	Configuring local users Configuring RADIUS schemes
	Required. Complete at least one task.

Task	Remarks	
	Configuring HWTACACS schemes	
Configuring AAA methods for ISP domains	Creating an ISP domain	Required.
	Configuring ISP domain attributes	Optional.
	Configuring AAA authentication methods for an ISP domain	Required. Complete at least one task.
	Configuring AAA authorization methods for an ISP domain	
	Configuring AAA accounting methods for an ISP domain	
Tearing down user connections	Optional.	
Configuring a NAS ID-VLAN binding	Optional.	
Specifying the device ID used in stateful failover mode	Optional.	
Configuring a switch as a RADIUS server	Optional.	

NOTE:

To use AAA methods to control access of login users, you must configure the user interfaces to use AAA by using the **authentication-mode** command. For more information about the configuration command, see *Fundamentals Command Reference*.

Configuring AAA schemes

Configuring local users

To implement local user authentication, authorization, and accounting, you must create local users and configure user attributes on the switch. The local users and attributes are stored in the local user database on the switch. A local user is uniquely identified by a username. Configurable local user attributes are as follows:

- Service type:
Types of services that the user can use. Local authentication checks the service types of a local user. If none of the service types is available, the user cannot pass authentication.
Service types include FTP, LAN access, portal, SSH, Telnet, terminal, and Web.
- User state:
Indicates whether or not a local user can request network services. There are two user states: active and blocked. A user in active state can request network services, but a user in blocked state cannot.
- Maximum number of users using the same local user account:
Indicates how many users can use the same local user account for local authentication.
- Validity time and expiration time:
Indicates the validity time and expiration time of a local user account. A user must use a valid local user account to pass local authentication. For temporary network access requirements, you can

create a guest account and specify a validity time and an expiration time for the account to control the validity of the account.

- User group:

Each local user belongs to a local user group and bears all attributes of the group, such as the password control attributes and authorization attributes. For more information about local user group, see "[Configuring user group attributes](#)."

- Password control attributes:

Password control attributes help you control the security of local users' passwords. Password control attributes include password aging time, minimum password length, and password composition policy.

You can configure a password control attribute in system view, user group view, or local user view, making the attribute effective for all local users, all local users in a group, or only the local user. A password control attribute with a smaller effective range has a higher priority. For more information about password management and global password configuration, see "[Configuring password control](#)."

- Binding attributes:

Binding attributes are used to control the scope of users. They are checked during local authentication of a user. If the attributes of a user do not match the binding attributes configured for the local user account, the user cannot pass authentication. Binding attributes include the ISDN calling number, IP address, access port, MAC address, and native VLAN. For more information about binding attributes, see "[Configuring local user attributes](#)." Be cautious when deciding which binding attributes to configure for a local user.

- Authorization attributes:

Authorization attributes indicate the rights that a user has after passing local authentication. Authorization attributes include the ACL, PPP callback number, idle cut function, user level, user role, user profile, VLAN, and FTP/SFTP work directory. For more information about authorization attributes, see "[Configuring local user attributes](#)."

Every configurable authorization attribute has its definite application environments and purposes. When you configure authorization attributes for a local user, consider which attributes are needed and which are not.

You can configure an authorization attribute in user group view or local user view to make the attribute effective for all local users in the group or only for the local user. The setting of an authorization attribute in local user view takes precedence over that in user group view.

Local user configuration task list

Task	Remarks
Configuring local user attributes	Required
Configuring user group attributes	Optional
Displaying and maintaining local users and local user groups	Optional

Configuring local user attributes

Step	Command	Remarks
1. Enter system view.	<code>system-view</code>	N/A

Step	Command	Remarks
2. Add a local user and enter local user view.	local-user <i>user-name</i>	No local user exists by default.
3. Configure a password for the local user.	password [{ cipher simple } <i>password</i>]	Optional. A local user with no password configured directly passes authentication after providing the valid local username and attributes. To enhance security, configure a password for each local user. If none of the parameters is specified, you enter the interactive mode to set a plaintext password. This interactive mode is supported only on switches that support the password control feature.
4. Specify the service types for the local user.	service-type { ftp lan-access { ssh telnet terminal } * portal web }	By default, no service is authorized to a local user.
5. Place the local user to the state of active or blocked.	state { active block }	Optional. When created, a local user is in active state by default, and the user can request network services.
6. Set the maximum number of concurrent users of the local user account.	access-limit <i>max-user-number</i>	Optional. By default, there is no limit to the maximum number of concurrent users of a local user account. The limit is effective only for local accounting, and is not effective for FTP users.
7. Configure the password control attributes for the local user.	<ul style="list-style-type: none"> Set the password aging time: password-control aging <i>aging-time</i> Set the minimum password length: password-control length <i>length</i> Configure the password composition policy: password-control composition <i>type-number type-number</i> [<i>type-length type-length</i>] 	Optional. By default, the password control attributes of the user group to which the local user belongs apply, and any password control attribute that is not configured in the user group uses the global setting. The global settings include a 90-day password aging time, a minimum password length of 10 characters, and at least one password composition type and at least one character required for each password composition type.
8. Configure the binding attributes for the local user.	bind-attribute { call-number <i>call-number</i> [: <i>subcall-number</i>] ip <i>ip-address</i> location port <i>slot-number subslot-number port-number</i> mac <i>mac-address</i> vlan <i>vlan-id</i> } *	Optional. By default, no binding attribute is configured for a local user. Binding attributes are only intended for and LAN users.

Step	Command	Remarks
9. Configure the authorization attributes for the local user.	authorization-attribute { acl <i>acl-number</i> callback-number <i>callback-number</i> idle-cut <i>minute</i> level <i>level</i> user-profile <i>profile-name</i> user-role { guest guest-manager security-audit } vlan <i>vlan-id</i> work-directory <i>directory-name</i> } *	Optional. By default, no authorization attribute is configured for a local user. For LAN and portal users, only acl , idle-cut , user-profile , and vlan are supported. For SSH, terminal, and Web users, only level is supported. For FTP users, only level and work-directory are supported. For Telnet users, only level and user-role is supported. For other types of local users, no binding attribute is supported.
10. Set the validity time of the local user.	validity-date <i>time</i>	Optional. Not set by default.
11. Set the expiration time of the local user.	expiration-date <i>time</i>	Optional. Not set by default.
12. Assign the local user to a user group.	group <i>group-name</i>	Optional. By default, a local user belongs to the default user group system .

- For more information about password control configuration commands, see *Security Command Reference*.
- If the user interface authentication mode (set by the **authentication-mode** command in user interface view) is AAA (**scheme**), which commands a login user can use after login depends on the privilege level authorized to the user. If the user interface authentication mode is password (**password**) or no authentication (**none**), which commands a login user can use after login depends on the level configured for the user interface (set by the **user privilege level** command in user interface view). For an SSH user using public key authentication, which commands are available depends on the level configured for the user interface. For more information about user interface authentication mode and user interface command level, see *Fundamentals Configuration Guide*.
- You can configure the user profile authorization attribute in local user view, user group view, and ISP domain view. The setting in local user view has the highest priority, and that in ISP domain view has the lowest priority. For more information about user profiles, see "[Configuring a user profile](#)."
- You cannot delete a local user who is the only security log manager in the system, nor can you change or delete the security log manager role of the user. To do so, you must specify a new security log manager first.

Configuring user group attributes

User groups simplify local user configuration and management. A user group consists of a group of local users and has a set of local user attributes. You can configure local user attributes for a user group to implement centralized user attributes management for the local users in the group. Configurable user attributes include password control attributes and authorization attributes.

By default, every newly added local user belongs to the system default user group system and bears all attributes of the group. To change the user group to which a local user belongs, use the **user-group** command in local user view.

To configure attributes for a user group:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a user group and enter user group view.	user-group <i>group-name</i>	N/A
3. Configure password control attributes for the user group.	<ul style="list-style-type: none"> Set the password aging time: password-control aging <i>aging-time</i> Set the minimum password length: password-control length <i>length</i> Configure the password composition policy: password-control composition <i>type-number type-number [type-length type-length]</i> 	Optional. By default, the global settings apply. The global settings include a 90-day password aging time, a minimum password length of 10 characters, and at least one password composition type and at least one character required for each password composition type.
4. Configure the authorization attributes for the user group.	authorization-attribute { acl <i>acl-number</i> callback-number <i>callback-number</i> idle-cut <i>minute</i> level <i>level</i> user-profile <i>profile-name</i> vlan <i>vlan-id</i> work-directory <i>directory-name</i> } *	Optional. By default, no authorization attribute is configured for a user group.
5. Set the guest attribute for the user group.	group-attribute allow-guest	Optional. By default, the guest attribute is not set for a user group, and guest users created by a guest manager through the Web interface cannot join the group.

NOTE:

For more information about password control attributes configuration commands, see *Security Command Reference*.

Displaying and maintaining local users and local user groups

Task	Command	Remarks
Display local user information	display local-user [idle-cut { disable enable } service-type { ftp lan-access portal ssh telnet terminal web } state { active block } user-name <i>user-name</i> vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display the user group configuration information.	display user-group [<i>group-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

Configuring RADIUS schemes

A RADIUS scheme specifies the RADIUS servers that the switch can cooperate with and defines a set of parameters that the switch uses to exchange information with the RADIUS servers. There may be authentication/authorization servers and accounting servers, or primary servers and secondary servers. The parameters include the IP addresses of the servers, the shared keys, and the RADIUS server type.

RADIUS scheme configuration task list

Task	Remarks
Creating a RADIUS scheme	Required
Specifying the RADIUS authentication/authorization servers	Required
Specifying the RADIUS accounting servers and the relevant parameters	Optional
Specifying the shared keys for secure RADIUS communication	Optional
Specifying the VPN to which the servers belong	Optional
Setting the username format and traffic statistics units	Optional
Setting the supported RADIUS server type	Optional
Setting the maximum number of RADIUS request transmission attempts	Optional
Setting the status of RADIUS servers	Optional
Specifying the source IP address for outgoing RADIUS packets	Optional
Specifying a backup source IP address for outgoing RADIUS packets	Optional
Setting timers for controlling communication with RADIUS servers	Optional
Configuring RADIUS accounting-on	Optional
Configuring the IP address of the security policy server	Optional
Configuring interpretation of RADIUS class attribute as CAR parameters	Optional
Enabling the trap function for RADIUS	Optional
Enabling the RADIUS listening port of the RADIUS client	Optional
Setting the DSCP value for RADIUS protocol packets	Optional
Displaying and maintaining RADIUS	Optional

Creating a RADIUS scheme

Before performing other RADIUS configurations, follow these steps to create a RADIUS scheme and enter RADIUS scheme view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a RADIUS scheme and enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	No RADIUS scheme exists by default.

NOTE:

A RADIUS scheme can be referenced by multiple ISP domains at the same time.

Specifying the RADIUS authentication/authorization servers

You can specify one primary authentication/authorization server and up to 16 secondary authentication/authorization servers for a RADIUS scheme. When the primary server is not available, a secondary server is used. In a scenario where redundancy is not required, specify only the primary server.

In RADIUS, user authorization information is piggybacked in authentication responses sent to RADIUS clients. There is no separate RADIUS authorization server.

You can enable the server status detection feature. With the feature, the switch periodically sends an authentication request to check whether or not the target RADIUS authentication/authorization server is reachable. If yes, the switch sets the status of the server to **active**. If not, the switch sets the status of the server to **block**. This feature can promptly notify authentication modules of latest server status information. For example, server status detection can work with the 802.1X critical VLAN feature, so that the switch can trigger 802.1X authentication for users in the critical VLAN immediately on detection of a reachable RADIUS authentication/authorization server.

Follow these guidelines when you specify RADIUS authentication/authorization servers:

- The IP addresses of the primary and secondary authentication/authorization servers for a scheme must be different from each other. Otherwise, the configuration fails.
- All servers for authentication/authorization and accounting, primary or secondary, must use IP addresses of the same IP version.
- You can specify a RADIUS authentication/authorization server as the primary authentication/authorization server for one scheme and as the secondary authentication/authorization server for another scheme at the same time.

To specify RADIUS authentication/authorization servers for a RADIUS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A

Step	Command	Remarks
3. Specify RADIUS authentication/authorization servers.	<ul style="list-style-type: none"> Specify the primary RADIUS authentication/authorization server: primary authentication { <i>ip-address</i> ipv6 <i>ipv6-address</i> } [<i>port-number</i> key [cipher simple] <i>key</i> probe username <i>name</i> [interval <i>interval</i>] vpn-instance <i>vpn-instance-name</i>] * Specify a secondary RADIUS authentication/authorization server: secondary authentication { <i>ip-address</i> ipv6 <i>ipv6-address</i> } [<i>port-number</i> key [cipher simple] <i>key</i> probe username <i>name</i> [interval <i>interval</i>] vpn-instance <i>vpn-instance-name</i>] * 	<p>Configure at least one command.</p> <p>No authentication/authorization server is specified by default.</p>

Specifying the RADIUS accounting servers and the relevant parameters

You can specify one primary accounting server and up to 16 secondary accounting servers for a RADIUS scheme. When the primary server is not available, a secondary server is used. When redundancy is not required, specify only the primary server.

By setting the maximum number of real-time accounting attempts for a scheme, you make the switch disconnect users for whom no accounting response is received before the number of accounting attempts reaches the limit.

When the switch receives a connection teardown request from a host or a connection teardown notification from an administrator, it sends a stop-accounting request to the accounting server. You can enable buffering of non-responded stop-accounting requests to allow the switch to buffer and resend a stop-accounting request until it receives a response or the number of stop-accounting attempts reaches the configured limit. In the latter case, the switch discards the packet.

Follow these guidelines when you specify RADIUS accounting servers:

- The IP addresses of the primary and secondary accounting servers must be different from each other. Otherwise, the configuration fails.
- All servers for authentication/authorization and accountings, primary or secondary, must use IP addresses of the same IP version.
- If you delete an accounting server that is serving users, the switch can no longer send real-time accounting requests and stop-accounting requests for the users to that server, or buffer the stop-accounting requests.
- You can specify a RADIUS accounting server as the primary accounting server for one scheme and as the secondary accounting server for another scheme at the same time.
- RADIUS does not support accounting for FTP users.

To specify RADIUS accounting servers and set relevant parameters for a scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A

Step	Command	Remarks
3. Specify RADIUS accounting servers.	<ul style="list-style-type: none"> Specify the primary RADIUS accounting server: primary accounting { <i>ip-address</i> ipv6 <i>ipv6-address</i> } [<i>port-number</i> key [cipher simple] <i>key</i> vpn-instance <i>vpn-instance-name</i>] * Specify a secondary RADIUS accounting server: secondary accounting { <i>ip-address</i> ipv6 <i>ipv6-address</i> } [<i>port-number</i> key [cipher simple] <i>key</i> vpn-instance <i>vpn-instance-name</i>] * 	<p>Configure at least one command.</p> <p>No accounting server is specified by default.</p>
4. Set the maximum number of real-time accounting attempts.	retry realtime-accounting <i>retry-times</i>	<p>Optional.</p> <p>The default setting is 5.</p>
5. Enable buffering of stop-accounting requests to which no responses are received.	stop-accounting-buffer enable	<p>Optional.</p> <p>Enabled by default.</p>
6. Set the maximum number of stop-accounting attempts.	retry stop-accounting <i>retry-times</i>	<p>Optional.</p> <p>The default setting is 500.</p>

Specifying the shared keys for secure RADIUS communication

The RADIUS client and RADIUS server use the MD5 algorithm to authenticate packets exchanged between them and use shared keys for packet authentication and user passwords encryption. They must use the same key for the same type of communication.

A shared key configured in this task is for all servers of the same type (accounting or authentication) in the scheme, and has a lower priority than a shared key configured individually for a RADIUS server.

To specify a shared key for secure RADIUS communication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Specify a shared key for secure RADIUS authentication/authorization or accounting communication.	key { accounting authentication } <i>key</i>	No shared key is specified by default.

NOTE:

A shared key configured on the switch must be the same as that configured on the RADIUS server.

Specifying the VPN to which the servers belong (available only on the HP 5500 EI)

After you specify a VPN for a RADIUS scheme, all the authentication/authorization/accounting servers specified for the scheme belong to the VPN. However, if you also specify a VPN when specifying a server for the scheme, the server belongs to the specific VPN.

To specify a VPN for a RADIUS scheme:

Step	Command
1. Enter system view.	system-view
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>
3. Specify a VPN for the RADIUS scheme.	vpn-instance <i>vpn-instance-name</i>

Setting the username format and traffic statistics units

A username is usually in the format of *userid@isp-name*, where *isp-name* represents the name of the ISP domain the user belongs to and is used by the switch to determine which users belong to which ISP domains. However, some earlier RADIUS servers cannot recognize usernames that contain an ISP domain name. In this case, the switch must remove the domain name of each username before sending the username. You can set the username format on the switch for this purpose.

The switch periodically sends accounting updates to RADIUS accounting servers to report the traffic statistics of online users. For normal and accurate traffic statistics, make sure the unit for data flows and that for packets on the switch are consistent with those on the RADIUS server.

Follow these guidelines when you set the username format and the traffic statistics units for a RADIUS scheme:

- If a RADIUS scheme defines that the username is sent without the ISP domain name, do not apply the RADIUS scheme to more than one ISP domain. Otherwise, users using the same username but in different ISP domains are considered the same user.
- For level switching authentication, the **user-name-format keep-original** and **user-name-format without-domain** commands produce the same results. They make sure usernames sent to the RADIUS server carry no ISP domain name.

To set the username format and the traffic statistics units for a RADIUS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Set the format for usernames sent to the RADIUS servers.	user-name-format { keep-original with-domain without-domain }	Optional. By default, the ISP domain name is included in a username.
4. Specify the unit for data flows or packets sent to the RADIUS servers.	data-flow-format { data { byte giga-byte kilo-byte mega-byte } packet { giga-packet kilo-packet mega-packet one-packet } }*	Optional. The default unit is byte for data flows and is one-packet for data packets.

Setting the supported RADIUS server type

The supported RADIUS server type determines the type of the RADIUS protocol that the switch uses to communicate with the RADIUS server. It can be standard or extended:

- **Standard**—Uses the standard RADIUS protocol, compliant to RFC 2865 and RFC 2866 or later.
- **Extended**—Uses the proprietary RADIUS protocol of HP.

When the RADIUS server runs on IMC, you must set the RADIUS server type to **extended**. When the RADIUS server runs third-party RADIUS server software, either RADIUS server type applies. For the switch to function as a RADIUS server to authenticate login users, you must set the RADIUS server type to **standard**.

To set the RADIUS server type:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Set the RADIUS server type.	server-type { extended standard }	Optional. The default RADIUS server type is standard .

NOTE:

Changing the RADIUS server type restores the unit for data flows and that for packets that are sent to the RADIUS server to the defaults.

Setting the maximum number of RADIUS request transmission attempts

Because RADIUS uses UDP packets to transfer data, the communication process is not reliable. RADIUS uses a retransmission mechanism to improve the reliability. If a NAS sends a RADIUS request to a RADIUS server but receives no response after the response timeout timer (defined by the **timer response-timeout** command) expires, it retransmits the request. If the number of transmission attempts exceeds the specified limit but it still receives no response, it tries to communicate with other RADIUS servers in active state. If no other servers are in active state at the time, it considers the authentication or accounting attempt a failure. For more information about RADIUS server states, see "[Setting the status of RADIUS servers.](#)"

To set the maximum number of RADIUS request transmission attempts for a scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Set the maximum number of RADIUS request transmission attempts.	retry <i>retry-times</i>	Optional. The default setting is 3.

NOTE:

- The maximum number of transmission attempts of RADIUS packets multiplied by the RADIUS server response timeout period cannot be greater than 75 seconds.
- For more information about the RADIUS server response timeout period, see "[Setting timers for controlling communication with RADIUS servers.](#)"

Setting the status of RADIUS servers

By setting the status of RADIUS servers to blocked or active, you can control which servers the switch communicates with for authentication, authorization, and accounting or turn to when the current servers

are not available anymore. In practice, you can specify one primary RADIUS server and multiple secondary RADIUS servers, with the secondary servers functioning as the backup of the primary servers. Generally, the switch chooses servers based on these rules:

- When the primary server is in active state, the switch communicates with the primary server. If the primary server fails, the switch changes the server's status to blocked and starts a quiet timer for the server, and then turns to a secondary server in active state (a secondary server configured earlier has a higher priority). If the secondary server is unreachable, the switch changes the server's status to blocked, starts a quiet timer for the server, and continues to check the next secondary server in active state. This search process continues until the switch finds an available secondary server or has checked all secondary servers in active state. If the quiet timer of a server expires or an authentication or accounting response is received from the server, the status of the server changes back to active automatically, but the switch does not check the server again during the authentication or accounting process. If no server is found reachable during one search process, the switch considers the authentication or accounting attempt a failure.
- Once the accounting process of a user starts, the switch keeps sending the user's real-time accounting requests and stop-accounting requests to the same accounting server. If you remove the accounting server, real-time accounting requests and stop-accounting requests for the user cannot be delivered to the server anymore.
- If you remove an authentication or accounting server in use, the communication of the switch with the server soon times out, and the switch looks for a server in active state from scratch by checking any primary server first and then secondary servers in the order they are configured.
- When the primary server and secondary servers are all in blocked state, the switch communicates with the primary server. If the primary server is available, its status changes to active. Otherwise, its status remains to be blocked.
- If one server is in active state and all the others are in blocked state, the switch only tries to communicate with the server in active state, even if the server is unavailable.
- After receiving an authentication/accounting response from a server, the switch changes the status of the server identified by the source IP address of the response to active if the current status of the server is blocked.

By default, the switch sets the status of all RADIUS servers to active. In cases such as a server failure, you can change the status of the server to blocked to avoid communication with the server.

To set the status of RADIUS servers in a RADIUS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A

Step	Command	Remarks
3. Set the RADIUS server status.	<ul style="list-style-type: none"> Set the status of the primary RADIUS authentication/authorization server: state primary authentication { active block } Set the status of the primary RADIUS accounting server: state primary accounting { active block } Set the status of a secondary RADIUS authentication/authorization server: state secondary authentication [ip ipv4-address ipv6 ipv6-address] { active block } Set the status of a secondary RADIUS accounting server: state secondary accounting [ip ipv4-address ipv6 ipv6-address] { active block } 	Optional. By default, all servers in the RADIUS scheme are in active state.

NOTE:

- The server status set by the **state** command cannot be saved to the configuration file. After the switch restarts, the status of each server is restored to active.
- To display the states of the servers, use the **display radius scheme** command.

Specifying the source IP address for outgoing RADIUS packets

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS configured on the RADIUS server. A RADIUS server identifies a NAS by its IP address. Upon receiving a RADIUS packet, a RADIUS server checks whether the source IP address of the packet is the IP address of any managed NAS. If yes, the server processes the packet. If not, the server drops the packet.

Usually, the source address of outgoing RADIUS packets can be the IP address of the NAS's any interface that can communicate with the RADIUS server. In some special scenarios, however, you must change the source IP address. For example, if a Network Address Translation (NAT) device is present between the NAS and the RADIUS server, the source IP address of outgoing RADIUS packets must be a public IP address of the NAS. If the NAS is configured with the Virtual Router Redundancy Protocol (VRRP) for stateful failover, the source IP address of outgoing RADIUS packets can be the virtual IP address of the VRRP group to which the uplink belongs.

You can specify a source IP address for outgoing RADIUS packets in RADIUS scheme view for a specific RADIUS scheme, or in system view for all RADIUS schemes whose servers are in a VPN or the public network. Before sending a RADIUS packet, a NAS selects a source IP address in this order:

- The source IP address specified for the RADIUS scheme.
- The source IP address specified in system view for the VPN or public network, depending on where the RADIUS server resides.
- The IP address of the outbound interface specified by the route.

To specify a source IP address for all RADIUS schemes in a VPN or the public network:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Specify a source IP address for outgoing RADIUS packets.	radius nas-ip { <i>ip-address</i> ipv6 <i>ipv6-address</i> } [vpn-instance <i>vpn-instance-name</i>]	By default, the IP address of the outbound interface is used as the source IP address.

To specify a source IP address for a specific RADIUS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Specify a source IP address for outgoing RADIUS packets.	nas-ip { <i>ip-address</i> ipv6 <i>ipv6-address</i> }	By default, the IP address of the outbound interface is used as the source IP address.

Specifying a backup source IP address for outgoing RADIUS packets (available only on the HP 5500 EI)

In a stateful failover scenario, the active switch authenticates portal users by interacting with the RADIUS server, and synchronizes its online portal user information to the standby switch through the backup link established between them. The standby switch only receives and processes synchronization messages from the active switch. However, when the active switch fails, the RADIUS server does not send RADIUS packets to the standby switch because it does not know the IP address of the standby switch. To solve this problem, configure the source IP address for outgoing RADIUS packets on each switch as the backup source IP address for outgoing RADIUS packets on the other switch. With such configuration, the active switch sends the source IP address for outgoing RADIUS packets that is configured on the standby switch to the RADIUS server, so that the RADIUS server can send unsolicited RADIUS packets to the standby switch.

You can specify a backup IP address for outgoing RADIUS packets in RADIUS scheme view for a specific RADIUS scheme, or in system view for all RADIUS schemes whose servers are in a VPN or the public network. Before sending a RADIUS packet, a NAS selects a backup source IP address in this order:

1. The backup source IP address specified for the RADIUS scheme.
2. The backup source IP address specified in system view for the VPN or public network, depending on where the RADIUS server resides.

If no backup source IP address is specified in the views, the NAS sends no backup source IP address to the server.

To specify a backup source IP address for all RADIUS schemes of a VPN or the public network:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify a backup source IP address for outgoing RADIUS packets.	radius nas-backup-ip <i>ip-address</i> [vpn-instance <i>vpn-instance-name</i>]	Not specified by default.

To specify a backup source IP address for a RADIUS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Specify a backup source IP address for outgoing RADIUS packets.	nas-backup-ip <i>ip-address</i>	Not specified by default.

NOTE:

The backup source IP address specified for outgoing RADIUS packets takes effect only when stateful failover is configured, and it must be the source IP address for outgoing RADIUS packets that is configured on the standby switch.

Setting timers for controlling communication with RADIUS servers

The switch uses the following types of timers to control the communication with a RADIUS server:

- **Server response timeout timer (response-timeout)**—Defines the RADIUS request retransmission interval. After sending a RADIUS request (authentication/authorization or accounting request), the switch starts this timer. If the switch receives no response from the RADIUS server before this timer expires, it resends the request.
- **Server quiet timer (quiet)**—Defines the duration to keep an unreachable server in blocked state. If a server is not reachable, the switch changes the server’s status to blocked, starts this timer for the server, and tries to communicate with another server in active state. After this timer expires, the switch changes the status of the server back to active.
- **Real-time accounting timer (realtime-accounting)**—Defines the interval at which the switch sends real-time accounting packets to the RADIUS accounting server for online users. To implement real-time accounting, the switch must periodically send real-time accounting packets to the accounting server for online users.

To set timers for controlling communication with RADIUS servers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Set the RADIUS server response timeout timer.	timer response-timeout <i>seconds</i>	Optional. The default RADIUS server response timeout timer is 3 seconds.
4. Set the quiet timer for the servers.	timer quiet <i>minutes</i>	Optional. The quiet timer is 5 minutes.
5. Set the real-time accounting timer.	timer realtime-accounting <i>minutes</i>	Optional. The default real-time accounting timer is 12 minutes.

- For a type of users, the maximum number of transmission attempts multiplied by the RADIUS server response timeout period must be less than the client connection timeout time and must not exceed

75 seconds. Otherwise, stop-accounting messages cannot be buffered, and the primary/secondary server switchover cannot take place. For example, the product of the two parameters must be less than 10 seconds for voice users, and less than 30 seconds for Telnet users because the client connection timeout period for voice users is 10 seconds and that for Telnet users is 30 seconds.

- When you configure the maximum number of RADIUS packet transmission attempts and the RADIUS server response timeout period, be sure to take the number of secondary servers into account. If the retransmission process takes too much time, the client connection in the access module may be timed out while the switch is trying to find an available server.
- When a number of secondary servers are configured, the client connections of access modules that have a short client connection timeout period may still be timed out during initial authentication or accounting, even if the packet transmission attempt limit and server response timeout period are configured with small values. In this case, the next authentication or accounting attempt may succeed because the switch has set the state of the unreachable servers to blocked and the time for finding a reachable server is shortened.
- Be sure to set the server quiet timer properly. Too short a quiet timer may result in frequent authentication or accounting failures because the switch has to repeatedly attempt to communicate with an unreachable server that is in active state.
- For more information about the maximum number of RADIUS packet transmission attempts, see "[Setting the maximum number of RADIUS request transmission attempts.](#)"

Configuring RADIUS accounting-on

The accounting-on feature enables a switch to send accounting-on packets to the RADIUS server after it reboots, making the server log out users who logged in through the switch before the reboot. Without this feature, users who were online before the reboot cannot re-log in after the reboot, because the RADIUS server considers they are already online.

If a switch sends an accounting-on packet to the RADIUS server but receives no response, it resends the packet to the server at a particular interval for a specified number of times.

To configure the accounting-on feature for a RADIUS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Enable accounting-on and configure parameters.	accounting-on enable [interval seconds send send-times] *	Disabled by default. The default interval is 3 seconds and the default number of send-times is 50.

NOTE:

The accounting-on feature requires the cooperation of the HP IMC network management system.

Configuring the IP address of the security policy server

The core of the HP EAD solution is integration and cooperation, and the security policy server is the management and control center. Using a collection of software, the security policy server provides functions such as user management, security policy management, security status assessment, security cooperation control, and security event audit.

The NAS checks the validity of received control packets and accepts only control packets from known servers. To use a security policy server that is independent of the AAA servers, you must configure the IP address of the security policy server on the NAS. To implement all EAD functions, configure both the IP address of the IMC security policy server and that of the IMC Platform on the NAS.

To configure the IP address of the security policy server for a scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Specify a security policy server.	security-policy-server <i>ip-address</i>	No security policy server is specified by default.

Configuring interpretation of RADIUS class attribute as CAR parameters

According to RFC 2865, a RADIUS server assigns the RADIUS class attribute (attribute 25) to a RADIUS client. However, the RFC only requires the RADIUS client to send the attribute to the accounting server on an "as is" basis. It does not require the RADIUS client to interpret the attribute. Some RADIUS servers use the class attribute to deliver the assigned committed access rate (CAR) parameters. In this case, the switch must interpret the attribute as the CAR parameters to implement user-based traffic monitoring and controlling.

To configure the switch to interpret the RADIUS class attribute as CAR parameters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter RADIUS scheme view.	radius scheme <i>radius-scheme-name</i>	N/A
3. Interpret the class attribute as CAR parameters.	attribute 25 car	By default, RADIUS attribute 25 is not interpreted as CAR parameters.

NOTE:

Whether interpretation of RADIUS class attribute as CAR parameters is supported depends on two factors:

- Whether the switch supports CAR parameters assignment.
- Whether the RADIUS server supports assigning CAR parameters through the class attribute.

Enabling the trap function for RADIUS

With the trap function, a NAS sends a trap message when either of the following events occurs:

- The status of a RADIUS server changes. If a NAS receives no response to an accounting or authentication request before the specified maximum number of RADIUS request transmission attempts is exceeded, it considers the server unreachable, sets the status of the server to **block** and sends a trap message. If the NAS receives a response from a RADIUS server that it considers unreachable, the NAS considers that the RADIUS server is reachable again, sets the status of the server to **active**, and sends a trap message.
- The ratio of the number of failed transmission attempts to the total number of authentication request transmission attempts reaches the threshold. This threshold ranges from 1% to 100% and defaults to 30%. This threshold can only be configured through the MIB.

The failure ratio is generally small. If a trap message is triggered because the failure ratio is higher than the threshold, troubleshoot the configuration on and the communication between the NAS and the RADIUS server.

To enable the trap function for RADIUS:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the trap function for RADIUS.	radius trap { accounting-server-down authentication-error-threshold authentication-server-down }	Disabled by default.

Enabling the RADIUS listening port of the RADIUS client

Only after you enable the RADIUS listening port of a RADIUS client, can the client receive and send RADIUS packets. If RADIUS is not required, disable the RADIUS listening port to avoid attacks that exploit RADIUS packets.

To enable the RADIUS listening port of a RADIUS client:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the RADIUS listening port of a RADIUS client.	radius client enable	Optional. Enabled by default.

Setting the DSCP value for RADIUS protocol packets

A field in an IPv4 or IPv6 header contains eight bits and is used to identify the service type of an IP packet. In an IPv4 packet, this field is called "Type of Service (ToS)." In an IPv6 packet, this field is called "Traffic class." According to RFC 2474, the ToS field is redefined as the differentiated services (DS) field, where a DSCP value is represented by the first six bits (0 to 5) and is in the range 0 to 63. The remaining two bits (6 and 7) are reserved. When a packet is being transmitted, the network devices can identify its DSCP value, and determines the transmission priority of the packet according to the DSCP value.

When you configure the DSCP value for some types of protocol packets, you should specify the ToS field value rather than the DSCP value. Because the DSCP field is the first six bits of the ToS field, each four continuous ToS field values, starting from 0, correspond to one DSCP value. An easier way to convert the DSCP value to the ToS value is to multiply the expected DSCP value by four to get the ToS field value.

To set the DSCP value for RADIUS protocol packets:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the DSCP value for IPv4 RADIUS protocol packets.	radius dscp dscp-value	Optional. By default, the DSCP value in IPv4 RADIUS protocol packets is 0.
3. Set the DSCP value for IPv6 RADIUS protocol packets.	radius ipv6 dscp dscp-value	Optional. By default, the DSCP value in IPv6 RADIUS protocol packets is 0.

Displaying and maintaining RADIUS

Task	Command	Remarks
Display the configuration information of RADIUS schemes.	display radius scheme [<i>radius-scheme-name</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the statistics for RADIUS packets .	display radius statistics [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about buffered stop-accounting requests for which no responses have been received .	display stop-accounting-buffer { radius-scheme <i>radius-server-name</i> session-id <i>session-id</i> time-range <i>start-time stop-time</i> user-name <i>user-name</i> } [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear RADIUS statistics .	reset radius statistics [slot <i>slot-number</i>]	Available in user view
Clear the buffered stop-accounting requests for which no responses have been receive.	reset stop-accounting-buffer { radius-scheme <i>radius-server-name</i> session-id <i>session-id</i> time-range <i>start-time stop-time</i> user-name <i>user-name</i> } [slot <i>slot-number</i>]	Available in user view

Configuring HWTACACS schemes

NOTE:

You cannot remove the HWTACACS schemes in use or change the IP addresses of the HWTACACS servers in use.

HWTACACS configuration task list

Task	Remarks
Creating an HWTACACS scheme	Required
Specifying the HWTACACS authentication servers	Required
Specifying the HWTACACS authorization servers	Optional
Specifying the HWTACACS accounting servers and the relevant parameters	Optional
Specifying the shared keys for secure HWTACACS communication	Required
Specifying the VPN to which the servers belong	Optional
Setting the username format and traffic statistics units	Optional
Specifying a source IP address for outgoing HWTACACS packets	Optional
Setting timers for controlling communication with HWTACACS servers	Optional
Displaying and maintaining HWTACACS	Optional

Creating an HWTACACS scheme

The HWTACACS protocol is configured on a per scheme basis. Before performing other HWTACACS configurations, follow these steps to create an HWTACACS scheme and enter HWTACACS scheme view:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an HWTACACS scheme and enter HWTACACS scheme view.	hwtacacs scheme <i>hwtacacs-scheme-name</i>	Not defined by default.

NOTE:

- Up to 16 HWTACACS schemes can be configured.
- A scheme can be deleted only when it is not referenced.

Specifying the HWTACACS authentication servers

You can specify one primary authentication server and up to one secondary authentication server for an HWTACACS scheme. When the primary server is not available, any secondary server is used. In a scenario where redundancy is not required, specify only the primary server.

Follow these guidelines when you specify HWTACACS authentication servers:

- An HWTACACS server can function as the primary authentication server of one scheme and as the secondary authentication server of another scheme at the same time.
- The IP addresses of the primary and secondary authentication servers cannot be the same. Otherwise, the configuration fails.
- You can remove an authentication server only when no active TCP connection for sending authentication packets is using it.

To specify HWTACACS authentication servers for an HWTACACS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter HWTACACS scheme view.	hwtacacs scheme <i>hwtacacs-scheme-name</i>	N/A
3. Specify HWTACACS authentication servers.	<ul style="list-style-type: none">• Specify the primary HWTACACS authentication server: primary authentication <i>ip-address</i> [<i>port-number</i> vpn-instance <i>vpn-instance-name</i>] *• Specify the secondary HWTACACS authentication server: secondary authentication <i>ip-address</i> [<i>port-number</i> vpn-instance <i>vpn-instance-name</i>] *	<ul style="list-style-type: none">• Configure at least one command.• No authentication server is specified by default.

Specifying the HWTACACS authorization servers

You can specify one primary authorization server and up to one secondary authorization server for an HWTACACS scheme. When the primary server is not available, any secondary server is used. In a scenario where redundancy is not required, specify only the primary server.

Follow these guidelines when you specify HWTACACS authorization servers:

- An HWTACACS server can function as the primary authorization server of one scheme and as the secondary authorization server of another scheme at the same time.
- The IP addresses of the primary and secondary authorization servers cannot be the same. Otherwise, the configuration fails.
- You can remove an authorization server only when no active TCP connection for sending authorization packets is using it.

To specify HWTACACS authorization servers for an HWTACACS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter HWTACACS scheme view.	hwtacacs scheme <i>hwtacacs-scheme-name</i>	N/A
3. Specify HWTACACS authorization servers.	<ul style="list-style-type: none">• Specify the primary HWTACACS authorization server: primary authorization <i>ip-address</i> [<i>port-number</i> vpn-instance <i>vpn-instance-name</i>] *• Specify the secondary HWTACACS authorization server: secondary authorization <i>ip-address</i> [<i>port-number</i> vpn-instance <i>vpn-instance-name</i>] *	Configure at least one command. No authorization server is specified by default.

Specifying the HWTACACS accounting servers and the relevant parameters

You can specify one primary accounting server and up to one secondary accounting server for an HWTACACS scheme. When the primary server is not available, any secondary server is used. In a scenario where redundancy is not required, specify only the primary server.

When the switch receives a connection teardown request from a host or a connection teardown command from an administrator, it sends a stop-accounting request to the accounting server. You can enable buffering of non-responded stop-accounting requests to allow the switch to buffer and resend a stop-accounting request until it receives a response or the number of stop-accounting attempts reaches the configured limit. In the latter case, the switch discards the packet.

Follow these guidelines when you specify HWTACACS accounting servers:

- An HWTACACS server can function as the primary accounting server of one scheme and as the secondary accounting server of another scheme at the same time.
- The IP addresses of the primary and secondary accounting servers cannot be the same. Otherwise, the configuration fails.
- You can remove an accounting server only when no active TCP connection for sending accounting packets is using it.
- HWTACACS does not support accounting for FTP users.

To specify HWTACACS accounting servers and set relevant parameters for an HWTACACS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter HWTACACS scheme view.	hwtacacs scheme <i>hwtacacs-scheme-name</i>	N/A
3. Specify HWTACACS accounting servers.	<ul style="list-style-type: none"> Specify the primary HWTACACS accounting server: primary accounting <i>ip-address</i> [<i>port-number</i> vpn-instance <i>vpn-instance-name</i>] * Specify the secondary HWTACACS accounting server: secondary accounting <i>ip-address</i> [<i>port-number</i> vpn-instance <i>vpn-instance-name</i>] * 	<p>Configure at least one command.</p> <p>No accounting server is specified by default.</p>
4. Enable buffering of stop-accounting requests to which no responses are received.	stop-accounting-buffer enable	Optional. Enabled by default.
5. Set the maximum number of stop-accounting attempts.	retry stop-accounting <i>retry-times</i>	Optional. The default setting is 100.

Specifying the shared keys for secure HWTACACS communication

The HWTACACS client and HWTACACS server use the MD5 algorithm to authenticate packets exchanged between them and use shared keys for packet authentication and user passwords encryption. They must use the same key for the same type of communication.

To specify a shared key for secure HWTACACS communication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter HWTACACS scheme view.	hwtacacs scheme <i>hwtacacs-scheme-name</i>	N/A
3. Specify a shared key for secure HWTACACS authentication, authorization, or accounting communication.	key { accounting authentication authorization } [cipher simple] key	No shared key is specified by default.

NOTE:

A shared key configured on the switch must be the same as that configured on the HWTACACS server.

Specifying the VPN to which the servers belong (available only on the HP 5500 EI)

After you specify a VPN for an HWTACACS scheme, all the authentication, authorization, and accounting servers specified for the scheme belong to the VPN. However, if you also specify a VPN when specifying a server for the scheme, the server belongs to the specific VPN.

To specify a VPN for an HWTACACS scheme:

Step	Command
1. Enter system view.	system-view
2. Enter HWTACACS scheme view.	hwtacacs scheme <i>hwtacacs-scheme-name</i>
3. Specify a VPN for the HWTACACS scheme.	vpn-instance <i>vpn-instance-name</i>

Setting the username format and traffic statistics units

A username is usually in the format of *userid@isp-name*, where *isp-name* represents the name of the ISP domain the user belongs to and is used by the switch to determine which users belong to which ISP domains. However, some HWTACACS servers cannot recognize usernames that contain an ISP domain name. In this case, the switch must remove the domain name of each username before sending the username. You can set the username format on the switch for this purpose.

The switch periodically sends accounting updates to HWTACACS accounting servers to report the traffic statistics of online users. For normal and accurate traffic statistics, make sure the unit for data flows and that for packets on the switch are consistent with those configured on the HWTACACS servers.

Follow these guidelines when you set the username format and the traffic statistics units for an HWTACACS scheme:

- If an HWTACACS server does not support a username that carries the domain name, configure the switch to remove the domain name before sending the username to the server.
- For level switching authentication, the **user-name-format keep-original** and **user-name-format without-domain** commands produce the same results. They make sure usernames sent to the HWTACACS server carry no ISP domain name.

To set the username format and the traffic statistics units for an HWTACACS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter HWTACACS scheme view.	hwtacacs scheme <i>hwtacacs-scheme-name</i>	N/A
3. Set the format for usernames sent to the HWTACACS servers.	user-name-format { keep-original with-domain without-domain }	Optional. By default, the ISP domain name is included in a username.
4. Specify the unit for data flows or packets sent to the HWTACACS servers.	data-flow-format { data { byte giga-byte kilo-byte mega-byte } packet { giga-packet kilo-packet mega-packet one-packet } } *	Optional. The default unit is byte for data flows and is one-packet for data packets.

Specifying a source IP address for outgoing HWTACACS packets

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS configured on the HWTACACS server. An HWTACACS server identifies a NAS by IP address. Upon receiving an HWTACACS packet, an HWTACACS server checks whether the source IP address of the packet is the IP address of any managed NAS. If yes, the server processes the packet. If not, the server drops the packet.

Usually, the source address of outgoing HWTACACS packets can be the IP address of the NAS's any interface that can communicate with the HWTACACS server. In some special scenarios, however, you

must change the source IP address. For example, if a Network Address Translation (NAT) device is present between the NAS and the HWTACACS server, the source IP address of outgoing HWTACACS packets must be a public IP address of the NAS. If the NAS is configured with the Virtual Router Redundancy Protocol (VRRP) for stateful failover, the source IP address of HWTACACS packets can be the virtual IP address of the VRRP group to which the uplink belongs.

You can specify the source IP address for outgoing HWTACACS packets in HWTACACS scheme view for a specific HWTACACS scheme, or in system view for all HWTACACS schemes whose servers are in a VPN or the public network.

Before sending an HWTACACS packet, a NAS selects a source IP address in this order:

1. The source IP address specified for the HWTACACS scheme.
2. The source IP address specified in system view for the VPN or public network, depending on where the HWTACACS server resides.
3. The IP address of the outbound interface specified by the route.

To specify a source IP address for all HWTACACS schemes of a VPN or the public network:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify a source IP address for outgoing HWTACACS packets.	hwtacacs nas-ip <i>ip-address</i> [vpn-instance <i>vpn-instance-name</i>]	By default, the IP address of the outbound interface is used as the source IP address.

To specify a source IP address for a specific HWTACACS scheme:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter HWTACACS scheme view.	hwtacacs scheme <i>hwtacacs-scheme-name</i>	N/A
3. Specify a source IP address for outgoing HWTACACS packets.	nas-ip <i>ip-address</i>	By default, the IP address of the outbound interface is used as the source IP address.

Setting timers for controlling communication with HWTACACS servers

The switch uses the following timers to control the communication with an HWTACACS server:

- **Server response timeout timer (response-timeout)**—Defines the HWTACACS request retransmission interval. After sending an HWTACACS request (authentication, authorization, or accounting request), the switch starts this timer. If the switch receives no response from the server before this timer expires, it resends the request.
- **Server quiet timer (quiet)**—Defines the duration to keep an unreachable server in blocked state. If a server is not reachable, the switch changes the server's status to blocked, starts this timer for the server, and tries to communicate with another server in active state. After this timer expires, the switch changes the status of the server back to active.
- **Real-time accounting timer (realtime-accounting)**—Defines the interval at which the switch sends real-time accounting updates to the HWTACACS accounting server for online users. To implement real-time accounting, the switch must send real-time accounting packets to the accounting server for online users periodically.

To set timers for controlling communication with HWTACACS servers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter HWTACACS scheme view.	hwtacacs scheme <i>hwtacacs-scheme-name</i>	N/A
3. Set the HWTACACS server response timeout timer.	timer response-timeout <i>seconds</i>	Optional. The default HWTACACS server response timeout timer is 5 seconds.
4. Set the quiet timer for the primary server.	timer quiet <i>minutes</i>	Optional. The default quiet timer for the primary server is 5 minutes.
5. Set the real-time accounting interval.	timer realtime-accounting <i>minutes</i>	Optional. The default real-time accounting interval is 12 minutes.

NOTE:

Consider the performance of the NAS and the HWTACACS server when you set the real-time accounting interval. A shorter interval requires higher performance. A shorter interval requires higher performance.

Displaying and maintaining HWTACACS

Task	Command	Remarks
Display the configuration information or statistics of HWTACACS schemes .	display hwtacacs [<i>hwtacacs-server-name</i> [statistics]] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about buffered stop-accounting requests for which no responses have been received .	display stop-accounting-buffer hwtacacs-scheme <i>hwtacacs-scheme-name</i> [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear HWTACACS statistics .	reset hwtacacs statistics { accounting all authentication authorization } [slot <i>slot-number</i>]	Available in user view
Clear buffered stop-accounting requests that get no responses.	reset stop-accounting-buffer hwtacacs-scheme <i>hwtacacs-scheme-name</i> [slot <i>slot-number</i>]	Available in user view

Configuring AAA methods for ISP domains

You configure AAA methods for an ISP domain by referencing configured AAA schemes in ISP domain view. Each ISP domain has a set of default AAA methods, which are local authentication, local authorization, and local accounting by default and can be customized. If you do not configure any AAA

methods for an ISP domain, the switch uses the system default AAA methods for authentication, authorization, and accounting of the users in the domain.

Configuration prerequisites

To use local authentication for users in an ISP domain, configure local user accounts (see "[Configuring local user attributes](#)") on the switch.

To use remote authentication, authorization, and accounting, create the required RADIUS, and HWTACACS, schemes as described in "[Configuring RADIUS schemes](#)," "[Configuring HWTACACS schemes](#)".

Creating an ISP domain

In a networking scenario with multiple ISPs, the switch may connect users of different ISPs, and users of different ISPs may have different user attributes, such as different username and password structures, different service types, and different rights. To distinguish the users of different ISPs, configure ISP domains, and configure different AAA methods and domain attributes for the ISP domains.

The switch can accommodate up to 16 ISP domains, including the system predefined ISP domain **system**. You can specify one of the ISP domains as the default domain.

On the switch, each user belongs to an ISP domain. If a user provides no ISP domain name at login, the switch considers the user belongs to the default ISP domain.

To create an ISP domain:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create an ISP domain and enter ISP domain view.	domain <i>isp-name</i>	N/A
3. Return to system view.	quit	N/A
4. Specify the default ISP domain.	domain default enable <i>isp-name</i>	Optional. By default, the default ISP domain is the system predefined ISP domain system .

NOTE:

To delete the ISP domain that is functioning as the default ISP domain, you must change it to a non-default ISP domain by using the **undo domain default enable** command.

Configuring ISP domain attributes

In an ISP domain, you can configure the following attributes for all users in the domain:

- Domain status:
By placing the ISP domain to the active or blocked state, you allow or deny network service requests from users in the domain.
- Maximum number of online users:
The switch controls the number of online users in a domain to ensure the system performance and service reliability.

- Idle cut:
This function enables the switch to check the traffic of each online user in the domain at the idle timeout interval, and to log out any user in the domain whose traffic during the idle timeout period is less than the specified minimum traffic.
- Self-service server location:
By using the information defined in this attribute, users can access the self-service server to manage their own accounts and passwords.
- Default authorization user profile:
If a user passes authentication but is authorized with no user profile, the switch authorizes the default user profile of the ISP domain to the user and restricts the user's behavior based on the profile.

To configure ISP domain attributes:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter ISP domain view.	domain <i>isp-name</i>	N/A
3. Place the ISP domain to the state of active or blocked.	state { active block }	Optional. By default, an ISP domain is in active state, and users in the domain can request network services.
4. Specify the maximum number of online users in the ISP domain.	access-limit enable <i>max-user-number</i>	Optional. No limit by default.
5. Configure the idle cut function.	idle-cut enable <i>minute</i> [<i>flow</i>]	Optional. Disabled by default. This command is effective for only LAN users and portal users.
6. Enable the self-service server location function and specify the URL of the self-service server.	self-service-url enable <i>url-string</i>	Optional. Disabled by default.
7. Specify the default authorization user profile.	authorization-attribute user-profile <i>profile-name</i>	Optional. By default, an ISP domain has no default authorization user profile.

NOTE:

- For more information about user profiles, see "[Configuring a user profile.](#)"
- A self-service RADIUS server, such as IMC, is required for the self-service server location function to work.

Configuring AAA authentication methods for an ISP domain

In AAA, authentication, authorization, and accounting are separate processes. Authentication refers to the interactive authentication process of username/password/user information during an access or service request. The authentication process does not send authorization information to a supplicant or trigger accounting.

AAA supports the following authentication methods:

- **No authentication (none)**—All users are trusted and no authentication is performed. Generally, do not use this method.
- **Local authentication (local)**—Authentication is performed by the NAS, which is configured with the user information, including the usernames, passwords, and attributes. Local authentication allows high speed and low cost, but the amount of information that can be stored is limited by the size of the storage space.
- **Remote authentication (scheme)**—The NAS cooperates with a RADIUS, or HWTACACS server to authenticate users. Remote authentication provides centralized information management, high capacity, high reliability, and support for centralized authentication service for multiple NASs. You can configure local or no authentication as the backup method, which is used when the remote server is not available. No authentication can only be configured for LAN users as the backup method of remote authentication.

You can configure AAA authentication to work alone without authorization and accounting. By default, an ISP domain uses the local authentication method.

Before configuring authentication methods, complete the following tasks:

1. For RADIUS or HWTACACS authentication, configure the RADIUS or HWTACACS scheme to be referenced first. The local and none authentication methods do not require a scheme.
2. Determine the access type or service type to be configured. With AAA, you can configure an authentication method for each access type and service type, limiting the authentication protocols that can be used for access.
3. Determine whether to configure an authentication method for all access types or service types.

Follow these guidelines when you configure AAA authentication methods for an ISP domain:

- The authentication method specified with the **authentication default** command is for all types of users and has a priority lower than that for a specific access type.
- With an authentication method that references a RADIUS scheme, AAA accepts only the authentication result from the RADIUS server. The Access-Accept message from the RADIUS server also carries the authorization information, but the authentication process ignores the information.
- If you specify the **radius-scheme radius-scheme-name local, hwtacacs-scheme hwtacacs-scheme-name local** option when you configure an authentication method, local authentication is the backup method and is used only when the remote server is not available.
- If you specify only the **local** or **none** keyword in an authentication method configuration command, the switch has no backup authentication method and performs only local authentication or does not perform any authentication.
- If the method for level switching authentication references an HWTACACS scheme, the switch uses the login username of a user for level switching authentication of the user by default. If the method for level switching authentication references a RADIUS scheme, the system uses the username configured for the corresponding privilege level on the RADIUS server for level switching authentication, rather than the login username. A username configured on the RADIUS server is in the format of **\$enab/level\$**, where *level* specifies the privilege level to which the user wants to switch. For example, if user **user1** of domain **aaa** wants to switch the privilege level to 3, the system uses **\$enab3@aaa\$** for authentication when the domain name is required and uses **\$enab3\$** for authentication when the domain name is not required.

To configure AAA authentication methods for an ISP domain:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter ISP domain view.	domain <i>isp-name</i>	N/A
3. Specify the default authentication method for all types of users.	authentication default { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] }	Optional. The default authentication method is local for all types of users.
4. Specify the authentication method for LAN users.	authentication lan-access { local none radius-scheme <i>radius-scheme-name</i> [local none] }	Optional. The default authentication method is used by default.
5. Specify the authentication method for login users.	authentication login { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] }	Optional. The default authentication method is used by default.
6. Specify the authentication method for portal users.	authentication portal { local none radius-scheme <i>radius-scheme-name</i> [local] }	Optional. The default authentication method is used by default.
7. Specify the authentication method for privilege level switching.	authentication super { hwtacacs-scheme <i>hwtacacs-scheme-name</i> radius-scheme <i>radius-scheme-name</i> }	Optional. The default authentication method is used by default.

Configuring AAA authorization methods for an ISP domain

In AAA, authorization is a separate process at the same level as authentication and accounting. Its responsibility is to send authorization requests to the specified authorization servers and to send authorization information to users after successful authorization. Authorization method configuration is optional in AAA configuration.

AAA supports the following authorization methods:

- **No authorization (none)**—The NAS performs no authorization exchange. After passing authentication, non-login users can access the network, FTP users can access the root directory of the NAS, and other login users have only the rights of Level 0 (visiting).
- **Local authorization (local)**—The NAS performs authorization according to the user attributes configured for users.
- **Remote authorization (scheme)**—The NAS cooperates with a RADIUS, or HWTACACS server to authorize users. RADIUS authorization is bound with RADIUS authentication. RADIUS authorization can work only after RADIUS authentication is successful, and the authorization information is carried in the Access-Accept message. HWTACACS authorization is separate from HWTACACS authentication, and the authorization information is carried in the authorization response after successful authentication. You can configure local authorization or no authorization as the backup method, which is used when the remote server is not available.

Before configuring authorization methods, complete the following tasks:

1. For HWTACACS authorization, configure the HWTACACS scheme to be referenced first. For RADIUS authorization, the RADIUS authorization scheme must be the same as the RADIUS authentication scheme. Otherwise, it does not take effect.

2. Determine the access type or service type to be configured. With AAA, you can configure an authorization scheme for each access type and service type, limiting the authorization protocols that can be used for access.
3. Determine whether to configure an authorization method for all access types or service types.

Follow these guidelines when you configure AAA authorization methods for an ISP domain:

- The authorization method specified with the **authorization default** command is for all types of users and has a priority lower than that for a specific access type.
- If you configure an authentication method and an authorization method that use RADIUS schemes for an ISP domain, the RADIUS scheme for authorization must be the same as that for authentication. If the RADIUS authorization configuration is invalid or RADIUS authorization fails, the RADIUS authentication also fails. Whenever RADIUS authorization fails, an error message is sent to the NAS, indicating that the server is not responding.
- If you specify the **radius-scheme** *radius-scheme-name* **local**, **hwtacacs-scheme** *hwtacacs-scheme-name* [**local** | **none**] option when you configure an authorization method, local authorization or no authorization is the backup method and is used only when the remote server is not available.
- If you specify only the **local** or **none** keyword in an authorization method configuration command, the switch has no backup authorization method and performs only local authorization or does not perform any authorization.

To configure AAA authorization methods for an ISP domain:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter ISP domain view.	domain <i>isp-name</i>	N/A
3. Specify the default authorization method for all types of users.	authorization default { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] }	Optional. The authorization method is local for all types of users.
4. Specify the command authorization method.	authorization command { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local none] local none }	Optional. The default authorization method is used by default.
5. Specify the authorization method for LAN users.	authorization lan-access { local none radius-scheme <i>radius-scheme-name</i> [local none] }	Optional. The default authorization method is used by default.
6. Specify the authorization method for login users.	authorization login { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] }	Optional. The default authorization method is used by default.
7. Specify the authorization method for portal users.	authorization portal { local none radius-scheme <i>radius-scheme-name</i> [local] }	Optional. The default authorization method is used by default.

Configuring AAA accounting methods for an ISP domain

In AAA, accounting is a separate process at the same level as authentication and authorization. This process sends accounting start/update/end requests to the specified accounting server. Accounting is optional.

AAA supports the following accounting methods:

- **No accounting (none)**—The system does not perform accounting for the users.
- **Local accounting (local)**—Local accounting is implemented on the NAS. It counts and controls the number of concurrent users who use the same local user account. It does not provide statistics for charging. The maximum number of concurrent users using the same local user account is set by the **access-limit** command in local user view.
- **Remote accounting (scheme)**—The NAS works with a RADIUS server or HWTACACS server for accounting. You can configure local or no accounting as the backup method, which is used when the remote server is not available.

By default, an ISP domain uses the local accounting method.

Before configuring accounting methods, complete the following tasks:

1. For RADIUS or HWTACACS accounting, configure the RADIUS or HWTACACS scheme to be referenced first. The local and none accounting methods do not require a scheme.
2. Determine the access type or service type to be configured. With AAA, you can configure an accounting method for each access type and service type, limiting the accounting protocols that can be used for access.
3. Determine whether to configure an accounting method for all access types or service types.

Follow these guidelines when you configure AAA accounting methods for an ISP domain:

- If you configure the **accounting optional** command, the limit on the number of local user connections is not effective.
- The accounting method specified with the **accounting default** command is for all types of users and has a priority lower than that for a specific access type.
- If you specify the **radius-scheme** *radius-scheme-name* **local** or **hwtacacs-scheme** *hwtacacs-scheme-name* **local** option when you configure an accounting method, local accounting is the backup method and is used only when the remote server is not available.
- If you specify only the **local** or **none** keyword in an accounting method configuration command, the switch has no backup accounting method and performs only local accounting or does not perform any accounting.
- Accounting is not supported for FTP services.

To configure AAA accounting methods for an ISP domain:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter ISP domain view.	domain <i>isp-name</i>	N/A

Step	Command	Remarks
3. Enable the accounting optional feature.	accounting optional	Optional. Disabled by default. With the accounting optional feature, a switch allows users to use network resources when no accounting server is available or communication with all accounting servers fails.
4. Specify the default accounting method for all types of users.	accounting default { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] }	Optional. The default accounting method is local for all types of users.
5. Specify the command accounting method.	accounting command hwtacacs-scheme <i>hwtacacs-scheme-name</i>	Optional. The default accounting method is used by default.
6. Specify the accounting method for LAN users.	accounting lan-access { local none radius-scheme <i>radius-scheme-name</i> [local none] }	Optional. The default accounting method is used by default.
7. Specify the accounting method for login users.	accounting login { hwtacacs-scheme <i>hwtacacs-scheme-name</i> [local] local none radius-scheme <i>radius-scheme-name</i> [local] }	Optional. The default accounting method is used by default.
8. Specify the accounting method for portal users.	accounting portal { local none radius-scheme <i>radius-scheme-name</i> [local] }	Optional. The default accounting method is used by default.

Tearing down user connections

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Tear down AAA user connections	cut connection { access-type { dot1x mac-authentication portal } all domain <i>isp-name</i> interface <i>interface-type</i> <i>interface-number</i> ip <i>ip-address</i> mac <i>mac-address</i> ucibindex <i>ucib-index</i> user-name <i>user-name</i> vlan <i>vlan-id</i> } [slot <i>slot-number</i>]	The command applies only to LAN and portal user connections.

Configuring a NAS ID-VLAN binding

The access locations of users can be identified by their access VLANs. In application scenarios where identifying the access locations of users is a must, configure NAS ID-VLAN bindings on the switch. Then, when a user gets online, the switch obtains the NAS ID by the access VLAN of the user and sends the NAS ID to the RADIUS server through the NAS-identifier attribute.

To configure a NAS ID-VLAN binding:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a NAS ID profile and enter NAS ID profile view.	aaa nas-id profile <i>profile-name</i>	You can apply a NAS ID profile to an interface enabled with portal. See " Configuring portal authentication. "
3. Configure a NAS ID-VLAN binding.	nas-id <i>nas-identifier</i> bind vlan <i>vlan-id</i>	By default, no NAS ID-VLAN binding exists.

Specifying the device ID used in stateful failover mode (available only on the HP 5500 EI)

Two switches working in stateful failover mode for portal services are uniquely identified by their device IDs. A device ID can only be 1 or 2. For more information about the stateful failover mode for portal services, see "[Configuring portal authentication.](#)"

Follow these guidelines when you specify the device ID used in stateful failover mode:

- Configuring or changing the device ID of a switch logs out all online users of the switch.
- HP recommends to save the configuration and reboot the switch after configuring or changing the device ID.
- The device ID is the symbol for stateful failover mode. Do not configure any device ID for a switch working in stand-alone mode.

To specify the device ID used in stateful failover mode:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify the device ID used in stateful failover mode.	nas device-id <i>device-id</i>	By default, a switch works in standalone mode and has no device ID.

Configuring a switch as a RADIUS server

RADIUS server functions configuration task list

Task	Remarks
Configuring a RADIUS user	Required
Specifying a RADIUS client	Required

Configuring a RADIUS user

This task is to create a RADIUS user and configure a set of attributes for the user on a switch that serves as the RADIUS server. The user attributes include the password, authorization attribute, expiration time,

and user description. After completing this task, the specified RADIUS user can use the username and password for RADIUS authentication on the switch.

You can use the **authorization-attribute** command to specify an authorization ACL and authorized VLAN, which is assigned by the RADIUS server to the RADIUS client (the NAS) after the RADIUS user passes authentication. The NAS then uses the assigned ACL and VLAN to control user access. If the assigned ACL does not exist on the NAS, ACL assignment fails and the NAS forcibly logs out the RADIUS user. If the assigned VLAN does not exist on the NAS, the NAS creates the VLAN and adds the RADIUS user or the access port to the VLAN.

To configure a RADIUS user:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a RADIUS user and enter RADIUS server user view.	radius-server user <i>user-name</i>	No RADIUS user exists by default.
3. Configure a password for the RADIUS user.	password [cipher simple] <i>password</i>	Optional. By default, no password is specified.
4. Configure the authorization attribute for the RADIUS user.	authorization-attribute { acl <i>acl-number</i> vlan <i>vlan-id</i> } *	Optional. Not configured by default.
5. Set the expiration time for the RADIUS user.	expiration-date <i>time</i>	Optional. By default, no expiration time is set, and the system does not check users' expiration time.
6. Configure a description for the RADIUS user.	description <i>text</i>	Optional. Not configured by default.

Specifying a RADIUS client

This task is to specify the IP address of a client to be managed by the RADIUS server and configure the shared key. The RADIUS server processes only the RADIUS packets sent from the specified clients.

To specify a RADIUS client

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify a RADIUS client.	radius-server client-ip <i>ip-address</i> [key [cipher simple] <i>string</i>]	No RADIUS client is specified by default.

NOTE:

- The IP address of a RADIUS client specified on the RADIUS server must be consistent with the source IP address of outgoing RADIUS packets configured on the RADIUS client.
- The shared key configured on the RADIUS server must be consistent with that configured on the RADIUS client.

Displaying and maintaining AAA

Task	Command	Remarks
Display the configuration information of ISP domains.	display domain [<i>isp-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about user connections.	display connection [access-type { dot1x mac-authentication portal } domain <i>isp-name</i> interface <i>interface-type interface-number</i> ip <i>ip-address</i> mac <i>mac-address</i> ucibindex <i>ucib-index</i> user-name <i>user-name</i> vlan <i>vlan-id</i>] [slot <i>slot-number</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

AAA configuration examples

AAA for Telnet users by an HWTACACS server

Network requirements

As shown in [Figure 11](#), configure the switch to use the HWTACACS server to provide authentication, authorization, and accounting services for Telnet users.

Set the shared keys for secure communication with the HWTACACS server to **expert**. Configure the switch to remove the domain name from a username before sending the username to the HWTACACS server.

Figure 11 Network diagram

Configuration procedure

1. Configure the switch:
 - # Assign IP addresses to the interfaces. (Details not shown.)
 - # Enable the Telnet server on the switch.
 - <Switch> system-view
 - [Switch] telnet server enable
 - # Configure the switch to use AAA for Telnet users.
 - [Switch] user-interface vty 0 4

```

[Switch-ui-vty0-4] authentication-mode scheme
[Switch-ui-vty0-4] quit
# Create HWTACACS scheme hwtac.
[Switch] hwtacacs scheme hwtac
# Specify the primary authentication server.
[Switch-hwtacacs-hwtac] primary authentication 10.1.1.1 49
# Specify the primary authorization server.
[Switch-hwtacacs-hwtac] primary authorization 10.1.1.1 49
# Specify the primary accounting server.
[Switch-hwtacacs-hwtac] primary accounting 10.1.1.1 49
# Set the shared keys for secure authentication, authorization, and accounting communication to
expert.
[Switch-hwtacacs-hwtac] key authentication simple expert
[Switch-hwtacacs-hwtac] key authorization simple expert
[Switch-hwtacacs-hwtac] key accounting simple expert
# Configure the scheme to remove the domain name from a username before sending the
username to the HWTACACS server.
[Switch-hwtacacs-hwtac] user-name-format without-domain
[Switch-hwtacacs-hwtac] quit
# Configure the AAA methods for the domain.
[Switch] domain bbb
[Switch-isp-bbb] authentication login hwtacacs-scheme hwtac
[Switch-isp-bbb] authorization login hwtacacs-scheme hwtac
[Switch-isp-bbb] accounting login hwtacacs-scheme hwtac
[Switch-isp-bbb] quit

```

2. Verify the configuration:

Telnet to the switch as a user and enter the correct username and password. You pass authentication and log in to the switch. Issuing the **display connection** command on the switch, you can see information about the user connection.

AAA for Telnet users by separate servers

Network requirements

As shown in [Figure 12](#), configure the switch to provide local authentication, HWTACACS authorization, and RADIUS accounting services for Telnet users. Set the shared keys for secure communication with the HWTACACS server and the RADIUS server to **expert**. Configure the switch to remove the domain name from a username before sending the username to the servers.

Figure 12 Network diagram

Configuration procedure

1. Configure the switch:

Assign IP addresses to interfaces. (Details not shown.)

Enable the Telnet server on the switch.

```
<Switch> system-view
```

```
[Switch] telnet server enable
```

Configure the switch to use AAA for Telnet users.

```
[Switch] user-interface vty 0 4
```

```
[Switch-ui-vty0-4] authentication-mode scheme
```

```
[Switch-ui-vty0-4] quit
```

Configure the HWTACACS scheme.

```
[Switch] hwtacacs scheme hwtac
```

```
[Switch-hwtacacs-hwtac] primary authorization 10.1.1.2 49
```

```
[Switch-hwtacacs-hwtac] key authorization expert
```

```
[Switch-hwtacacs-hwtac] user-name-format without-domain
```

```
[Switch-hwtacacs-hwtac] quit
```

Configure the RADIUS scheme.

```
[Switch] radius scheme rd
```

```
[Switch-radius-rd] primary accounting 10.1.1.1 1813
```

```
[Switch-radius-rd] key accounting expert
```

```
[Switch-radius-rd] server-type extended
```

```
[Switch-radius-rd] user-name-format without-domain
```

```
[Switch-radius-rd] quit
```

Create a local user named **hello**.

```
[Switch] local-user hello
```

```
[Switch-luser-hello] service-type telnet
```

```
[Switch-luser-hello] password simple hello
```

```
[Switch-luser-hello] quit
```

Configure the AAA methods for the ISP domain.

```
[Switch] domain bbb
```

```
[Switch-isp-bbb] authentication login local
```

```
[Switch-isp-bbb] authorization login hwtacacs-scheme hwtac
```

```
[Switch-isp-bbb] accounting login radius-scheme rd
```

```
[Switch-isp-bbb] quit
```

2. Verify the configuration:

Telnet to the switch as a user and enter the username **hello@bbb** and the correct password. You pass authentication and log in to the switch. Issuing the **display connection** command on the switch, you can see information about the user connection.

Authentication/authorization for SSH/Telnet users by a RADIUS server

The configuration of authentication and authorization for SSH users is similar to that for Telnet users. The following example describes the configuration for SSH users.

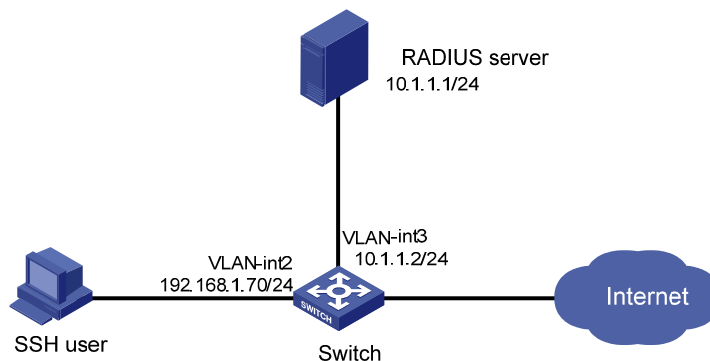

Network requirements

As shown in [Figure 13](#), configure the switch to use the RADIUS server for SSH user authentication and authorization, and to include the domain name in a username sent to the RADIUS server.

Configure IMC to act as the RADIUS server, add an account with the username **hello@bbb** on the RADIUS server, and configure the RADIUS server to assign the privilege level of 3 to the user after the user passes authentication.

Set the shared keys for secure RADIUS communication to **expert**.

Figure 13 Network diagram

Configuring the RADIUS server

This example assumes that the RADIUS server runs on IMC PLAT 5.0 (E0101) and IMC UAM 5.0 (E0101).

1. Add the switch to IMC as an access device:
 - a. Log in to IMC, click the **Service** tab, and select **User Access Manager > Access Device** from the navigation tree.
 - b. Click **Add**.
 - c. Configure the following parameters:
 - Set the shared key for secure authentication and accounting communication to **expert**.
 - Specify the ports for authentication and accounting as 1812 and 1813, respectively.
 - Select **Device Management Service** as the service type.
 - Select **HP** as the access device type.
 - Select the switch from the device list or manually add the switch with the IP address of 10.1.1.2.
 - d. Click **OK**.

NOTE:

The IP address of the access device specified here must be the same as the source IP address of the RADIUS packets sent from the switch, which is the IP address of the outbound interface by default, or otherwise the IP address specified with the **nas-ip** or **radius nas-ip** command on the switch.

2. Add a user for device management:
 - a. Click the **User** tab, and select **Device Management User** from the navigation tree.
 - b. Click **Add**.
 - c. Configure the following parameters:
 - Enter **hello@bbb** as the username and set the password.
 - Select **SSH** as the service type.
 - Set the EXEC privilege level to 3. This value identifies the privilege level of the SSH user after login and defaults to 0.
 - Specify the IP address range of the hosts to be managed as 10.1.1.0 through 10.1.1.255.
 - d. Click **OK**.

Configuring the switch

Configure the IP address of VLAN interface 2, through which the SSH user accesses the switch.

```
<Switch> system-view
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.70 255.255.255.0
[Switch-Vlan-interface2] quit
```

Configure the IP address of VLAN-interface 3, through which the switch access the server.

```
[Switch] interface vlan-interface 3
[Switch-Vlan-interface3] ip address 10.1.1.2 255.255.255.0
[Switch-Vlan-interface3] quit
```

Generate RSA and DSA key pairs and enable the SSH server.

```
[Switch] public-key local create rsa
[Switch] public-key local create dsa
[Switch] ssh server enable
```

Configure the switch to use AAA for SSH users.

```
[Switch] user-interface vty 0 4
[Switch-ui-vty0-4] authentication-mode scheme
```

Configure the user interfaces to support SSH.

```
[Switch-ui-vty0-4] protocol inbound ssh
[Switch-ui-vty0-4] quit
```

Create RADIUS scheme **rad**.

```

[Switch] radius scheme rad
# Specify the primary authentication server.
[Switch-radius-rad] primary authentication 10.1.1.1 1812
# Set the shared key for secure authentication communication to expert.
[Switch-radius-rad] key authentication expert
# Configure the scheme to include the domain names in usernames to be sent to the RADIUS server.
[Switch-radius-rad] user-name-format with-domain
# Specify the service type for the RADIUS server, which must be extended when the RADIUS server runs
on IMC.
[Switch-radius-rad] server-type extended
[Switch-radius-rad] quit
# Configure the AAA methods for the domain.
[Switch] domain bbb
[Switch-isp-bbb] authentication login radius-scheme rad
[Switch-isp-bbb] authorization login radius-scheme rad
[Switch-isp-bbb] quit

```

Verifying the configuration

After you complete the configuration, the SSH user should be able to use the configured account to access the user interface of the switch and can access the demands of level 0 through level 3. .

Use the **display connection** command to view the connection information on the switch.

```

[Switch] display connection
Index=1      ,Username=hello@bbb
IP=192.168.1.58
IPv6=N/A
Total 1 connection(s) matched.

```

AAA for portal users by a RADIUS server

Network requirements

As shown in [Figure 16](#), the host automatically obtains a public network IP address through DHCP.

Configure the switch to:

- Use the RADIUS server for authentication, authorization, and accounting of portal users.
- Provide direct portal authentication so that the host can access only the portal server before passing portal authentication and can access the Internet after passing portal authentication.
- Keep the domain names in usernames sent to the RADIUS server.

On the RADIUS server, add a service that charges 120 dollars for up to 120 hours per month, create an account for portal users, and assign the service to the account.

Set the shared keys for secure RADIUS communication to **expert**. Set the ports for authentication/authorization and accounting to 1812 and 1813, respectively.

Figure 16 Network diagram

Configuration prerequisites

Configure IP addresses for the devices as shown in [Figure 16](#) and make sure devices can reach each other.

Configuring the RADIUS server

This example assumes that the RADIUS/portal server runs on IMC PLAT 5.0 (E0101), IMC UAM 5.0 (E0101), and IMC CAMS 5.0 (E0101).

1. Add the switch to IMC as an access device:
 - a. Log in to IMC, click the **Service** tab, and select **User Access Manager > Access Device** from the navigation tree.
 - b. Click **Add**.
 - c. Configure the following parameters:
 - Set the shared key for secure authentication and accounting communication to **expert**.
 - Specify the ports for authentication and accounting as 1812 and 1813, respectively.
 - Select **LAN Access Service** as the service type.
 - Select **HP** as the access device type.
 - Select the switch from the device list or manually add the switch whose IP address is 10.1.1.2.
 - Leave the default settings in other fields.
 - d. Click **OK**.

NOTE:

The IP address of the access device specified here must be the same as the source IP address of the RADIUS packets sent from the switch, which is the IP address of the outbound interface by default, or otherwise the IP address specified with the **nas-ip** or **radius nas-ip** command on the switch.

2. Define a charging policy:
 - a. Click the **Service** tab, and select **Accounting Manager > Charging Plans** from the navigation tree.
 - b. Click **Add**.
 - c. Configure the following parameters:
 - Enter **UserAcct** as the plan name.
 - Select **Flat rate** as the charging template.
 - In the **Basic Plan Settings** field, configure the fixed fee as 120 dollars per month.
 - In the **Service Usage Limit** field, set the **Usage Threshold** to 120 hours, allowing the user to access the Internet for up to 120 hours per month.
 - Leave the default settings in other fields.
 - d. Click **OK**.

5. Validate the configuration:

Select **User Access Manager > Service Parameters > Validate System Configuration** from the navigation tree.

Configuring the switch

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Set the server type for the RADIUS scheme. When you use IMC, set the server type to **extended**.

```
[Switch-radius-rs1] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 10.1.1.1
[Switch-radius-rs1] primary accounting 10.1.1.1
```

```
[Switch-radius-rs1] key authentication expert
[Switch-radius-rs1] key accounting expert
# Configure the scheme to keep the domain names in usernames to be sent to the RADIUS server.
[Switch-radius-rs1] user-name-format with-domain
[Switch-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure the ISP domain to use RADIUS scheme **rs1**.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure **dm1** as the default ISP domain for all users. Then, if a user enters a username without any ISP domain at login, the authentication and accounting methods of the default domain is used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure the portal server.

```
[Switch] portal server newpt ip 10.1.1.1 key portal port 50100 url
http://10.1.1.1:8080/portal
```

Enable portal authentication on the interface connecting the host.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] portal server newpt method direct
[Switch-Vlan-interface2] quit
```

Verifying the configuration

The user can initiate portal authentication by using HP iNode client or by accessing a Web page. All initiated Web requests are redirected to the portal authentication page at <http://10.1.1.1:8080/portal>. Before passing portal authentication, the user can access only the authentication page. After passing portal authentication, the user can access the Internet.

After the user passes the portal authentication, use the following command to view the portal user information on the switch.

```
[Switch] display portal user interface vlan-interface 2
```

```
Index:19
```

```
State:ONLINE
```

```
SubState:NONE
```

```
ACL:NONE
```

```
Work-mode:stand-alone
```

```
MAC                IP                Vlan  Interface
```

```
-----
0015-e9a6-7cfe    192.168.1.58      2     Vlan-interface2
```

```
Total 1 user(s) matched, 1 listed.
```

Use the **display connection** command to view the connection information on the switch.

```
[Switch] display connection
```

```
Index=20  ,Username=portal@dm1
```

IP=192.168.1.58
IPv6=N/A
MAC=00-15-E9-A6-7C-FE

Total 1 connection(s) matched.

AAA for 802.1X users by a RADIUS server

Network requirements

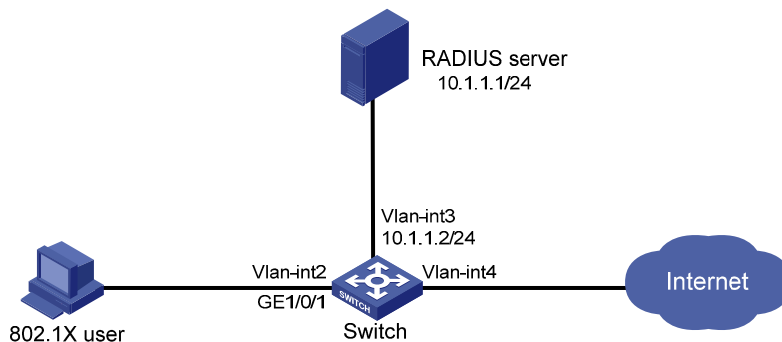

As shown in [Figure 26](#), configure the switch to:

- Use the RADIUS server for authentication, authorization, and accounting of 802.1X users.
- Use MAC-based access control on GigabitEthernet 1/0/1 to authenticate all 802.1X users on the port separately.
- Keep the domain names in usernames sent to the RADIUS server.

On the RADIUS server, add a service that charges 120 dollars for up to 120 hours per month and assigns authenticated users to VLAN 4, create an account named **dot1x@bbb** for 802.1X users, and assign the service to the account.

Set the shared keys for secure RADIUS communication to **expert**. Set the ports for authentication/authorization and accounting to 1812 and 1813, respectively.

Figure 26 Network diagram

Configuration prerequisites

Configure the interfaces and VLANs as shown in [Figure 26](#). Make sure the host can get a new IP address manually or automatically and can access resources in the authorized VLAN after passing authentication.

Configuring the RADIUS server

This example assumes that the RADIUS server runs on IMC PLAT 5.0 (E0101), IMC UAM 5.0 (E0101), and IMC CAMS 5.0 (E0101).

1. Add the switch to IMC as an access device:
 - a. Log in to IMC, click the **Service** tab, and select **User Access Manager > Access Device** from the navigation tree.
 - b. Click **Add**.
 - c. Configure the following parameters:
Set the shared key for secure authentication and accounting communication to **expert**.

Specify the ports for authentication and accounting as 1812 and 1813, respectively.

Select **LAN Access Service** as the service type.

Select **HP** as the access device type.

Select the switch from the device list or manually add the switch whose IP address is 10.1.1.2.

Leave the default settings in other fields.

- d. Click **OK**.

NOTE:

The IP address of the access device specified here must be the same as the source IP address of the RADIUS packets sent from the switch, which is the IP address of the outbound interface by default, or otherwise the IP address specified with the **nas-ip** or **radius nas-ip** command on the switch.

Figure 27 Adding the switch to IMC as an access device

Service >> User Access Manager >> Access Device >> Add Access Device Help

Access Configuration

* Shared Key	expert	* Authentication Port	1812
* Accounting Port	1813	Service Type	LAN Access Service
Access Device Type	HP(A-Series)	RADIUS Accounting	Fully Supported
Service Group	Ungrouped	Access Area	--

Device List

Select Add Manually Clear All Click OK to save your change.

Total Items: 1.

Device Name	Device IP	Device Model	Delete
	10.1.1.2		✘

OK Cancel

2. Define a charging policy:

- a. Click the **Service** tab, and select **Accounting Manager > Charging Plans** from the navigation tree.

- b. Click **Add**.

- c. Configure the following parameters:

Enter **UserAcct** as the plan name.

Select **Flat rate** as the charging template.

In the **Basic Plan Settings** field, configure to charge the fixed fee of 120 dollars per month.

In the **Service Usage Limit** field, set the **Usage Threshold** to 120 hours, allowing the user to access the Internet for up to 120 hours per month.

Leave the default settings in other fields.

- d. Click **OK**.

Figure 28 Defining a charging policy

Basic Information

* Plan Name: UserAcct

Charging Template: Flat rate

Service Group: Ungrouped

Description:

Basic Plan Settings

Charge Based on: time

Billing Term: Monthly

* Fixed Fee: 120 dollar

Service Usage Limit

Usage Threshold: 120 ? in hr

OK Cancel

3. Add a service:

- a. Click the **Service** tab, and select **User Access Manager > Service Configuration** from the navigation tree.
- b. Click **Add**.
- c. Configure the following parameters:

Enter **Dot1x auth** as the service name and **bbb** as the service suffix. The service suffix indicates the authentication domain for 802.1X users. When the service suffix is configured, you must configure the switch to keep the domain names of usernames to be sent to the RADIUS server.

Enter **UserAcct** as the **Charging Plan**.

Select **Deploy VLAN** and set the ID of the VLAN to be assigned to 4.

Configure other parameters as needed.

- d. Click **OK**.

Figure 29 Adding a service

4. Create an account for 802.1X users:
 - a. Click the **User** tab, and select **All Access Users** from the navigation tree.
 - b. Click **Add**.
 - c. Configure the following parameters:
 - Select the user **test**, or add the user if it does not exist.
 - Enter **dot1x** as the account name and set the password.
 - Select the access service **Dot1x auth**.
 - Configure other parameters as needed.
 - d. Click **OK**.

Access Service

	Service Name	Service Suffix	Status	Charging Plan	Allocate IP
<input checked="" type="checkbox"/>	Dot1x auth	bbb	Available	UserAcct	

Configuring the switch

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rad** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rad
```

Set the server type for the RADIUS scheme. When you use IMC, set the server type to **extended**.

```
[Switch-radius-rad] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rad] primary authentication 10.1.1.1
[Switch-radius-rad] primary accounting 10.1.1.1
[Switch-radius-rad] key authentication expert
[Switch-radius-rad] key accounting expert
```

Configure the scheme to include the domain names in usernames to be sent to the RADIUS server.

```
[Switch-radius-rad] user-name-format with-domain
[Switch-radius-rad] quit
```

2. Configure an authentication domain:

Create an ISP domain named **bbb** and enter its view.

```
[Switch] domain bbb
```

Configure the ISP domain to use RADIUS scheme **rad**.

```
[Switch-isp-bbb] authentication lan-access radius-scheme rad
[Switch-isp-bbb] authorization lan-access radius-scheme rad
[Switch-isp-bbb] accounting lan-access radius-scheme rad
[Switch-isp-bbb] quit
```

Configure **bbb** as the default ISP domain for all users. Then, if a user enters a username without any ISP domain at login, the authentication and accounting methods of the default domain is used for the user.

```
[Switch] domain default enable bbb
```

3. Configure 802.1X authentication:

Enable 802.1X globally.

```
[Switch] dot1x
```

Enable 802.1X for port GigabitEthernet 1/0/1.

```
[Switch] interface gigabitethernet 1/0/1
```

```
[Switch-GigabitEthernet1/0/1] dot1x
```

```
[Switch-GigabitEthernet1/0/1] quit
```

Configure the access control method. (Optional. The default setting meets the requirement.)

```
[Switch] dot1x port-method macbased interface gigabitethernet 1/0/1
```

Verifying the configuration

When you use HP iNode client, no advanced authentication options are required, and the user can pass authentication after entering username **dot1x@bbb** and the correct password in the client property page.

If the 802.1X client of Windows XP is used, select the **Enable IEEE 802.1X authentication for this network** option and select **MD5-Challenge** as the EAP type on the **Authentication** tab of the network connection properties window. The user passes authentication after entering the correct username and password in the pop-up authentication page.

After the user passes authentication, the server assigns the port connecting the client to VLAN 4.

Use the **display connect** command to view the connection information on the switch.

```
[Switch] display connection
```

```
Slot: 1
```

```
Index=22 , Username=dot1x@bbb
```

```
IP=192.168.1.58
```

```
IPv6=N/A
```

```
MAC=0015-e9a6-7cfe
```

```
Total 1 connection(s) matched on slot 1.
```

```
Total 1 connection(s) matched.
```

View the information of the specified connection on the switch.

```
[Switch] display connection ucibindex 22
```

```
Slot: 1
```

```
Index=22 , Username=dot1x@bbb
```

```
IP=192.168.1.58
```

```
IPv6=N/A
```

```
MAC=0015-e9a6-7cfe
```

```
Access=8021X , AuthMethod=CHAP
```

```
Port Type=Ethernet, Port Name=GigabitEthernet1/0/1
```

```
Initial VLAN=2, Authorization VLAN=4
```

```
ACL Group=Disable
```

```
User Profile=N/A
```

```
CAR=Disable
```

```
Priority=Disable
```

```
Start=2011-04-26 19:41:12 , Current=2011-04-26 19:41:25 , Online=00h00m14s
```

Total 1 connection matched.

As the **Authorized VLAN** field in the output shows, VLAN 4 has been assigned to the user.

Level switching authentication for Telnet users by an HWTACACS server

Network requirements

As shown in [Figure 31](#), configure the switch to:

- Use local authentication for the Telnet user and assign the privilege level of 0 to the user after the user passes authentication.
- Use the HWTACACS server for level switching authentication of the Telnet user, and use local authentication as the backup.

Figure 31 Network diagram

Configuration considerations

1. Configure the switch to use AAA, particularly, local authentication for Telnet users:
 - Create ISP domain **bbb** and configure it to use local authentication for Telnet users.
 - Create a local user account, configure the password, and assign the user privilege level.
2. On the switch, configure the authentication method for user privilege level switching:
 - Specify to use HWTACACS authentication and, if HWTACACS authentication is not available, use local authentication for user level switching authentication.
 - Configure HWTACACS scheme **hwtac** and assign an IP address to the HWTACACS server. Set the shared keys for message exchange and specify that usernames sent to the HWTACACS server carry no domain name. Configure the domain to use the HWTACACS scheme **hwtac** for user privilege level switching authentication.
 - Configure the password for local privilege level switching authentication.
3. On the HWTACACS server, add the username and password for user privilege level switching authentication.

Configuration procedure

1. Configure the switch:

Configure the IP address of VLAN-interface 2, through which the Telnet user accesses the switch.

```
<Switch> system-view
[Switch] interface vlan-interface 2
```

```

[Switch-Vlan-interface2] ip address 192.168.1.70 255.255.255.0
[Switch-Vlan-interface2] quit
# Configure the IP address of VLAN-interface 3, through which the switch communicates with the
server.
[Switch] interface vlan-interface 3
[Switch-Vlan-interface3] ip address 10.1.1.2 255.255.255.0
[Switch-Vlan-interface3] quit
# Enable the switch to provide Telnet service.
[Switch] telnet server enable
# Configure the switch to use AAA for Telnet users.
[Switch] user-interface vty 0 4
[Switch-ui-vty0-4] authentication-mode scheme
[Switch-ui-vty0-4] quit
# Use HWTACACS authentication for user level switching authentication and, if HWTACACS
authentication is not available, use local authentication.
[Switch] super authentication-mode scheme local
# Create an HWTACACS scheme named hwtac.
[Switch] hwtacacs scheme hwtac
# Specify the IP address for the primary authentication server as 10.1.1.1 and the port for
authentication as 49.
[Switch-hwtacacs-hwtac] primary authentication 10.1.1.1 49
# Set the shared key for secure authentication communication to expert.
[Switch-hwtacacs-hwtac] key authentication simple expert
# Configure the scheme to remove the domain name from a username before sending the
username to the HWTACACS server.
[Switch-hwtacacs-hwtac] user-name-format without-domain
[Switch-hwtacacs-hwtac] quit
# Create ISP domain bbb.
[Switch] domain bbb
# Configure the ISP domain to use local authentication for Telnet users.
[Switch-isp-bbb] authentication login local
# Configure to use HWTACACS scheme hwtac for privilege level switching authentication.
[Switch-isp-bbb] authentication super hwtacacs-scheme hwtac
[Switch-isp-bbb] quit
# Create a local Telnet user named test.
[Switch] local-user test
[Switch-luser-test] service-type telnet
[Switch-luser-test] password simple aabbcc
# Configure the user level of the Telnet user to 0 after user login.
[Switch-luser-test] authorization-attribute level 0
[Switch-luser-test] quit
# Configure the password for local privilege level switching authentication to 654321.
[Switch] super password simple 654321
[Switch] quit

```

2. Configure the HWTACACS server:

NOTE:

The HWTACACS server in this example runs ACSv4.0.

Add a user named **test** on the HWTACACS server and configure advanced attributes for the user as shown in [Figure 32](#):

- Select **Max Privilege for any AAA Client** and set the privilege level to level 3. After these configurations, the user uses the password **enabpass** when switching to level 1, level 2, or level 3.
- Select **Use separate password** and specify the password as **enabpass**.

Figure 32 Configuring advanced attributes for the Telnet user

Advanced TACACS+ Settings

TACACS+ Enable Control:

- Use Group Level Setting
- No Enable Privilege
- Max Privilege for any AAA Client
Level 3

TACACS+ Enable Password

- Use CiscoSecure PAP password
- Use external database password
Windows Database

Use separate password

Password: [Redacted]

Confirm Password: [Redacted]

TACACS+ Outbound Password
(Used for SendPass and SendAuth clients such as routers)

Password: [Redacted]

Confirm Password: [Redacted]

3. Verify the configuration:

After you complete the configuration, the Telnet user should be able to telnet to the switch and use username **test@bbb** and password **aabbcc** to enter the user interface of the switch, and access all level 0 commands.

```
<Switch> telnet 192.168.1.70
Trying 192.168.1.70 ...
Press CTRL+K to abort
Connected to 192.168.1.70 ...
*****

* Without the owner's prior written consent, *
* no decompiling or reverse-engineering shall be allowed. *
*****
```

Login authentication

```
Username:test@bbb
```

```
Password:
```

```
<Switch> ?
```

```
User view commands:
```

```
display  Display current system information
ping     Ping function
quit     Exit from current command view
ssh2     Establish a secure shell client connection
super    Set the current user priority level
telnet   Establish one TELNET connection
tracert  Trace route function
```

When switching to user privilege level 3, the Telnet user only needs to enter password **enabpass** as prompted.

```
<Switch> super 3
```

```
Password:
```

```
User privilege level is 3, and only those commands can be used
whose level is equal or less than this.
```

```
Privilege note: 0-VISIT, 1-MONITOR, 2-SYSTEM, 3-MANAGE
```

If the HWTACACS server is not available, the Telnet user needs to enter password **654321** as prompted for local authentication.

```
<Switch> super 3
```

```
Password: ← Enter the password for HWTACACS privilege level switch authentication
Error: Invalid configuration or no response from the authentication server.
```

```
Info: Change authentication mode to local.
```

```
Password: ← Enter the password for local privilege level switch authentication
```

```
User privilege level is 3, and only those commands can be used
whose level is equal or less than this.
```

```
Privilege note: 0-VISIT, 1-MONITOR, 2-SYSTEM, 3-MANAGE
```

RADIUS authentication and authorization for Telnet users by a switch

Network requirements

As shown in [Figure 33](#), configure Switch B to act as a RADIUS server to provide authentication and authorization for the Telnet user on port 1645.

Configure Switch A to use the RADIUS server for Telnet user authentication and authorization, and to remove the domain name in a username sent to the server.

Set the shared keys for secure communication between the NAS and the RADIUS server to **abc**.

Figure 33 Network diagram

Configuration procedure

1. Assign an IP address to each interface as shown in Figure 33. (Details not shown.)
2. Configure the NAS:
 - # Enable the Telnet server on Switch A.

```
<SwitchA> system-view
[SwitchA] telnet server enable
```
 - # Configure Switch A to use AAA for Telnet users.

```
[SwitchA] user-interface vty 0 4
[SwitchA-ui-vty0-4] authentication-mode scheme
[SwitchA-ui-vty0-4] quit
```
 - # Create RADIUS scheme **rad**.

```
[SwitchA] radius scheme rad
```
 - # Specify the IP address for the primary authentication server as 10.1.1.2, the port for authentication as 1645, and the shared key for secure authentication communication as **abc**.

```
[SwitchA-radius-rad] primary authentication 10.1.1.2 1645 key abc
```
 - # Configure the scheme to remove the domain name from a username before sending the username to the RADIUS server.

```
[SwitchA-radius-rad] user-name-format without-domain
```
 - # Set the source IP address for RADIUS packets as 10.1.1.1.

```
[SwitchA-radius-rad] nas-ip 10.1.1.1
[SwitchA-radius-rad] quit
```
 - # Create ISP domain **bbb**.

```
[SwitchA] domain bbb
```
 - # Specify the authentication method for Telnet users as **rad**.

```
[SwitchA-isp-bbb] authentication login radius-scheme rad
```
 - # Specify the authorization method for Telnet users as **rad**.

```
[SwitchA-isp-bbb] authorization login radius-scheme rad
```
 - # Specify the accounting method for Telnet users as **none**.

```
[SwitchA-isp-bbb] accounting login none
```
 - # Configure the RADIUS server type as **standard**. When a switch is configured to serve as a RADIUS server, the server type must be set to **standard**.

```
[SwitchA-isp-bbb] server-type standard
[SwitchA-isp-bbb] quit
```
 - # Configure **bbb** as the default ISP domain. Then, if a user enters a username without any ISP domain at login, the authentication and accounting methods of the default domain is used for the user.

```
[SwitchA] domain default enable bbb
```
3. Configure the RADIUS server:
 - # Create RADIUS user **aaa** and enter its view.

```

<SwitchB> system-view
[SwitchB] radius-server user aaa
# Configure plaintext password aabbcc for user aaa.
[SwitchB-rdsuser-aaa] password simple aabbcc
[SwitchB-rdsuser-aaa] quit
# Specify the IP address of the RADIUS client as 10.1.1.1 and the plaintext shared key as abc.
[SwitchB] radius-server client-ip 10.1.1.1 key simple abc

```

4. Verify the configuration:

After entering username **aaa@bbb** or **aaa** and password **aabbcc**, user **aaa** can telnet to Switch A. Use the **display connection** command to view the connection information on Switch A.

```

<SwitchA> display connection

Index=1      ,Username=aaa@bbb
IP=192.168.1.2
IPv6=N/A
Total 1 connection(s) matched.

```

Troubleshooting AAA

Troubleshooting RADIUS

Symptom 1

User authentication/authorization always fails.

Analysis

1. A communication failure exists between the NAS and the RADIUS server.
2. The username is not in the format of *userid@isp-name* or the ISP domain for the user authentication is not correctly configured on the NAS.
3. The user is not configured on the RADIUS server.
4. The password entered by the user is incorrect.
5. The RADIUS server and the NAS are configured with different shared key.

Solution

Check that:

1. The NAS and the RADIUS server can ping each other.
2. The username is in the *userid@isp-name* format and the ISP domain for the user authentication is correctly configured on the NAS.
3. The user is configured on the RADIUS server.
4. The correct password is entered.
5. The same shared key is configured on both the RADIUS server and the NAS.

Symptom 2

RADIUS packets cannot reach the RADIUS server.

Analysis

1. The NAS and the RADIUS server cannot communicate with each other.
2. The NAS is not configured with the IP address of the RADIUS server.
3. The UDP ports for authentication/authorization and accounting are not correct.
4. The port numbers of the RADIUS server for authentication, authorization and accounting are being used by other applications.

Solution

Check that:

1. The communication links between the NAS and the RADIUS server work well at both physical and link layers.
2. The IP address of the RADIUS server is correctly configured on the NAS.
3. UDP ports for authentication/authorization/accounting configured on the NAS are the same as those configured on the RADIUS server.
4. The port numbers of the RADIUS server for authentication, authorization and accounting are available.

Symptom 3

A user is authenticated and authorized, but accounting for the user is not normal.

Analysis

1. The accounting port number is not correct.
2. Configuration of the authentication/authorization server and the accounting server are not correct on the NAS. For example, one server is configured on the NAS to provide all the services of authentication/authorization and accounting, but in fact the services are provided by different servers.

Solution

Check that:

1. The accounting port number is correctly set.
2. The authentication/authorization server and the accounting server are correctly configured on the NAS.

Troubleshooting HWTACACS

Similar to RADIUS troubleshooting. See "[Troubleshooting RADIUS](#)."

802.1X fundamentals

802.1X is a port-based network access control protocol initially proposed by the IEEE 802 LAN/WAN committee for securing wireless LANs (WLANs), and it has also been widely used on Ethernet networks for access control.

802.1X controls network access by authenticating the devices connected to 802.1X-enabled LAN ports.

802.1X architecture

802.1X operates in the client/server model. It comprises three entities: the client (the supplicant), the network access device (the authenticator), and the authentication server.

Figure 34 802.1X architecture

- **The client**—A user terminal seeking access to the LAN. It must have 802.1X software to authenticate to the network access device.
- **The network access device**—Authenticates the client to control access to the LAN. In a typical 802.1X environment, the network access device uses an authentication server to perform authentication.
- **The authentication server**—Provides authentication services for the network access device. It authenticates 802.1X clients by using the data sent from the network access device, and returns the authentication results for the network access device to make access decisions. The authentication server is typically a Remote Authentication Dial-in User Service (RADIUS) server. In a small LAN, you can also use the network access device as the authentication server.

Controlled/uncontrolled port and port authorization status

802.1X defines two logical ports for the network access port: controlled port and uncontrolled port. Any packet arriving at the network access port is visible to both logical ports.

- **Controlled port**—Allows incoming and outgoing traffic to pass through when it is in the authorized state, and denies incoming and outgoing traffic when it is in the unauthorized state, as shown in Figure 35. The controlled port is set in the authorized state if the client has passed authentication, and in the unauthorized state, if the client has failed authentication.
- **Uncontrolled port**—Is always open to receive and transmit EAPOL frames.

Figure 35 Authorization state of a controlled port

In the unauthorized state, a controlled port controls traffic in one of the following ways:

- Performs bidirectional traffic control to deny traffic to and from the client.
- Performs unidirectional traffic control to deny traffic from the client.

The HP devices support only unidirectional traffic control.

802.1X-related protocols

802.1X uses the Extensible Authentication Protocol (EAP) to transport authentication information for the client, the network access device, and the authentication server. EAP is an authentication framework that uses the client/server model. It supports a variety of authentication methods, including MD5-Challenge, EAP-Transport Layer Security (EAP-TLS), and Protected EAP (PEAP).

802.1X defines EAP over LAN (EAPOL) for passing EAP packets between the client and the network access device over a wired or wireless LAN. Between the network access device and the authentication server, 802.1X delivers authentication information in one of the following methods:

- Encapsulates EAP packets in RADIUS by using EAP over RADIUS (EAPOR), as described in "[EAP relay](#)."
- Extracts authentication information from the EAP packets and encapsulates the information in standard RADIUS packets, as described in "[EAP termination](#)."

Packet formats

EAP packet format

Figure 36 shows the EAP packet format.

Figure 36 EAP packet format

- **Code**—Type of the EAP packet. Options include Request (1), Response (2), Success (3), or Failure (4).
- **Identifier**—Used for matching Responses with Requests.
- **Length**—Length (in bytes) of the EAP packet. The EAP packet length is the sum of the Code, Identifier, Length, and Data fields.
- **Data**—Content of the EAP packet. This field appears only in a Request or Response EAP packet. The field comprises the request type (or the response type) and the type data. Type 1 (Identify) and type 4 (MD5-challenge) are two examples for the type field.

EAPOL packet format

Figure 37 shows the EAPOL packet format.

Figure 37 EAPOL packet format

- **PAE Ethernet type**—Protocol type. It takes the value 0x888E for EAPOL.
- **Protocol version**—The EAPOL protocol version used by the EAPOL packet sender.
- **Type**—Type of the EAPOL packet. Table 5 lists the types of EAPOL packets supported by HP implementation of 802.1X.

Table 5 EAPOL packet types

Value	Type	Description
0x00	EAP-Packet	The client and the network access device uses EAP-Packets to transport authentication information.
0x01	EAPOL-Start	The client sends an EAPOL-Start message to initiate 802.1X authentication to the network access device.

Value	Type	Description
0x02	EAPOL-Logoff	The client sends an EAPOL-Logoff message to tell the network access device that it is logging off.

- **Length**—Data length in bytes, or length of the Packet body. If packet type is EAPOL-Start or EAPOL-Logoff, this field is set to 0, and no Packet body field follows.
- **Packet body**—Content of the packet. When the EAPOL packet type is EAP-Packet, the Packet body field contains an EAP packet.

EAP over RADIUS

RADIUS adds two attributes, EAP-Message and Message-Authenticator, for supporting EAP authentication. For the RADIUS packet format, see "[Configuring AAA](#)."

EAP-Message

RADIUS encapsulates EAP packets in the EAP-Message attribute, as shown in [Figure 38](#). The Type field takes 79, and the Value field can be up to 253 bytes. If an EAP packet is longer than 253 bytes, RADIUS encapsulates it in multiple EAP-Message attributes.

Figure 38 EAP-Message attribute format

Message-Authenticator

RADIUS includes the Message-Authenticator attribute in all packets that have an EAP-Message attribute to check their integrity. The packet receiver drops the packet if the calculated packet integrity checksum is different than the Message-Authenticator attribute value. The Message-Authenticator prevents EAP authentication packets from being tampered with during EAP authentication.

Figure 39 Message-Authenticator attribute format

Initiating 802.1X authentication

Both the 802.1X client and the access device can initiate 802.1X authentication.

802.1X client as the initiator

The client sends an EAPOL-Start packet to the access device to initiate 802.1X authentication. The destination MAC address of the packet is the IEEE 802.1X specified multicast address 01-80-C2-00-00-03 or the broadcast MAC address. If any intermediate device between the client and

the authentication server does not support the multicast address, you must use an 802.1X client, the HP iNode 802.1X client for example, that can send broadcast EAPOL-Start packets.

Access device as the initiator

The access device initiates authentication, if a client, the 802.1X client available with Windows XP for example, cannot send EAPOL-Start packets.

The access device supports the following modes:

- **Multicast trigger mode**—The access device multicasts Identity EAP-Request packets periodically (every 30 seconds by default) to initiate 802.1X authentication.
- **Unicast trigger mode**—Upon receiving a frame with the source MAC address not in the MAC address table, the access device sends an Identity EAP-Request packet out of the receiving port to the unknown MAC address. It retransmits the packet if no response has been received within a certain time interval.

802.1X authentication procedures

802.1X authentication has two approaches: EAP relay and EAP termination. You choose either mode depending on the support of the RADIUS server for EAP packets and EAP authentication methods.

- EAP relay mode

EAP relay is defined in IEEE 802.1X. In this mode, the network device uses EAPoR packets to send authentication information to the RADIUS server, as shown in [Figure 40](#).

In EAP relay mode, the client must use the same authentication method as the RADIUS server. On the network access device, you only need to execute the **dot1x authentication-method eap** command to enable EAP relay.

Figure 40 EAP relay

- EAP termination mode

In EAP termination mode, the network access device terminates the EAP packets received from the client, encapsulates the client authentication information in standard RADIUS packets, and uses (Password Authentication Protocol) PAP or (Password Authentication Protocol) CHAP to authenticate to the RADIUS server, as shown in [Figure 41](#).

Figure 41 EAP termination

A comparison of EAP relay and EAP termination

Packet exchange method	Benefits	Limitations
EAP relay	<ul style="list-style-type: none">• Supports various EAP authentication methods.• The configuration and processing is simple on the network access device	The RADIUS server must support the EAP-Message and Message-Authenticator attributes, and the EAP authentication method used by the client.
EAP termination	Works with any RADIUS server that supports PAP or CHAP authentication.	<ul style="list-style-type: none">• Supports only MD5-Challenge EAP authentication and the "username + password" EAP authentication initiated by an HP iNode 802.1X client.• The processing is complex on the network access device.

EAP relay

Figure 42 shows the basic 802.1X authentication procedure in EAP relay mode, assuming that EAP-MD5 is used.

Figure 42 802.1X authentication procedure in EAP relay mode

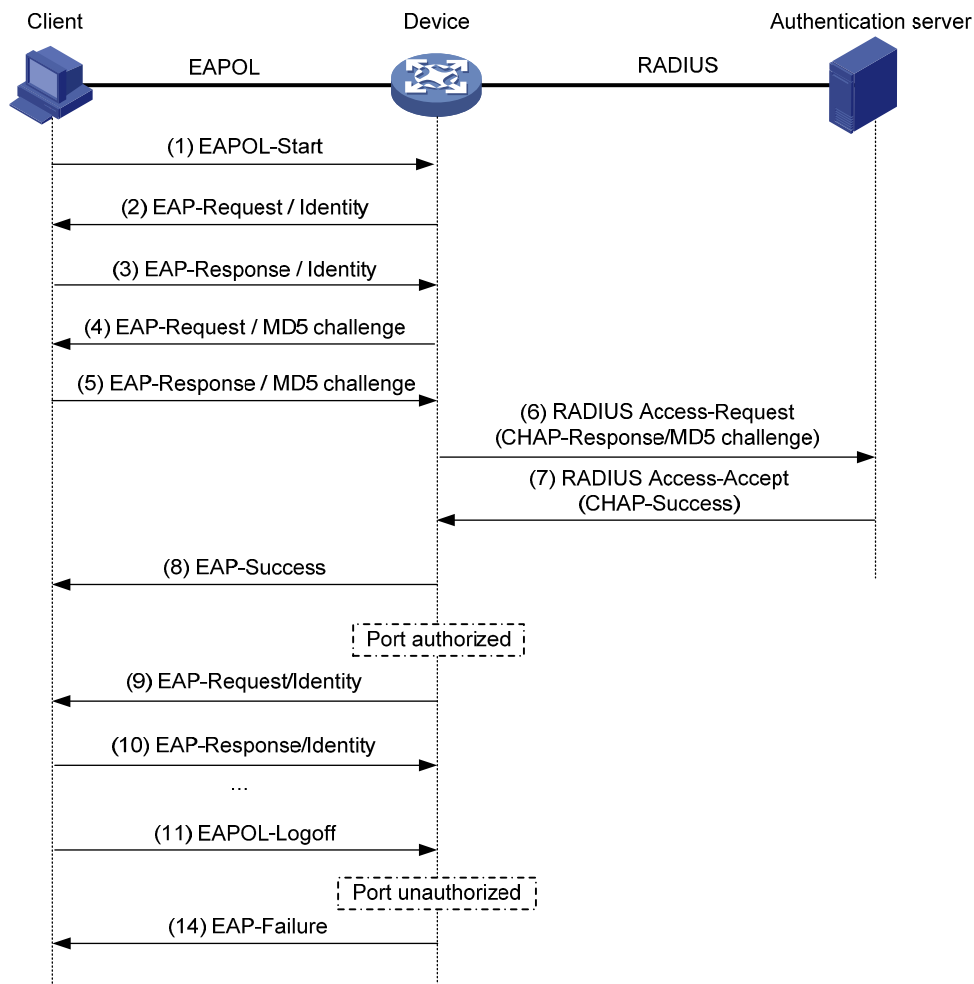

1. When a user launches the 802.1X client software and enters a registered username and password, the 802.1X client software sends an EAPOL-Start packet to the network access device.
2. The network access device responds with an Identity EAP-Request packet to ask for the client username.
3. In response to the Identity EAP-Request packet, the client sends the username in an Identity EAP-Response packet to the network access device.
4. The network access device relays the Identity EAP-Response packet in a RADIUS Access-Request packet to the authentication server.
5. The authentication server uses the identity information in the RADIUS Access-Request to search its user database. If a matching entry is found, the server uses a randomly generated challenge (EAP-Request/MD5 challenge) to encrypt the password in the entry, and sends the challenge in a RADIUS Access-Challenge packet to the network access device.
6. The network access device relays the EAP-Request/MD5 Challenge packet in a RADIUS Access-Request packet to the client.
7. The client uses the received challenge to encrypt the password, and sends the encrypted password in an EAP-Response/MD5 Challenge packet to the network access device.
8. The network access device relays the EAP-Response/MD5 Challenge packet in a RADIUS Access-Request packet to the authentication server.

9. The authentication server compares the received encrypted password with the one it generated at step 5. If the two are identical, the authentication server considers the client valid and sends a RADIUS Access-Accept packet to the network access device.
10. Upon receiving the RADIUS Access-Accept packet, the network access device sends an EAP-Success packet to the client, and sets the controlled port in the authorized state so the client can access the network.
11. After the client comes online, the network access device periodically sends handshake requests to check whether the client is still online. By default, if two consecutive handshake attempts fail, the device logs off the client.
12. Upon receiving a handshake request, the client returns a response. If the client fails to return a response after a certain number of consecutive handshake attempts (two by default), the network access device logs off the client. This handshake mechanism enables timely release of the network resources used by 802.1X users that have abnormally gone offline.
13. The client can also send an EAPOL-Logoff packet to ask the network access device for a logoff. Then
14. In response to the EAPOL-Logoff packet, the network access device changes the status of the controlled port from authorized to unauthorized and sends an EAP-Failure packet to the client.

EAP termination

Figure 43 shows the basic 802.1X authentication procedure in EAP termination mode, assuming that CHAP authentication is used.

Figure 43 802.1X authentication procedure in EAP termination mode

In EAP termination mode, it is the network access device rather than the authentication server generates an MD5 challenge for password encryption (see Step 4). The network access device then sends the MD5 challenge together with the username and encrypted password in a standard RADIUS packet to the RADIUS server.

Configuring 802.1X

This chapter describes how to configure 802.1X on an HP device.

You can also configure the port security feature to perform 802.1X. Port security combines and extends 802.1X and MAC authentication. It applies to a network that requires different authentication methods for different users on a port. Port security is beyond the scope of this chapter. It is described in "[Configuring port security](#)."

HP implementation of 802.1X

Access control methods

HP implements port-based access control as defined in the 802.1X protocol, and extends the protocol to support MAC-based access control.

- **Port-based access control**—Once an 802.1X user passes authentication on a port, any subsequent user can access the network through the port without authentication. When the authenticated user logs off, all other users are logged off.
- **MAC-based access control**—Each user is separately authenticated on a port. When a user logs off, no other online users are affected.

Using 802.1X authentication with other features

VLAN assignment

You can configure the authentication server to assign a VLAN for an 802.1X user that has passed authentication. The way that the network access device handles VLANs on an 802.1X-enabled port differs by 802.1X access control mode.

For more information about VLAN configuration and MAC-based VLAN, see *Layer 2—LAN Switching Configuration Guide*.

Access control	VLAN manipulation
Port-based	<p>Assigns the VLAN to the port as the port VLAN ID (PVID). All subsequent 802.1X users can access the port VLAN without authentication.</p> <p>When the user logs off, the previous PVID restores, and all other online users are logged off.</p>
MAC-based	<ul style="list-style-type: none">• If the port is a hybrid port with MAC-based VLAN enabled, maps the MAC address of each user to the VLAN assigned by the authentication server. The PVID of the port does not change. When a user logs off, the MAC-to-VLAN mapping for the user is removed.• If the port is an access, trunk, or MAC-based VLAN disabled hybrid port, assigns the first authenticated user's VLAN to the port as the PVID. If a different VLAN is assigned to a subsequent user, the user cannot pass the authentication. To avoid the authentication failure of subsequent users, be sure to assign the same VLAN to all 802.1X users on these ports.

With 802.1X authentication, a hybrid port is always assigned to a VLAN as an untagged member. After the assignment, do not re-configure the port as a tagged member in the VLAN.

On a periodic online user re-authentication enabled port, if a user has been online before you enable the MAC-based VLAN function, the access device does not create a MAC-to-VLAN mapping for the user unless the user passes re-authentication and the VLAN for the user has changed.

Guest VLAN

You can configure a guest VLAN on a port to accommodate users that have not performed 802.1X authentication, so they can access a limited set of network resources, such as a software server, to download anti-virus software and system patches. After a user in the guest VLAN passes 802.1X authentication, it is removed from the guest VLAN and can access authorized network resources. The way that the network access device handles VLANs on the port differs by 802.1X access control mode.

For more information about VLAN configuration and MAC-based VLAN, see *Layer 2—LAN Switching Configuration Guide*.

1. On a port that performs port-based access control

Authentication status	VLAN manipulation
No 802.1X user has performed authentication within 90 seconds after 802.1X is enabled	Assigns the 802.1X guest VLAN to the port as the PVID. All 802.1X users on this port can access only resources in the guest VLAN. If no 802.1X guest VLAN is configured, the access device does not perform any VLAN operation.
A user in the 802.1X guest VLAN fails 802.1X authentication	If an 802.1X Auth-Fail VLAN (see " Auth-Fail VLAN ") is available, assigns the Auth-Fail VLAN to the port as the PVID. All users on this port can access only resources in the Auth-Fail VLAN. If no Auth-Fail VLAN is configured, the PVID on the port is still the 802.1X guest VLAN. All users on the port are in the guest VLAN.
A user in the 802.1X guest VLAN passes 802.1X authentication	<ul style="list-style-type: none"> Assigns the VLAN specified for the user to the port as the PVID, and removes the port from the 802.1X guest VLAN. After the user logs off, the user configured PVID restores. If the authentication server assigns no VLAN, the user-configured PVID applies. The user and all subsequent 802.1X users are assigned to the user-configured port VLAN. After the user logs off, the PVID remains unchanged.

2. On a port that performs MAC-based access control

To use the 802.1X guest VLAN function on a port that performs MAC-based access control, make sure that the port is a hybrid port, and enable MAC-based VLAN on the port.

Authentication status	VLAN manipulation
A user has not passed 802.1X authentication yet	Creates a mapping between the MAC address of the user and the 802.1X guest VLAN. The user can access resources in the guest VLAN.
A user in the 802.1X guest VLAN fails 802.1X authentication	If an 802.1X Auth-Fail VLAN is available, re-maps the MAC address of the user to the Auth-Fail VLAN. The user can access only resources in the Auth-Fail VLAN. If no 802.1X Auth-Fail VLAN is configured, the user is still in the 802.1X guest VLAN.

Authentication status	VLAN manipulation
A user in the 802.1X guest VLAN passes 802.1X authentication	Re-maps the MAC address of the user to the VLAN specified for the user. If the authentication server assigns no VLAN, re-maps the MAC address of the user to the initial PVID on the port.

NOTE:

The network device assigns a hybrid port to an 802.1X guest VLAN as an untagged member.

Auth-Fail VLAN

You can configure an Auth-Fail VLAN to accommodate users that have failed 802.1X authentication because of the failure to comply with the organization security strategy, such as using a wrong password. Users in the Auth-Fail VLAN can access a limited set of network resources, such as a software server, to download anti-virus software and system patches.

The Auth-Fail VLAN does not accommodate 802.1X users that have failed authentication for authentication timeouts or network connection problems. The way that the network access device handles VLANs on the port differs by 802.1X access control mode.

For more information about VLAN configuration and MAC-based VLAN, see *Layer 2—LAN Switching Configuration Guide*.

1. On a port that performs port-based access control

Authentication status	VLAN manipulation
A user fails 802.1X authentication	Assigns the Auth-Fail VLAN to the port as the PVID. All 802.1X users on this port can access only resources in the Auth-Fail VLAN.
A user in the Auth-Fail VLAN fails 802.1X re-authentication	The Auth-Fail VLAN is still the PVID on the port, and all 802.1X users on this port are in this VLAN.
A user passes 802.1X authentication	<ul style="list-style-type: none"> • Assigns the VLAN specified for the user to the port as the PVID, and removes the port from the Auth-Fail VLAN. After the user logs off, the user-configured PVID restores. • If the authentication server assigns no VLAN, the initial PVID applies. The user and all subsequent 802.1X users are assigned to the user-configured PVID. After the user logs off, the PVID remains unchanged.

2. On a port that performs MAC-based access control

To perform the 802.1X Auth-Fail VLAN function on a port that performs MAC-based access control, you must make sure that the port is a hybrid port, and enable MAC-based VLAN on the port.

Authentication status	VLAN manipulation
A user fails 802.1X authentication	Re-maps the MAC address of the user to the Auth-Fail VLAN. The user can access only resources in the Auth-Fail VLAN.

Authentication status	VLAN manipulation
A user in the Auth-Fail VLAN fails 802.1X re-authentication	The user is still in the Auth-Fail VLAN.
A user in the Auth-Fail VLAN passes 802.1X authentication	Re-maps the MAC address of the user to the server-assigned VLAN. If the authentication server assigns no VLAN, re-maps the MAC address of the user to the initial PVID on the port.

NOTE:

The network device assigns a hybrid port to an 802.1X Auth-Fail VLAN as an untagged member.

Critical VLAN

You configure an 802.1X critical VLAN on a port to accommodate 802.1X users that fail authentication because none of the RADIUS authentication servers in their ISP domain is reachable (active). Users in the critical VLAN can access a limit set of network resources depending on your configuration.

The critical VLAN feature takes effect when 802.1X authentication is performed only through RADIUS servers. If an 802.1X user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN. For more information about RADIUS configuration, see "[Configuring AAA](#)."

For more information about VLAN configuration and MAC-based VLAN, see *Layer 2—LAN Switching Configuration Guide*.

The way that the network access device handles VLANs on an 802.1X-enabled port differs by 802.1X access control mode.

1. On a port that performs port-based access control

Authentication status	VLAN manipulation
A user that has not been assigned to any VLAN fails 802.1X authentication because all the RADIUS servers are unreachable.	Assigns the critical VLAN to the port as the PVID. The 802.1X user and all subsequent 802.1X users on this port can access only resources in the critical VLAN.
A user in the 802.1X critical VLAN fails authentication because all the RADIUS servers are unreachable.	The critical VLAN is still the PVID of the port, and all 802.1X users on this port are in this VLAN.
A user in the 802.1X critical VLAN fails authentication for any other reason than server unreachable.	If an Auth-Fail VLAN has been configured, the PVID of the port changes to Auth-Fail VLAN ID, and all 802.1X users on this port are moved to the Auth-Fail VLAN.
A user in the critical VLAN passes 802.1X authentication.	<ul style="list-style-type: none"> • Assigns the VLAN specified for the user to the port as the PVID, and removes the port from the critical VLAN. After the user logs off, the default or user-configured PVID restores. • If the authentication server assigns no VLAN, the default or user-configured PVID applies. The user and all subsequent 802.1X users are assigned to this port VLAN. After the user logs off, this PVID remains unchanged.

Authentication status	VLAN manipulation
-----------------------	-------------------

A user in the 802.1X guest VLAN or the Auth-Fail VLAN fails authentication because all the RADIUS servers is reachable.

The PVID of the port remains unchanged. All 802.1X users on this port can access only resources in the guest VLAN or the Auth-Fail VLAN.

2. On a port that performs MAC-based access control

To perform the 802.1X critical VLAN function on a port that performs MAC-based access control, you must make sure that the port is a hybrid port, and enable MAC-based VLAN on the port.

Authentication status	VLAN manipulation
-----------------------	-------------------

A user that has not been assigned to any VLAN fails 802.1X authentication because all the RADIUS servers are unreachable.

Maps the MAC address of the user to the critical VLAN. The user can access only resources in the critical VLAN.

A user in the 802.1X critical VLAN fails authentication because all the RADIUS servers are unreachable.

The user is still in the critical VLAN.

A user in the critical VLAN fails 802.1X authentication for any other reason than server unreachable.

If an Auth-Fail VLAN has been configured, re-maps the MAC address of the user to the Auth-Fail VLAN ID.

A user in the critical VLAN passes 802.1X authentication.

Re-maps the MAC address of the user to the server-assigned VLAN.
If the authentication server assigns no VLAN, re-maps the MAC address of the user to the default or user-configured PVID on the port.

A user in the 802.1X guest VLAN or the Auth-Fail VLAN fails authentication because all the RADIUS server are unreachable.

The user remains in the 802.1X VLAN or the Auth-Fail VLAN.

A user in the MAC authentication guest VLAN fails 802.1X authentication because all the 802.1X authentication server are unreachable.

The user is removed from the MAC authentication VLAN and mapped to the 802.1X critical VLAN.

NOTE:

The network device assigns a hybrid port to an 802.1X critical VLAN as an untagged member.

Any of the following RADIUS authentication server changes in the ISP domain for 802.1X users on a port can cause the users to be removed from the critical VLAN:

- An authentication server is reconfigured, added, or removed.
- The status of any RADIUS authentication server automatically changes to active or is administratively set to active.

- The RADIUS server probing function detects that a RADIUS authentication server is reachable and sets its state to active.

You can use the **dot1x critical recovery-action reinitialize** command to configure the port to trigger 802.1X re-authentication when the port or an 802.1X user on the port is removed from the critical VLAN.

- If MAC-based access control is used, the port sends a unicast Identity EAP/Request to the 802.1X user to trigger authentication.
- If port-based access control is used, the port sends a multicast Identity EAP/Request to the 802.1X users to trigger authentication.

ACL assignment

You can specify an ACL for an 802.1X user to control its access to network resources. After the user passes 802.1X authentication, the authentication server, either the local access device or a RADIUS server, assigns the ACL to the port to filter the traffic from this user. In either case, you must configure the ACL on the access device. You can change ACL rules while the user is online.

Configuration prerequisites

- Configure an ISP domain and AAA scheme (local or RADIUS authentication) for 802.1X users.
- If RADIUS authentication is used, create user accounts on the RADIUS server.
- If local authentication is used, create local user accounts on the access device and set the service type to **lan-access**.

802.1X configuration task list

Task	Remarks
Enabling 802.1X	Required
Enabling EAP relay or EAP termination	Optional
Setting the port authorization state	Optional
Specifying an access control method	Optional
Setting the maximum number of concurrent 802.1X users on a port	Optional
Setting the maximum number of authentication request attempts	Optional
Setting the 802.1X authentication timeout timers	Optional
Configuring the online user handshake function	Optional
Configuring the authentication trigger function	Optional
Specifying a mandatory authentication domain on a port	Optional
Configuring the quiet timer	Optional
Enabling the periodic online user re-authentication function	Optional
Configuring an 802.1X guest VLAN	Optional
Configuring an Auth-Fail VLAN	Optional
Configuring an 802.1X critical VLAN	Optional
Specifying supported domain name delimiters	Optional

Enabling 802.1X

Configuration guidelines

- If the PVID of a port is a voice VLAN, the 802.1X function cannot take effect on the port. For more information about voice VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- 802.1X is mutually exclusive with link aggregation and service loopback group configuration on a port.
- Do not use the BPDU drop feature on an 802.1X-enabled port. The BPDU drop feature discards 802.1X packets arrived on the port.
- On an 802.1X and MAC authentication enabled port, the EAP packet from an unknown MAC address immediately triggers 802.1X authentication, and any other type of packet from an unknown MAC address triggers MAC authentication 30 seconds after its arrival.

Configuration procedure

To enable 802.1X on a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable 802.1X globally.	dot1x	By default, 802.1X is disabled globally.
3. Enable 802.1X on a port.	<ul style="list-style-type: none">• (Approach 1) In system view: dot1x interface <i>interface-list</i>• (Approach 2) In Ethernet interface view:<ul style="list-style-type: none">a. interface <i>interface-type</i> <i>interface-number</i>b. dot1x	Use either approach. By default, 802.1X is disabled on a port.

Enabling EAP relay or EAP termination

When you configure EAP relay or EAP termination, consider the following factors:

- The support of the RADIUS server for EAP packets
- The authentication methods supported by the 802.1X client and the RADIUS server

If the client is using only MD5-Challenge EAP authentication or the "username + password" EAP authentication initiated by an HP iNode 802.1X client, you can use both EAP termination and EAP relay. To use EAP-TL, PEAP, or any other EAP authentication methods, you must use EAP relay. When you make your decision, see "[A comparison of EAP relay and EAP termination](#)" for help.

For more information about EAP relay and EAP termination, see "[802.1X authentication procedures](#)."

To configure EAP relay or EAP termination:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure EAP relay or EAP termination.	dot1x authentication-method { chap eap pap }	Optional. By default, the network access device performs EAP termination and uses CHAP to communicate with the RADIUS server. Specify the eap keyword to enable EAP termination. Specify the chap or pap keyword to enable CHAP-enabled or PAP-enabled EAP relay.

NOTE:

If EAP relay mode is used, the **user-name-format** command configured in RADIUS scheme view does not take effect. The access device sends the authentication data from the client to the server without any modification.

Setting the port authorization state

The port authorization state determines whether the client is granted access to the network. You can control the authorization state of a port by using the **dot1x port-control** command and the following keywords:

- **authorized-force**—Places the port in the authorized state, enabling users on the port to access the network without authentication.
- **unauthorized-force**—Places the port in the unauthorized state, denying any access requests from users on the port.
- **auto**—Places the port initially in the unauthorized state to allow only EAPOL packets to pass, and after a user passes authentication, sets the port in the authorized state to allow access to the network. You can use this option in most scenarios.

You can set authorization state for one port in Ethernet interface view, or for multiple ports in system view. If different authorization state is set for a port in system view and Ethernet interface view, the one set later takes effect.

To set the authorization state of a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the port authorization state.	<ul style="list-style-type: none"> • (Approach 1) In system view: dot1x port-control { authorized-force auto unauthorized-force } [interface <i>interface-list</i>] • (Approach 2) In Ethernet interface view: <ul style="list-style-type: none"> a. interface <i>interface-type</i> <i>interface-number</i> b. dot1x port-control { authorized-force auto unauthorized-force } 	Optional. Use either approach. By default, auto applies.

Specifying an access control method

You can specify an access control method for one port in Ethernet interface view, or for multiple ports in system view. If different access control methods are specified for a port in system view and Ethernet interface view, the one specified later takes effect.

To use both 802.1X and portal authentication on a port, you must specify MAC-based access control. For information about portal authentication, see "[Configuring portal authentication](#)."

To specify the access control method:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify an access control method.	<ul style="list-style-type: none">• (Approach 1) In system view: dot1x port-method { macbased portbased } [interface <i>interface-list</i>]• (Approach 2) In Ethernet interface view:<ul style="list-style-type: none">a. interface <i>interface-type interface-number</i>b. dot1x port-method { macbased portbased }	Optional. Use either approach. By default, MAC-based access control applies.

Setting the maximum number of concurrent 802.1X users on a port

You can set the maximum number of concurrent 802.1X users for ports individually in Ethernet interface view or in bulk in system view. If different settings are configured for a port in both views, the setting configured later takes effect.

To set the maximum number of concurrent 802.1X users on a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the maximum number of concurrent 802.1X users on a port.	<ul style="list-style-type: none">• (Approach 1) In system view: dot1x max-user <i>user-number</i> [interface <i>interface-list</i>]• (Approach 2) In Ethernet interface view:<ul style="list-style-type: none">a. interface <i>interface-type interface-number</i>b. dot1x max-user <i>user-number</i> [interface <i>interface-list</i>]	Optional. Use either approach. The default maximum number of concurrent 802.1X users on a port is 256.

Setting the maximum number of authentication request attempts

The network access device retransmits an authentication request if it receives no response to the request it has sent to the client within a period of time (specified by using the **dot1x timer tx-period tx-period-value** command or the **dot1x timer supp-timeout supp-timeout-value** command). The network access device stops retransmitting the request, if it has made the maximum number of request transmission attempts but still received no response.

To set the maximum number of authentication request attempts:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the maximum number of attempts for sending an authentication request.	dot1x retry max-retry-value	Optional. The default setting is 2.

Setting the 802.1X authentication timeout timers

The network device uses the following 802.1X authentication timeout timers:

- **Client timeout timer**—Starts when the access device sends an EAP-Request/MD5 Challenge packet to a client. If no response is received when this timer expires, the access device retransmits the request to the client.
- **Server timeout timer**—Starts when the access device sends a RADIUS Access-Request packet to the authentication server. If no response is received when this timer expires, the access device retransmits the request to the server.

You can set the client timeout timer to a high value in a low-performance network, and adjust the server timeout timer to adapt to the performance of different authentication servers. In most cases, the default settings are sufficient.

To set the 802.1X authentication timeout timers:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the client timeout timer.	dot1x timer supp-timeout supp-timeout-value	Optional. The default is 30 seconds.
3. Set the server timeout timer.	dot1x timer server-timeout server-timeout-value	Optional. The default is 100 seconds.

Configuring the online user handshake function

The online user handshake function checks the connectivity status of online 802.1X users. The network access device sends handshake messages to online users at the interval specified by the **dot1x timer handshake-period** command. If no response is received from an online user after the maximum number

of handshake attempts (set by the **dot1x retry** command) has been made, the network access device sets the user in the offline state.

If iNode clients are deployed, you can also enable the online handshake security function to check for 802.1X users that use illegal client software to bypass security inspection such as proxy detection and dual network interface cards (NICs) detection. This function checks the authentication information in client handshake messages. If a user fails the authentication, the network access device logs the user off.

Configuration guidelines

Follow these guidelines when you configure the online user handshake function:

- To use the online handshake security function, make sure the online user handshake function is enabled. HP recommends that you use the iNode client software and IMC server to guarantee the normal operation of the online user handshake security function.
- If the network has 802.1X clients that cannot exchange handshake packets with the network access device, disable the online user handshake function to prevent their connections from being inappropriately torn down.

Configuration procedure

To configure the online user handshake function:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the handshake timer.	dot1x timer handshake-period <i>handshake-period-value</i>	Optional. The default is 15 seconds.
3. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable the online handshake function.	dot1x handshake	Optional. By default, the function is enabled.
5. Enable the online handshake security function.	dot1x handshake secure	Optional. By default, the function is disabled.

Configuring the authentication trigger function

The authentication trigger function enables the network access device to initiate 802.1X authentication when 802.1X clients cannot initiate authentication.

This function provides the following types of authentication trigger:

- **Multicast trigger**—Periodically multicasts Identity EAP-Request packets out of a port to detect 802.1X clients and trigger authentication.
- **Unicast trigger**—Enables the network device to initiate 802.1X authentication when it receives a data frame from an unknown source MAC address. The device sends a unicast Identity EAP/Request packet to the unknown source MAC address, and retransmits the packet if it has received no response within a period of time. This process continues until the maximum number of request attempts set with the **dot1x retry** command (see "[Setting the maximum number of authentication request attempts](#)") is reached.

The identity request timeout timer sets both the identity request interval for the multicast trigger and the identity request timeout interval for the unicast trigger.

Configuration guidelines

Follow these guidelines when you configure the authentication trigger function:

- Enable the multicast trigger on a port when the clients attached to the port cannot send EAPOL-Start packets to initiate 802.1X authentication.
- Enable the unicast trigger on a port if only a few 802.1X clients are attached to the port and these clients cannot initiate authentication.
- To avoid duplicate authentication packets, do not enable both triggers on a port.

Configuration procedure

To configure the authentication trigger function on a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the username request timeout timer.	dot1x timer tx-period <i>tx-period-value</i>	Optional. The default is 30 seconds.
3. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable an authentication trigger.	dot1x { multicast-trigger unicast-trigger }	Required if you want to enable the unicast trigger. By default, the multicast trigger is enabled, and the unicast trigger is disabled.

Specifying a mandatory authentication domain on a port

You can place all 802.1X users in a mandatory authentication domain for authentication, authorization, and accounting on a port. No user can use an account in any other domain to access the network through the port. The implementation of a mandatory authentication domain enhances the flexibility of 802.1X access control deployment.

To specify a mandatory authentication domain for a port:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify a mandatory 802.1X authentication domain on the port.	dot1x mandatory-domain <i>domain-name</i>	By default, no mandatory 802.1X authentication domain is specified.

Configuring the quiet timer

The quiet timer enables the network access device to wait a period of time before it can process any authentication request from a client that has failed an 802.1X authentication.

You can set the quiet timer to a high value in a vulnerable network or a low value for quicker authentication response.

To configure the quiet timer:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable the quiet timer.	dot1x quiet-period	By default, the timer is disabled.
3. Set the quiet timer.	dot1x timer quiet-period <i>quiet-period-value</i>	Optional. The default is 60 seconds.

Enabling the periodic online user re-authentication function

Periodic online user re-authentication tracks the connection status of online users and updates the authorization attributes assigned by the server, such as the ACL, VLAN, and user profile-based QoS. The re-authentication interval is user configurable.

Configuration guidelines

- The periodic online user re-authentication timer can also be set by the authentication server in the session-timeout attribute. The server-assigned timer overrides the timer setting on the access device, and enables periodic online user re-authentication, even if the function is not configured. Support for the server assignment of re-authentication timer and the re-authentication timer configuration on the server vary with servers.
- The VLAN assignment status must be consistent before and after re-authentication. If the authentication server has assigned a VLAN before re-authentication, it must also assign a VLAN at re-authentication. If the authentication server has assigned no VLAN before re-authentication, it must not assign one at re-authentication. Violation of either rule can cause the user to be logged off. The VLANs assigned to an online user before and after re-authentication can be the same or different.
- If no critical VLAN is configured, RADIUS server unreachable can cause an online user being re-authenticated to be logged off. If a critical VLAN is configured, the user remains online and in the original VLAN.

Configuration procedure

To enable the periodic online user re-authentication function:

Step	Command	Remarks
1. Enter system view.	system-view	N/A

Step	Command	Remarks
2. Set the periodic re-authentication timer.	dot1x timer reauth-period <i>reauth-period-value</i>	Optional. The default is 3600 seconds.
3. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
4. Enable periodic online user re-authentication.	dot1x re-authenticate	By default, the function is disabled.

Configuring an 802.1X guest VLAN

Configuration guidelines

Follow these guidelines when you configure an 802.1X guest VLAN:

- You can configure only one 802.1X guest VLAN on a port. The 802.1X guest VLANs on different ports can be different.
- Assign different IDs to the voice VLAN, the port VLAN, and the 802.1X guest VLAN on a port, so the port can correctly process incoming VLAN tagged traffic.
- With 802.1X authentication, a hybrid port is always assigned to a VLAN as an untagged member. After the assignment, do not re-configure the port as a tagged member in the VLAN.
- Use [Table 6](#) when configuring multiple security features on a port.

Table 6 Relationships of the 802.1X guest VLAN and other security features

Feature	Relationship description	Reference
Super VLAN	You cannot specify a VLAN as both a super VLAN and an 802.1X guest VLAN.	See <i>Layer 2—LAN Switching Configuration Guide</i>
MAC authentication guest VLAN on a port that performs MAC-based access control	Only the 802.1X guest VLAN take effect. A user that fails MAC authentication will not be assigned to the MAC authentication guest VLAN.	See " Configuring MAC authentication "
802.1X Auth-Fail VLAN on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN has a higher priority	See " Using 802.1X authentication with other features "
Port intrusion protection on a port that performs MAC-based access control	The 802.1X guest VLAN function has higher priority than the block MAC action but lower priority than the shut down port action of the port intrusion protection feature.	See " Configuring port security "

Configuration prerequisites

- Create the VLAN to be specified as the 802.1X guest VLAN.
- If the 802.1X-enabled port performs port-based access control, enable 802.1X multicast trigger (**dot1x multicast-trigger**).

- If the 802.1X-enabled port performs MAC-based access control, configure the port as a hybrid port, enable MAC-based VLAN on the port, and assign the port to the 802.1X guest VLAN as an untagged member. For more information about the MAC-based VLAN function, see *Layer 2—LAN Switching Configuration Guide*.

Configuration procedure

To configure an 802.1X guest VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure an 802.1X guest VLAN for one or more ports.	<ul style="list-style-type: none"> • (Approach 1) In system view: dot1x guest-vlan <i>guest-vlan-id</i> [interface <i>interface-list</i>] • (Approach 2) In Ethernet interface view: <ol style="list-style-type: none"> interface <i>interface-type interface-number</i> dot1x guest-vlan <i>guest-vlan-id</i> 	<p>Use either approach.</p> <p>By default, no 802.1X guest VLAN is configured on any port.</p>

Configuring an Auth-Fail VLAN

Configuration guidelines

Follow these guidelines when configuring an 802.1X Auth-Fail VLAN:

- Assign different IDs to the voice VLAN, the port VLAN, and the 802.1X Auth-Fail VLAN on a port, so the port can correctly process VLAN tagged incoming traffic.
- You can configure only one 802.1X Auth-Fail VLAN on a port. The 802.1X Auth-Fail VLANs on different ports can be different.
- Use [Table 7](#) when configuring multiple security features on a port.

Table 7 Relationships of the 802.1X Auth-Fail VLAN with other features

Feature	Relationship description	Reference
Super VLAN	You cannot specify a VLAN as both a super VLAN and an 802.1X Auth-Fail VLAN.	See <i>Layer 2—LAN Switching Configuration Guide</i>
MAC authentication guest VLAN on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN has a high priority.	See " Configuring MAC authentication "
Port intrusion protection on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN function has higher priority than the block MAC action but lower priority than the shut down port action of the port intrusion protection feature.	See " Configuring port security "

Configuration prerequisites

- Create the VLAN to be specified as the 802.1X Auth-Fail VLAN.
- If the 802.1X-enabled port performs port-based access control, enable 802.1X multicast trigger (**dot1x multicast-trigger**).
- If the 802.1X-enabled port performs MAC-based access control, configure the port as a hybrid port, enable MAC-based VLAN on the port, and assign the port to the Auth-Fail VLAN as an untagged member. For more information about the MAC-based VLAN function, see *Layer 2—LAN Switching Configuration Guide*.

Configuration procedure

To configure an Auth-Fail VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure the Auth-Fail VLAN on the port.	dot1x auth-fail vlan <i>authfail-vlan-id</i>	By default, no Auth-Fail VLAN is configured.

Configuring an 802.1X critical VLAN

Configuration guidelines

- Assign different IDs to the voice VLAN, the port VLAN, and the 802.1X critical VLAN on a port, so the port can correctly process VLAN tagged incoming traffic.
- You can configure only one 802.1X critical VLAN on a port. The 802.1X critical VLANs on different ports can be different.
- You cannot specify a VLAN as both a super VLAN and an 802.1X critical VLAN. For information about super VLANs, see *Layer 2—LAN Switching Configuration Guide*.

Configuration prerequisites

- Create the VLAN to be specified as a critical VLAN.
- If the 802.1X-enabled port performs port-based access control, enable 802.1X multicast trigger (**dot1x multicast-trigger**).
- If the 802.1X-enabled port performs MAC-based access control, configure the port as a hybrid port, enable MAC-based VLAN on the port, and assign the port to the Auth-Fail VLAN as an untagged member. For more information about the MAC-based VLAN function, see *Layer 2—LAN Switching Configuration Guide*.

Configuration procedure

To configure an 802.1X critical VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an 802.1X critical VLAN on the port.	dot1x critical vlan <i>vlan-id</i>	By default, no critical VLAN is configured.
4. Configure the port to trigger 802.1X authentication on detection of a reachable authentication server for users in the critical VLAN.	dot1x critical recovery-action reinitialize	Optional. By default, when a reachable RADIUS server is detected, the system removes the port or 802.1X users from the critical VLAN without triggering authentication.

Specifying supported domain name delimiters

By default, the access device supports the at sign (@) as the delimiter. You can also configure the access device to accommodate 802.1X users that use other domain name delimiters.

The configurable delimiters include the at sign (@), back slash (\), and forward slash (/).

If an 802.1X username string contains multiple configured delimiters, the leftmost delimiter is the domain name delimiter. For example, if you configure @, /, and \ as delimiters, the domain name delimiter for the username string 123/22\@abc is the forward slash (/).

If a username string contains none of the delimiters, the access device authenticates the user in the mandatory or default ISP domain. The access selects a domain delimiter from the delimiter set in this order: @, /, and \.

Follow the steps to specify a set of domain name delimiters:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify a set of domain name delimiters for 802.1X users.	dot1x domain-delimiter <i>string</i>	Optional. By default, only the at sign (@) delimiter is supported.

NOTE:

If you configure the access device to include the domain name in the username sent to the RADIUS server, make sure the domain delimiter in the username can be recognized by the RADIUS server. For username format configuration, see the **user-name-format** command in *Security Command Reference*.

Displaying and maintaining 802.1X

Task	Command	Remarks
Display 802.1X session information, statistics, or configuration information of specified or all ports.	<code>display dot1x [sessions statistics] [interface interface-list] [{ begin exclude include } regular-expression]</code>	Available in any view
Clear 802.1X statistics.	<code>reset dot1x statistics [interface interface-list]</code>	Available in user view

802.1X authentication configuration example

Network requirements

As shown in [Figure 44](#), the access device performs 802.1X authentication for users that connect to port GigabitEthernet 1/0/1. Implement MAC-based access control on the port, so the logoff of one user does not affect other online 802.1X users.

Use RADIUS servers to perform authentication, authorization, and accounting for the 802.1X users. If RADIUS authentication fails, perform local authentication on the access device. If RADIUS accounting fails, the access device logs the user off.

Configure the host at 10.1.1.1 as the primary authentication and accounting servers, and the host at 10.1.1.2 as the secondary authentication and accounting servers. Assign all users to the ISP domain **aabcc.net**, which accommodates up to 30 users.

Configure the shared key as **name** for packets between the access device and the authentication server, and the shared key as **money** for packets between the access device and the accounting server.

Figure 44 Network diagram

Configuration procedure

1. Configure the 802.1X client. If HP iNode is used, do not select the **Carry version info** option in the client configuration. (Details not shown.)
2. Configure the RADIUS servers and add user accounts for the 802.1X users. For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*. (Details not shown.)
3. Assign an IP address to each interface on the access device. (Details not shown.)
4. Configure user accounts for the 802.1X users on the access device:

Add a local user with the username **localuser**, and password **localpass** in plaintext. (Make sure the username and password are the same as those configured on the RADIUS server.)

```
<Device> system-view
[Device] local-user localuser
[Device-luser-localuser] service-type lan-access
[Device-luser-localuser] password simple localpass
# Configure the idle cut function to log off any online user that has been idled for 20 minutes.
[Device-luser-localuser] authorization-attribute idle-cut 20
[Device-luser-localuser] quit
```

5. Configure a RADIUS scheme:

Create the RADIUS scheme **radius1** and enter its view.

```
[Device] radius scheme radius1
# Specify the IP addresses of the primary authentication and accounting RADIUS servers.
[Device-radius-radius1] primary authentication 10.1.1.1
[Device-radius-radius1] primary accounting 10.1.1.1
# Configure the IP addresses of the secondary authentication and accounting RADIUS servers.
[Device-radius-radius1] secondary authentication 10.1.1.2
[Device-radius-radius1] secondary accounting 10.1.1.2
# Specify the shared key between the access device and the authentication server.
[Device-radius-radius1] key authentication name
# Specify the shared key between the access device and the accounting server.
[Device-radius-radius1] key accounting money
# Exclude the ISP domain name from the username sent to the RADIUS servers.
[Device-radius-radius1] user-name-format without-domain
[Device-radius-radius1] quit
```

NOTE:

The access device must use the same username format as the RADIUS server. If the RADIUS server includes the ISP domain name in the username, so must the access device.

6. Configure the ISP domain:

Create the ISP domain **aabbcc.net** and enter its view.

```
[Device] domain aabbcc.net
# Apply the RADIUS scheme radius1 to the ISP domain, and specify local authentication as the secondary authentication method.
[Device-isp-aabbcc.net] authentication lan-access radius-scheme radius1 local
[Device-isp-aabbcc.net] authorization lan-access radius-scheme radius1 local
[Device-isp-aabbcc.net] accounting lan-access radius-scheme radius1 local
# Set the maximum number of concurrent users in the domain to 30.
[Device-isp-aabbcc.net] access-limit enable 30
# Configure the idle cut function to log off any online domain user that has been idle for 20 minutes.
[Device-isp-aabbcc.net] idle-cut enable 20
[Device-isp-aabbcc.net] quit
# Specify aabbcc.net as the default ISP domain. If a user does not provide any ISP domain name, it is assigned to the default ISP domain.
```

```
[Device] domain default enable aabbcc.net
```

7. Configure 802.1X:

```
# Enable 802.1X globally.
```

```
[Device] dot1x
```

```
# Enable 802.1X on port GigabitEthernet 1/0/1.
```

```
[Device] interface gigabitethernet 1/0/1
```

```
[Device-GigabitEthernet1/0/1] dot1x
```

```
[Device-GigabitEthernet1/0/1] quit
```

```
# Enable MAC-based access control on the port. (Optional. MAC-based access control is the default setting.)
```

```
[Device] dot1x port-method macbased interface gigabitethernet 1/0/1
```

Verifying the configuration

Use the **display dot1x interface gigabitethernet 1/0/1** command to verify the 802.1X configuration. After an 802.1X user passes RADIUS authentication, you can use the **display connection** command to view the user connection information. If the user fails RADIUS authentication, local authentication is performed.

802.1X with guest VLAN and VLAN assignment configuration example

Network requirements

As shown in [Figure 45](#):

- A host is connected to port GigabitEthernet 1/0/2 of the device and must pass 802.1X authentication to access the Internet. GigabitEthernet 1/0/2 is in VLAN 1.
- GigabitEthernet 1/0/2 implements port-based access control.
- GigabitEthernet 1/0/3 is in VLAN 5 and is for accessing the Internet.
- The authentication server runs RADIUS and is in VLAN 2.
- The update server in VLAN 10 is for client software download and upgrade.

If no user performs 802.1X authentication on GigabitEthernet 1/0/2 within a period of time, the device adds GigabitEthernet 1/0/2 to its guest VLAN, VLAN 10. The host and the update server are both in VLAN 10 and the host can access the update server and download the 802.1X client software.

After the host passes 802.1X authentication, the network access device assigns the host to VLAN 5 where GigabitEthernet 1/0/3 is. The host can access the Internet.

Figure 45 Network diagram

Configuration procedure

The following configuration procedure covers most AAA/RADIUS configuration commands on the device. The configuration on the 802.1X client and RADIUS server are not shown. For more information about AAA/RADIUS configuration commands, see *Security Command Reference*.

1. Make sure the 802.1X client can update its IP address after the access port is assigned to the guest VLAN or a server-assigned VLAN. (Details not shown.)
2. Configure the RADIUS server to provide authentication, authorization, and accounting services. Configure user accounts and server-assigned VLAN, VLAN 5 in this example. (Details not shown.)
3. Create VLANs, and assign ports to the VLANs.

```
<Device> system-view
[Device] vlan 1
[Device-vlan1] port gigabitethernet 1/0/2
[Device-vlan1] quit
[Device] vlan 10
[Device-vlan10] port gigabitethernet 1/0/1
[Device-vlan10] quit
[Device] vlan 2
[Device-vlan2] port gigabitethernet 1/0/4
[Device-vlan2] quit
[Device] vlan 5
[Device-vlan5] port gigabitethernet 1/0/3
[Device-vlan5] quit
```

4. Configure a RADIUS scheme:

```
# Configure RADIUS scheme 2000 and enter its view.
<Device> system-view
[Device] radius scheme 2000

# Specify primary and secondary authentication and accounting servers. Set the shared key to abc
for authentication and accounting packets.
[Device-radius-2000] primary authentication 10.11.1.1 1812
[Device-radius-2000] primary accounting 10.11.1.1 1813
[Device-radius-2000] key authentication abc
[Device-radius-2000] key accounting abc

# Exclude the ISP domain name from the username sent to the RADIUS server.
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain:

```
# Create ISP domain bbb and enter its view.
[Device] domain bbb

# Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and
accounting.
[Device-isp-bbb] authentication lan-access radius-scheme 2000
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

6. Configure 802.1X:

```
# Enable 802.1X globally.
[Device] dot1x

# Enable 802.1X for port GigabitEthernet 1/0/2.
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] dot1x

# Implement port-based access control on the port.
[Device-GigabitEthernet1/0/2] dot1x port-method portbased

# Set the port authorization mode to auto. This step is optional. By default, the port is in auto mode.
[Device-GigabitEthernet1/0/2] dot1x port-control auto
[Device-GigabitEthernet1/0/2] quit

# Set VLAN 10 as the 802.1X guest VLAN for port GigabitEthernet 1/0/2.
[Device] dot1x guest-vlan 10 interface gigabitethernet 1/0/2
```

Verifying the configuration

Use the **display dot1x interface gigabitethernet 1/0/2** command to verify the 802.1X guest VLAN configuration on GigabitEthernet 1/0/2. If no user passes authentication on the port within a specific period of time, use the **display vlan 10** command to verify whether GigabitEthernet 1/0/2 is assigned to VLAN 10.

After a user passes authentication, you can use the **display interface gigabitethernet 1/0/2** command to verify that port GigabitEthernet 1/0/2 has been added to VLAN 5.

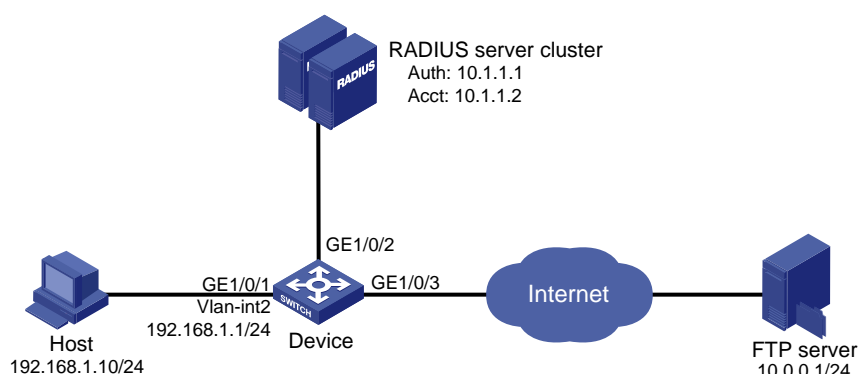

802.1X with ACL assignment configuration example

Network requirements

As shown in [Figure 46](#), the host at 192.168.1.10 connects to port GigabitEthernet 1/0/1 of the network access device.

Perform 802.1X authentication on the port. Use the RADIUS server at 10.1.1.1 as the authentication and authorization server and the RADIUS server at 10.1.1.2 as the accounting server. Assign an ACL to GigabitEthernet 1/0/1 to deny the access of 802.1X users to the FTP server at 10.0.0.1/24 on weekdays during business hours from 8:00 to 18:00.

Figure 46 Network diagram

Configuration procedure

The following configuration procedure provides the major AAA and RADIUS configuration on the access device. The configuration procedures on the 802.1X client and RADIUS server are beyond the scope of this configuration example. For information about AAA and RADIUS configuration commands, see *Security Command Reference*.

1. Configure 802.1X client. Make sure the client is able to update its IP address after the access port is assigned to the 802.1X guest VLAN or a server-assigned VLAN. (Details not shown.)
2. Configure the RADIUS servers, user accounts, and authorization ACL, ACL 3000 in this example. (Details not shown.)
3. Configure the access device:

Assign IP addresses to interfaces. (Details not shown.)

Configure the RADIUS scheme.

```
<Device> system-view
[Device] radius scheme 2000
[Device-radius-2000] primary authentication 10.1.1.1 1812
[Device-radius-2000] primary accounting 10.1.1.2 1813
[Device-radius-2000] key authentication abc
[Device-radius-2000] key accounting abc
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

Create an ISP domain and specify the RADIUS scheme 2000 as the default AAA schemes for the domain.

```
[Device] domain 2000
[Device-isp-2000] authentication default radius-scheme 2000
[Device-isp-2000] authorization default radius-scheme 2000
[Device-isp-2000] accounting default radius-scheme 2000
[Device-isp-2000] quit
```

Configure a time range **ftp** for the weekdays from 8:00 to 18:00.

```
[Device] time-range ftp 8:00 to 18:00 working-day
```

Configure ACL 3000 to deny packets destined for the FTP server at 10.0.0.1 on the weekdays during business hours.

```
[Device] acl number 3000
[Device-acl-adv-3000] rule 0 deny ip destination 10.0.0.1 0 time-range ftp
[Device-acl-adv-3000] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

Enable 802.1X on port GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x
```

Verifying the configuration

Use the user account to pass authentication, and then ping the FTP server on any weekday during business hours.

```
C:\>ping 10.0.0.1
```

```
Pinging 10.0.0.1 with 32 bytes of data:
```

```
Request timed out.
Request timed out.
Request timed out.
Request timed out.
```

```
Ping statistics for 10.0.0.1:
```

```
    Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

The output shows that ACL 3000 has taken effect on the user, and the user cannot access the FTP server.

Configuring EAD fast deployment

Overview

Endpoint Admission Defense (EAD) is an HP integrated endpoint access control solution, which enables the security client, security policy server, access device, and third-party server to work together to improve the threat defensive capability of a network. If a terminal device seeks to access an EAD network, it must have an EAD client, which performs 802.1X authentication.

EAD fast deployment enables the access device to redirect a user seeking to access the network to download and install EAD client. This function eliminates the tedious job of the administrator to deploy EAD clients.

EAD fast deployment is implemented by the following functions:

- [Free IP](#)
- [URL redirection](#)

Free IP

A free IP is a freely accessible network segment, which has a limited set of network resources such as software and DHCP servers. An unauthenticated user can access only this segment to download EAD client, obtain a dynamic IP address from a DHCP server, or perform some other tasks to be compliant with the network security strategy.

URL redirection

If an unauthenticated 802.1X user is using a web browser to access the network, the EAD fast deployment function redirects the user to a specific URL, for example, the EAD client software download page.

The server that provides the URL must be on the free IP accessible to unauthenticated users.

Configuration prerequisites

- Enable 802.1X globally.
- Enable 802.1X on the port, and set the port authorization mode to **auto**.

Configuring a free IP

Follow these guidelines when you configure a free IP:

- When a free IP is configured, the EAD fast deployment is enabled. To allow a user to obtain a dynamic IP address before passing 802.1X authentication, make sure the DHCP server is on the free IP segment.
- When global MAC authentication, Layer-2 portal authentication, or port security is enabled, the free IP does not take effect.
- If you use free IP, guest VLAN, and Auth-Fail VLAN features together, make sure that the free IP segments are in both guest VLAN and Auth-Fail VLAN. Users can access only the free IP segments.

To configure a free IP:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a free IP.	dot1x free-ip <i>ip-address</i> { <i>mask-address</i> <i>mask-length</i> }	By default, no free IP is configured.

Configuring the redirect URL

Follow these guidelines when you configure the redirect URL:

- The redirect URL must be on the free IP subnet.

To configure a redirect URL:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the redirect URL.	dot1x url <i>url-string</i>	By default, no redirect URL is configured.

Setting the EAD rule timer

EAD fast deployment automatically creates an ACL rule, or an EAD rule, to open access to the redirect URL for each redirected user seeking to access the network. The EAD rule timer sets the lifetime of each ACL rule. When the timer expires or the user passes authentication, the rule is removed. If users fail to download EAD client or fail to pass authentication before the timer expires, they must reconnect to the network to access the free IP.

To prevent ACL rule resources from being used up, you can shorten the timer when the amount of EAD users is large.

To set the EAD rule timer:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the EAD rule timer.	dot1x timer ead-timeout <i>ead-timeout-value</i>	Optional. The default timer is 30 minutes.

Displaying and maintaining EAD fast deployment

Task	Command	Remarks
Display 802.1X session information, statistics, or configuration information.	display dot1x [sessions statistics] [interface <i>interface-list</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view

EAD fast deployment configuration example

Network requirements

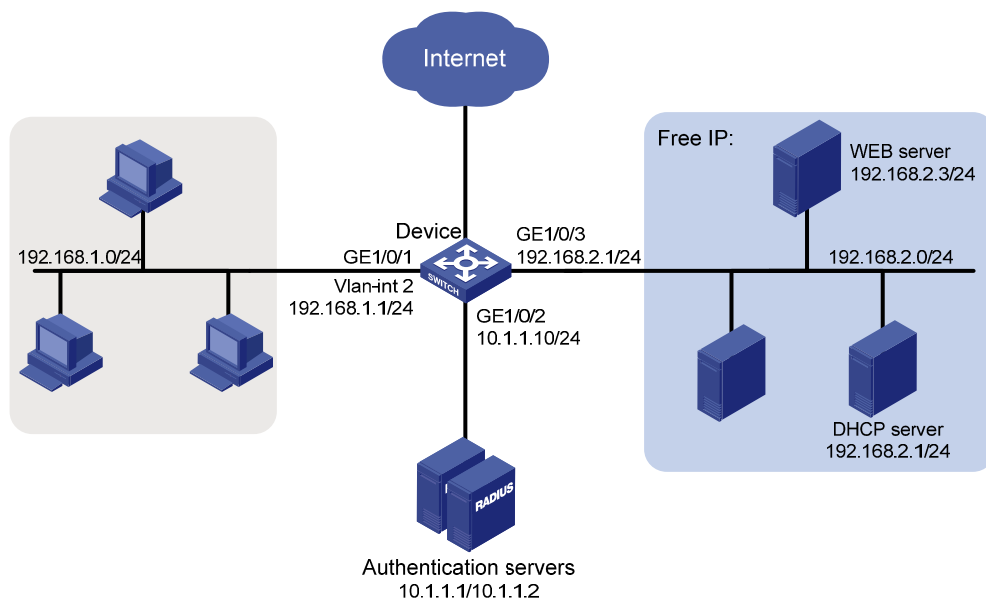

As shown in Figure 47, the hosts on the intranet 192.168.1.0/24 are attached to port GigabitEthernet 1/0/1 of the network access device, and they use DHCP to obtain IP addresses.

Deploy EAD solution for the intranet so that all hosts must pass 802.1X authentication to access the network.

To allow all intranet users to install and update 802.1X client program from a web server, configure the following:

- Allow unauthenticated users to access the segment of 192.168.2.0/24, and to obtain IP address on the segment of 192.168.1.0/24 through DHCP.
- Redirect unauthenticated users to a preconfigured web page when the users use a web browser to access any external network except 192.168.2.0/24. The web page allows users to download the 802.1X client program.
- Allow authenticated 802.1X users to access the network.

Figure 47 Network diagram

In addition to the configuration on the access device, complete the following tasks:

- Configure the DHCP server so that the host can obtain an IP address on the segment of 192.168.1.0/24.
- Configure the web server so that users can log in to the web page to download 802.1X clients.

- Configure the authentication server to provide authentication, authorization, and accounting services.

Configuration procedure

1. Configure an IP address for each interface. (Details not shown.)
2. Configure DHCP relay:

Enable DHCP.

```
<Device> system-view
```

```
[Device] dhcp enable
```

Configure a DHCP server for a DHCP server group.

```
[Device] dhcp relay server-group 1 ip 192.168.2.2
```

Enable the relay agent on VLAN interface 2.

```
[Device] interface vlan-interface 2
```

```
[Device-Vlan-interface2] dhcp select relay
```

Correlate VLAN interface 2 to the DHCP server group.

```
[Device-Vlan-interface2] dhcp relay server-select 1
```

```
[Device-Vlan-interface2] quit
```

3. Configure a RADIUS scheme and an ISP domain.

For more information about configuration procedure, see "Configuring 802.1X."

4. Configure 802.1X:

Configure the free IP.

```
[Device] dot1x free-ip 192.168.2.0 24
```

Configure the redirect URL for client software download.

```
[Device] dot1x url http://192.168.2.3
```

Enable 802.1X globally.

```
[Device] dot1x
```

Enable 802.1X on the port.

```
[Device] interface gigabitethernet 1/0/1
```

```
[Device-GigabitEthernet1/0/1] dot1x
```

Verifying the configuration

Use the **display dot1x** command to display the 802.1X configuration. After the host obtains an IP address from a DHCP server, use the **ping** command from the host to ping an IP address on the network segment specified by free IP.

```
C:\>ping 192.168.2.3
```

```
Pinging 192.168.2.3 with 32 bytes of data:
```

```
Reply from 192.168.2.3: bytes=32 time<1ms TTL=128
```

```
Reply from 192.168.2.3: bytes=32 time<1ms TTL=128
```

```
Reply from 192.168.2.3: bytes=32 time<1ms TTL=128
```

```
Reply from 192.168.2.3: bytes=32 time<1ms TTL=128
```

```
Ping statistics for 192.168.2.3:
```

```
Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),  
Approximate round trip times in milli-seconds:  
Minimum = 0ms, Maximum = 0ms, Average = 0ms
```

The output shows that you can access that segment before passing 802.1X authentication. If you use a web browser to access any external website beyond the free IP segments, you are redirected to the web server, which provides the 802.1X client software download service. Enter the external website address in dotted decimal notation, for example, 3.3.3.3 or <http://3.3.3.3>, in the address bar.

Troubleshooting EAD fast deployment

Web browser users cannot be correctly redirected

Symptom

Unauthenticated users are not redirected to the specified redirect URL after they enter external website addresses in their web browsers.

Analysis

Redirection will not happen for one of the following reasons:

- The address is in the string format. The operating system of the host regards the string as a website name and tries to resolve it. If the resolution fails, the operating system sends an ARP request, but the target address is not in the dotted decimal notation. The redirection function does not redirect this kind of ARP request.
- The address is within a free IP segment. No redirection will take place, even if no host is present with the address.
- The redirect URL is not in a free IP segment, no server is using the redirect URL, or the server with the URL does not provide web services.

Solution

1. Enter a dotted decimal IP address that is not in any free IP segment.
2. Make sure that the network access device and the server are correctly configured.

Configuring MAC authentication

MAC authentication overview

MAC authentication controls network access by authenticating source MAC addresses on a port. It does not require client software. A user does not need to input a username and password for network access. The device initiates a MAC authentication process when it detects an unknown source MAC address on a MAC authentication enabled port. If the MAC address passes authentication, the user can access authorized network resources. If the authentication fails, the device marks the MAC address as a silent MAC address, drops the packet, and starts a quiet timer. The device drops all subsequent packets from the MAC address within the quiet time. This quiet mechanism avoids repeated authentication during a short time.

NOTE:

If the MAC address that has failed authentication is a static MAC address or a MAC address that has passed any security authentication, the device does not mark it as a silent address.

User account policies

MAC authentication supports the following user account policies:

- One MAC-based user account for each user. The access device uses the source MAC addresses in packets as the usernames and passwords of users for MAC authentication. This policy is suitable for an insecure environment.
- One shared user account for all users. You specify one username and password, which are not necessarily a MAC address, for all MAC authentication users on the access device. This policy is suitable for a secure environment.

Authentication approaches

You can perform MAC authentication on the access device (local authentication) or through a Remote Authentication Dial-In User Service (RADIUS) server.

Suppose a source MAC unknown packet arrives at a MAC authentication enabled port.

In the local authentication approach:

- If MAC-based accounts are used, the access device uses the source MAC address of the packet as the username and password to search its local account database for a match.
- If a shared account is used, the access device uses the shared account username and password to search its local account database for a match.

In the RADIUS authentication approach:

- If MAC-based accounts are used, the access device sends the source MAC address as the username and password to the RADIUS server for authentication.
- If a shared account is used, the access device sends the shared account username and password to the RADIUS server for authentication.

For more information about configuring local authentication and RADIUS authentication, see "[Configuring AAA](#)."

MAC authentication timers

MAC authentication uses the following timers:

- **Offline detect timer**—Sets the interval that the device waits for traffic from a user before it regards the user idle. If a user connection has been idle for two consecutive intervals, the device logs the user out and stops accounting for the user.
- **Quiet timer**—Sets the interval that the device must wait before it can perform MAC authentication for a user that has failed MAC authentication. All packets from the MAC address are dropped during the quiet time. This quiet mechanism prevents repeated authentication from affecting system performance.
- **Server timeout timer**—Sets the interval that the access device waits for a response from a RADIUS server before it regards the RADIUS server unavailable. If the timer expires during MAC authentication, the user cannot access the network.

Using MAC authentication with other features

VLAN assignment

You can specify a VLAN in the user account for a MAC authentication user to control the account's access to network resources. After the user passes MAC authentication, the authentication server, either the local access device or a RADIUS server, assigns the VLAN to the port as the default VLAN. After the user logs off, the initial default VLAN, or the default VLAN configured before any VLAN is assigned by the authentication server, restores. If the authentication server assigns no VLAN, the initial default VLAN applies.

A hybrid port is always assigned to a server-assigned VLAN as an untagged member. After the assignment, do not re-configure the port as a tagged member in the VLAN.

If MAC-based VLAN is enabled on a hybrid port, the device maps the server-assigned VLAN to the MAC address of the user. The default VLAN of the hybrid port does not change.

ACL assignment

You can specify an ACL in the user account for a MAC authentication user to control its access to network resources. After the user passes MAC authentication, the authentication server, either the local access device or a RADIUS server, assigns the ACL to the access port to filter the traffic from this user. You must configure the ACL on the access device for the ACL assignment function. You can change ACL rules while the user is online.

Guest VLAN

You can configure a guest VLAN to accommodate MAC authentication users that have failed MAC authentication on the port. Users in the MAC authentication guest VLAN can access a limited set of network resources, such as a software server, to download anti-virus software and system patches. If no MAC authentication guest VLAN is configured, the user that fails MAC authentication cannot access any network resources.

If a user in the guest VLAN passes MAC authentication, it is removed from the guest VLAN and can access all authorized network resources. If not, the user is still in the MAC authentication guest VLAN.

A hybrid port is always assigned to a guest VLAN as an untagged member. After the assignment, do not re-configure the port as a tagged member in the VLAN.

Critical VLAN

You can configure a MAC authentication critical VLAN on a port to accommodate users that fail MAC authentication because no RADIUS authentication server is reachable. Users in a MAC authentication critical VLAN can access a limit set of network resources depending on your configuration.

The critical VLAN feature takes effect when MAC authentication is performed only through RADIUS servers. If a MAC authentication user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN. For more information about RADIUS configuration, see "[Configuring AAA](#)."

Any of the following RADIUS authentication server changes in the ISP domain for MAC authentication users on a port can cause users to be removed from the critical VLAN:

- An authentication server is reconfigured, added, or removed.
- The status of any RADIUS authentication server automatically changes to active or is administratively set to active.
- The RADIUS server probing function detects that a RADIUS authentication server is reachable and sets its state to active.

Configuration task list

Task	Remarks	
Basic configuration for MAC authentication	Configuring MAC authentication globally	Required
	Configuring MAC authentication on a port	Required
Specifying a MAC authentication domain	Optional	
Configuring a MAC authentication guest VLAN	Optional	
Configuring a MAC authentication critical VLAN	Optional	

Basic configuration for MAC authentication

- Create and configure an authentication domain, also called "an ISP domain."
- For local authentication, create local user accounts, and specify the **lan-access** service for the accounts.
- For RADIUS authentication, check that the device and the RADIUS server can reach each other, and create user accounts on the RADIUS server.

If you are using MAC-based accounts, make sure that the username and password for each account is the same as the MAC address of the MAC authentication users.

MAC authentication can take effect on a port only when it is enabled globally and on the port.

Configuring MAC authentication globally

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable MAC authentication globally.	mac-authentication	Disabled by default.
3. Configure MAC authentication timers.	mac-authentication timer { offline-detect <i>offline-detect-value</i> quiet <i>quiet-value</i> server-timeout <i>server-timeout-value</i> }	Optional. By default, the offline detect timer is 300 seconds, the quiet timer is 60 seconds, and the server timeout timer is 100 seconds.
4. Configure the properties of MAC authentication user accounts.	mac-authentication user-name-format { fixed [account <i>name</i>] [password { cipher simple } <i>password</i>] mac-address [{ with-hyphen without-hyphen } [lowercase uppercase]] }	Optional. By default, the username and password for a MAC authentication user account must be a MAC address in lower case without hyphens.

NOTE:

When global MAC authentication is enabled, the EAD fast deployment function cannot take effect.

Configuring MAC authentication on a port

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable MAC authentication.	<ul style="list-style-type: none"> • (Approach 1) In system view: mac-authentication interface <i>interface-list</i> • (Approach 2) In interface view: <ol style="list-style-type: none"> a. interface <i>interface-type</i> <i>interface-number</i> b. mac-authentication 	Disabled by default. Enable MAC authentication for ports in bulk in system view or an individual port in Ethernet interface view.
3. Set the maximum number of concurrent MAC authentication users allowed on a port.	mac-authentication max-user <i>user-number</i>	Optional. By default, the maximum number of concurrent MAC authentication users is 256.

NOTE:

You cannot add a MAC authentication enabled port in to a link aggregation group, or enable MAC authentication on a port already in a link aggregation group.

Specifying a MAC authentication domain

By default, MAC authentication users are in the system default authentication domain. To implement different access policies for users, you can specify authentication domains for MAC authentication users in the following ways:

- Specify a global authentication domain in system view. This domain setting applies to all ports.
- Specify an authentication domain for an individual port in Ethernet interface view.

MAC authentication chooses an authentication domain for users on a port in this order: the interface-specific domain, the global domain, and the default domain. For more information about authentication domains, see "[Configuring AAA](#)."

To specify an authentication domain for MAC authentication users:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify an authentication domain for MAC authentication users.	<ul style="list-style-type: none">• (Approach 1) In system view: mac-authentication domain <i>domain-name</i>• (Approach 2) In interface view:<ul style="list-style-type: none">a. interface <i>interface-type</i> <i>interface-number</i>b. mac-authentication domain <i>domain-name</i>	Use either approach. By default, the system default authentication domain is used for MAC authentication users.

Configuring a MAC authentication guest VLAN

Before you configure a MAC authentication guest VLAN on a port, complete the following tasks:

- Enable MAC authentication.
- Enable MAC-based VLAN on the port.
- Create the VLAN to be specified as the MAC authentication guest VLAN.

To configure a MAC authentication guest VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Ethernet port view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify a MAC authentication guest VLAN.	mac-authentication guest-vlan <i>guest-vlan-id</i>	By default, no MAC authentication guest VLAN is configured. You can configure only one MAC authentication guest VLAN on a port.

Follow the guidelines in [Table 8](#) when configuring a MAC authentication guest VLAN on a port.

Table 8 Relationships of the MAC authentication guest VLAN with other security features

Feature	Relationship description	Reference
Quiet function of MAC authentication	The MAC authentication guest VLAN function has higher priority. A user can access any resources in the guest VLAN.	See " MAC authentication timers "
Super VLAN	You cannot specify a VLAN as both a super VLAN and a MAC authentication guest VLAN.	See <i>Layer 2—LAN Switching Configuration Guide</i>
Port intrusion protection	The MAC authentication guest VLAN function has higher priority than the block MAC action but lower priority than the shut down port action of the port intrusion protection feature.	See " Configuring port security "
802.1X guest VLAN on a port that performs MAC-based access control	The MAC authentication guest VLAN has a lower priority.	See " Configuring 802.1X "

Configuring a MAC authentication critical VLAN

Before you configure a MAC authentication critical VLAN on a port, complete the following tasks:

- Enable MAC authentication.
- Enable MAC-based VLAN on the port.
- Create the VLAN to be specified as the MAC authentication critical VLAN.

To configure a MAC authentication critical VLAN:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet port view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify a MAC authentication critical VLAN.	mac-authentication critical vlan <i>critical-vlan-id</i>	By default, no MAC authentication critical VLAN is configured. You can configure only one MAC authentication critical VLAN on a port.

Follow the guidelines in [Table 9](#) when you configure a MAC authentication critical VLAN on a port.

Table 9 Relationships of the MAC authentication critical VLAN with other security features

Feature	Relationship description	Reference
Quiet function of MAC authentication	The MAC authentication critical VLAN function has higher priority. When a user fails MAC authentication because no RADIUS authentication server is reachable, the user can access the resources in the critical VLAN, and the user's MAC address is not marked as a silent MAC address.	See " MAC authentication timers "
Super VLAN	You cannot specify a VLAN as both a super VLAN and a MAC authentication critical VLAN.	See <i>Layer 2—LAN Switching Configuration Guide</i>
Port intrusion protection	The MAC authentication critical VLAN function has higher priority than the block MAC action but lower priority than the shut down port action of the port intrusion protection feature.	See " Configuring port security "

Displaying and maintaining MAC authentication

Task	Command	Remarks
Display MAC authentication information.	display mac-authentication [interface <i>interface-list</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear MAC authentication statistics.	reset mac-authentication statistics [interface <i>interface-list</i>]	Available in user view

MAC authentication configuration examples

Local MAC authentication configuration example

Network requirements

In the network in [Figure 48](#), perform local MAC authentication on port GigabitEthernet 1/0/1 to control Internet access. Make sure that:

- All users belong to domain aabbcc.net.
- Local users use their MAC address as the username and password for MAC authentication. The MAC addresses are hyphen separated and in lower case.
- The access device detects whether a user has gone offline every 180 seconds. When a user fails authentication, the device does not authenticate the user within 180 seconds.

Figure 48 Network diagram

Configuration procedure

Add a local user account, set both the username and password to 00-e0-fc-12-34-56, the MAC address of the user host, and enable LAN access service for the account.

```
<Device> system-view
[Device] local-user 00-e0-fc-12-34-56
[Device-luser-00-e0-fc-12-34-56] password simple 00-e0-fc-12-34-56
[Device-luser-00-e0-fc-12-34-56] service-type lan-access
[Device-luser-00-e0-fc-12-34-56] quit
```

Configure ISP domain **aabbcc.net** to perform local authentication for LAN access users.

```
[Device] domain aabbcc.net
[Device-isp-aabbcc.net] authentication lan-access local
[Device-isp-aabbcc.net] quit
```

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Enable MAC authentication on port GigabitEthernet 1/0/1.

```
[Device] mac-authentication interface gigabitethernet 1/0/1
```

Specify the ISP domain for MAC authentication.

```
[Device] mac-authentication domain aabbcc.net
```

Set the MAC authentication timers.

```
[Device] mac-authentication timer offline-detect 180
[Device] mac-authentication timer quiet 180
```

Configure MAC authentication to use MAC-based accounts. The MAC address usernames and passwords are hyphenated and in lowercase.

```
[Device] mac-authentication user-name-format mac-address with-hyphen lowercase
```

Verifying the configuration

Display MAC authentication settings and statistics.

```
<Device> display mac-authentication
MAC address authentication is enabled.
User name format is MAC address in lowercase, like xx-xx-xx-xx-xx-xx
Fixed username:mac
Fixed password:not configured
    Offline detect period is 180s
    Quiet period is 180s.
    Server response timeout value is 100s
    The max allowed user number is 1024 per slot
    Current user number amounts to 1
    Current domain is aabbcc.net
Silent Mac User info:
```

```

MAC Addr          From Port          Port Index
GigabitEthernet1/0/1 is link-up
MAC address authentication is enabled
Authenticate success: 1, failed: 0
Max number of on-line users is 256
Current online user number is 1
MAC Addr          Authenticate state      Auth Index
00e0-fc12-3456    MAC_AUTHENTICATOR_SUCCESS    29

```

After the user passes authentication, use the **display connection** command to display the online user information.

```

<Device> display connection
Slot: 1
Index=29 ,Username=00-e0-fc-12-34-56@aabbcc.net
IP=N/A
IPv6=N/A
MAC=00e0-fc12-3456
Total 1 connection(s) matched on slot 1.
Total 1 connection(s) matched.

```

RADIUS-based MAC authentication configuration example

Network requirements

As shown in [Figure 49](#), a host connects to port GigabitEthernet 1/0/1 on the access device. The device uses RADIUS servers for authentication, authorization, and accounting.

Perform MAC authentication on port GigabitEthernet 1/0/1 to control Internet access. Make sure that:

- The device detects whether a user has gone offline every 180 seconds. If a user fails authentication, the device does not authenticate the user within 180 seconds.
- All MAC authentication users belong to ISP domain 2000 and share the user account **aaa** with password **123456**.

Figure 49 Network diagram

Configuration procedure

1. Make sure the RADIUS server and the access device can reach each other.
2. Create a shared account for MAC authentication users on the RADIUS server, and set the username **aaa** and password **123456** for the account.
3. Configure the device:

```

# Configure a RADIUS scheme.
<Device> system-view
[Device] radius scheme 2000
[Device-radius-2000] primary authentication 10.1.1.1 1812
[Device-radius-2000] primary accounting 10.1.1.2 1813
[Device-radius-2000] key authentication abc
[Device-radius-2000] key accounting abc
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit

# Apply the RADIUS scheme to ISP domain 2000 for authentication, authorization, and
accounting.
[Device] domain 2000
[Device-isp-2000] authentication default radius-scheme 2000
[Device-isp-2000] authorization default radius-scheme 2000
[Device-isp-2000] accounting default radius-scheme 2000
[Device-isp-2000] quit

# Enable MAC authentication globally.
[Device] mac-authentication

# Enable MAC authentication on port GigabitEthernet 1/0/1.
[Device] mac-authentication interface gigabitethernet 1/0/1

# Specify the ISP domain for MAC authentication.
[Device] mac-authentication domain 2000

# Set the MAC authentication timers.
[Device] mac-authentication timer offline-detect 180
[Device] mac-authentication timer quiet 180

# Specify username aaa and plaintext password 123456 for the account shared by MAC
authentication users.
[Device] mac-authentication user-name-format fixed account aaa password simple 123456

```

Verifying the configuration

```

# Display MAC authentication settings and statistics.
<Device> display mac-authentication
MAC address authentication is enabled.
User name format is fixed account
Fixed username:aaa
Fixed password: *****
    Offline detect period is 180s
    Quiet period is 180s.
    Server response timeout value is 100s
    The max allowed user number is 1024 per slot
    Current user number amounts to 1
    Current domain is 2000
Silent Mac User info:
    MAC ADDR           From Port           Port Index
Gigabitethernet1/0/1 is link-up
    MAC address authentication is enabled
    Authenticate success: 1, failed: 0

```

```

Max number of on-line users is 256
Current online user number is 1
MAC ADDR           Authenticate state           Auth Index
00e0-fc12-3456    MAC_AUTHENTICATOR_SUCCESS         29

```

After a user passes MAC authentication, use the **display connection** command to display online user information.

```

<Device> display connection
Slot: 1
Index=29 ,Username=aaa@2000
IP=N/A
IPv6=N/A
MAC=00e0-fc12-3456
Total 1 connection(s) matched on slot 1.
Total 1 connection(s) matched.

```

ACL assignment configuration example

Network requirements

As shown in [Figure 50](#), a host connects to the device's port GigabitEthernet 1/0/1, and the device uses RADIUS servers to perform authentication, authorization, and accounting.

Perform MAC authentication on port GigabitEthernet 1/0/1 to control Internet access. Make sure that an authenticated user can access the Internet but the FTP server at 10.0.0.1.

Use MAC-based user accounts for MAC authentication users. The MAC addresses are hyphen separated and in lower case.

Figure 50 Network diagram

Configuration procedure

1. Make sure the RADIUS server and the access device can reach each other.
2. Configure the ACL assignment:

```
# Configure ACL 3000 to deny packets destined for 10.0.0.1.
```

```

<Sysname> system-view
[Sysname] acl number 3000
[Sysname-acl-adv-3000] rule 0 deny ip destination 10.0.0.1 0
[Sysname-acl-adv-3000] quit

```

3. Configure RADIUS-based MAC authentication on the device:

Configure a RADIUS scheme.

```
[Sysname] radius scheme 2000
[Sysname-radius-2000] primary authentication 10.1.1.1 1812
[Sysname-radius-2000] primary accounting 10.1.1.2 1813
[Sysname-radius-2000] key authentication simple abc
[Sysname-radius-2000] key accounting simple abc
[Sysname-radius-2000] user-name-format without-domain
[Sysname-radius-2000] quit
```

Apply the RADIUS scheme to an ISP domain for authentication, authorization, and accounting.

```
[Sysname] domain 2000
[Sysname-isp-2000] authentication default radius-scheme 2000
[Sysname-isp-2000] authorization default radius-scheme 2000
[Sysname-isp-2000] accounting default radius-scheme 2000
[Sysname-isp-2000] quit
```

Enable MAC authentication globally.

```
[Sysname] mac-authentication
```

Specify the ISP domain for MAC authentication.

```
[Sysname] mac-authentication domain 2000
```

Configure the device to use MAC-based user accounts, and the MAC addresses are hyphen separated and in lowercase.

```
[Sysname] mac-authentication user-name-format mac-address with-hyphen lowercase
```

Enable MAC authentication for port GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication
```

4. Configure the RADIUS servers:

Add a user account with **00-e0-fc-12-34-56** as both the username and password on the RADIUS server, and specify ACL 3000 as the authorization ACL for the user account. (Details not shown.)

Verifying the configuration

After the host passes authentication, perform the **display connection** command on the device to view online user information.

```
[Sysname-GigabitEthernet1/0/1] display connection
Slot: 1
Index=9 , Username=00-e0-fc-12-34-56@2000
IP=N/A
IPv6=N/A
MAC=00e0-fc12-3456
```

```
Total 1 connection(s) matched on slot 1.
```

```
Total 1 connection(s) matched.
```

Ping the FTP server from the host to verify that the ACL 3000 has been assigned to port GigabitEthernet 1/0/1 to deny access to the FTP server.

```
C:\>ping 10.0.0.1
```

```
Pinging 10.0.0.1 with 32 bytes of data:
```

Request timed out.

Request timed out.

Request timed out.

Request timed out.

Ping statistics for 10.0.0.1:

Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),

Configuring portal authentication

The IPv6 portal configuration is available only on the HP 5500 EI switch series.

Overview

Portal authentication helps control access to the Internet. It is also called "web authentication." A website implementing portal authentication is called a portal website.

With portal authentication, an access device redirects all users to the portal authentication page. All users can access the free services provided on the portal website; but to access the Internet, a user must pass portal authentication.

A user can access a known portal website and enter a username and password for authentication. This authentication mode is called active authentication. There is another authentication mode, forced authentication, in which the access device forces a user who is trying to access the Internet through Hypertext Transfer Protocol (HTTP) to log on to a portal website for authentication.

The portal feature provides the flexibility for Internet service providers (ISPs) to manage services. A portal website can, for example, present advertisements and deliver community and personalized services. In this way, broadband network providers, equipment vendors, and content service providers form an industrial ecological system.

Extended portal functions

By forcing patching and anti-virus policies, extended portal functions help users to defend against viruses. Portal authentication supports the following extended functions:

- **Security check**—Works after identity authentication succeeds to check whether the required anti-virus software, virus definition file, and operating system patches are installed, and whether there is any unauthorized software installed on the user host.
- **Resource access restriction**—Allows users passing identity authentication to access only network resources in the quarantined area, such as the anti-virus server and the patch server. Only users passing both identity authentication and security check can access restricted network resources.

Portal system components

A typical portal system comprises these basic components: authentication client, access device, portal server, authentication/accounting server, and security policy server.

Figure 51 Portal system components

Authentication client

An authentication client is an entity seeking access to network resources. It is typically an end-user terminal, such as a PC. A client can use a browser or a portal client software for portal authentication. Client security check is implemented through communications between the client and the security policy server.

Access device

Access devices control user access. An access device can be a switch or router that provides the following functions:

- Redirecting all HTTP requests from unauthenticated users to the portal server.
- Interacting with the portal server, the security policy server, and the authentication/accounting server for identity authentication, security check, and accounting.
- Allowing users who have passed identity authentication and security check to access granted Internet resources.

Portal server

A portal server listens to authentication requests from authentication clients and exchanges client authentication information with the access device. It provides free portal services and pushes web authentication pages to users.

NOTE:

A portal server can be an entity independent of the access device or an entity embedded in the access device. In this document, the term portal server refers to an independent portal server, and the term local portal server refers to an embedded portal server. Only the HP 5500 EI series support an independent portal server.

Authentication/accounting server

An authentication/accounting server implements user authentication and accounting through interaction with the access device.

Only a RADIUS server can serve as the remote authentication/accounting server in a portal system.

Security policy server

A security policy server interacts with authentication clients and access devices for security check and resource authorization.

The components of a portal system interact in the following procedure:

1. When an unauthenticated user enters a website address in the browser's address bar to access the Internet, an HTTP request is created and sent to the access device, which redirects the HTTP request to the portal server's web authentication homepage. For extended portal functions, authentication clients must run the portal client software.
2. On the authentication homepage/authentication dialog box, the user enters and submits the authentication information, which the portal server then transfers to the access device.
3. Upon receipt of the authentication information, the access device communicates with the authentication/accounting server for authentication and accounting.
4. After successful authentication, the access device checks whether there is a corresponding security policy for the user. If not, it allows the user to access the Internet. Otherwise, the client communicates with the access device and the security policy server for security check. If the client passes security check, the security policy server authorizes the user to access the Internet resources.

NOTE:

To implement security check, the client must be the HP iNode client.

Portal authentication supports NAT traversal whether it is initiated by a web client or an HP iNode client. When the portal authentication client is on a private network, but the portal server is on a public network and the access device is enabled with NAT, network address translations performed on the access device do not affect portal authentication. However, in such a case, HP recommends using an interface's public IP address as the source address of outgoing portal packets.

Portal system using the local portal server

System components

In addition to use a separate device as the portal server, a portal system can also use the local portal server function of the access device to authenticate web users directly. A portal system using the local portal server does not support extended portal functions. No security policy server is needed for local portal service. In this case, the portal system consists of only three components: authentication client, access device, and authentication/accounting server, as shown in [Figure 52](#).

Figure 52 Portal system using the local portal server

NOTE:

The local portal server function of the access device implements only some simple portal server functions. It only allows users to log on and log off through the web interface. It cannot take the place of an independent portal server.

Protocols used for interaction between the client and local portal server

HTTP and Hypertext Transfer Protocol Secure (HTTPS) can be used for interaction between an authentication client and an access device providing the local portal server function. If HTTP is used, there are potential security problems because HTTP packets are transferred in plain text; if HTTPS is used, secure data transmission is ensured because HTTPS packets are transferred in cipher text based on SSL.

Authentication page customization support

The local portal server function allows you to customize authentication pages. You can customize authentication pages by editing the corresponding HTML files and then compress and save the files to the storage medium of the device. A set of customized authentication pages consists of six authentication pages—the logon page, the logon success page, the online page, the logoff success page, the logon failure page, and the system busy page. A local portal server will push a corresponding authentication page at each authentication phase. If you do not customize the authentication pages, the local portal server will push the default authentication pages.

For the rules of customizing authentication pages, see "[Customizing authentication pages.](#)"

Portal authentication modes

Portal authentication may work at Layer 2 or Layer 3 of the OSI model.

Layer 2 portal authentication

You can enable Layer 2 portal authentication on an access device's Layer 2 ports that connect authentication clients, so that only clients whose MAC addresses pass authentication can access the external network. Only the local portal server provided by the access device supports Layer 2 portal authentication.

Layer 2 portal authentication allows the authentication server to assign different VLANs according to user authentication results so that access devices can thereby control user access to resources. After a client passes authentication, the authentication server can assign an authorized VLAN to allow the user to access the resources in the VLAN. If a client fails authentication, the authentication server can assign an Auth-Fail VLAN. Layer 3 portal authentication does not support VLAN assignment.

Layer 3 portal authentication (available only on the HP 5500 EI series)

You can enable Layer 3 authentication on an access device's Layer 3 interfaces that connect authentication clients. Portal authentication performed on a Layer 3 interface can be direct authentication, re-DHCP authentication, or cross-subnet authentication. In direct authentication and re-DHCP authentication, no Layer-3 forwarding devices exist between the authentication client and the access device. In cross-subnet authentication, Layer-3 forwarding devices may exist between the authentication client and the access device.

- Direct authentication
Before authentication, a user manually configures a public IP address or directly obtains a public IP address through DHCP, and can access only the portal server and predefined free websites. After passing authentication, the user can access the network resources. The process of direct authentication is simpler than that of re-DHCP authentication.
- Re-DHCP authentication
Before authentication, a user gets a private IP address through DHCP and can access only the portal server and predefined free websites. After passing authentication, the user is allocated a public IP address and can access the network resources. No public IP address is allocated to those who fail authentication. This solves the IP address planning and allocation problem and can be

useful. For example, a service provider can allocate public IP addresses to broadband users only when they access networks beyond the residential community network.

The local portal server does not support re-DHCP portal authentication.

IPv6 portal authentication does not support the re-DHCP authentication mode.

- Cross-subnet authentication

Cross-subnet authentication is similar to direct authentication, but it allows Layer 3 forwarding devices to be present between the authentication client and the access device.

In direct authentication, re-DHCP authentication, and cross-subnet authentication, the client's IP address is used for client identification. After a client passes authentication, the access device generates an access control list (ACL) for the client based on the client's IP address to permit packets from the client to go through the access port. Because no Layer 3 devices are present between the authentication clients and the access device in direct authentication and re-DHCP authentication, the access device can directly learn the clients' MAC addresses, and can enhance the capability of controlling packet forwarding by also using the learned MAC addresses.

Portal support for EAP (available only on the HP 5500 EI series)

Authentication by using the username and password is less secure. Digital certificate authentication is usually used to ensure higher security.

The Extensible Authentication Protocol (EAP) supports several digital certificate-based authentication methods, for example, EAP-TLS. Working together with EAP, portal authentication can implement digital certificate-based user authentication.

Figure 53 Portal support for EAP working flow diagram

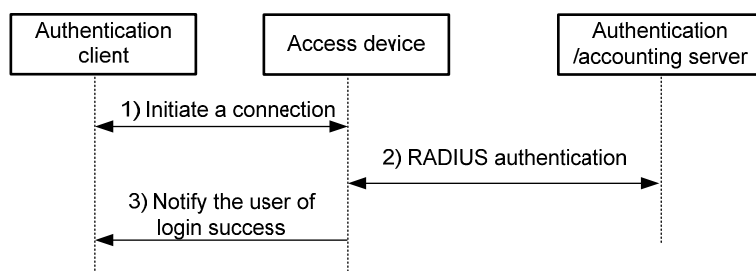

As shown in Figure 53, the authentication client and the portal server exchange EAP authentication packets. The portal server and the access device exchange portal authentication packets that carry the EAP-Message attributes. The access device and the RADIUS server exchange RADIUS packets that carry the EAP-Message attributes. The RADIUS server that supports the EAP server function processes the EAP packets encapsulated in the EAP-Message attributes, and provides the EAP authentication result. During the whole EAP authentication process, the access device does not process the packets that carry the EAP-Message attributes but only transports them between the portal server and the RADIUS server. Therefore, no additional configuration is needed on the access device.

NOTE:

- To use portal authentication that supports EAP, the portal server and client must be the IMC portal server and the iNode portal client.
 - Only Layer 3 portal authentication that uses a remote portal server supports EAP authentication.
-

Layer 2 portal authentication process

Figure 54 Local Layer 2 portal authentication process

Local Layer 2 portal authentication takes the following procedure:

1. The portal authentication client sends an HTTP or HTTPS request. Upon receiving the HTTP request, the access device redirects it to the listening IP address of the local portal server, which then pushes a web authentication page to the authentication client. The user types the username and password on the web authentication page. The listening IP address of the local portal server is the IP address of a Layer 3 interface on the access device that can communicate with the portal client. Usually, it is a loopback interface's IP address.
2. The access device and the RADIUS server exchange RADIUS packets to authenticate the user.
3. If the user passes RADIUS authentication, the local portal server pushes a logon success page to the authentication client.

Authorized VLAN

Layer 2 portal authentication supports VLAN assignment by the authentication server. After a user passes portal authentication, if the authentication server is configured with an authorized VLAN for the user, the authentication server assigns the authorized VLAN to the access device. Then, the access device adds the user to the authorized VLAN and generates a MAC VLAN entry. If the authorized VLAN does not exist, the access device first creates the VLAN.

By deploying the authorized VLAN assignment function, you can control which authenticated users can access which network resources.

Auth-Fail VLAN

The Auth-Fail VLAN feature allows users failing authentication to access a VLAN that accommodates network resources such as the patches server, virus definitions server, client software server, and anti-virus software server, so that the users can upgrade their client software or other programs. Such a VLAN is called an Auth-Fail VLAN.

Layer 2 portal authentication supports Auth-Fail VLAN on a port that performs MAC-based access control. With an Auth-Fail VLAN configured on a port, if a user on the port fails authentication, the access device creates a MAC VLAN entry based on the MAC address of the user and adds the user to the Auth-Fail VLAN. Then, the user can access the non-HTTP resources in the Auth-Fail VLAN, and all HTTP requests of the user will be redirected to the authentication page. If the user passes authentication, the access device adds the user to the assigned VLAN or return the user to the initial VLAN of the port, depending on whether the authentication server assigns a VLAN. If the user fails the authentication, the access device keeps the user in the Auth-Fail VLAN. If an access port receives no traffic from a user in the Auth-Fail VLAN during a specified period of time (90 seconds by default), it removes the user from the Auth-Fail VLAN and adds the user to the initial VLAN of the port.

NOTE:

After a user is added to the authorized VLAN or Auth-Fail VLAN, the IP address of the client needs to be automatically or manually updated to make sure that the client can communicate with the hosts in the VLAN.

Assignment of authorized ACLs

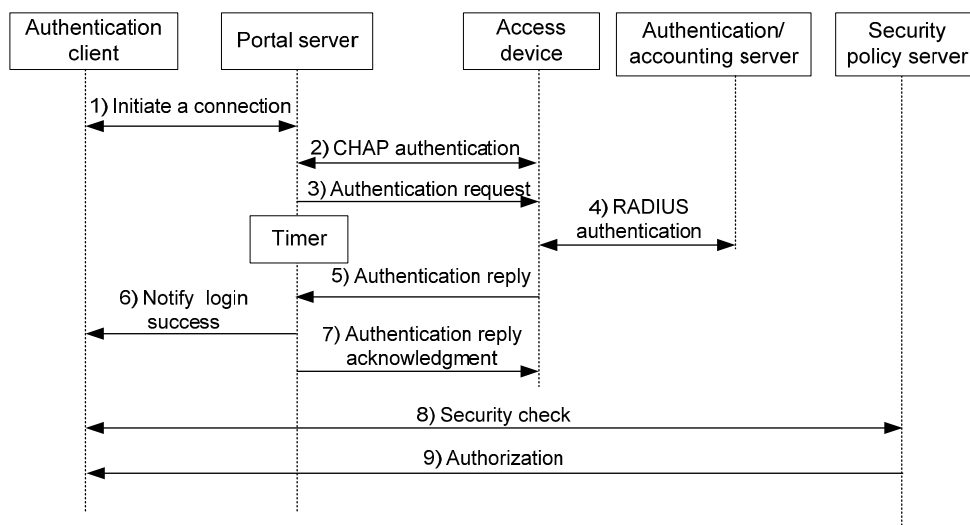

The device can use ACLs to control user access to network resources and limit user access rights. With authorized ACLs specified on the authentication server, when a user passes authentication, the authentication server assigns an authorized ACL for the user, and the device filters traffic from the user on the access port according to the authorized ACL. You must configure the authorized ACLs on the access device if you specify authorized ACLs on the authentication server. To change the access right of a user, specify a different authorized ACL on the authentication server or change the rules of the corresponding authorized ACL on the device.

Layer 3 portal authentication process (available only on the HP 5500 EI series)

Direct authentication and cross-subnet authentication share the same authentication process, while re-DHCP authentication has a different process because of the presence of two address allocation procedures.

Direct authentication/cross-subnet authentication process (with CHAP/PAP authentication)

Figure 55 Direct authentication/cross-subnet authentication process

The direct authentication/cross-subnet authentication takes the following procedure:

1. An authentication client initiates authentication by sending an HTTP request. When the HTTP packet arrives at the access device, the access device allows it to pass if it is destined for the portal server or a predefined free website, or redirects it to the portal server if it is destined for other websites. The portal server pushes a web authentication page to the user and the user enters the username and password.
2. The portal server and the access device exchange Challenge Handshake Authentication Protocol (CHAP) messages. For Password Authentication Protocol (PAP) authentication, this step is skipped.

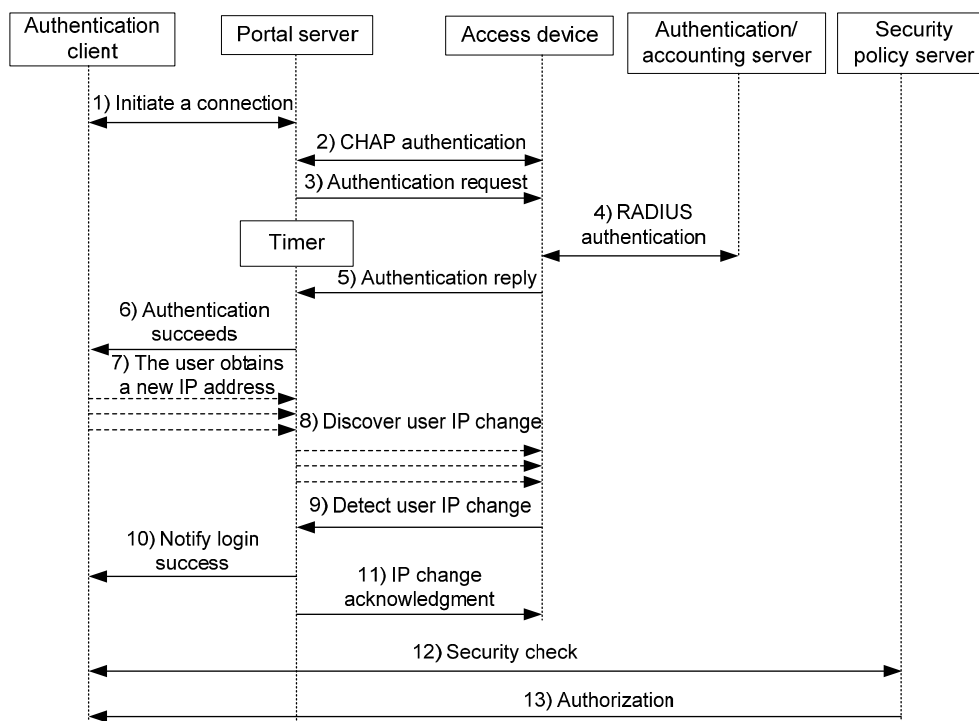

3. The portal server assembles the username and password into an authentication request message and sends it to the access device. Meanwhile, the portal server starts a timer to wait for an authentication acknowledgment message.
4. The access device and the RADIUS server exchange RADIUS packets to authenticate the user.
5. The access device sends an authentication reply to the portal server.
6. The portal server sends an authentication success message to the authentication client to notify it of logon success.
7. The portal server sends an authentication reply acknowledgment message to the access device.

With extended portal functions, the process includes additional steps:

8. The security policy server exchanges security check information with the authentication client to check whether the authentication client meets the security requirements.
9. Based on the security check result, the security policy server authorizes the user to access certain resources, and sends the authorization information to the access device. The access device then controls access of the user based on the authorization information.

Re-DHCP authentication process (with CHAP/PAP authentication)

Figure 56 Re-DHCP authentication process

The re-DHCP authentication takes the following procedure:

The first steps are the same as those in the direct authentication/cross-subnet authentication process.

7. After receiving the authentication success message, the authentication client obtains a new public IP address through DHCP and notifies the portal server that it has obtained a public IP address.
8. The portal server notifies the access device that the authentication client has obtained a new public IP address.
9. Detecting the change of the IP address by examining ARP packets received, the access device notifies the portal server of the change.

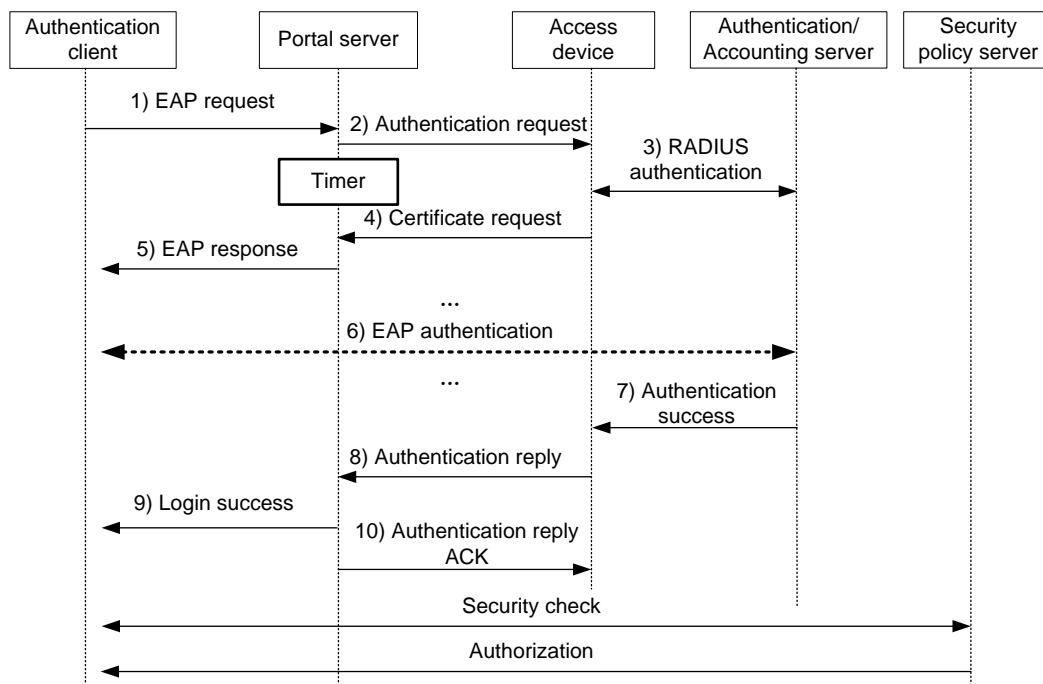

10. The portal server notifies the authentication client of logon success.
11. The portal server sends a user IP address change acknowledgment message to the access device.

With extended portal functions, the process includes additional steps:

12. The security policy server exchanges security check information with the authentication client to check whether the authentication client meets the security requirements.
13. Based on the security check result, the security policy server authorizes the user to access certain resources, and sends the authorization information to the access device. The access device then controls access of the user based on the authorization information.

Portal support for EAP authentication process

Figure 57 Portal support for EAP authentication process

All portal authentication modes share the same EAP authentication steps. The following takes the direct portal authentication as an example to show the EAP authentication process:

1. The authentication client sends an EAP Request/Identity message to the portal server to initiate an EAP authentication process.
2. The portal server sends a portal authentication request to the access device, and starts a timer to wait for the portal authentication reply. The portal authentication request contains several EAP-Message attributes, which are used to encapsulate the EAP packet sent from the authentication client and carry the certificate information of the client.
3. After the access device receives the portal authentication request, it constructs a RADIUS authentication request and sends it to the RADIUS server. The EAP-Message attributes in the RADIUS authentication request are those carried in the received portal authentication request.
4. The access device sends a certificate request to the portal server according to the reply received from the RADIUS server. The certificate request also contains several EAP-Message attributes, which are used to transfer the certificate information of the RADIUS server. The EAP-Message attributes in the certificate request are those carried in the RADIUS authentication reply.

5. After receiving the certificate request, the portal server sends an EAP authentication reply to the authentication client, carrying the EAP-Message attribute values.
6. The authentication client sends another EAP request to continue the EAP authentication with the RADIUS server, during which there may be several portal authentication requests. The subsequent authentication processes are the same as that initiated by the first EAP request, except that the EAP request types vary with the EAP authentication phases.
7. After the authentication client passes the EAP authentication, the RADIUS server sends an authentication reply to the access device. This reply carries the EAP-Success message in the EAP-Message attribute.
8. The access device sends an authentication reply to the portal server. This reply carries the EAP-Success message in the EAP-Message attribute.
9. The portal server notifies the authentication client of the authentication success.
10. The portal server sends an authentication reply acknowledgment to the access device.

The remaining steps are for extended portal authentication. For more information about the steps, see the portal authentication process with CHAP/PAP authentication.

Portal stateful failover (available only on the HP 5500 EI series)

Overview

The stateful failover feature supports hot backup of services on two devices. It can be configured on key devices to avoid service interruptions caused by single point failures. When working normally, the two devices synchronize the service information of each other. If one device fails, the other device takes over the services.

To implement stateful failover, specify a dedicated VLAN (called the "backup VLAN") on each device for stateful failover packets. If both a failover link and a backup VLAN are configured, add the physical ports at the two ends of the failover link to the backup VLAN. For more information about the stateful failover feature, see *High Availability Configuration Guide*.

Figure 58 Network diagram for portal stateful failover configuration

As shown in [Figure 58](#), users have to pass portal authentication to access the Internet. To avoid portal service interruption caused by single point failures, you can deploy two access devices (Gateway A and Gateway B) and configure the portal stateful failover function on them, so that they back up the portal online user information of each other through the failover link. When one of them (Gateway A or Gateway B) fails, the other can guarantee the normal data communication of the online portal users and perform portal authentication for new portal users.

Basic concepts

1. Device states
 - Independence: A stable running status of a device when it does not establish the failover link with the other device.
 - Synchronization: A stable running status of a device when it establishes the failover link with the other device successfully and is ready for data backup.
2. User modes
 - Stand-alone: Indicates that the user data is stored on the local device only. Currently, the local device is in independence state or it is in synchronization state but has not synchronized the user data to the peer device yet.
 - Primary: Indicates that the user logs in from the local device, and the user data is generated on the local device. The local device is in synchronization state and ready for receiving and processing packets from the server.

- Secondary: Indicates that the user logs in from the peer device, and the user data is synchronized from the peer device to the local device. The local device is in synchronization state. It only receives and processes the synchronization messages and does not process packets from the server.

Portal authentication across VPNs (available only on the HP 5500 EI series)

This feature is not applicable to VPNs with overlapping address spaces.

In a scenario where the branches belong to different VPNs that are isolated from each other and all portal users in the branches need to be authenticated by the server at the headquarters, you can deploy portal authentication across MPLS VPNs. As shown in [Figure 59](#), the PE connecting the authentication clients serves as the NAS. The NAS is configured with portal authentication and AAA authentication, both of which support authentication across VPNs. The NAS can transmit a client's portal authentication packets in a VPN transparently through the MPLS backbone to the servers in another VPN. This feature implements centralized client authentication across different VPNs while ensuring the separation of packets of the different VPNs.

Figure 59 Network diagram for portal authentication across VPNs

Portal authentication configured on MCE devices can also support authentication across VPNs. For information about MCE, see "[Layer 3—IP Routing Configuration Guid.](#)"

For information about AAA implementation across VPNs, see "[Configuring AAA.](#)"

Portal configuration task list

The HP 5500 SI switch series supports only Layer 2 portal configuration.

Complete these tasks to configure Layer 2 portal authentication:

Task	Remarks	
Specifying the local portal server for Layer 2 portal authentication	Required	
Configuring the local portal server	Customizing authentication pages	Optional
	Configuring the local portal server	Required
Enabling Layer 2 portal authentication	Required	
Controlling access of portal	Configuring a portal-free rule	Optional

Task	Remarks
users	Setting the maximum number of online portal users
	Specifying an authentication domain for portal users
	Configuring Layer 2 portal authentication to support web proxy
	Enabling support for portal user moving
Specifying an Auth-Fail VLAN for portal authentication	Optional
Specifying an auto redirection URL for authenticated portal users	Optional
Configuring online Layer 2 portal user detection	Optional
Logging off portal users	Optional

Complete these tasks to configure Layer 3 portal authentication:

Task	Remarks
Specifying a portal server for Layer 3 portal authentication	Required
Enabling Layer 3 portal authentication	Required
Controlling access of portal users	Configuring a portal-free rule
	Configuring an authentication source subnet
	Setting the maximum number of online portal users
	Specifying an authentication domain for portal users
Configuring RADIUS related attributes	Specifying NAS-Port-Type for an interface
	Specifying a NAS ID profile for an interface
Specifying a source IP address for outgoing portal packets	Optional
Configuring portal stateful failover (available only on the HP 5500 EI series)	Optional
Specifying an auto redirection URL for authenticated portal users	Optional
Configuring portal detection functions	Configuring the portal server detection function
	Configuring portal user information synchronization
Logging off portal users	Optional

Configuration prerequisites

The portal feature provides a solution for user identity authentication and security check. However, the portal feature cannot implement this solution by itself. RADIUS authentication needs to be configured on the access device to cooperate with the portal feature to complete user authentication.

The prerequisites for portal authentication configuration are as follows:

- The portal server and the RADIUS server have been installed and configured properly. Local portal authentication requires no independent portal server be installed.

- With re-DHCP authentication, the IP address check function of the DHCP relay agent is enabled on the access device, and the DHCP server is installed and configured properly. (Available only on the HP 5500 EI series)
- The portal client, access device, and servers can reach each other.
- With RADIUS authentication, usernames and passwords of the users are configured on the RADIUS server, and the RADIUS client configurations are performed on the access device. For information about RADIUS client configuration, see "[Configuring AAA.](#)"
- To implement extended portal functions, install and configure IMC EAD, and make sure that the ACLs configured on the access device correspond to those specified for the resources in the quarantined area and for the restricted resources on the security policy server. For information about security policy server configuration on the access device, see "[Configuring AAA.](#)"

For installation and configuration about the security policy server, see *IMC EAD Security Policy Help*.

The ACL for resources in the quarantined area and that for restricted resources correspond to isolation ACL and security ACL, respectively, on the security policy server.

You can modify the authorized ACLs on the access device. However, your changes take effect only for portal users logging on after the modification.

For portal authentication to work normally, make sure that the system name of the access device is no more than 16 characters.

Specifying the portal server

Specifying the local portal server for Layer 2 portal authentication

Layer 2 portal authentication uses the local portal server. Specify the IP address of a Layer 3 interface on the device that is routable to the portal client as the listening IP address of the local portal server. HP recommends using the IP address of a loopback interface rather than a physical Layer 3 interface, because:

- The status of a loopback interface is stable. There will be no authentication page access failures caused by interface failures.
- A loopback interface does not forward received packets to any network, avoiding impact on system performance when there are many network access requests.

To specify the local portal server for Layer 2 portal authentication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify the listening IP address of the local portal server for Layer 2 portal authentication.	portal local-server ip <i>ip-address</i>	By default, no listening IP address is specified.

NOTE:

The specified listening IP address can be changed or deleted only if Layer 2 portal authentication is not enabled on any port.

Specifying a portal server for Layer 3 portal authentication (available only on the HP 5500 EI series)

This task allows you to specify the portal server parameters for Layer 3 portal authentication, including the portal server IP address, shared encryption key, server port, and the URL address for web authentication. According to the networking environment, you can configure a remote portal server or a local portal server as needed.

- To configure a remote portal server, specify the IP address of the remote portal server.

When you specify a portal server for Layer 3 portal authentication, follow these guidelines:

- If the portal server is in an MPLS VPN, specify the VPN instance when specifying the portal server on the device, so the device can send packets to the portal server.

To specify a portal server for Layer 3 authentication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify a portal server and configure related parameters.	portal server <i>server-name</i> ip <i>ip-address</i> [key [cipher simple] <i>key-string</i> port <i>port-id</i> url <i>url-string</i> vpn-instance <i>vpn-instance-name</i>] * ipv6 <i>ipv6-address</i> [key [cipher simple] <i>key-string</i> port <i>port-id</i> url <i>url-string</i>] * }	By default, no portal server is specified.

NOTE:

The specified parameters of a portal server can be modified or deleted only if the portal server is not referenced on any interface.

Configuring the local portal server

Configuring a local portal server is required only for local portal authentication. During local portal authentication, the local portal server pushes authentication pages to users. You can define the authentication pages for users; otherwise, the default authentication pages will be used during the authentication process.

Customizing authentication pages

Customized authentication pages exist in the form of HTML files. You can compress them and then save them in the storage medium of the access device.

A set of authentication pages includes six main authentication pages and their page elements. The six main authentication pages are the logon page, the logon success page, the logon failure page, the online page, the system busy page, and the logoff success page. The page elements refer to the files that the authentication pages reference, for example, **back.jpg** for page **Logon.htm**. Each main authentication page can reference multiple page elements. If you define only some of the main authentication pages, the system will use the default authentication pages for the undefined ones.

For the local portal server to operate normally and steadily, follow the following rules when customizing authentication pages:

Rules on file names

The main authentication pages have predefined file names, which cannot be changed.

Table 10 Main authentication page file names

Main authentication page	File name
Logon page	logon.htm
Logon success page	logonSuccess.htm
Logon failure page	logonFail.htm
Online page Pushed after the user gets online for online notification	online.htm
System busy page Pushed when the system is busy or the user is in the logon process	busy.htm
Logoff success page	logoffSuccess.htm

NOTE:

You can define the names of the files other than the main authentication page files. The file names and directory names are case-insensitive.

Rules on page requests

The local portal server supports only Post and Get requests.

- Get requests are used to get the static files in the authentication pages and allow no recursion. For example, if file Logon.htm includes contents that perform Get action on file ca.htm, file ca.htm cannot include any reference to file Logon.htm.
- Post requests are used when users submit username and password pairs, log on the system, and log off the system.

Rules on Post request attributes

1. Observe the following requirements when editing a form of an authentication page:
 - An authentication page can have multiple forms, but there must be one and only one form whose action is **logon.cgi**. Otherwise, user information cannot be sent to the local portal server.
 - The username attribute is fixed as **PtUser**, and the password attribute is fixed as **PtPwd**.
 - Attribute **PtButton** is required to indicate the action that the user requests, which can be **Logon** or **Logoff**.
 - A logon Post request must contain **PtUser**, **PtPwd**, and **PtButton** attributes.
 - A logoff Post request must contain the **PtButton** attribute.
2. Authentication pages **logon.htm** and **logonFail.htm** must contain the logon Post request.

The following example shows part of the script in page **logon.htm**.

```
<form action=logon.cgi method = post >  
<p>User name:<input type="text" name = "PtUser" style="width:160px;height:22px"  
maxlength=64>
```

```

<p>Password :<input type="password" name = "PtPwd" style="width:160px;height:22px"
maxlength=32>
<p><input type=SUBMIT value="Logon" name = "PtButton" style="width:60px;"
onclick="form.action=form.action+location.search;"
</form>

```

3. Authentication pages **logonSuccess.htm** and **online.htm** must contain the logoff Post request.

The following example shows part of the script in page **online.htm**.

```

<form action=logon.cgi method = post >
<p><input type=SUBMIT value="Logoff" name="PtButton" style="width:60px;" >
</form>

```

Rules on page file compression and saving

- A set of authentication page files must be compressed into a standard zip file. The name of a zip file can contain only letters, numerals, and underscores. The zip file of the default authentication pages must be saved with name **defaultfile.zip**.
- The set of authentication pages must be located in the root directory of the zip file.
- Zip files can be transferred to the device through FTP or TFTP. The default authentication pages file must be saved in the root directory of the device, and other authentication files can be saved in the root directory or the **portal** directory under the root directory of the device.

Examples of zip files on the device:

```

<Sysname> dir
Directory of flash:/portal/
 0  -rw-    1405  Feb 28 2011 15:53:31  ssid2.zip
 1  -rw-    1405  Feb 28 2011 15:53:20  ssid1.zip
 2  -rw-    1405  Feb 28 2011 15:53:39  ssid3.zip
 3  -rw-    1405  Feb 28 2011 15:53:44  ssid4.zip
2540 KB total (1319 KB free)

```

Rules on file size and contents

For the system to push customized authentication pages smoothly, you need comply with the following size and content requirements on authentication pages.

- The size of the zip file of each set of authentication pages, including the main authentication pages and the page elements, must be no more than 500 KB.
- The size of a single page, including the main authentication page and its page elements, must be no more than 50 KB before being compressed.
- Page elements can contain only static contents such as HTML, JS, CSS, and pictures.

Logging off a user who closes the logon success or online page

After a user passes authentication, the system pushes the logon success page named logonSuccess.htm. If the user initiates another authentication through the logon page, the system pushes the online page named online.htm. You can configure the device to forcibly log off the user when the user closes either of these two pages. To do so, add the following contents in logonSuccess.htm and online.htm:

1. Reference to JS file pt_private.js.
2. Function pt_unload(), which is used to trigger page unloading.
3. Function pt_submit(), the event handler function for Form.
4. Function pt_init(), which is for triggering page loading.

The following is a script example with the added contents highlighted in gray:

```

<html>
<head>
<script type="text/javascript" language="javascript" src="pt_private.js"></script>
</head>
<body onload="pt_init();" onbeforeunload="return pt_unload();">
... ..
<form action=logon.cgi method = post onsubmit="pt_submit()">
... ..
</body>
</html>

```

Redirecting authenticated users to a specified web page

To make the device automatically redirect authenticated users to a specified web page, do the following in logon.htm and logonSuccess.htm:

1. In logon.htm, set the target attribute of Form to **blank**.

See the contents in gray:

```
<form method=post action=logon.cgi target="blank">
```

2. Add the function for page loading pt_init() to logonSuccess.htm.

See the contents in gray:

```

<html>
<head>
<title>LogonSucceeded</title>
<script type="text/javascript" language="javascript"
src="pt_private.js"></script>
</head>
<body onload="pt_init();" onbeforeunload="return pt_unload();">
... ..
</body>
</html>

```

HP recommends using browser IE 6.0 or above on the authentication clients. Make sure the browser of an authentication client permits pop-ups or permits pop-ups from the access device. Otherwise, the user cannot log off by closing the logon success or online page and can only click **Cancel** to return back to the logon success or online page.

If a user refreshes the logon success or online page, or jumps to another web site from either of the pages, the device also logs off the user.

Only IE, Firefox, and Safari browsers support the device to log off the user when the user closes the logon success or online page. Other browsers, such as Chrome and Opera do not support this function.

Configuring the local portal server

To make the local portal server take effect, specify the protocol to be used for communication between the portal client and local portal server.

Configuration prerequisites

To configure the local portal server to support HTTPS, complete these configurations at first:

- Configure PKI policies, obtain the CA certificate, and apply for a local certificate. For more information, see "[Configuring PKI](#)."
- Configure the SSL server policy, and specify the PKI domain to be used, which is configured in the above step. For more information, see "[Configuring SSL](#)."

When you specify the protocol for the local portal server to support, the local portal server will load the default authentication page file, which is supposed to be saved in the root directory of the device. Therefore, to make sure that the local portal server uses the user-defined default authentication pages, you must edit and save them properly. Otherwise, the system default authentication pages are used.

Configuration procedure

To configure the local portal server:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the protocol type for the local portal server to support and load the default authentication page file.	portal local-server { http https server-policy <i>policy-name</i> }	By default, the local portal server does not support any protocol.
3. Configure the welcome banner of the default authentication pages of the local portal server.	portal server banner <i>banner-string</i>	Optional. No welcome banner by default.

Enabling portal authentication

Only after you enable portal authentication on an access interface, can the access interface perform portal authentication for connected clients.

Enabling Layer 2 portal authentication

Before enabling Layer 2 portal authentication, make sure that:

- The listening IP address of the local portal server is specified.
- Layer 3 portal authentication is not enabled on any interface.

Follow these guidelines when you enable Layer 2 portal authentication:

- To ensure normal operation of portal authentication on a Layer 2 port, do not enable port security, guest VLAN of 802.1X, or EAD fast deployment of 802.1X on the port.
- To support assignment of authorized VLANs, you must enable the MAC-based VLAN function on the port.

To enable Layer 2 portal authentication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet port view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
3.	Enable Layer 2 portal authentication on the port.	portal local-server enable Not enabled by default.

Enabling Layer 3 portal authentication (available only on the HP 5500 EI series)

Before enabling Layer 3 portal authentication on an interface, make sure that:

- An IP address is configured for the interface.
- The interface is not added to any port aggregation group.
- Layer 2 portal authentication is not enabled on any ports.

Follow these guidelines when you enable Layer 3 portal authentication:

- The destination port number that the device uses for sending unsolicited packets to the portal server must be the same as the port number that the remote portal server actually uses.
- Cross-subnet authentication mode (**portal server server-name method layer3**) does not require Layer 3 forwarding devices between the access device and the authentication clients. However, if Layer 3 forwarding devices exist between the authentication client and the access device, you must select the cross-subnet portal authentication mode.
- In re-DHCP authentication mode, a client can use a public IP address to send packets before passing portal authentication. However, responses to the packets are restricted.
- An IPv6 portal server does not support the re-DHCP portal authentication mode.
- You can enable both an IPv4 portal server and an IPv6 portal server for Layer 3 portal authentication on an interface, but you cannot enable two IPv4 or two IPv6 portal servers on the interface.

To enable Layer 3 portal authentication:

Step	Command	Remarks
1.	Enter system view.	system-view N/A
2.	Enter interface view.	interface <i>interface-type</i> <i>interface-number</i> N/A
3.	Enable Layer 3 portal authentication on the interface.	portal server server-name method { direct layer3 redhcp } Not enabled by default.

NOTE:

The portal server and its parameters can be deleted or modified only when the portal server is not referenced by any interface.

Controlling access of portal users

Configuring a portal-free rule

A portal-free rule allows specified users to access specified external websites without portal authentication.

The matching items for a portal-free rule include the source and destination IP address, source MAC address, inbound interface, and VLAN. Packets matching a portal-free rule will not trigger portal authentication, so that users sending the packets can directly access the specified external websites.

For Layer 2 portal authentication, you can configure only a portal-free rule that is from any source address to any or a specified destination address. If you configure a portal-free rule that is from any source address to a specified destination address, users can access the specified address directly, without being redirected to the portal authentication page for portal authentication. Usually, you can configure the IP address of a server that provides certain services (such as software upgrading service) as the destination IP address of a portal-free rule, so that Layer 2 portal authentication users can access the services without portal authentication.

Follow these guidelines when you configure a portal-free rule:

- If you specify both a VLAN and an interface in a portal-free rule, the interface must belong to the VLAN. Otherwise, the rule does not take effect.
- You cannot configure two or more portal-free rules with the same filtering criteria. Otherwise, the system prompts that the rule already exists.
- A Layer 2 interface in an aggregation group cannot be specified as the source interface of a portal-free rule, and the source interface of a portal-free rule cannot be added to an aggregation group.

To configure a portal-free rule:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure a portal-free rule.	<ul style="list-style-type: none">• To configure an IPv4 portal-free rule: portal free-rule <i>rule-number</i> { destination { any ip { <i>ip-address</i> mask { <i>mask-length</i> <i>netmask</i> } any } } source { any [interface <i>interface-type interface-number</i> ip { <i>ip-address</i> mask { <i>mask-length</i> <i>mask</i> } any } mac <i>mac-address</i> vlan <i>vlan-id</i>] * } } *• To configure an IPv6 portal-free rule: portal free-rule <i>rule-number</i> { destination { any ipv6 { <i>ipv6-address</i> <i>prefix-length</i> any } } source { any [interface <i>interface-type</i> <i>interface-number</i> ipv6 { <i>ipv6-address</i> <i>prefix-length</i> any } mac <i>mac-address</i> vlan <i>vlan-id</i>] * } } *	Configure at least one command.

NOTE:

Regardless of whether portal authentication is enabled or not, you can only add or remove a portal-free rule. You cannot modify it.

Configuring an authentication source subnet (available only on the HP 5500 EI series)

Only Layer 3 portal authentication supports this feature.

By configuring authentication source subnets, you specify that only HTTP packets from users on the authentication source subnets can trigger portal authentication. If an unauthenticated user is not on any authentication source subnet, the access device discards all the user's HTTP packets that do not match any portal-free rule.

To configure an authentication source subnet:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Configure an authentication source subnet.	portal auth-network <i>network-address</i> { <i>mask-length</i> <i>mask</i> }	Optional. By default, the source IPv4 subnet is 0.0.0.0/0, and the source IPv6 subnet is ::/0, meaning that users from any IPv4 or IPv6 subnet must pass portal authentication to access network resources. You can configure multiple authentication source subnets by executing the portal auth-network command repeatedly.

NOTE:

Configuration of authentication source subnets applies to only cross-subnet authentication. In direct authentication mode, the authentication source subnet is 0.0.0.0/0. In re-DHCP authentication mode, the authentication source subnet of an interface is the subnet to which the private IP address of the interface belongs.

Setting the maximum number of online portal users

You can use this feature to control the total number of online portal users in the system.

If the maximum number of online portal users to be set is less than that of the current online portal users, the limit can be set successfully and does not impact the online portal users, but the system does not allow new portal users to log on until the number drops down below the limit.

To set the maximum number of online portal users allowed in the system:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Set the maximum number of online portal users.	portal max-user <i>max-number</i>	By default, the maximum number is 3000 on the HP 5500 EI series and 1000 on the HP 5500 SI series.

NOTE:

The maximum number of online portal users the switch actually assigns depends on the ACL resources on the switch.

Specifying an authentication domain for portal users

After you specify an authentication domain for portal users on an interface, the device uses the authentication domain for authentication, authorization, and accounting (AAA) of all portal users on the interface, ignoring the domain names carried in the usernames. This allows you to specify different authentication domains for different interfaces as needed.

To specify an authentication domain for portal users on an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify an authentication domain for portal users on the interface.	portal domain [<i>ipv6</i>] <i>domain-name</i>	By default, no authentication domain is specified for portal users.

The switch selects the authentication domain for a portal user on an interface in this order: the authentication domain specified for the interface, the authentication domain carried in the username, and the system default authentication domain. For information about the default authentication domain, see "[Configuring AAA](#)."

Configuring Layer 2 portal authentication to support web proxy

By default, proxied HTTP requests cannot trigger Layer 2 portal authentication but are silently dropped. To allow such HTTP requests to trigger portal authentication, configure the port numbers of the web proxy servers on the switch.

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover web proxy servers, add the port numbers of the web proxy servers on the switch, and configure portal-free rules to allow user packets destined for the IP address of the WPAD server to pass without authentication.

You must add the port numbers of the web proxy servers on the switch and users must make sure their browsers that use a web proxy server do not use the proxy server for the listening IP address of the local portal server. Thus, HTTP packets that the portal user sends to the local portal server are not sent to the web proxy server.

To configure Layer 2 portal authentication to support a web proxy:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Add a web proxy server port number.	portal web-proxy port <i>port-number</i>	By default, no web proxy server port number is configured and proxied HTTP requests cannot trigger portal authentication.

Enabling support for portal user moving

Only Layer 2 portal authentication supports this feature.

In scenarios where there are hubs, Layer 2 switches, or APs between users and the access devices, if an authenticated user moves from the current access port to another Layer 2-portal-authentication-enabled port of the device without logging off, the user cannot get online when the original port is still up. The reason is that the original port is still maintaining the authentication information of the user and the device does not permit such a user to get online from another port by default.

To solve the problem described above, enable support for portal user moving on the device. Then, when a user moves from a port of the device to another, the device provides services in either of the following ways:

- If the original port is still up and the two ports belong to the same VLAN, the device allows the user to continue to access the network without re-authentication, and uses the new port information for user accounting.
- If the original port is down or the two ports belong to different VLANs, the device removes the authentication information of the user from the original port and authenticates the user on the new port.

To enable support for portal user moving:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enable support for portal user moving.	portal move-mode auto	Disabled by default

For a user with authorization information (such as authorized VLAN) configured, after the user moves from a port to another, the switch tries to assign the authorization information to the new port. If the operation fails, the switch deletes the user's information from the original port and re-authenticates the user on the new port.

Specifying an Auth-Fail VLAN for portal authentication

Only Layer 2 portal authentication supports this feature.

This task sets the Auth-Fail VLAN to be assigned to users failing portal authentication. You can specify different Auth-Fail VLANs for portal authentication on different ports. A port can be specified with only one Auth-Fail VLAN for portal authentication.

Before specifying an Auth-Fail VLAN, be sure to create the VLAN.

To specify an Auth-Fail VLAN for portal authentication:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter Layer 2 Ethernet interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify an Auth-Fail VLAN for portal authentication on the port.	portal auth-fail vlan <i>authfail-vlan-id</i>	Not specified by default

After you specify an Auth-Fail VLAN for portal authentication on a port, you must also enable the MAC-based VLAN function on the port to make the specified Auth-Fail VLAN take effect. For information about MAC VLAN, see *Layer 2—LAN Switching Configuration Guide*.

The MAC-VLAN entries generated in response to portal authentication failures do not overwrite the MAC-VLAN entries already generated in other authentication modes.

Configuring RADIUS related attributes

Only Layer 3 portal authentication supports this feature.

Specifying NAS-Port-Type for an interface

NAS-Port-Type is a standard RADIUS attribute for indicating a user access port type. With this attribute specified on an interface, when a portal user logs on from the interface, the device uses the specified NAS-Port-Type value as that in the RADIUS request to be sent to the RADIUS server. If NAS-Port-Type is not specified, the device uses the access port type obtained.

If there are multiple network devices between the Broadband Access Server (BAS, the portal authentication access device) and a portal client, the BAS may not be able to obtain a user's correct access port information. For example, for a wireless client using portal authentication, the access port type obtained by the BAS may be the type of the wired port that authenticates the user. To make sure that the BAS delivers the right access port information to the RADIUS server, specify the NAS-Port-Type according to the practical access environment.

To specify the NAS-Port-Type value for an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Specify the NAS-Port-Type value for the interface.	portal nas-port-type { ethernet wireless }	Not configured by default

Specifying a NAS ID profile for an interface

In some networks, users' access points are identified by their access VLANs. Network carriers need to use NAS-identifiers to identify user access points. With a NAS ID profile specified on an interface, when a user logs in from the interface, the access device checks the specified profile to obtain the NAS ID that is bound with the access VLAN. The value of this NAS ID is used as that of the NAS-identifier attribute in the RADIUS packets to be sent to the RADIUS server.

A NAS ID profile defines the binding relationship between VLANs and NAS IDs. A NAS ID-VLAN binding is defined by the **nas-id id-value bind vlan vlan-id** command, which is described in detail in AAA configuration commands in the *Security Command Reference*.

If no NAS-ID profile is specified for an interface or no matching binding is found in the specified profile, the switch uses the device name as the interface NAS ID.

To configure a NAS ID profile for an interface:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Create a NAS ID profile and enter NAS ID profile view.	aaa nas-id profile <i>profile-name</i>	For more information about the command, see <i>Security Command Reference</i> .
3. Bind a NAS ID with a VLAN.	nas-id nas-identifier bind vlan <i>vlan-id</i>	For more information about the command, see <i>Security Command Reference</i> .
4. Return to system view.	quit	N/A
5. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
6. Specify a NAS ID profile for the interface.	portal nas-id-profile <i>profile-name</i>	By default, an interface is specified with no NAS ID profile.

Specifying a source IP address for outgoing portal packets

After you specify a source IP address for outgoing portal packets on an interface, the IP address is used as the source IP address of packets that the access device sends to the portal server, and the destination IP address of packets that the portal server sends to the access device.

To specify a source IP address for outgoing portal packets to be sent:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A

Step	Command	Remarks
3.	Specify a source IP address for outgoing portal packets.	Optional. By default, no source IP address is specified for outgoing portal packets and the IP address of the user logon interface is used as the source IP address of the outgoing portal packets. In NAT environments, HP recommends specifying the interface's public IP address as the source IP address of outgoing portal packets.

Configuring portal stateful failover (available only on the HP 5500 E1 series)

Only Layer 3 portal authentication supports this feature.

To implement stateful failover for portal, configure VRRP for traffic switchover, and perform the following configurations for service backup on each of the two devices that back up each other:

- Specify an interface for backing up portal services, which is called portal service backup interface in this document, and enable portal on the portal service backup interface. The portal service backup interface is different from the stateful failover interface. Stateful failover interfaces only forward state negotiation messages and backup data.
- Specify the portal group to which the portal service backup interface belongs. Be sure to specify the same portal group for the portal service backup interfaces that back up each other on the two devices.
- Specify the device ID. Make sure that the device ID of the local device is different from that of the peer device.
- Specify the backup source IP address for RADIUS packets to be sent as the source IP address for RADIUS packets that is configured on the peer device, so that the peer device can receive packets from the server. (This configuration is optional.)
- Specify the backup VLAN, and enable stateful failover. For related configuration, see *High Availability Configuration Guide*.

After the working state of the two devices changes from independence to synchronization and the portal group takes effect, the two devices start to back up the data of online portal users for each other.

The AAA and portal configuration must be consistent on the two devices that back up each other. For example, you must configure the same portal server on the two devices.

To configure stateful failover:

Step	Command	Remarks
1.	Enter system view.	N/A
2.	Enter interface view.	N/A

Step	Command	Remarks
3. Specify the portal group to which the portal service backup interface belongs.	portal backup-group <i>group-id</i>	By default, the portal service backup interface does not belong to any portal group. The portal service backup interfaces on the two devices for stateful failover must belong to the same portal group.
4. Return to system view.	quit	N/A
5. Specify the device ID in stateful failover mode.	nas device-id <i>device-id</i>	By default, the device operates in stand-alone mode, and thus has no device ID configured. For more information about the command, see <i>Security Command Reference</i> .
	radius nas-backup-ip <i>ip-address</i>	Optional. Use either approach. By default, no backup source IP address is specified.
6. Specify the backup source IP address for RADIUS packets to be sent.	radius scheme <i>radius-scheme-name</i> nas-backup-ip <i>ip-address</i>	You do not need to specify the backup source IP address if the device uses the virtual IP address of the VRRP group to which the uplink belongs as the source IP address of outgoing RADIUS packets. For more information about the command, see <i>Security Command Reference</i> .

After you configure portal stateful failover for two devices, note the following issues:

- In stateful failover mode, the device does not support re-DHCP portal authentication on the portal service backup interface.
- In stateful failover mode, if a user on either device is logged out, the information of the user on the other device is deleted, too. You can log off a user on the device or on the portal server. For example, you can use the **cut connection** and **portal delete-user** commands on the device to log off users.
- Specifying or changing the device ID of a device will log off all online users on the device. Therefore, perform the configuration only when necessary and, after the configuration, save the configuration and restart the device.
- Do not delete the configured backup source IP addresses. Otherwise, online users on the backup device may not be able to receive packets from the server.

Specifying an auto redirection URL for authenticated portal users

After a user passes portal authentication, if the access device is configured with an auto redirection URL, it redirects the user to the URL after a specified period of time.

Follow these guidelines to specify an auto redirection URL for authenticated portal users:

- To use this feature for remote Layer 3 portal authentication, the portal server must be the IMC portal server that supports the page auto-redirection function.
- The **wait-time** *period* option is effective to only local portal authentication.
- When no auto redirection URL is specified for authenticated portal users, an authenticated user is usually redirected to the URL the user typed in the address bar before portal authentication. However, with local portal authentication, if the URL a user typed in the address bar before portal authentication is more than 255 characters, the user cannot be redirected to the page of the URL after passing portal authentication.

To specify an auto redirection URL for authenticated portal users:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Specify an auto redirection URL for authenticated portal users.	portal redirect-url <i>url-string</i> [wait-time <i>period</i>]	By default, an authenticated user is redirected to the URL the user typed in the address bar before portal authentication.

Configuring portal detection functions

Configuring online Layer 2 portal user detection

Only Layer 2 portal authentication supports this feature.

After a Layer 2 portal user gets online, the device starts a detection timer for the user, and checks whether the user's MAC address entry has been aged out or the user's MAC address entry has been matched (a match means a packet has been received from the user) at the interval. If the device finds no MAC address entry for the user or receives no packets from the user during two successive detection intervals, the device considers that the user has gone offline and clears the authentication information of the user.

To set the Layer 2 portal user detection interval:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Enter interface view.	interface <i>interface-type</i> <i>interface-number</i>	N/A
3. Set the Layer 2 portal user detection interval.	portal offline-detect interval <i>offline-detect-interval</i>	300 seconds by default

Configuring the portal server detection function (available only on the HP 5500 EI series)

Only Layer 3 portal authentication supports this feature.

During portal authentication, if the communication between the access device and portal server is broken, new portal users are not able to log on and the online portal users are not able to log off normally. To address this problem, the access device must be able to detect the reachability changes of the portal server quickly and take corresponding actions to deal with the changes. For example, after the access device detects that the portal server is unreachable, it allows portal users to access network resources without authentication. This function is referred to as "portal authentication bypass." It allows for flexible user access control.

With the portal server detection function, the device can detect the status of a specific portal server. The specific configurations include:

1. Detection methods (you can choose either or both)
 - **Probing HTTP connections**—The access device periodically sends TCP connection requests to the HTTP service port of the portal servers configured on its interfaces. If the TCP connection with a portal server can be established, the access device considers that the probe succeeds (the HTTP service of the portal server is open and the portal server is reachable). If the TCP connection cannot be established, the access device considers that the probe fails and the portal server is unreachable.
 - **Probing portal heartbeat packets**—A portal server that supports the portal heartbeat function, (only the IMC portal server supports this function), sends portal heartbeat packets to portal access devices periodically. If an access device receives a portal heartbeat packet or an authentication packet within a probe interval, the access device considers that the probe succeeds and the portal server is reachable; otherwise, it considers that the probe fails and the portal server is unreachable.
2. Probe parameters
 - **Probe interval**—Interval at which probe attempts are made.
 - **Maximum number of probe attempts**—Maximum number of consecutive probe attempts allowed. If the number of consecutive probes reaches this value, the access device considers that the portal server is unreachable.
3. Actions to be taken when the server reachability status changes (you can choose one or more)
 - **Sending a trap message**—When the status of a portal server changes, the access device sends a trap message to the network management server (NMS). The trap message contains the portal server name and the current state of the portal server.
 - **Sending a log**—When the status of a portal server changes, the access device sends a log message. The log message indicates the portal server name and the current state and original state of the portal server.
 - **Disabling portal authentication (enabling portal authentication bypass)**—When the device detects that a portal server is unreachable, it disables portal authentication on the interfaces that use the portal server (allows all portal users on the interfaces to access network resources). When the device receives from the portal server portal heartbeat packets or authentication packets (such as logon requests and logout requests), it re-enables the portal authentication function.

You can configure any combination of the configuration items described as needed, with respect to the following:

- If both detection methods are specified, a portal server is regarded as unreachable as long as one detection method fails, and an unreachable portal server is regarded as recovered only when both detection methods succeed.
- If multiple actions are specified, the access device executes all the specified actions when the status of a portal server changes.

- The detection function configured for a portal server takes effect on an interface only after you enable portal authentication and reference the portal server on the interface.

To configure the portal server detection function:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the portal server detection function.	portal server <i>server-name</i> server-detect method { http portal-heartbeat } * action { log permit-all trap } * [interval <i>interval</i>] [retry <i>retries</i>]	Not configured by default. The portal server specified in the command must exist.

The portal heartbeat detection method works only when the portal server supports the portal server heartbeat function. Only the IMC portal server supports the portal server heartbeat function. To implement detection with this method, you also need to configure the portal server heartbeat function on the IMC portal server and make sure that the product of **interval** and **retry** is greater than or equal to the portal server heartbeat interval. HP recommends configuring the **interval** to be greater than the portal server heartbeat interval configured on the portal server.

Configuring portal user information synchronization (available only on the HP 5500 EI series)

Only Layer 3 portal authentication supports this feature.

Once the device loses communication with a portal server, the portal user information on the device and that on the portal server may be inconsistent after the communication resumes. To solve this problem, the device provides the portal user information synchronization function. This function is implemented by sending and detecting the portal synchronization packet. The process is as follows:

1. The portal server sends the online user information to the access device in a user synchronization packet at the user heartbeat interval, which is set on the portal server.
2. Upon receiving the user synchronization packet, the access device checks the user information carried in the packet with its own. If the device finds a nonexistent user in the packet, it informs the portal server of the information and the portal server will delete the user. If the device finds that one of its users does not appear in the user synchronization packets within N consecutive synchronization probe intervals (N is equal to the value of *retries* configured in the **portal server user-sync** command), it considers that the user does not exist on the portal server and logs the user off.

To configure the portal user information synchronization function:

Step	Command	Remarks
1. Enter system view.	system-view	N/A
2. Configure the portal user information synchronization function.	portal server <i>server-name</i> user-sync [interval <i>interval</i>] [retry <i>retries</i>]	Not configured by default. The portal server specified in the command must exist. This function can take effect only when the specified portal server is referenced on the interface connecting the users.

The user information synchronization function requires that a portal server supports the portal user heartbeat function. Only the IMC portal server supports the portal user heartbeat function. To implement the portal user synchronization function, you also need to configure the user heartbeat function on the portal server and make sure the product of **interval** and **retry** is greater than or equal to the portal user heartbeat interval. HP recommends that you configure the **interval** to be greater than the portal user heartbeat interval configured on the portal server.

For redundant user information on the device (information for users who are considered nonexistent on the portal server), the device deletes the information during the (N+1)th interval, where N is equal to the value of *retries* configured in the **portal server user-sync** command.

Logging off portal users

Logging off a user terminates the authentication process for the user or removes the user from the authenticated users list.

To log off users:

Step	Command
1. Enter system view.	system-view
2. Log off users.	portal delete-user { <i>ipv4-address</i> all interface <i>interface-type</i> <i>interface-number</i> ipv6 <i>ipv6-address</i> }

Displaying and maintaining portal

Task	Command	Remarks
Display the ACLs on an interface (available only on the HP 5500 EI series).	display portal acl { all dynamic static } interface <i>interface-type</i> <i>interface-number</i> [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display portal connection statistics on a specific interface or all interfaces (available only on the HP 5500 EI series).	display portal connection statistics { all interface <i>interface-type</i> <i>interface-number</i> } [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about a portal-free rule or all portal-free rules.	display portal free-rule [<i>rule-number</i>] [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display the portal configuration of an interface.	display portal interface <i>interface-type</i> <i>interface-number</i> [[{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display configuration information about the local portal server.	display portal local-server [[{ begin exclude include } <i>regular-expression</i>]	Available in any view

Task	Command	Remarks
Display information about a specific portal server or all portal servers (available only on the HP 5500 EI series).	display portal server [<i>server-name</i>] [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display portal server statistics on a specific interface or all interfaces (available only on the HP 5500 EI series).	display portal server statistics { all interface <i>interface-type interface-number</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display TCP spoofing statistics.	display portal tcp-cheat statistics [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Display information about portal users on a specific interface or all interfaces.	display portal user { all interface <i>interface-type interface-number</i> } [{ begin exclude include } <i>regular-expression</i>]	Available in any view
Clear portal connection statistics on a specific interface or all interfaces (available only on the HP 5500 EI series).	reset portal connection statistics { all interface <i>interface-type interface-number</i> }	Available in user view
Clear portal server statistics on a specific interface or all interfaces (available only on the HP 5500 EI series).	reset portal server statistics { all interface <i>interface-type interface-number</i> }	Available in user view
Clear TCP spoofing statistics.	reset portal tcp-cheat statistics	Available in user view

Portal configuration examples

The HP 5500 EI series supports Layer 2 and Layer 3 portal authentication. The HP 5500 SI series supports only Layer 2 portal authentication. Therefore, only the example "[Configuring Layer 2 portal authentication](#)" is applicable to the HP 5500 SI series.

Configuring direct portal authentication

Network requirements

As shown in [Figure 60](#):

- The host is directly connected to the switch and the switch is configured for direct authentication. The host is assigned with a public network IP address either manually or through DHCP. Before passing portal authentication, users can access only the portal server. After passing portal authentication, users can access Internet resources.
- A RADIUS server serves as the authentication, authorization, and accounting server.

Figure 60 Network diagram

Configure IP addresses for the host, switch, and servers as shown in Figure 60 and make sure that they can reach each other.

Configure the RADIUS server properly to provide authentication and accounting functions for users.

Configuring the portal server (IMC PLAT 5.0)

This example assumes that the portal server runs on IMC PLAT 5.0(E0101) and IMC UAM 5.0(E0101).

Configure the portal server.

Log in to IMC and select the **Service** tab. Then, select **User Access Manager > Portal Service Management > Server** from the navigation tree to enter the portal server configuration page, as shown in Figure 61.

- Configure the portal server parameters as needed. This example uses the default settings.

Figure 61 Portal server configuration

The screenshot shows the IMC configuration interface for a Portal Server. The breadcrumb path is Service >> User Access Manager >> Portal Service Management >> Server. The configuration is divided into Basic Information and Advanced Information sections.

Basic Information:

- Log Level: Info
- Request Timeout: 5 Seconds
- Server Heartbeat Interval: 20 Seconds
- User Heartbeat Interval: 5 Minutes
- Portal Page: http://192.168.0.111:8080/portal

Advanced Information:

Service Type List

Add

Total Items: 0.

Service Type ID	Service Type	Delete
-----------------	--------------	--------

OK

Configure the IP address group.

Select **User Access Manager > Portal Service Management > IP Group** from the navigation tree to enter the portal IP address group configuration page. Then, click **Add** to enter the page shown in [Figure 62](#).

- Enter the IP group name.
- Enter the start IP address and end IP address of the IP group. Make sure that the host IP address is in the IP group.
- Select a service group. By default, the group **Ungrouped** is used.
- Select the IP group type **Normal**.

Figure 62 Adding an IP address group

Service >> User Access Manager >> Portal Service Management >> Portal IP Group Configuration >> Add IP Group

Add IP Group

* IP Group Name

* Start IP

* End IP

Service Group ▼

* Action ▼

OK Cancel

Add a portal device.

Select **User Access Manager > Portal Service Management > Device** from the navigation tree to enter the portal device configuration page. Then, click **Add** to enter the page shown in [Figure 63](#).

- Enter the device name **NAS**.
- Enter the IP address of the switch's interface connected to the user.
- Enter the key, which must be the same as that configured on the switch.
- Set whether to enable IP address reallocation. This example uses direct portal authentication, and therefore select **No** from the **Reallocate IP** list.
- Select whether to support sever heartbeat and user heartbeat functions. In this example, select **No** for both **Support Server Heartbeat** and **Support User Heartbeat**.

Figure 63 Adding a portal device

Service >> User Access Manager >> Portal Service Management >> Portal Device Configuration >> Add Device

Add Device

* Device Name	<input type="text" value="NAS"/>	* IP Address	<input type="text" value="2.2.2.1"/>
* Version	<input type="text" value="Portal 2.0"/> ▾	* Key	<input type="text" value="portal"/>
* Listening Port	<input type="text" value="2000"/>	* Local Challenge	<input type="text" value="No"/> ▾
* Authentication Retries	<input type="text" value="2"/>	* Logout Retries	<input type="text" value="4"/>

Device Description	<input type="text"/>		

Associate the portal device with the IP address group.

As shown in [Figure 64](#), click the icon in the **Port Group Information Management** column of device **NAS** to enter the port group configuration page.

Figure 64 Device list

Device Information List							
<input type="button" value="Add"/>							
1-2 of 2. Page 1 of 1.						Items per Page: 8 15 [50] 100 200	
Device Name	Version	Service Group	IP Address	Port Group Information Management	Details	Modify	Delete
NAS	Portal 2.0	Ungrouped	2.2.2.1				

On the port group configuration page, click **Add** to enter the page shown in [Figure 65](#). Perform the following configurations:

- Enter the port group name.
- Select the configured IP address group. The IP address used by the user to access the network must be within this IP address group.
- Use the default settings for other parameters.

Figure 65 Adding a port group

The screenshot shows the 'Add Port Group Info' configuration window. The fields are as follows:

- Port Group Name: group
- Start Port: 0
- End Port: zzzzzz
- Protocol: HTTP
- NAT or Not: No
- Authentication Type: CHAP
- Heartbeat Interval: 10 Minutes
- Language: Dynamic Detection
- Quick Authentication: No
- Error Transparent Transmission: Yes
- IP Group: Portal_user
- Heartbeat Timeout: 30 Minutes
- User Domain: (empty)
- Port Group Description: (empty)
- User Attribute Type: (empty)
- Default Authentication Type: Web Identity AuthN
- Default Authentication Page: index_default.jsp

Buttons: OK, Cancel

Select **User Access Manager > Service Parameters > Validate System Configuration** from the navigation tree to validate the configurations.

Configuring the switch

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Set the server type for the RADIUS scheme. When using the IMC server, set the server type to **extended**.

```
[Switch-radius-rs1] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.112
[Switch-radius-rs1] primary accounting 192.168.0.112
[Switch-radius-rs1] key authentication radius
[Switch-radius-rs1] key accounting radius
```

Specify that the ISP domain name should not be included in the username sent to the RADIUS server.

```
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure dm1 as the default ISP domain for all users. Then, if a user enters the username without the ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal server on the switch, making sure that the IP address, port number and URL match those of the actual portal server.

```
[Switch] portal server newpt ip 192.168.0.111 key portal port 50100 url  
http://192.168.0.111:8080/portal
```

Enable portal authentication on the interface connecting the host.

```
[Switch] interface vlan-interface 100  
[Switch-Vlan-interface100] portal server newpt method direct  
[Switch-Vlan-interface100] quit
```

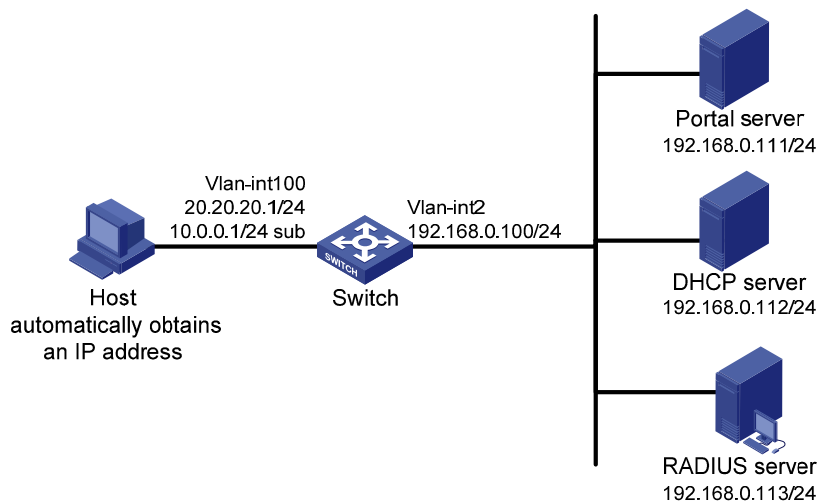

Configuring re-DHCP portal authentication

Network requirements

As shown in Figure 66:

- The host is directly connected to the switch and the switch is configured for re-DHCP authentication. The host is assigned with an IP address through the DHCP server. Before passing portal authentication, the host uses an assigned private IP address. After passing portal authentication, the host can get a public IP address and access Internet resources.
- A RADIUS server serves as the authentication/accounting server.

Figure 66 Network diagram

Configuration procedure

When you configure re-DHCP portal authentication, follow these guidelines:

- Configure a public address pool (20.20.20.0/24, in this example) and a private address pool (10.0.0.0/24, in this example) on the DHCP server. (Details not shown)
- The switch must be configured as a DHCP relay agent and the portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private

IP address). For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.

- Make sure the IP address of the portal device added on the portal server is the public IP address of the interface connecting users (20.20.20.1 in this example), the private IP address range for the IP address group associated with the portal device is the private network segment where the users reside (10.0.0.0/24 in this example), and the public IP address range for the IP address group is the public network segment 20.20.20.0/24.
- Configure IP addresses for the switch and servers as shown in [Figure 66](#) and make sure that the host, switch, and servers can reach each other.
- Configure the RADIUS server properly to provide authentication and accounting functions for users.

Perform the following configuration to configure re-DHCP authentication on the switch:

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
```

```
[Switch] radius scheme rs1
```

Set the server type for the RADIUS scheme. When using the IMC server, set the server type to **extended**.

```
[Switch-radius-rs1] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.113
```

```
[Switch-radius-rs1] primary accounting 192.168.0.113
```

```
[Switch-radius-rs1] key authentication radius
```

```
[Switch-radius-rs1] key accounting radius
```

Specify that the ISP domain name should not be included in the username sent to the RADIUS server.

```
[Switch-radius-rs1] user-name-format without-domain
```

```
[Switch-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
```

```
[Switch-isp-dm1] authorization portal radius-scheme rs1
```

```
[Switch-isp-dm1] accounting portal radius-scheme rs1
```

```
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain for all users. Then, if a user enters the username without the ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure the portal server as follows:

- Name: newpt
- IP address: 192.168.0.111
- Key: portal

- Port number: 50100
- URL: `http://192.168.0.111:8080/portal`.

```
[Switch] portal server newpt ip 192.168.0.111 key portal port 50100 url
http://192.168.0.111:8080/portal
```

Configure the switch as a DHCP relay agent, and enable the IP address check function.

```
[Switch] dhcp enable
[Switch] dhcp relay server-group 0 ip 192.168.0.112
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] ip address 20.20.20.1 255.255.255.0
[Switch-Vlan-interface100] ip address 10.0.0.1 255.255.255.0 sub
[Switch-Vlan-interface100] dhcp select relay
[Switch-Vlan-interface100] dhcp relay server-select 0
[Switch-Vlan-interface100] dhcp relay address-check enable
```

Enable re-DHCP portal authentication on the interface connecting the host.

```
[Switch-Vlan-interface100] portal server newpt method redhcp
[Switch-Vlan-interface100] quit
```

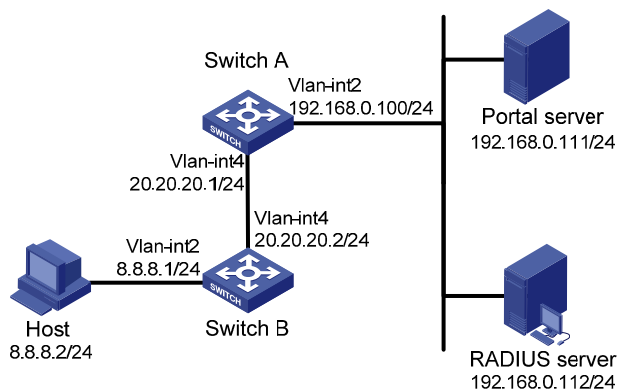

Configuring cross-subnet portal authentication

Network requirements

As shown in [Figure 67](#):

- Switch A is configured for cross-subnet portal authentication. Before passing portal authentication, the host can access only the portal server. After passing portal authentication, the host can access Internet resources.
- The host accesses Switch A through Switch B.
- A RADIUS server serves as the authentication/accounting server.

Figure 67 Network diagram

Configuration procedure

When configuring cross-subnet portal authentication, follow these guidelines:

- Configure IP addresses for the host, switches, and servers as shown in [Figure 67](#) and make sure they can reach each other.
- Configure the RADIUS server properly to provide authentication and accounting functions for users.

- Make sure the IP address of the portal device added on the portal server is the IP address of the interface connecting users (20.20.20.1 in this example), and the IP address group associated with the portal device is the network segment where the users reside (8.8.8.0/24 in this example).

Perform the following configuration to configure cross-subnet portal authentication on Switch A:

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<SwitchA> system-view
```

```
[SwitchA] radius scheme rs1
```

Set the server type for the RADIUS scheme. When using the IMC server, set it to **extended**.

```
[SwitchA-radius-rs1] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[SwitchA-radius-rs1] primary authentication 192.168.0.112
```

```
[SwitchA-radius-rs1] primary accounting 192.168.0.112
```

```
[SwitchA-radius-rs1] key authentication radius
```

```
[SwitchA-radius-rs1] key accounting radius
```

Specify that the ISP domain name should not be included in the username sent to the RADIUS server.

```
[SwitchA-radius-rs1] user-name-format without-domain
```

```
[SwitchA-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[SwitchA] domain dm1
```

Configure AAA methods for the ISP domain.

```
[SwitchA-isp-dm1] authentication portal radius-scheme rs1
```

```
[SwitchA-isp-dm1] authorization portal radius-scheme rs1
```

```
[SwitchA-isp-dm1] accounting portal radius-scheme rs1
```

```
[SwitchA-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain for all users. Then, if a user enters the username without the ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.

```
[SwitchA] domain default enable dm1
```

3. Configure portal authentication:

Configure the portal server as follows:

- Name: newpt
- IP address: 192.168.0.111
- Key: portal
- Port number: 50100
- URL: http://192.168.0.111:8080/portal.

```
[SwitchA] portal server newpt ip 192.168.0.111 key portal port 50100 url
```

```
http://192.168.0.111:8080/portal
```

Enable portal authentication on the interface connecting Switch B.

```
[SwitchA] interface vlan-interface 4
```

```
[SwitchA-Vlan-interface4] portal server newpt method layer3
```

```
[SwitchA-Vlan-interface4] quit
```

On Switch B, configure a default route to subnet 192.168.0.0/24, setting the next hop as 20.20.20.1. (Details not shown.)

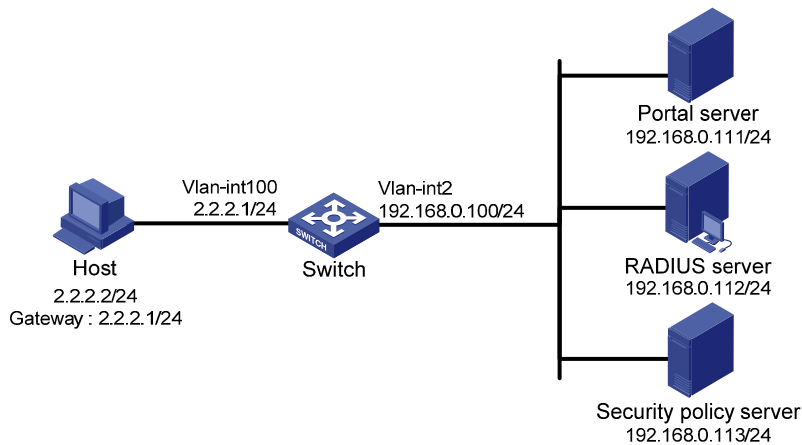

Configuring direct portal authentication with extended functions

Network requirements

As shown in [Figure 68](#):

- The host is directly connected to the switch and the switch is configured for direct extended portal authentication. The host is assigned with a public network IP address either manually or through DHCP. If the host fails security check after passing identity authentication, the host can access only subnet 192.168.0.0/24. After passing security check, the host can access Internet resources.
- A RADIUS server serves as the authentication/accounting server.

Figure 68 Network diagram

Configuration procedure

Configure IP addresses for the host, switch, and servers as shown in [Figure 68](#) and make sure they can reach each other.

Configure the RADIUS server properly to provide authentication and accounting functions for users.

Configure the switch:

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Set the server type for the RADIUS scheme. When using the IMC server, set the server type to **extended**.

```
[Switch-radius-rs1] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.112
[Switch-radius-rs1] primary accounting 192.168.0.112
[Switch-radius-rs1] key accounting radius
```

```
[Switch-radius-rs1] key authentication radius
[Switch-radius-rs1] user-name-format without-domain
# Configure the IP address of the security policy server.
[Switch-radius-rs1] security-policy-server 192.168.0.113
[Switch-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain for all users. Then, if a user enters the username without the ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure the ACL (ACL 3000) for resources on subnet 192.168.0.0/24 and the ACL (ACL 3001) for Internet resources:

```
[Switch] acl number 3000
[Switch-acl-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
[Switch-acl-adv-3000] rule deny ip
[Switch-acl-adv-3000] quit
[Switch] acl number 3001
[Switch-acl-adv-3001] rule permit ip
[Switch-acl-adv-3001] quit
```

On the security policy server, specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

4. Configure portal authentication:

Configure the portal server as follows:

- Name: newpt
- IP address: 192.168.0.111
- Key: portal
- Port number: 50100
- URL: <http://192.168.0.111:8080/portal>.

```
[Switch] portal server newpt ip 192.168.0.111 key portal port 50100 url
http://192.168.0.111:8080/portal
```

Configure a portal-free rule on the interface connecting the portal server.

```
[Switch] portal free-rule 1 source interface ethernet 1/0/1 destination any
[Switch] quit
```

Enable portal authentication on the interface connecting the host.

```
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] portal server newpt method direct
[Switch-Vlan-interface100] quit
```

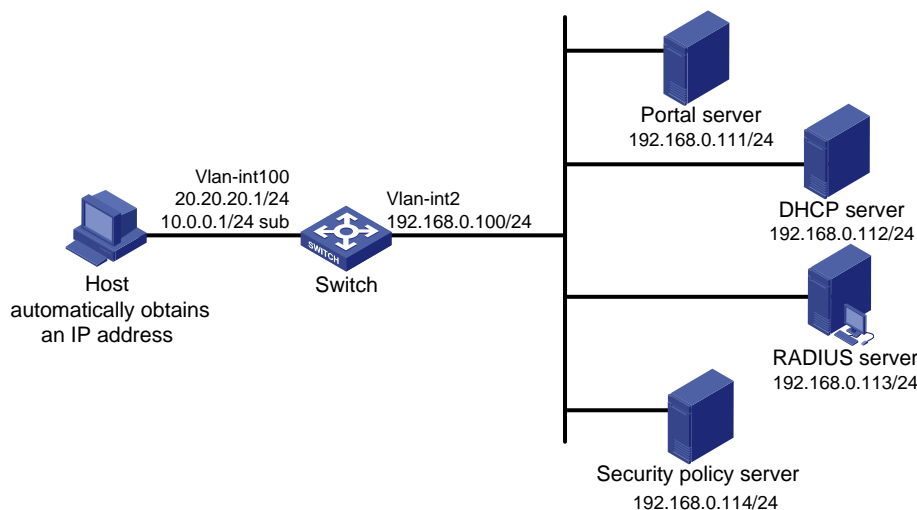

Configuring re-DHCP portal authentication with extended functions

Network requirements

As shown in [Figure 69](#):

- The host is directly connected to the switch and the switch is configured for re-DHCP authentication. The host is assigned with an IP address through the DHCP server. Before passing portal authentication, the host uses an assigned private IP address. After passing portal authentication, the host can get a public IP address.
- If the host fails security check after passing identity authentication, the host can access only subnet 192.168.0.0/24. After passing the security check, the host can access Internet resources.
- A RADIUS server serves as the authentication/accounting server.

Figure 69 Network diagram

Configuration procedure

When you configure re-DHCP portal authentication, follow these guidelines:

- For re-DHCP portal authentication, configure a public address pool (20.20.20.0/24, in this example) and a private address pool (10.0.0.0/24, in this example) on the DHCP server. (Details not shown)
- For re-DHCP portal authentication, the switch must be configured as a DHCP relay agent and the portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private IP address). For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.
- Make sure the IP address of the portal device added on the portal server is the public IP address of the interface connecting users (20.20.20.1 in this example), the private IP address range for the IP address group associated with the portal device is the private network segment where the users reside (10.0.0.0/24 in this example), and the public IP address range for the IP address group is the public network segment 20.20.20.0/24.
- Configure IP addresses for the switch and servers as shown in [Figure 69](#) and make sure that the host, switch, and servers can reach each other.
- Configure the RADIUS server properly to provide authentication and accounting functions for users.

Perform the following configuration to configure re-DHCP portal authentication with extended functions on the switch:

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
```

```
[Switch] radius scheme rs1
```

Set the server type for the RADIUS scheme. When using the IMC server, set the server type to **extended**.

```
[Switch-radius-rs1] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.113
```

```
[Switch-radius-rs1] primary accounting 192.168.0.113
```

```
[Switch-radius-rs1] key accounting radius
```

```
[Switch-radius-rs1] key authentication radius
```

```
[Switch-radius-rs1] user-name-format without-domain
```

Configure the IP address of the security policy server.

```
[Switch-radius-rs1] security-policy-server 192.168.0.114
```

```
[Switch-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
```

```
[Switch-isp-dm1] authorization portal radius-scheme rs1
```

```
[Switch-isp-dm1] accounting portal radius-scheme rs1
```

```
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain for all users. Then, if a user enters the username without the ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure the ACL (ACL 3000) for resources on subnet 192.168.0.0/24 and the ACL (ACL 3001) for Internet resources:

```
[Switch] acl number 3000
```

```
[Switch-acl-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
```

```
[Switch-acl-adv-3000] rule deny ip
```

```
[Switch-acl-adv-3000] quit
```

```
[Switch] acl number 3001
```

```
[Switch-acl-adv-3001] rule permit ip
```

```
[Switch-acl-adv-3001] quit
```

On the security policy server, specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

4. Configure portal authentication:

Configure the portal server as follows:

- o Name: newpt

- IP address: 192.168.0.111
- Key: portal
- Port number: 50100
- URL: http://192.168.0.111:8080/portal.

```
[Switch] portal server newpt ip 192.168.0.111 key portal port 50100
url http://192.168.0.111:8080/portal
```

Configure the switch as a DHCP relay agent, and enable the IP address check function.

```
[Switch] dhcp enable
[Switch] dhcp relay server-group 0 ip 192.168.0.112
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] ip address 20.20.20.1 255.255.255.0
[Switch-Vlan-interface100] ip address 10.0.0.1 255.255.255.0 sub
[Switch-Vlan-interface100] dhcp select relay
[Switch-Vlan-interface100] dhcp relay server-select 0
[Switch-Vlan-interface100] dhcp relay address-check enable
```

Enable re-DHCP portal authentication on the interface connecting the host.

```
[Switch-Vlan-interface100] portal server newpt method redhcp
[Switch-Vlan-interface100] quit
```

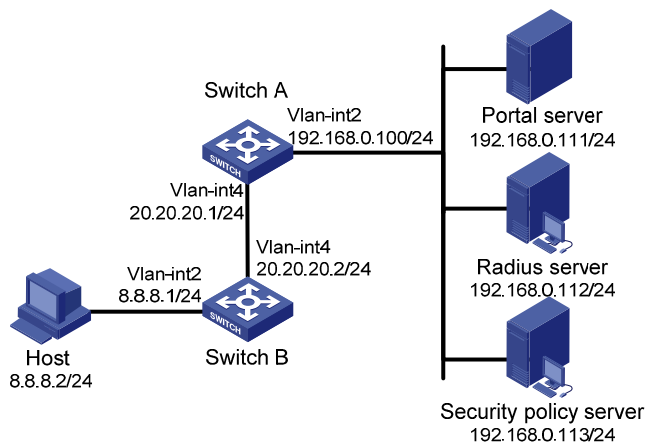

Configuring cross-subnet portal authentication with extended functions

Network requirements

As shown in [Figure 70](#):

- Switch A is configured for cross-subnet extended portal authentication. If the host fails security check after passing identity authentication, the host can access only subnet 192.168.0.0/24. After passing security check, the host can access Internet resources.
- The host accesses Switch A through Switch B.
- A RADIUS server serves as the authentication/accounting server.

Figure 70 Network diagram

Configuration procedure

Make sure the IP address of the portal device added on the portal server is the IP address of the interface connecting users (20.20.20.1 in this example), and the IP address group associated with the portal device is the network segment where the users reside (8.8.8.0/24 in this example).

Configure IP addresses for the host, switches, and servers as shown in [Figure 70](#) and make sure that they can reach each other.

Configure the RADIUS server properly to provide authentication and accounting functions for users.

Configure Switch A:

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<SwitchA> system-view
```

```
[SwitchA] radius scheme rs1
```

Set the server type for the RADIUS scheme. When using the IMC server, set the server type to **extended**.

```
[SwitchA-radius-rs1] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[SwitchA-radius-rs1] primary authentication 192.168.0.112
```

```
[SwitchA-radius-rs1] primary accounting 192.168.0.112
```

```
[SwitchA-radius-rs1] key accounting radius
```

```
[SwitchA-radius-rs1] key authentication radius
```

```
[SwitchA-radius-rs1] user-name-format without-domain
```

Configure the IP address of the security policy server.

```
[SwitchA-radius-rs1] security-policy-server 192.168.0.113
```

```
[SwitchA-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[SwitchA] domain dm1
```

Configure AAA methods for the ISP domain.

```
[SwitchA-isp-dm1] authentication portal radius-scheme rs1
```

```
[SwitchA-isp-dm1] authorization portal radius-scheme rs1
```

```
[SwitchA-isp-dm1] accounting portal radius-scheme rs1
```

```
[SwitchA-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain for all users. Then, if a user enters the username without the ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.

```
[SwitchA] domain default enable dm1
```

3. Configure the ACL (ACL 3000) for resources on subnet 192.168.0.0/24 and the ACL (ACL 3001) for Internet resources:

```
[SwitchA] acl number 3000
```

```
[SwitchA-acl-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
```

```
[SwitchA-acl-adv-3000] rule deny ip
```

```
[SwitchA-acl-adv-3000] quit
```

```
[SwitchA] acl number 3001
```

```
[SwitchA-acl-adv-3001] rule permit ip
```

```
[SwitchA-acl-adv-3001] quit
```

On the security policy server, specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

4. Configure portal authentication

Configure the portal server as follows:

- o Name: newpt
- o IP address: 192.168.0.111
- o Key: portal
- o Port number: 50100
- o URL: http://192.168.0.111:8080/portal.

```
[SwitchA] portal server newpt ip 192.168.0.111 key portal port 50100 url  
http://192.168.0.111:8080/portal
```

Enable portal authentication on the interface connecting Switch B.

```
[SwitchA] interface vlan-interface 4  
[SwitchA-Vlan-interface4] portal server newpt method layer3  
[SwitchA-Vlan-interface4] quit
```

On Switch B, configure a default route to subnet 192.168.0.0/24, setting the next hop as 20.20.20.1. (Details not shown.)

Configuring portal stateful failover

Network requirements

As shown in [Figure 71](#), a failover link is present between Switch A and Switch B. Both Switch A and Switch B support portal authentication. Configure stateful failover between Switch A and Switch B to support portal service backup and use VRRP to implement traffic switchover between the switches. More specifically,

- When Switch A works normally, Host accesses Switch A for portal authentication before accessing the Internet; when Switch A fails, Host accesses the Internet through Switch B. The VRRP uplink/downlink detection mechanism is used to ensure non-stop traffic forwarding.
- Use the RADIUS server as the authentication/accounting server. In this example, Server takes the responsibilities of the portal server and the RADIUS server.
- Switch A and Switch B use the failover link to transmit stateful failover related packets and specify VLAN 8 on the switches as the VLAN dedicated for stateful failover related packets.

Figure 71 Network diagram

Configure IP addresses for the host, server, and switches as shown in [Figure 71](#) and make sure that they can reach to each other.

Make sure that Host can access the authentication server through Switch A and Switch B.

Configure VRRP group 1 and VRRP group 2 to implement backup for downstream and upstream links, respectively. For more information about VRRP, see *High Availability Configuration Guide*.

For information about stateful failover configuration, see *High Availability Configuration Guide*.

Configuring the portal server (IMC PLAT 5.0)

This example assumes that the portal server runs on IMC PLAT 5.0(E0101) and IMC UAM 5.0(E0101).

Configure the portal server.

Log in to IMC and select the **Service** tab. Then, select **User Access Manager > Portal Service Management > Server** from the navigation tree to enter the portal server configuration page, as shown in [Figure 72](#).

Configure the portal server parameters as needed. This example uses the default settings.

Figure 72 Portal server configuration

OK		

Configure the IP address group.

Select **User Access Manager > Portal Service Management > IP Group** from the navigation tree to enter the portal IP address group configuration page. Then, click **Add** to enter the page shown in [Figure 62](#).

- Enter the IP group name.
- Enter the start IP address and end IP address of the IP group. Make sure that the host IP address is in the IP group.
- Select a service group. By default, the group **Ungrouped** is used.
- Select the IP group type **Normal**.

Figure 73 Adding an IP address group

Service >> User Access Manager >> Portal Service Management >> Portal IP Group Configuration >> Add IP Group

Add IP Group

* IP Group Name:

* Start IP:

* End IP:

Service Group: Ungrouped (dropdown)

* Action: Normal (dropdown)

Add a portal device.

Select **User Access Manager > Portal Service Management > Device** from the navigation tree to enter the portal device configuration page. Then, click **Add** to enter the page shown in [Figure 63](#).

- Enter the device name **NAS**.
- Enter the virtual IP address of the VRRP group that holds the portal-enabled interface.
- Enter the key, which must be the same as that configured on the switch.
- Set whether to enable IP address reallocation. This example uses direct portal authentication, and therefore select **No** from the **Reallocate IP** list.
- Select whether to support sever heartbeat and user heartbeat functions. In this example, select **No** for both **Support Server Heartbeat** and **Support User Heartbeat**.

Figure 74 Adding a portal device

Select **User Access Manager > Service Parameters > Validate System Configuration** from the navigation tree to validate the configurations.

Configuring Switch A

1. Configure VRRP:

Create VRRP group 1, and configure the virtual IP address of the VRRP group 1 as 9.9.1.1.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] vrrp vrid 1 virtual-ip 9.9.1.1
```

Set the priority of VLAN-interface 10 in VRRP group 1 to 200.

```
[SwitchA-Vlan-interface10] vrrp vrid 1 priority 200
```

On VLAN-interface 10, configure the interface to be tracked as VLAN-interface 20 and reduce the priority of VLAN-interface 10 in VRRP group 1 by 150 when the interface state of VLAN-interface 20 becomes Down or Removed.

```
[SwitchA-Vlan-interface10] vrrp vrid 1 track interface vlan-interface20 reduced 150
[SwitchA-Vlan-interface10] quit
```

Create VRRP group 2, and configure the virtual IP address of the VRRP group 2 as 192.168.0.1.

```
[SwitchA] interface vlan-interface 20
[SwitchA-Vlan-interface20] vrrp vrid 2 virtual-ip 192.168.0.1
```

Set the priority of VLAN-interface 20 in VRRP group 2 to 200.

```
[SwitchA-Vlan-interface20] vrrp vrid 2 priority 200
```

On VLAN-interface 20, configure the interface to be tracked as VLAN-interface 10 and reduce the priority of VLAN-interface 20 in VRRP group 2 by 150 when the interface state of VLAN-interface 10 becomes Down or Removed.

```
[SwitchA-Vlan-interface20] vrrp vrid 2 track interface vlan-interface10 reduced 150
[SwitchA-Vlan-interface20] quit
```

2. Configure a RADIUS scheme:

Create RADIUS scheme **rs1** and enter its view.

```
[SwitchA] radius scheme rs1
```

Configure the server type for the RADIUS scheme. When using the IMC server, configure the RADIUS server type as **extended**.

```
[SwitchA-radius-rs1] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[SwitchA-radius-rs1] primary authentication 192.168.0.111
```

```
[SwitchA-radius-rs1] primary accounting 192.168.0.111
```

```
[SwitchA-radius-rs1] key authentication expert
```

```
[SwitchA-radius-rs1] key accounting expert
```

Configure the access device to not carry the ISP domain name in the username sent to the RADIUS server. (Optional, configure the username format as needed.)

```
[SwitchA-radius-rs1] user-name-format without-domain
```

```
[SwitchA-radius-rs1] quit
```

3. Configure an authentication domain:

Create ISP domain **dm1** and enter its view.

```
[SwitchA] domain dm1
```

Configure AAA methods for the ISP domain.

```
[SwitchA-isp-dm1] authentication portal radius-scheme rs1
```

```
[SwitchA-isp-dm1] authorization portal radius-scheme rs1
```

```
[SwitchA-isp-dm1] accounting portal radius-scheme rs1
```

```
[SwitchA-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain for all users. Then, if a user enters a username without any ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.

```
[SwitchA] domain default enable dm1
```

4. Enable portal authentication on the interface connecting the host:

Configure a portal server on the switch, making sure that the IP address, port number and URL match those of the actual portal server.

```
[SwitchA] portal server newpt ip 192.168.0.111 key portal port 50100 url
```

```
http://192.168.0.111:8080/portal
```

Enable portal authentication on the interface connecting the host.

```
[SwitchA] interface vlan-interface 10
```

```
[SwitchA-Vlan-interface10] portal server newpt method layer3
```

Specify the source IP address of outgoing portal packets as 9.9.1.1, the virtual IP address of VRRP group 1.

```
[SwitchA-Vlan-interface10] portal nas-ip 9.9.1.1
```

5. Configure portal stateful failover:

Assign interface VLAN-interface 10 to portal group 1.

```
[SwitchA-Vlan-interface10] portal backup-group 1
```

```
[SwitchA-Vlan-interface10] quit
```

Set the device ID for Switch A in stateful failover mode to 1.

```
[SwitchA] nas device-id 1
```

Specify the source IP address of outgoing RADIUS packets as 192.168.0.1, the virtual IP address of VRRP group 2.

```
[SwitchA] radius nas-ip 192.168.0.1
```

Make sure you have added the access device with IP address 192.168.0.1 on the RADIUS server.

6. Configure the stateful failover function:

```
# Configure the VLAN for stateful failover as VLAN 8.
[SwitchA] dnbk vlan 8
# Enable stateful failover and configure it to support the symmetric path.
[SwitchA] dnbk enable backup-type symmetric-path
```

Configuring Switch B

1. Configure VRRP:

```
# Create VRRP group 1, and configure the virtual IP address of the VRRP group 1 as 9.9.1.1.
<SwitchB> system-view
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] vrrp vrid 1 virtual-ip 9.9.1.1
# Set the priority of VLAN-interface 10 in VRRP group 1 to 150.
[SwitchB-Vlan-interface10] vrrp vrid 1 priority 150
[SwitchB-Vlan-interface10] quit
# Create VRRP group 2, and configure the virtual IP address of the VRRP group 2 as 192.168.0.1.
[SwitchB] interface vlan-interface 20
[SwitchB-Vlan-interface20] vrrp vrid 2 virtual-ip 192.168.0.1
# Set the priority of VLAN-interface 20 in VRRP group 2 to 150.
[SwitchB-Vlan-interface20] vrrp vrid 2 priority 150
[SwitchB-Vlan-interface20] quit
```

2. Configure a RADIUS scheme:

```
# Create RADIUS scheme rs1 and enter its view.
[SwitchB] radius scheme rs1
# Configure the server type for the RADIUS scheme. When using the IMC server, configure the
RADIUS server type as extended.
[SwitchB-radius-rs1] server-type extended
# Specify the primary authentication server and primary accounting server, and configure the keys
for communication with the servers.
[SwitchB-radius-rs1] primary authentication 192.168.0.111
[SwitchB-radius-rs1] primary accounting 192.168.0.111
[SwitchB-radius-rs1] key authentication expert
[SwitchB-radius-rs1] key accounting expert
# Configure the access device to not carry the ISP domain name in the username sent to the
RADIUS server. (Optional, configure the username format as needed.)
[SwitchB-radius-rs1] user-name-format without-domain
[SwitchB-radius-rs1] quit
```

3. Configure an authentication domain:

```
# Create ISP domain dm1 and enter its view.
[SwitchB] domain dm1
# Configure AAA methods for the ISP domain.
[SwitchB-isp-dm1] authentication portal radius-scheme rs1
[SwitchB-isp-dm1] authorization portal radius-scheme rs1
[SwitchB-isp-dm1] accounting portal radius-scheme rs1
[SwitchB-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain for all users. Then, if a user enters a username without any ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.

```
[SwitchB] domain default enable dm1
```

4. Enable portal authentication on the interface connecting the host:

Configure the portal server as needed.

```
[SwitchB] portal server newpt ip 192.168.0.111 key portal port 50100 url
http://192.168.0.111:8080/portal
```

Enable portal authentication on the interface connecting the host.

```
[SwitchB] interface vlan-interface 10
```

```
[SwitchB-Vlan-interface10] portal server newpt method layer3
```

Specify the source IP address of outgoing portal packets as 9.9.1.1, the virtual IP address of VRRP group 1.

```
[SwitchA-Vlan-interface10] portal nas-ip 9.9.1.1
```

5. Configure portal stateful failover:

Assign interface VLAN-interface 10 to portal group 1.

```
[SwitchB-Vlan-interface10] portal backup-group 1
```

```
[SwitchB-Vlan-interface10] quit
```

Set the ID of the device in the stateful failover mode to 2.

```
[SwitchB] nas device-id 2
```

Specify the source IP address of outgoing RADIUS packets as 192.168.0.1, the virtual IP address of VRRP group 2.

```
[SwitchB] radius nas-backup-ip 192.168.0.1
```

Make sure you have added the access device with IP address 192.168.0.1 on the RADIUS server.

6. Configure stateful failure:

Configure the VLAN for stateful failover as VLAN 8.

```
[SwitchB] dmbk vlan 8
```

Enable stateful failover and configure it to support the symmetric path.

```
[SwitchB] dmbk enable backup-type symmetric-path
```

Verifying the configuration

After user Host logs in through Switch A, display the user authentication information by using the **display portal user** command on Switch A and Switch B.

```
[SwitchA] display portal user all
```

```
Index:3
```

```
State:ONLINE
```

```
SubState:NONE
```

```
ACL:NONE
```

```
Work-mode: primary
```

```
VPN instance:NONE
```

```
MAC                IP                Vlan  Interface
```

```
-----
```

```
000d-88f8-0eac      9.9.1.2           10    Vlan-interface10
```

```
Total 1 user(s) matched, 1 listed.
```

```
[SwitchB] display portal user all
```

```
Index:2
```

```

State:ONLINE
SubState:NONE
ACL:NONE
Work-mode: secondary
VPN instance:NONE
MAC                IP                Vlan  Interface
-----
000d-88f8-0eac     9.9.1.2          10    Vlan-interface10
Total 1 user(s) matched, 1 listed.

```

The output shows that the information of user Host is saved on both Switch A and Switch B. The user's working mode on Switch A is primary, and that on Switch B is secondary, which indicate that the user logged in through Switch A and the user information on Switch B was synchronized from Switch A.

Configuring portal server detection and portal user information synchronization

Network requirements

As shown in [Figure 77](#), a host is directly connected to a switch (the access device) and must pass portal authentication before it can access the Internet. A RADIUS server serves as the authentication/accounting server.

Detailed requirements are as follows:

- The host is assigned with a public network IP address either manually or through DHCP. Before passing portal authentication, the host can access only the portal server. After passing portal authentication, the host can access the Internet.
- The access device (Switch) can detect whether the portal server is reachable and send trap messages upon state changes. When the portal server is unreachable due to a connection failure, network device failure, or portal server failure, for example, the access device can disable portal authentication, allowing users to access the Internet without authentication.
- The access device can synchronize portal user information with the portal server periodically.

Figure 77 Network diagram

Configuration considerations

1. Configure the portal server and enable portal server heartbeat function and the portal user heartbeat function.
2. Configure the RADIUS server to implement authentication and accounting.

3. Configure direct portal authentication on interface VLAN-interface 100, which is connected with the user host.
4. Configure the portal server detection function on the access device, so that the access device can detect the status of the portal server by cooperating with the portal server heartbeat function.
5. Configure the portal user information synchronization function, so that the access device can synchronize portal user information with the portal server by cooperating with the portal user heartbeat function.

Configure IP addresses for the host, switch, and servers as shown in [Figure 77](#) and make sure that they can reach each other.

Configure the RADIUS server properly to provide authentication and accounting functions for users.

Configuring the portal server (IMC PLAT 5.0)

This example assumes that the portal server runs IMC PLAT 5.0(E0101) and IMC UAM 5.0(E0101).

Configure the portal server.

Log in to IMC and select the **Service** tab. Then, select **User Access Manager > Portal Service Management > Server** from the navigation tree to enter the portal server configuration page, as shown in [Figure 78](#).

- Configure the portal server heartbeat interval and user heartbeat interval.
- Use the default value for other parameters.

Figure 78 Portal server configuration

Configure the IP address group.

Select **User Access Manager > Portal Service Management > IP Group** from the navigation tree to enter the portal IP address group configuration page. Then, click **Add** to enter the page shown in [Figure 62](#).

- Enter the IP group name.

- Enter the start IP address and end IP address of the IP group. Make sure that the host IP address is in the IP group.
- Select a service group. By default, the group **Ungrouped** is used.
- Select the IP group type **Normal**.

Figure 79 Adding an IP address group

Service >> User Access Manager >> Portal Service Management >> Portal IP Group Configuration >> Add IP Group

Add IP Group

Add a portal device.

Select **User Access Manager > Portal Service Management > Device** from the navigation tree to enter the portal device configuration page. Then, click **Add** to enter the page shown in [Figure 63](#).

- Enter the device name **NAS**.
- Enter the IP address of the switch's interface connected to the user.
- Enter the key, which must be the same as that configured on the switch.
- Set whether to enable IP address reallocation. This example uses direct portal authentication, and therefore select **No** from the **Reallocate IP** list.
- Set whether to support the portal server heartbeat and user heartbeat functions. In this example, select **Yes** for both **Support Server Heartbeat** and **Support User Heartbeat**.

Device Name	Version	Service Group	IP Address	Port Group Information Management	Details	Modify	Delete
NAS	Portal 2.0	Ungrouped	2.2.2.1				

On the port group configuration page, click **Add** to enter the page shown in [Figure 65](#). Perform the following configurations:

- Enter the port group name.
- Select the configured IP address group. The IP address used by the user to access the network must be within this IP address group.
- Use the default settings for other parameters.

Figure 82 Adding a port group

Service >> User Access Manager >> Portal Service Management >> Portal Device Configuration >> Port Group Info Config >> Add 

Port Group Info

Add Port Group Info

* Port Group Name	<input type="text" value="group"/>	* Language	Dynamic Detection <input type="button" value="v"/>
* Start Port	<input type="text" value="0"/>	* End Port	<input type="text" value="zzzzz"/>
* Protocol	HTTP <input type="button" value="v"/>	* Quick Authentication	No <input type="button" value="v"/>
* NAT or Not	No <input type="button" value="v"/>	* Error Transparent Transmission	Yes <input type="button" value="v"/>
* Authentication Type	CHAP <input type="button" value="v"/>	* IP Group	Portal_user <input type="button" value="v"/>
* Heartbeat Interval	<input type="text" value="10"/> Minutes	* Heartbeat Timeout	<input type="text" value="30"/> Minutes
User Domain	<input type="text"/>	Port Group Description	<input type="text"/>
User Attribute Type	<input type="button" value="v"/>	Default Authentication Page	<input type="text" value="index_default.jsp"/>
Default Authentication Type	Web Identity AuthN <input type="button" value="v"/>		

Select **User Access Manager > Service Parameters > Validate System Configuration** from the navigation tree to validate the configurations.

Configure the switch

1. Configure a RADIUS scheme:

Create RADIUS scheme **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Configure the server type for the RADIUS scheme. When using the IMC server, configure the RADIUS server type as **extended**.

```
[Switch-radius-rs1] server-type extended
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.112
[Switch-radius-rs1] primary accounting 192.168.0.112
[Switch-radius-rs1] key authentication radius
[Switch-radius-rs1] key accounting radius
```

Configure the access device to not carry the ISP domain name in the username sent to the RADIUS server.

```
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```

2. Configure an authentication domain:

Create ISP domain **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain for all users. Then, if a user enters a username without the ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal server on the switch, making sure that the IP address, port number and URL match those of the actual portal server.

```
[Switch] portal server newpt ip 192.168.0.111 key portal port 50100 url
http://192.168.0.111:8080/portal
```

Enable portal authentication on the interface connecting the host.

```
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] portal server newpt method direct
[Switch-Vlan-interface100] quit
```

4. Configure the portal server detection function:

Configure the access device to detect portal server **newpt**, specifying the detection method as portal heartbeat probe, setting the server probe interval to 40 seconds, and specifying the access device to send a server unreachable trap message and disable portal authentication to permit unauthenticated portal users if two consecutive probes fail.

```
[Switch] portal server newpt server-detect method portal-heartbeat action trap
permit-all interval 40 retry 2
```

The product of **interval** and **retry** must be greater than or equal to the portal server heartbeat interval, and HP recommends configuring the **interval** as a value greater than the portal server heartbeat interval configured on the portal server.

5. Configure portal user synchronization:

Configure the access device to synchronize portal user information with portal server **newpt**, setting the synchronization probe interval to 600 seconds, and specifying the access device to log off users if the users do not appear in the user synchronization packets sent from the server in two consecutive probe intervals.

```
[Switch] portal server newpt user-sync interval 600 retry 2
```

The product of **interval** and **retry** must be greater than or equal to the portal user heartbeat interval, and HP recommends configuring the **interval** as a value greater than the portal user heartbeat interval configured on the portal server.

Verifying the configuration

Use the following command to view information about the portal server:

```
<Switch> display portal server newpt
Portal server:
 1)newpt:
   IP   : 192.168.0.111
   Key  : *****
   Port : 50100
   URL  : http://192.168.0.111:8080/portal
   Status : Up
```

Configuring Layer 2 portal authentication

Network requirements

As shown in [Figure 83](#), a host is directly connected to a switch. The switch performs Layer 2 portal authentication on users connected to port GigabitEthernet 1/0/1. More specifically,

- Use the remote RADIUS server for authentication, authorization and accounting.
- Use the remote DHCP server to assign IP addresses to users.
- The listening IP address of the local portal server is 4.4.4.4. The local portal server pushes the user-defined authentication pages to users and uses HTTPS to transmit authentication data.
- Add users passing authentication to VLAN 3.
- Add users failing authentication to VLAN 2, to allow the users to access resources on the update server.
- The host obtains an IP address through DHCP. Before authentication, the DHCP server assigns an IP address in segment 192.168.1.0/24 to the host. When the host passes the authentication, the DHCP server assigns an IP address in segment 3.3.3.0/24 to the host. When the host fails authentication, the DHCP server assigns an IP address in segment 2.2.2.0/24 to the host.

Figure 83 Network diagram

Configuration procedures

Follow these guidelines to configure Layer 2 portal authentication:

- Make sure that the host, switch, and servers can reach each other before portal authentication is enabled.
- Configure the RADIUS server properly to provide normal authentication/authorization/accounting functions for users. In this example, you must create a portal user account with the account name **userpt** on the RADIUS server, and configure an authorized VLAN for the account.
- On the DHCP server, you must specify the IP address ranges (192.168.1.0/24, 3.3.3.0/24, 2.2.2.0/24), specify the default gateway addresses (192.168.1.1, 3.3.3.1, 2.2.2.1), exclude the update server's address 2.2.2.2 from the address ranges for address allocation, specify the leases for the assigned IP addresses and make sure there is a route to the host. To shorten the IP address update time in case of an authentication state change, set a short lease for each address.
- Because the DHCP server and the DHCP client are not in the same subnet, you need to configure a DHCP relay agent on the subnet of the client. For more information about DHCP relay agent, see *Layer 3—IP Services Configuration Guide*.

Perform the following configuration on the switch to implement Layer 2 portal authentication:

1. Configure portal authentication:

Add Ethernet ports to related VLANs and configure IP addresses for the VLAN interfaces. (Details not shown.)

Configure PKI domain **pkidm**, and apply for a local certificate and CA certificate. For more configuration information, see "[Configuring PKI](#)."

Edit the user-defined authentication pages file, compress it into a zip file named **defaultfile**, and save the file in the root directory of the access device.

Configure SSL server policy **sslsvr**, and specify to use PKI domain **pkidm**.

```
<Switch> system-view
[Switch] ssl server-policy sslsvr
[Switch-ssl-server-policy-sslsvr] pki pkidm
[Switch-ssl-server-policy-sslsvr] quit
```

```

# Configure the local portal server to support HTTPS and reference SSL server policy sslsvr.
[Switch] portal local-server https server-policy sslsvr
# Configure the IP address of loopback interface 12 as 4.4.4.4.
[Switch] interface loopback 12
[Switch-LoopBack12] ip address 4.4.4.4 32
[Switch-LoopBack12] quit
# Specify IP address 4.4.4.4 as the listening IP address of the local portal server for Layer 2 portal authentication.
[Switch] portal local-server ip 4.4.4.4
# Enable portal authentication on port GigabitEthernet 1/0/1, and specify the Auth-Fail VLAN of the port as VLAN 2.
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] port link-type hybrid
[Switch-GigabitEthernet1/0/1] mac-vlan enable
[Switch-GigabitEthernet1/0/1] portal local-server enable
[Switch-GigabitEthernet1/0/1] portal auth-fail vlan 2
[Switch-GigabitEthernet1/0/1] quit

```

2. Configure a RADIUS scheme:

```

# Create a RADIUS scheme named rs1 and enter its view.
<Switch> system-view
[Switch] radius scheme rs1
# Set the server type for the RADIUS scheme. When using the IMC server, set the server type to extended.
[Switch-radius-rs1] server-type extended
# Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.
[Switch-radius-rs1] primary authentication 1.1.1.2
[Switch-radius-rs1] primary accounting 1.1.1.2
[Switch-radius-rs1] key accounting radius
[Switch-radius-rs1] key authentication radius
[Switch-radius-rs1] quit

```

3. Configure an authentication domain:

```

# Create and enter ISP domain triple.
[Switch] domain triple
# Configure AAA methods for the ISP domain.
[Switch-isp-triple] authentication portal radius-scheme rs1
[Switch-isp-triple] authorization portal radius-scheme rs1
[Switch-isp-triple] accounting portal radius-scheme rs1
[Switch-isp-triple] quit
# Configure domain triple as the default ISP domain for all users. Then, if a user enters a username without any ISP domain at logon, the authentication and accounting methods of the default domain are used for the user.
[Switch] domain default enable triple

```

4. Configure the DHCP relay agent:

```

# Enable DHCP.
[Switch] dhcp enable

```

```

# Create DHCP server group 1 and add DHCP server 1.1.1.3 into the group.
[Switch] dhcp relay server-group 1 ip 1.1.1.3
# Enable the DHCP relay agent on VLAN-interface 8.
[Switch] interface vlan-interface 8
[Switch-Vlan-interface8] dhcp select relay
# Correlate DHCP server group 1 with VLAN-interface 8.
[Switch-Vlan-interface8] dhcp relay server-select 1
[Switch-Vlan-interface8] quit
# Enable the DHCP relay agent on VLAN-interface 2.
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] dhcp select relay
# Correlate DHCP server group 1 with VLAN-interface 2.
[Switch-Vlan-interface2] dhcp relay server-select 1
[Switch-Vlan-interface2] quit
# Enable the DHCP relay agent on VLAN-interface 3.
[Switch] interface vlan-interface 3
[Switch-Vlan-interface3] dhcp select relay
# Correlate DHCP server group 1 with VLAN-interface 3.
[Switch-Vlan-interface3] dhcp relay server-select 1
[Switch-Vlan-interface3] quit

```

Verifying the configuration

Before user **userpt** accesses a web page, the user is in VLAN 8 (the initial VLAN), and is assigned with an IP address on subnet 192.168.1.0/24. When the user accesses a web page on the external network, the web request will be redirected to authentication page **https://4.4.4.4/portal/logon.htm**. After entering the correct username and password, the user can pass the authentication. Then, the device will move the user from VLAN 8 to VLAN 3, the authorized VLAN. You can use the **display connection ucibindex** command to view the online user information

```

<Switch> display connection ucibindex 30
Slot: 1
Index=30 , Username=userpt@triple
MAC=0015-e9a6-7cfe
IP=192.168.1.2
IPv6=N/A
Access=PORTAL ,AuthMethod=PAP
Port Type=Ethernet,Port Name=GigabitEthernet1/0/1
Initial VLAN=8, Authorization VLAN=3
ACL Group=Disable
User Profile=N/A
CAR=Disable
Priority=Disable
Start=2009-11-26 17:40:02 ,Current=2009-11-26 17:48:21 ,Online=00h08m19s
Total 1 connection matched.

```

Use the **display mac-vlan all** command to view the generated MAC-VLAN entries, which record the MAC addresses passing authentication and the corresponding VLANs.

```

[Switch] display mac-vlan all
The following MAC VLAN addresses exist:

```

```

S:Static  D:Dynamic
MAC ADDR          MASK                VLAN ID  PRIO    STATE
-----
0015-e9a6-7cfe   ffff-ffff-ffff  3        0       D
Total MAC VLAN address count:1

```

If a client fails authentication, it is added to VLAN 2. Use the previously mentioned commands to view the assigned IP address and the generated MAC-VLAN entry for the client.

Troubleshooting portal

Inconsistent keys on the access device and the portal server

Symptom

When a user is forced to access the portal server, the portal server displays a blank web page, rather than the portal authentication page or an error message.

Analysis

The keys configured on the access device and the portal server are inconsistent, causing CHAP message exchange failure. As a result, the portal server does not display the authentication page.

Solution

- Use the **display portal server** command to display the key for the portal server on the access device and view the key for the access device on the portal server.
- Use the **portal server** command to modify the key on the access device or modify the key for the access device on the portal server to make sure that the keys are consistent.

Incorrect server port number on the access device

Symptom

After a user passes the portal authentication, you cannot force the user to log off by executing the **portal delete-user** command on the access device, but the user can log off by using the **disconnect** attribute on the authentication client.

Analysis

When you execute the **portal delete-user** command on the access device to force the user to log off, the access device actively sends a REQ_LOGOUT message to the portal server. The default listening port of the portal server is 50100. However, if the listening port configured on the access device is not 50100, the destination port of the REQ_LOGOUT message is not the actual listening port on the server, and the portal server cannot receive the REQ_LOGOUT message. As a result, you cannot force the user to log off the portal server.

When the user uses the **disconnect** attribute on the client to log off, the portal server actively sends a REQ_LOGOUT message to the access device. The source port is 50100 and the destination port of the ACK_LOGOUT message from the access device is the source port of the REQ_LOGOUT message so that the portal server can receive the ACK_LOGOUT message correctly, no matter whether the listening port is configured on the access device. The user can log off the portal server.

Solution

Use the **display portal server** command to display the listening port of the portal server configured on the access device and use the **portal server** command in the system view to modify it to make sure that it is the actual listening port of the portal server.

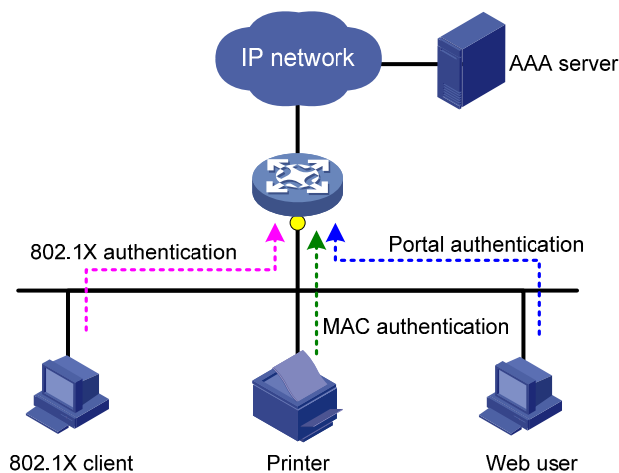

Configuring triple authentication

Overview

Triple authentication enables a Layer 2 access port to perform portal, MAC, and 802.1X authentication. A terminal can access the network if it passes one type of authentication.

Triple authentication is suitable for a LAN that comprises terminals that require different authentication services. For example, the triple authentication-enabled access port in [Figure 84](#) can perform MAC authentication for the printer, 802.1X authentication for a PC installed with the 802.1X client, and port authentication for the other PC.

Figure 84 Triple authentication network diagram

For more information about portal authentication, MAC authentication and 802.1X authentication, see "[Configuring portal authentication](#)," "[Configuring MAC authentication](#)," and "[Configuring 802.1X](#)."

Triple authentication mechanism

The three types of authentication are triggered by different packets:

- The access port performs MAC authentication for a terminal when it receives an ARP or DHCP broadcast packet from the terminal for the first time. If the terminal passes MAC authentication, the terminal can access the network. If the MAC authentication fails, the access port performs 802.1X or portal authentication.
- The access port performs 802.1X authentication when it receives an EAP packet from an 802.1X client. If the unicast trigger function of 802.1X is enabled on the access port, any packet from an 802.1X client can trigger an 802.1X authentication.
- The access port performs portal authentication when it receives an HTTP packet from a terminal.

If a terminal triggers different types of authentication, the authentications are processed at the same time. The failure of one type of authentication does not affect the others. When a terminal passes one type of authentication, the other types of authentication being performed are terminated. Then, whether the other types of authentication can be triggered varies:

- If a terminal passes 802.1X or portal authentication, no other types of authentication will be triggered for the terminal.
- If the terminal passes MAC authentication, no portal authentication can be triggered for the terminal, but 802.1X authentication can be triggered. When the terminal passes 802.1X authentication, the 802.1X authentication information will overwrite the MAC authentication information for the terminal.

Using triple authentication with other features

A triple authentication enabled access port supports working with the following features.

VLAN assignment

After a terminal passes authentication, the authentication server assigns an authorized VLAN to the access port for the access terminal. The terminal can then access the network resources in the authorized VLAN.

Auth-Fail VLAN or MAC authentication guest VLAN

After a terminal fails authentication, the access port:

- Adds the terminal to an Auth-Fail VLAN, if it uses 802.1X or portal authentication service.
- Adds the terminal to a MAC authentication guest VLAN, if it uses MAC authentication service.

A terminal may undergo all three types of authentication. If it fails to pass all types of authentication, the access port adds the terminal to the 802.1X Auth-Fail VLAN.

ACL assignment

You can specify an authorization ACL for an authenticated user to control its access to network resources. After the user passes MAC authentication, the authentication server, either the local access device or a RADIUS server, assigns the ACL onto the access port to filter traffic for the user.

You must configure the ACLs on the access device, whether the authentication server is the access device or a remote AAA server.

Detection of online terminals

- You can enable an online detection timer, which is configurable, to detect online portal clients.
- You can enable the online handshake or periodic re-authentication function to detect online 802.1X clients at a configurable interval.
- You can enable an offline detection timer to detect online MAC authentication terminals at a configurable interval.

For more information about the extended functions, see "[Configuring 802.1X](#)," "[Configuring MAC authentication](#)," and "[Configuring portal authentication](#)."

Configuring triple authentication

Step	Command	Remarks
1. Configure 802.1X authentication.	See " Configuring 802.1X "	Configure at least one type of authentication.
2. Configure MAC authentication.	See " Configuring MAC authentication "	802.1X authentication must use

Step	Command	Remarks
3. Configure Layer-2 portal authentication.	See " Configuring portal authentication "	MAC-based access control. HP does not recommend you configure 802.1X guest VLANs for triple authentication.

Triple authentication configuration examples

Triple authentication basic function configuration example

Network requirements

As shown in [Figure 85](#), the terminals are connected to a switch to access the IP network. Configure triple authentication on the Layer-2 interface of the switch that connects to the terminals so that a terminal passing one of the three authentication methods, 802.1X authentication, portal authentication, and MAC authentication, can access the IP network.

- Configure static IP addresses in network 192.168.1.0/24 for the terminals.
- Use the remote RADIUS server to perform authentication, authorization, and accounting and configure the switch to send usernames carrying no ISP domain names to the RADIUS server.
- The local portal authentication server on the switch uses listening IP address 4.4.4.4. The switch sends a default authentication page to the web user and forwards authentication data using HTTP.

Figure 85 Network diagram

Configuration procedure

Make sure that the terminals, the server, and the switch can reach each other.

The host of the web user must have a route to the listening IP address of the local portal server.

1. Configure the RADIUS server, and make sure the authentication, authorization, and accounting functions work normally. In this example, configure on the RADIUS server an 802.1X user (with username **userdot**), a portal user (with username **userpt**), and a MAC authentication user (with a username and password both being the MAC address of the printer **001588f80dd7**).
2. Configure portal authentication:
 - # Configure VLANs and IP addresses for the VLAN interfaces, and add ports to specific VLANs. (Details not shown.)

- ```
Configure the local portal server to support HTTP.
<Switch> system-view
[Switch] portal local-server http

Configure the IP address of interface loopback 0 as 4.4.4.4.
[Switch] interface loopback 0
[Switch-LoopBack0] ip address 4.4.4.4 32
[Switch-LoopBack0] quit

Specify the listening IP address of the local portal server for Layer-2 portal authentication as 4.4.4.4.
[Switch] portal local-server ip 4.4.4.4

Enable Layer-2 portal authentication on GigabitEthernet 1/0/1.
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] portal local-server enable
[Switch-GigabitEthernet1/0/1] quit
```
- 3. Configure 802.1X authentication:**
- ```
# Enable 802.1X authentication globally.
[Switch] dot1x

# Enable 802.1X authentication (MAC-based access control required) on GigabitEthernet 1/0/1.
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] dot1x port-method macbased
[Switch-GigabitEthernet1/0/1] dot1x
[Switch-GigabitEthernet1/0/1] quit
```
- 4. Configure MAC authentication:**
- ```
Enable MAC authentication globally.
[Switch] mac-authentication

Enable MAC authentication on GigabitEthernet 1/0/1.
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] mac-authentication
[Switch-GigabitEthernet1/0/1] quit
```
- 5. Configure a RADIUS scheme:**
- ```
# Create a RADIUS scheme named rs1.
[Switch] radius scheme rs1

# Specify the server type for the RADIUS scheme, which must be extended when the IMC server is used.
[Switch-radius-rs1] server-type extended

# Specify the primary authentication and accounting servers and keys.
[Switch-radius-rs1] primary authentication 1.1.1.2
[Switch-radius-rs1] primary accounting 1.1.1.2
[Switch-radius-rs1] key authentication radius
[Switch-radius-rs1] key accounting radius

# Specify usernames sent to the RADIUS server to carry no domain names.
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```
- 6. Configure an ISP domain:**
- ```
Create an ISP domain named triple.
```

```

[Switch] domain triple
Configure the default AAA methods for all types of users in the domain.
[Switch-isp-triple] authentication default radius-scheme rs1
[Switch-isp-triple] authorization default radius-scheme rs1
[Switch-isp-triple] accounting default radius-scheme rs1
[Switch-isp-triple] quit
Configure domain triple as the default domain. If a username input by a user includes no ISP
domain name, the authentication scheme of the default domain is used.
[Switch] domain default enable triple

```

## Verifying the configuration

User **userdot** uses the 802.1X client to initiate authentication. After inputting the correct username and password, the user can pass 802.1X authentication. Web user **userpt** uses a web browser to access an external network. The web request is redirected to the authentication page <http://4.4.4.4/portal/logon.htm>. After inputting the correct username and password, the web user can pass portal authentication. The printer can pass MAC authentication after being connected to the network.

Use the **display connection** command to view online users.

```

[Switch] display connection
Slot: 1
Index=30 , Username=userpt@triple
IP=192.168.1.2
IPv6=N/A
MAC=0015-e9a6-7cfe
Index=31 , Username=userdot@triple
IP=192.168.1.3
IPv6=N/A
MAC=0002-0002-0001
Index=32 , Username=001588f80dd7@triple
IP=192.168.1.4
IPv6=N/A
MAC=0015-88f8-0dd7

Total 3 connection(s) matched on slot 1.
Total 3 connection(s) matched.

```

## Triple authentication supporting VLAN assignment and Auth-Fail VLAN configuration example

### Network requirement

As shown in [Figure 86](#), the terminals are connected to a switch to access the IP network. Configure triple authentication on the Layer-2 interface of the switch which connects to the terminals so that a terminal passing one of the three authentication methods, 802.1X authentication, portal authentication, and MAC authentication, can access the IP network.

- Portal terminals use DHCP to get IP addresses in 192.168.1.0/24 before authentication and in 3.3.3.0/24 after passing authentication.

- 802.1X terminals use IP addresses in 192.168.1.0/24 before authentication, and request IP addresses in 3.3.3.0/24 through DHCP after passing authentication. If the terminal fails authentication, it uses an IP address in 2.2.2.0/24.
- After passing authentication, the printer obtains the IP address 3.3.3.111/24 that is bound with its MAC address through DHCP.
- Use the remote RADIUS server to perform authentication, authorization, and accounting and configure the switch to remove the ISP domain names from usernames sent to the RADIUS server.
- The local portal authentication server on the switch uses listening IP address 4.4.4.4. The switch sends a default authentication page to the web user and forwards authentication data by using HTTPS.
- Configure VLAN 3 as the authorized VLAN on the RADIUS server. Users passing authentication are added to this VLAN.
- Configure VLAN 2 as the Auth-Fail VLAN on the access device. Users failing authentication are added to this VLAN, and are allowed to access only the Update server.

**Figure 86 Network diagram**

## Configuration procedure

Make sure that the terminals, the servers, and the switch can reach each other.

When using an external DHCP server, make sure that the terminals can get IP addresses from the server before and after authentication.

1. Configure the RADIUS server, and make sure the authentication, authorization, and accounting functions work normally. In this example, configure on the RADIUS server an 802.1X user (with username **userdot**), a portal user (with username **userpt**), a MAC authentication user (with a username and password both being the MAC address of the printer **001588f80dd7**), and an authorized VLAN (VLAN 3).
2. Configure PKI domain **pkidm** and acquire the local and CA certificates. For more information, see "[Configuring PKI.](#)"
3. Complete the editing of a self-defined default authentication page file, compress the file to a zip file named defaultfile and save the zip file at the root directory.
4. Configure DHCP:

# Configure VLANs and IP addresses for the VLAN interfaces, and add ports to specific VLANs. (Details not shown.)

# Enable DHCP.

```
<Switch> system-view
[Switch] dhcp enable
```

# Exclude the IP address of the update server from assignment.

```
[Switch] dhcp server forbidden-ip 2.2.2.2
```

# Configure IP address pool 1, including the address range, lease and gateway address. A short lease is recommended to shorten the time terminals use to re-acquire IP addresses after the terminals passing or failing authentication.

```
[Switch] dhcp server ip-pool 1
[Switch-dhcp-pool-1] network 192.168.1.0 mask 255.255.255.0
[Switch-dhcp-pool-1] expired day 0 hour 0 minute 1
[Switch-dhcp-pool-1] gateway-list 192.168.1.1
[Switch-dhcp-pool-1] quit
```

A short lease is recommended to shorten the time that terminals use to re-acquire IP addresses after passing or failing authentication. However, in some applications, a terminal can require a new IP address before the lease duration expires. For example, the iNode 802.1X client automatically renews its IP address after disconnecting from the server.

# Configure IP address pool 2, including the address range, lease and gateway address. A short lease is recommended to shorten the time terminals use to re-acquire IP addresses after the terminals pass authentication.

```
[Switch] dhcp server ip-pool 2
[Switch-dhcp-pool-2] network 2.2.2.0 mask 255.255.255.0
[Switch-dhcp-pool-2] expired day 0 hour 0 minute 1
[Switch-dhcp-pool-2] gateway-list 2.2.2.1
[Switch-dhcp-pool-2] quit
```

# Configure IP address pool 3, including the address range, lease and gateway address. A short lease is recommended to shorten the time terminals use to re-acquire IP addresses after the terminals are offline.

```
[Switch] dhcp server ip-pool 3
[Switch-dhcp-pool-3] network 3.3.3.0 mask 255.255.255.0
[Switch-dhcp-pool-3] expired day 0 hour 0 minute 1
[Switch-dhcp-pool-3] gateway-list 3.3.3.1
[Switch-dhcp-pool-3] quit
```

# Configure IP address pool 4, and bind the printer MAC address 0015-e9a6-7cfe to the IP address 3.3.3.111/24 in this address pool.

```
[Switch] dhcp server ip-pool 4
[Switch-dhcp-pool-4] static-bind ip-address 3.3.3.111 mask 255.255.255.0
[Switch-dhcp-pool-4] static-bind mac-address 0015-e9a6-7cfe
[Switch-dhcp-pool-4] quit
```

## 5. Configure portal authentication:

# Create SSL server policy **sslsvr** and specify it to use PKI domain **pkidm**.

```
[Switch] ssl server-policy sslsvr
[Switch-ssl-server-policy-sslsvr] pki pkidm
[Switch-ssl-server-policy-sslsvr] quit
```

# Configure the local portal server to support HTTPS and use SSL server policy **sslsvr**.

```
[Switch] portal local-server https server-policy sslsvr
Configure IP address 4.4.4.4 for interface loopback 12.
[Switch] interface loopback 12
[Switch-LoopBack12] ip address 4.4.4.4 32
[Switch-LoopBack12] quit
Specify the listening IP address of the local portal server as 4.4.4.4.
[Switch] portal local-server ip 4.4.4.4
Enable Layer-2 portal authentication on GigabitEthernet 1/0/1 and specify VLAN 2 as the
Auth-Fail VLAN, to which terminals failing authentication are added.
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] port link-type hybrid
[Switch-GigabitEthernet1/0/1] mac-vlan enable
[Switch-GigabitEthernet1/0/1] portal local-server enable
[Switch-GigabitEthernet1/0/1] portal auth-fail vlan 2
[Switch-GigabitEthernet1/0/1] quit
```

#### 6. Configure 802.1X authentication:

# Enable 802.1X authentication globally.

```
[Switch] dot1x
```

# Enable 802.1X authentication (MAC-based access control required) on GigabitEthernet 1/0/1, and specify VLAN 2 as the Auth-Fail VLAN.

```
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] dot1x port-method macbased
[Switch-GigabitEthernet1/0/1] dot1x
[Switch-GigabitEthernet1/0/1] dot1x auth-fail vlan 2
[Switch-GigabitEthernet1/0/1] quit
```

#### 7. Configure MAC authentication:

# Enable MAC authentication globally.

```
[Switch] mac-authentication
```

# Enable MAC authentication on GigabitEthernet 1/0/1, and specify VLAN 2 as the Auth-Fail VLAN

```
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] mac-authentication
[Switch-GigabitEthernet1/0/1] mac-authentication guest-vlan 2
[Switch-GigabitEthernet1/0/1] quit
```

#### 8. Configure a RADIUS scheme:

# Create a RADIUS scheme named **rs1**.

```
[Switch] radius scheme rs1
```

# Specify the server type for the RADIUS scheme, which must be **extended** when the IMC server is used.

```
[Switch-radius-rs1] server-type extended
```

# Specify the primary authentication and accounting servers and keys.

```
[Switch-radius-rs1] primary authentication 1.1.1.2
```

```
[Switch-radius-rs1] primary accounting 1.1.1.2
```

```
[Switch-radius-rs1] key authentication radius
```

```
[Switch-radius-rs1] key accounting radius
```

# Specify usernames sent to the RADIUS server to carry no domain names.

```
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```

## 9. Configure an ISP domain:

# Create an ISP domain named triple.

```
[Switch] domain triple
```

# Configure the default AAA methods for all types of users in the domain.

```
[Switch-isp-triple] authentication default radius-scheme rs1
```

```
[Switch-isp-triple] authorization default radius-scheme rs1
```

```
[Switch-isp-triple] accounting default radius-scheme rs1
```

```
[Switch-isp-triple] quit
```

# Configure domain **triple** as the default domain. If a username input by a user includes no ISP domain name, the authentication scheme of the default domain is used.

```
[Switch] domain default enable triple
```

## Verifying the configuration

User **userdot** uses the 802.1X client to initiate authentication. After inputting the correct username and password, the user can pass 802.1X authentication. Web user **userpt** uses a web browser to access an external network. The web request is redirected to the authentication page <http://4.4.4.4/portal/logon.htm>. After inputting the correct username and password, the web user can pass portal authentication. The printer can pass MAC authentication after being connected to the network.

Use the **display connection** command to view connection information about online users.

```
[Switch] display connection
Slot: 1
Index=30 , Username=userpt@triple
IP=192.168.1.2
IPv6=N/A
MAC=0015-e9a6-7cfe
Index=31 , Username=userdot@triple
IP=3.3.3.2
IPv6=N/A
MAC=0002-0002-0001
Index=32 , Username=001588f80dd7@triple
IP=N/A
IPv6=N/A
MAC=0015-88f8-0dd7
```

Total 3 connection(s) matched on slot 1.

Total 3 connection(s) matched.

Use the **display mac-vlan all** command to view the MAC-VLAN entries of online users. VLAN 3 is the authorized VLAN.

```
[Switch] display mac-vlan all
The following MAC VLAN addresses exist:
S:Static D:Dynamic
MAC ADDR MASK VLAN ID PRIO STATE

0015-e9a6-7cfe ffff-ffff-ffff 3 0 D
```

```
0002-0002-0001 ffff-ffff-ffff 3 0 D
0015-88f8-0dd7 ffff-ffff-ffff 3 0 D
Total MAC VLAN address count:3
```

Use the **display dhcp server ip-in-use** command to view the IP addresses assigned to online users.

```
[Switch] display dhcp server ip-in-use all
```

```
Pool utilization: 0.59%
```

| IP address | Client-identifier/<br>Hardware address | Lease expiration     | Type           |
|------------|----------------------------------------|----------------------|----------------|
| 3.3.3.111  | 0015-88f8-0dd7                         | Dec 15 2009 17:40:52 | Auto:COMMITTED |
| 3.3.3.2    | 0002-0002-0001                         | Dec 15 2009 17:41:02 | Auto:COMMITTED |
| 3.3.3.3    | 0015-e9a6-7cfe                         | Unlimited            | Manual         |

```
--- total 3 entry ---
```

When a terminal fails authentication, it is added to VLAN 2. You can also use the display commands to view the MAC-VLAN entry and IP address of the terminal.

---

# Configuring port security

## Overview

Port security combines and extends 802.1X and MAC authentication to provide MAC-based network access control. It applies to a network that requires different authentication methods for different users on a port.

Port security prevents unauthorized access to the network by checking the source MAC address of inbound traffic and prevents access to unauthorized devices by checking the destination MAC address of outbound traffic.

Port security can control MAC address learning and authentication on a port to make sure that the port learns only trusted MAC addresses.

A frame is illegal, if its source MAC address cannot be learned in a port security mode or it is from a client that has failed 802.1X or MAC authentication.

The port security feature can automatically take a pre-defined action on illegal frames. This automatic mechanism enhances network security and reduces human intervention.

---

### NOTE:

For scenarios that require only 802.1X authentication or MAC authentication, HP recommends you configure 802.1X authentication or MAC authentication rather than port security. For more information about 802.1X and MAC authentication, see "[Configuring 802.1X](#)" and "[Configuring MAC authentication](#)."

---

## Port security features

### NTK

The need to know (NTK) feature prevents traffic interception by checking the destination MAC address in the outbound frames. The feature guarantees that frames are sent only to hosts that have passed authentication or whose MAC addresses have been learned or configured on the access device.

### Intrusion protection

The intrusion protection feature checks the source MAC address in inbound frames for illegal frames and takes a pre-defined action on each detected illegal frame. The action can be disabling the port temporarily, disabling the port permanently, or blocking frames from the illegal MAC address for three minutes (not user configurable).

### Port security traps

You can configure the port security module to send traps for port security events such as login, logoff, and MAC authentication. These traps help you monitor user behaviors.

## Port security modes

Port security supports the following categories of security modes:

- **MAC learning control**—Includes two modes, autoLearn and secure. MAC address learning is permitted on a port in autoLearn mode and disabled in secure mode.
- **Authentication**—Security modes in this category implement MAC authentication, 802.1X authentication, or a combination of these two authentication methods.

Upon receiving a frame, the port in a security mode searches the MAC address table for the source MAC address. If a match is found, the port forwards the frame. If no match is found, the port learns the MAC address or performs authentication, depending on the security mode. If the frame is illegal, the port takes the pre-defined NTK, intrusion protection, or trapping action.

The maximum number of users a port supports equals the maximum number of MAC addresses that port security allows or the maximum number of concurrent users the authentication mode in use allows, whichever is smaller. For example, if 802.1X allows more concurrent users than port security's limit on the number of MAC addresses on the port in userLoginSecureExt mode, port security's limit takes effect.

Table 11 describes the port security modes and the security features.

**Table 11 Port security modes**

| Purpose                                                                  | Security mode                                                                                                                      | Features that can be triggered   |                          |
|--------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|--------------------------|
| Turning off the port security feature                                    | noRestrictions (the default mode)<br>In this mode, port security is disabled on the port and access to the port is not restricted. | N/A                              |                          |
| Controlling MAC address learning                                         | autoLearn                                                                                                                          | NTK/intrusion protection         |                          |
|                                                                          | secure                                                                                                                             |                                  |                          |
| Performing 802.1X authentication                                         | userLogin                                                                                                                          | N/A                              |                          |
|                                                                          | userLoginSecure                                                                                                                    |                                  |                          |
|                                                                          | userLoginSecureExt                                                                                                                 |                                  |                          |
|                                                                          | userLoginWithOUI                                                                                                                   |                                  |                          |
| Performing MAC authentication                                            | macAddressWithRadius                                                                                                               | NTK/intrusion protection         |                          |
| Performing a combination of MAC authentication and 802.1X authentication | Or                                                                                                                                 | macAddressOrUserLoginSecure      | NTK/intrusion protection |
|                                                                          |                                                                                                                                    | macAddressOrUserLoginSecureExt   |                          |
|                                                                          | Else                                                                                                                               | macAddressElseUserLoginSecure    |                          |
|                                                                          |                                                                                                                                    | macAddressElseUserLoginSecureExt |                          |

**TIP:**

- **userLogin** specifies 802.1X authentication and port-based access control.
- **macAddress** specifies MAC authentication.
- **Else** specifies that the authentication method before **Else** is applied first. If the authentication fails, whether to turn to the authentication method following **Else** depends on the protocol type of the authentication request.
- Typically, in a security mode with **Or**, the authentication method to be used depends on the protocol type of the authentication request.
- **userLogin** with **Secure** specifies 802.1X authentication and MAC-based access control.
- **Ext** indicates allowing multiple 802.1X users to be authenticated and serviced at the same time. A security mode without **Ext** allows only one user to pass 802.1X authentication.

## Controlling MAC address learning

- autoLearn

A port in this mode can learn MAC addresses, and allows frames from learned or configured MAC addresses to pass. The automatically learned MAC addresses are secure MAC addresses. You can also configure secure MAC addresses by using the **port-security mac-address security** command. A secure MAC address never ages out by default.

When the number of secure MAC addresses reaches the upper limit, the port transitions to secure mode.

The dynamic MAC address learning function in MAC address management is disabled on ports operating in autoLearn mode, but you can configure MAC addresses by using the **mac-address dynamic** and **mac-address static** commands.

- secure

MAC address learning is disabled on a port in secure mode. You configure MAC addresses by using the **mac-address static** and **mac-address dynamic** commands. For more information about configuring MAC address table entries, see *Layer 2—LAN Switching Configuration Guide*.

A port in secure mode allows only frames sourced from secure MAC addresses and manually configured MAC addresses to pass.

## Performing 802.1X authentication

- userLogin

A port in this mode performs 802.1X authentication and implements port-based access control. The port can service multiple 802.1X users. If one 802.1X user passes authentication, all the other 802.1X users of the port can access the network without authentication.

- userLoginSecure

A port in this mode performs 802.1X authentication and implements MAC-based access control. The port services only one user passing 802.1X authentication.

- userLoginSecureExt

This mode is similar to the userLoginSecure mode except that this mode supports multiple online 802.1X users.

- userLoginWithOUI

This mode is similar to the userLoginSecure mode. The difference is that a port in this mode also permits frames from one user whose MAC address contains a specific organizationally unique identifier (OUI).

For wired users, the port performs 802.1X authentication upon receiving 802.1X frames, and performs OUI check upon receiving non-802.1X frames.

## Performing MAC authentication

macAddressWithRadius: A port in this mode performs MAC authentication and services multiple users.

## Performing a combination of MAC authentication and 802.1X authentication

- macAddressOrUserLoginSecure

This mode is the combination of the macAddressWithRadius and userLoginSecure modes.

For wired users, the port performs MAC authentication upon receiving non-802.1X frames and performs 802.1X authentication upon receiving 802.1X frames.

- macAddressOrUserLoginSecureExt

This mode is similar to the `macAddressOrUserLoginSecure` mode except that a port in this mode supports multiple 802.1X and MAC authentication users.

- `macAddressElseUserLoginSecure`

This mode is the combination of the `macAddressWithRadius` and `userLoginSecure` modes, with MAC authentication having a higher priority as the **Else** keyword implies.

For non-802.1X frames, a port in this mode performs only MAC authentication. For 802.1X frames, it performs MAC authentication and then, if the authentication fails, 802.1X authentication.

- `macAddressElseUserLoginSecureExt`

This mode is similar to the `macAddressElseUserLoginSecure` mode except that a port in this mode supports multiple 802.1X and MAC authentication users as the keyword **Ext** implies.

#### NOTE:

An OUI, as defined by the IEEE, is the first 24 bits of the MAC address, which uniquely identifies a device vendor.

## Working with guest VLAN and Auth-Fail VLAN

An 802.1X guest VLAN is the VLAN that a user is in before initiating authentication. An 802.1X Auth-Fail VLAN or a MAC authentication guest VLAN is the VLAN that a user is in after failing authentication. Support for the guest VLAN and Auth-Fail VLAN features varies with security modes.

- You can use the 802.1X guest VLAN and 802.1X Auth-Fail VLAN features together with port security modes that support 802.1X authentication. For more information about the 802.1X guest VLAN and Auth-Fail VLAN on a port that performs MAC-based access control, see "[Configuring 802.1X](#)."
- You can use the MAC authentication VLAN feature together with security modes that support MAC authentication. For more information about the MAC authentication guest VLAN, see "[Configuring MAC authentication](#)."
- If you configure both an 802.1X Auth-Fail VLAN and a MAC authentication guest VLAN on a port that performs MAC-based access control, the 802.1X Auth-Fail VLAN has a higher priority.

## Configuration task list

| Task                                                                                   | Remarks                                          |                                             |
|----------------------------------------------------------------------------------------|--------------------------------------------------|---------------------------------------------|

| <a href="#">Ignoring authorization information from the server</a>                     | Optional.                                        |                                             |

## Enabling port security

Enabling or disabling port security resets the following security settings to the default:

- 802.1X access control mode is MAC-based, and the port authorization state is auto.
- Port security mode is noRestrictions.

When port security is enabled, you cannot manually enable 802.1X or MAC authentication, or change the access control mode or port authorization state. The port security automatically modifies these settings in different security modes.

You cannot disable port security when online users are present.

Before enabling port security, disable 802.1X and MAC authentication globally.

To enable port security:

| Step                     | Command                     | Remarks                                    |
|--------------------------|-----------------------------|--------------------------------------------|
| 1. Enter system view.    | <b>system-view</b>          | N/A                                        |
| 2. Enable port security. | <b>port-security enable</b> | By default, the port security is disabled. |

For more information about 802.1X configuration, see "[Configuring 802.1X](#)." For more information about MAC authentication configuration, see "[Configuring MAC authentication](#)."

## Setting port security's limit on the number of MAC addresses on a port

You can set the maximum number of MAC addresses that port security allows on a port for the following purposes:

- Controlling the number of concurrent users on the port. The maximum number of concurrent users on the port equals this limit or the limit of the authentication mode (802.1X for example) in use, whichever is smaller.
- Controlling the number of secure MAC addresses on the port in autoLearn mode.

The port security's limit on the number of MAC addresses on a port is independent of the MAC learning limit described in MAC address table configuration in the *Layer 2—LAN Switching Configuration Guide*.

To set the maximum number of secure MAC addresses allowed on a port:

| Step                                                              | Command                                                           | Remarks                 |
|-------------------------------------------------------------------|-------------------------------------------------------------------|-------------------------|
| 1. Enter system view.                                             | <b>system-view</b>                                                | N/A                     |
| 2. Enter Layer 2 Ethernet interface view.                         | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                     |
| 3. Set the limit of port security on the number of MAC addresses. | <b>port-security max-mac-count</b><br><i>count-value</i>          | Not limited by default. |

# Setting the port security mode

After enabling port security, you can change the port security mode of a port only when the port is operating in noRestrictions (the default) mode. To change the port security mode for a port in any other mode, first use the **undo port-security port-mode** command to restore the default port security mode.

You can specify a port security mode when port security is disabled, but your configuration cannot take effect.

You cannot change the port security mode of a port when online users are present.

## Configuration prerequisites

Before you set a port security mode for a port, complete the following tasks:

- Disable 802.1X and MAC authentication.
- Verify that the port does not belong to any aggregation group or service loopback group.
- If you are configuring the autoLearn mode, set port security's limit on the number of MAC addresses. You cannot change the setting when the port is operating in autoLearn mode.

## Configuration procedure

To enable a port security mode:

| Step                                         | Command                                                                                                                                                                                                                                                                                                                                               | Remarks                                                                                                                        |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                        | <b>system-view</b>                                                                                                                                                                                                                                                                                                                                    | N/A                                                                                                                            |
| 2. Set an OUI value for user authentication. | <b>port-security oui <i>oui-value</i> index <i>index-value</i></b>                                                                                                                                                                                                                                                                                    | Required for the <b>userlogin-withoui</b> mode.<br>Not configured by default.<br>To set multiple OUI values, repeat this step. |
| 3. Enter Layer 2 Ethernet interface view.    | <b>interface <i>interface-type</i> <i>interface-number</i></b>                                                                                                                                                                                                                                                                                        | N/A                                                                                                                            |
| 4. Set the port security mode.               | <b>port-security port-mode { <b>autolearn</b>   <b>mac-authentication</b>   <b>mac-else-userlogin-secure</b>   <b>mac-else-userlogin-secure-ext</b>   <b>secure</b>   <b>userlogin</b>   <b>userlogin-secure</b>   <b>userlogin-secure-ext</b>   <b>userlogin-secure-or-mac</b>   <b>userlogin-secure-or-mac-ext</b>   <b>userlogin-withoui</b> }</b> | By default, a port operates in noRestrictions mode.                                                                            |

# Configuring port security features

## Configuring NTK

The NTK feature checks the destination MAC addresses in outbound frames to make sure that frames are forwarded only to authenticated devices. Any unicast frame with an unknown destination MAC address is discarded. Not all port security modes support triggering the NTK feature. For more information, see [Table 11](#).

The NTK feature supports the following modes:

- **ntkonly**—Forwards only unicast frames with authenticated destination MAC addresses.
- **ntk-withbroadcasts**—Forwards only broadcast frames and unicast frames with authenticated destination MAC addresses.
- **ntk-withmulticasts**—Forwards only broadcast frames, multicast frames, and unicast frames with authenticated destination MAC addresses.

To configure the NTK feature:

| Step                                      | Command                                                                                                        | Remarks                                                                      |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| 1. Enter system view.                     | <b>system-view</b>                                                                                             | N/A                                                                          |
| 2. Enter Layer 2 Ethernet interface view. | <b>interface</b> <i>interface-type</i><br><i>interface-number</i>                                              | N/A                                                                          |
| 3. Configure the NTK feature.             | <b>port-security ntk-mode</b><br>{ <b>ntk-withbroadcasts</b>  <br><b>ntk-withmulticasts</b>   <b>ntkonly</b> } | By default, NTK is disabled on a port and all frames are allowed to be sent. |

## Configuring intrusion protection

Intrusion protection enables a device to take one of the following actions in response to illegal frames:

- **blockmac**—Adds the source MAC addresses of illegal frames to the blocked MAC addresses list and discards the frames. All subsequent frames sourced from a blocked MAC address will be dropped. A blocked MAC address is restored to normal state after being blocked for three minutes. The interval is fixed and cannot be changed.
- **disableport**—Disables the port until you bring it up manually.
- **disableport-temporarily**—Disables the port for a specific period of time. The period can be configured with the **port-security timer disableport** command.

On a port operating in either the `macAddressElseUserLoginSecure` mode or the `macAddressElseUserLoginSecureExt` mode, intrusion protection is triggered only after both MAC authentication and 802.1X authentication for the same frame fail.

To configure the intrusion protection feature:

| Step                  | Command            | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | <b>system-view</b> | N/A     |

| Step                                                                    | Command                                                                                                             | Remarks                                       |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| 2. Enter Layer 2 Ethernet interface view.                               | <b>interface</b> <i>interface-type</i><br><i>interface-number</i>                                                   | N/A                                           |
| 3. Configure the intrusion protection feature.                          | <b>port-security intrusion-mode</b><br>{ <b>blockmac</b>   <b>disableport</b>  <br><b>disableport-temporarily</b> } | By default, intrusion protection is disabled. |
| 4. Return to system view.                                               | <b>quit</b>                                                                                                         | N/A                                           |
| 5. Set the silence timeout period during which a port remains disabled. | <b>port-security timer disableport</b><br><i>time-value</i>                                                         | Optional.<br>20 seconds by default.           |

## Enabling port security traps

You can configure the port security module to send traps for the following categories of events:

- **addresslearned**—Learning of new MAC addresses.
- **dot1xlogfailure/dot1xlogon/dot1xlogoff**—802.1X authentication failure, success, and 802.1X user logoff.
- **ralmlogfailure/ralmlogon/ralmlogoff**—MAC authentication failure, MAC authentication user logon, and MAC authentication user logoff.
- **intrusion**—Detection of illegal frames.

To enable port security traps:

| Step                           | Command                                                                                                                                                                                                             | Remarks                                       |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| 1. Enter system view.          | <b>system-view</b>                                                                                                                                                                                                  | N/A                                           |
| 2. Enable port security traps. | <b>port-security trap</b> { <b>addresslearned</b><br>  <b>dot1xlogfailure</b>   <b>dot1xlogoff</b>  <br><b>dot1xlogon</b>   <b>intrusion</b>  <br><b>ralmlogfailure</b>   <b>ralmlogoff</b>  <br><b>ralmlogon</b> } | By default, port security traps are disabled. |

## Configuring secure MAC addresses

Secure MAC addresses are configured or learned in autoLearn mode and can survive link down/up events. You can bind a secure MAC address to only one port in a VLAN.

### ⓘ IMPORTANT:

When the maximum number of secure MAC address entries is reached, the port changes to secure mode, and no more secure MAC addresses can be added or learned. The port allows only frames sourced from a secure MAC address or a MAC address configured by using the **mac-address dynamic** or **mac-address static** command to pass through.

Secure MAC addresses fall into static, sticky and dynamic secure MAC addresses.

**Table 12 A comparison of static, sticky, and dynamic secure MAC addresses**

| Type    | Address sources                                                                                                                        | Aging mechanism                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Can be saved and survive a device reboot?                   |
|---------|----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Static  | Manually added                                                                                                                         | Not available.<br>They never age out unless you manually remove them, change the port security mode, or disable the port security feature.                                                                                                                                                                                                                                                                                                                                                                                                                        | Yes.                                                        |
| Sticky  | Manually added or automatically learned when the dynamic secure MAC function ( <b>port-security mac-address dynamic</b> ) is disabled. | Sticky MAC addresses by default do not age out, but you can configure an aging timer or use the aging timer together with the inactivity aging function to delete old sticky MAC addresses: <ul style="list-style-type: none"> <li>If only an aging timer is configured, the aging timer counts up regardless of whether traffic data has been sent from the sticky MAC address.</li> <li>If both an aging timer and the inactivity aging function are configured, the aging timer restarts once traffic data is detected from the sticky MAC address.</li> </ul> | Yes.<br>The secure MAC aging timer restarts at a reboot.    |
| Dynamic | Converted from sticky MAC addresses or automatically learned after the dynamic secure MAC function is enabled.                         | Same as sticky MAC addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | No.<br>All dynamic secure MAC addresses are lost at reboot. |

## Configuration prerequisites

- Enable port security.
- Set port security's limit on the number of MAC addresses on the port. Perform this task before you enable autoLearn mode.
- Set the port security mode to autoLearn.

## Configuration procedure

To configure a secure MAC address:

| Step                               | Command                                               | Remarks                                                                                                                                                                                                                                       |
|------------------------------------|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.              | <b>system-view</b>                                    | N/A                                                                                                                                                                                                                                           |
| 2. Set the secure MAC aging timer. | <b>port-security timer autolearn aging time-value</b> | Optional.<br>By default, secure MAC addresses do not age out, and you can remove them only by performing the <b>undo port-security mac-address security</b> command, changing the port security mode, or disabling the port security feature. |

| Step                                       | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Remarks                                                                                                                            |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 3. | 4. Enter Layer 2 Ethernet interface view.  | <b>interface</b> <i>interface-type</i><br><i>interface-number</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | N/A                                                                                                                                |
| 5. Enable inactivity aging.                | <b>port-security mac-address aging-type inactivity</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Optional.<br>By default, the inactivity aging function is disabled.                                                                |
| 6. Enable the dynamic secure MAC function. | <b>port-security mac-address dynamic</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Optional.<br>By default, sticky MAC addresses can be saved to the configuration file, and once saved, can survive a device reboot. |

**NOTE:**

You can display dynamic secure MAC addresses only by using the **display port-security mac-address security** command.

## Ignoring authorization information from the server

The authorization information is delivered by the RADIUS server to the device after an 802.1X user or MAC authenticated user passes RADIUS authentication. You can configure a port to ignore the authorization information from the RADIUS server.

To configure a port to ignore the authorization information from the RADIUS server:

| Step                                                            | Command                                                           | Remarks                                                                       |
|-----------------------------------------------------------------|-------------------------------------------------------------------|-------------------------------------------------------------------------------|
| 1. Enter system view.                                           | <b>system-view</b>                                                | N/A                                                                           |
| 2. Enter Layer 2 Ethernet interface view.                       | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                                                                           |
| 3. Ignore the authorization information from the RADIUS server. | <b>port-security authorization ignore</b>                         | By default, a port uses the authorization information from the RADIUS server. |

## Displaying and maintaining port security

| Task                                                                                                                         | Command                                                                                                                                                                                                                                                 | Remarks               |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Display port security configuration information, operation information, and statistics about one or more ports or all ports. | <b>display port-security</b> [ <b>interface</b> <i>interface-list</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]                                                                                              | Available in any view |
| Display information about secure MAC addresses.                                                                              | <b>display port-security mac-address security</b> [ <b>interface</b> <i>interface-type</i> <i>interface-number</i> ] [ <b>vlan</b> <i>vlan-id</i> ] [ <b>count</b> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view |
| Display information about blocked MAC addresses.                                                                             | <b>display port-security mac-address block</b> [ <b>interface</b> <i>interface-type</i> <i>interface-number</i> ] [ <b>vlan</b> <i>vlan-id</i> ] [ <b>count</b> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]    | Available in any view |

## Port security configuration examples

### Configuring the autoLearn mode

#### Network requirements

See [Figure 87](#). Configure port GigabitEthernet 1/0/1 on the Device, as follows:

- Accept up to 64 users on the port without authentication.
- Permit the port to learn and add MAC addresses as sticky MAC addresses, and set the sticky MAC aging timer to 30 minutes.
- After the number of secure MAC addresses reaches 64, the port stops learning MAC addresses. If any frame with an unknown MAC address arrives, intrusion protection starts, and the port shuts down and stays silent for 30 seconds.

**Figure 87 Network diagram**

#### Configuration procedure

```
Enable port security.
<Device> system-view
[Device] port-security enable

Set the secure MAC aging timer to 30 minutes.
[Device] port-security timer autolearn aging 30

Enable intrusion protection traps on port GigabitEthernet 1/0/1.
[Device] port-security trap intrusion
[Device] interface gigabitethernet 1/0/1
```

```

Set port security's limit on the number of MAC addresses to 64 on the port.
[Device-GigabitEthernet1/0/1] port-security max-mac-count 64

Set the port security mode to autoLearn.
[Device-GigabitEthernet1/0/1] port-security port-mode autolearn

Configure the port to be silent for 30 seconds after the intrusion protection feature is triggered.
[Device-GigabitEthernet1/0/1] port-security intrusion-mode disableport-temporarily
[Device-GigabitEthernet1/0/1] quit
[Device] port-security timer disableport 30

```

## Verifying the configuration

```

Display the port security configuration.
<Device> display port-security interface gigabitethernet 1/0/1
 Equipment port-security is enabled
 Intrusion trap is enabled
AutoLearn aging time is 30 minutes
 Disableport Timeout: 30s
 OUI value:

GigabitEthernet1/0/1 is link-up
 Port mode is autoLearn
 NeedToKnow mode is disabled
 Intrusion Protection mode is DisablePortTemporarily
 Max MAC address number is 64
 Stored MAC address number is 0
 Authorization is permitted
 Security MAC address learning mode is sticky
 Security MAC address aging type is absolute

```

The output shows that the port security's limit on the number of secure MAC addresses on the port is 64, the port security mode is autoLearn, intrusion protection traps are enabled, and the intrusion protection action is disabling the port (DisablePortTemporarily) for 30 seconds.

# Repeatedly perform the **display port-security** command to track the number of MAC addresses learned by the port, or use the **display this** command in Layer 2 Ethernet interface view to display the secure MAC addresses.

```

<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] display this
#
interface GigabitEthernet1/0/1
 port-security max-mac-count 64
 port-security port-mode autolearn
 port-security mac-address security sticky 0002-0000-0015 vlan 1
 port-security mac-address security sticky 0002-0000-0014 vlan 1
 port-security mac-address security sticky 0002-0000-0013 vlan 1
 port-security mac-address security sticky 0002-0000-0012 vlan 1
 port-security mac-address security sticky 0002-0000-0011 vlan 1
#

```

Execute the **display port-security interface** command after the number of MAC addresses learned by the port reaches 64, and you can see that the port security mode has changed to secure. When any frame with a new MAC address arrives, intrusion protection is triggered and you can see the following trap message.

```
#Jan 14 10:39:47:135 2011 Device PORTSEC/4/VIOLATION: Trap1.3.6.1.4.1.25506.2.26.1.3.2:
```

```
An intrusion occurs!
IfIndex: 9437185
Port: 9437185
MAC Addr: 00:02:00:00:00:32
VLAN ID: 1
IfAdminStatus: 1
```

# Execute the **display interface** command, and can see that the port security feature has disabled the port.

```
[Device-GigabitEthernet1/0/1] display interface gigabitethernet 1/0/1
GigabitEthernet1/0/1 current state: DOWN (Port Security Disabled)
IP Packet Frame Type: PKTFMT_ETHNT_2, Hardware Address: 000f-cb00-5558
Description: GigabitEthernet1/0/1 Interface
.....
```

The port should be re-enabled 30 seconds later.

```
[Device-GigabitEthernet1/0/1] display interface gigabitethernet 1/0/1
GigabitEthernet1/0/1 current state: UP
IP Packet Frame Type: PKTFMT_ETHNT_2, Hardware Address: 000f-cb00-5558
Description: GigabitEthernet1/0/1 Interface
.....
```

Delete several secure MAC addresses, and you can see that the port security mode of the port changes to autoLearn, and the port can learn MAC addresses again.

## Configuring the userLoginWithOUI mode

### Network requirements

As shown in [Figure 88](#), a client is connected to the Device through port GigabitEthernet 1/0/1. The Device authenticates the client with a RADIUS server. If the authentication succeeds, the client is authorized to access the Internet.

- The RADIUS server at 192.168.1.2 functions as the primary authentication server and the secondary accounting server, and the RADIUS server at 192.168.1.3 functions as the secondary authentication server and the primary accounting server. The shared key for authentication is name, and that for accounting is money.
- All users use the default authentication, authorization, and accounting methods of ISP domain **sun**, which can accommodate up to 30 users.
- The RADIUS server response timeout time is five seconds and the maximum number of RADIUS packet retransmission attempts is five. The Device sends real-time accounting packets to the RADIUS server at an interval of 15 minutes, and sends usernames without domain names to the RADIUS server.

Configure port GigabitEthernet 1/0/1 of the Device to:

- Allow only one 802.1X user to be authenticated.

- Allow up to 16 OUI values to be configured and allow one terminal that uses any of the OUI values to access the port in addition to an 802.1X user.

**Figure 88 Network diagram**

## Configuration procedure

Configurations on the host and RADIUS servers are not shown. The following configuration steps cover some AAA/RADIUS configuration commands. For more information about the commands, see *Security Command Referenced*.

1. Configure the RADIUS protocol:

# Configure a RADIUS scheme named **radsun**.

```
<Device> system-view
[Device] radius scheme radsun
[Device-radius-radsun] primary authentication 192.168.1.2
[Device-radius-radsun] primary accounting 192.168.1.3
[Device-radius-radsun] secondary authentication 192.168.1.3
[Device-radius-radsun] secondary accounting 192.168.1.2
[Device-radius-radsun] key authentication name
[Device-radius-radsun] key accounting money
[Device-radius-radsun] timer response-timeout 5
[Device-radius-radsun] retry 5
[Device-radius-radsun] timer realtime-accounting 15
[Device-radius-radsun] user-name-format without-domain
[Device-radius-radsun] quit
```

# Configure ISP domain **sun** to use RADIUS scheme **radsun** for authentication, authorization, and accounting of all types of users. Specify that the ISP domain can contain up to 30 users.

```
[Device] domain sun
[Device-isp-sun] authentication default radius-scheme radsun
[Device-isp-sun] authorization default radius-scheme radsun
[Device-isp-sun] accounting default radius-scheme radsun
[Device-isp-sun] access-limit enable 30
[Device-isp-sun] quit
```

2. Configure 802.1X:

# Set the 802.1X authentication method to CHAP. (This configuration is optional. By default, the authentication method is CHAP for 802.1X.)

```
[Device] dot1x authentication-method chap
```

3. Configure port security:

# Enable port security.

```

[Device] port-security enable
Add five OUI values.
[Device] port-security oui 1234-0100-1111 index 1
[Device] port-security oui 1234-0200-1111 index 2
[Device] port-security oui 1234-0300-1111 index 3
[Device] port-security oui 1234-0400-1111 index 4
[Device] port-security oui 1234-0500-1111 index 5
[Device] interface gigabitethernet 1/0/1
Set the port security mode to userLoginWithOUI.
[Device-GigabitEthernet1/0/1] port-security port-mode userlogin-withoui

```

## Verifying the configuration

```

Display the RADIUS scheme radsun.
<Device> display radius scheme radsun
SchemeName : radsun

 Authorization attributes:
```

# Display the port security configuration.

```
<Device> display port-security interface gigabitethernet 1/0/1
 Equipment port-security is enabled
 Trap is disabled
 Disableport Timeout: 20s
 OUI value:
 Index is 1, OUI value is 123401
 Index is 2, OUI value is 123402
 Index is 3, OUI value is 123403
 Index is 4, OUI value is 123404
 Index is 5, OUI value is 123405
```

```
GigabitEthernet1/0/1 is link-up
 Port mode is userLoginWithOUI
 NeedToKnow mode is disabled
 Intrusion Protection mode is NoAction
 Max MAC address number is not configured
 Stored MAC address number is 0
 Authorization is permitted
 Security MAC address learning mode is sticky
 Security MAC address aging type is absolute
```

After an 802.1X user gets online, you can see that the number of secure MAC addresses stored is 1.

# Display 802.1X information.

```
<Device> display dot1x interface gigabitethernet 1/0/1
 Equipment 802.1X protocol is enabled
 CHAP authentication is enabled
 EAD quick deploy is disabled

 Configuration: Transmit Period 30 s, Handshake Period 15 s
 Quiet Period 60 s, Quiet Period Timer is disabled
 Supp Timeout 30 s, Server Timeout 100 s
 Reauth Period 3600 s
 The maximal retransmitting times 2
 EAD quick deploy configuration:
```

EAD timeout: 30m

The maximum 802.1X user resource number is 1024 per slot  
Total current used 802.1X resource number is 1

GigabitEthernet1/0/1 is link-up  
802.1X protocol is enabled  
Handshake is enabled  
Handshake secure is disabled  
802.1X unicast-trigger is enabled  
Periodic reauthentication is disabled  
The port is an authenticator  
Authentication Mode is Auto  
Port Control Type is Mac-based  
802.1X Multicast-trigger is enabled  
Mandatory authentication domain: NOT configured  
Guest VLAN: NOT configured  
Auth-Fail VLAN: NOT configured  
Critical VLAN: NOT configured  
Critical recovery-action: NOT configured  
Max number of on-line users is 256

EAPOL Packet: Tx 16331, Rx 102  
Sent EAP Request/Identity Packets : 16316  
EAP Request/Challenge Packets: 6  
EAP Success Packets: 4, Fail Packets: 5  
Received EAPOL Start Packets : 6  
EAPOL LogOff Packets: 2  
EAP Response/Identity Packets : 80  
EAP Response/Challenge Packets: 6  
Error Packets: 0

1. Authenticated user : MAC address: 0002-0000-0011

Controlled User(s) amount to 1

In addition, the port allows an additional user whose MAC address has an OUI among the specified OUIs to access the port.

# Display MAC address information for interface GigabitEthernet 1/0/1.

<Device> display mac-address interface gigabitethernet 1/0/1

| MAC ADDR       | VLAN ID | STATE   | PORT INDEX           | AGING TIME(s) |
|----------------|---------|---------|----------------------|---------------|
| 1234-0300-0011 | 1       | Learned | GigabitEthernet1/0/1 | AGING         |

--- 1 mac address(es) found ---

# Configuring the macAddressElseUserLoginSecure mode

## Network requirements

As shown in [Figure 88](#), a client is connected to the Device through GigabitEthernet 1/0/1. The Device authenticates the client by a RADIUS server. If the authentication succeeds, the client is authorized to access the Internet.

Restrict port GigabitEthernet 1/0/1 of the Device:

- Allow more than one MAC authenticated user to log on.
- For 802.1X users, perform MAC authentication first and then, if MAC authentication fails, 802.1X authentication. Allow only one 802.1X user to log on.
- Set fixed username and password for MAC authentication. Set the total number of MAC authenticated users and 802.1X authenticated users to 64.
- Enable NTK to prevent frames from being sent to unknown MAC addresses.

## Configuration procedure

Configurations on the host and RADIUS servers are not shown.

1. Configure the RADIUS protocol:

Configure the RADIUS authentication/accounting and ISP domain settings the same as in [Configuring the userLoginWithOUI mode](#).

2. Configure port security:

# Enable port security.

```
<Device> system-view
[Device] port-security enable
```

# Configure a MAC authentication user, setting the username and password to aaa and 123456 respectively.

```
[Device] mac-authentication user-name-format fixed account aaa password simple 123456
[Device] interface gigabitethernet 1/0/1
```

# Specify ISP domain **sun** for MAC authentication.

```
[Device] mac-authentication domain sun
[Device] interface gigabitethernet 1/0/1
```

# Set the 802.1X authentication method to CHAP. (This configuration is optional. By default, the authentication method is CHAP for 802.1X.)

```
[Device] dot1x authentication-method chap
```

# Set port security's limit on the number of MAC addresses to 64 on the port.

```
[Device-GigabitEthernet1/0/1] port-security max-mac-count 64
```

# Set the port security mode to macAddressElseUserLoginSecure.

```
[Device-GigabitEthernet1/0/1] port-security port-mode mac-else-userlogin-secure
```

# Set the NTK mode of the port to ntkonly.

```
[Device-GigabitEthernet1/0/1] port-security ntk-mode ntkonly
```

## Verifying the configuration

# Display the port security configuration.

```
<Device> display port-security interface gigabitethernet 1/0/1
Equipment port-security is enabled
Trap is disabled
```

Disableport Timeout: 20s

OUI value:

GigabitEthernet1/0/1 is link-up

Port mode is macAddressElseUserLoginSecure

NeedToKnow mode is NeedToKnowOnly

Intrusion Protection mode is NoAction

Max MAC address number is 64

Stored MAC address number is 0

Authorization is permitted

Security MAC address learning mode is sticky

Security MAC address aging type is absolute

### # Display MAC authentication information.

<Device> display mac-authentication interface gigabitethernet 1/0/1

MAC address authentication is enabled.

User name format is fixed account

Fixed username:aaa

Fixed password: \*\*\*\*\*

Offline detect period is 60s

Quiet period is 5s

Server response timeout value is 100s

The max allowed user number is 1024 per slot

Current user number amounts to 3

Current domain is mac

Silent MAC User info:

| MAC Addr | From Port | Port Index |
|----------|-----------|------------|
|----------|-----------|------------|

GigabitEthernet1/0/1 is link-up

MAC address authentication is enabled

Authenticate success: 3, failed: 7

Max number of on-line users is 256

Current online user number is 3

| MAC ADDR       | Authenticate state        | Auth Index |
|----------------|---------------------------|------------|
| 1234-0300-0011 | MAC_AUTHENTICATOR_SUCCESS | 13         |
| 1234-0300-0012 | MAC_AUTHENTICATOR_SUCCESS | 14         |
| 1234-0300-0013 | MAC_AUTHENTICATOR_SUCCESS | 15         |

### # Display 802.1X authentication information.

<Device> display dot1x interface gigabitethernet 1/0/1

Equipment 802.1X protocol is enabled

CHAP authentication is enabled

EAD quick deploy is disabled

|                                |       |                                |       |

| Supp Timeout                   | 30 s, | Server Timeout                 | 100 s |

```
The maximal retransmitting times 2
EAD quick deploy configuration:
 EAD timeout: 30m

Total maximum 802.1X user resource number is 1024 per slot
Total current used 802.1X resource number is 1
```

```
GigabitEthernet1/0/1 is link-up
 802.1X protocol is enabled
 Handshake is enabled
 Handshake secure is disabled
 802.1X unicast-trigger is enabled
 Periodic reauthentication is disabled
 The port is an authenticator
 Authentication Mode is Auto
 Port Control Type is Mac-based
 802.1X Multicast-trigger is enabled
 Mandatory authentication domain: NOT configured
 Guest VLAN: NOT configured
 Auth-Fail VLAN: NOT configured
 Critical VLAN: NOT configured
 Critical recovery-action: NOT configured
 Max number of on-line users is 256
```

```
EAPOL Packet: Tx 16331, Rx 102
Sent EAP Request/Identity Packets : 16316
 EAP Request/Challenge Packets: 6
 EAP Success Packets: 4, Fail Packets: 5
Received EAPOL Start Packets : 6
 EAPOL LogOff Packets: 2
 EAP Response/Identity Packets : 80
 EAP Response/Challenge Packets: 6
 Error Packets: 0
1. Authenticated user : MAC address: 0002-0000-0011
```

Controlled User(s) amount to 1

As NTK is enabled, frames with unknown destination MAC addresses, multicast addresses, and broadcast addresses will be discarded.

## Troubleshooting port security

### Cannot set the port security mode

#### Symptom

Cannot set the port security mode.

```
[Device-GigabitEthernet1/0/1] port-security port-mode autolearn
```

Error:When we change port-mode, we should first change it to noRestrictions, then change it to the other.

## Analysis

For a port operating in a port security mode other than noRestrictions, you cannot change the port security mode by using the **port-security port-mode** command directly.

## Solution

Set the port security mode to noRestrictions first.

```
[Device-GigabitEthernet1/0/1] undo port-security port-mode
[Device-GigabitEthernet1/0/1] port-security port-mode autolearn
```

# Cannot configure secure MAC addresses

## Symptom

Cannot configure secure MAC addresses.

```
[Device-GigabitEthernet1/0/1] port-security mac-address security 1-1-2 vlan 1
Error: Security MAC address configuration failed.
```

## Analysis

No secure MAC address can be configured on a port operating in a port security mode other than autoLearn.

## Solution

Set the port security mode to autoLearn.

```
[Device-GigabitEthernet1/0/1] undo port-security port-mode
[Device-GigabitEthernet1/0/1] port-security max-mac-count 64
[Device-GigabitEthernet1/0/1] port-security port-mode autolearn
[Device-GigabitEthernet1/0/1] port-security mac-address security 1-1-2 vlan 1
```

# Cannot change port security mode when a user is online

## Symptom

Port security mode cannot be changed when an 802.1X authenticated or MAC authenticated user is online.

```
[DeviceGigabitEthernet1/0/1] undo port-security port-mode
Error:Cannot configure port-security for there is 802.1X user(s) on line on port
GigabitEthernet1/0/1.
```

## Analysis

Changing port security mode is not allowed when an 802.1X authenticated or MAC authenticated user is online.

## Solution

Use the **cut** command to forcibly disconnect the user from the port before changing the port security mode.

```
[Device-GigabitEthernet1/0/1] quit
[Device] cut connection interface gigabitethernet 1/0/1
[Device] interface gigabitethernet 1/0/1
```

```
[Device-GigabitEthernet1/0/1] undo port-security port-mode
```

---

# Configuring a user profile

## User profile overview

A user profile provides a configuration template to save predefined configurations, such as a Quality of Service (QoS) policy. Different user profiles are applicable to different application scenarios.

The user profile supports working with 802.1X authentication and portal authentication. It is capable of restricting authenticated users' behaviors. After the authentication server verifies a user, it sends the device the name of the user profile that is associated with the user. Then the device applies the configurations in the user profile if the profile is enabled, and allows user access based on all valid configurations. If the user profile is not enabled, the device denies the user access. After the user logs out, the device automatically disables the configurations in the user profile, and the restrictions on the users are removed.

Without user profiles, service applications are based on interface, VLAN, or globally, and a policy applies to any user that accesses the interface, or VLAN, or device. If a user moves between ports to access a device, to restrict the user behavior, you must remove the policy from the previous port and then configure the same policy on the port that the user uses. The configuration task is tedious and error prone.

User profiles provide flexible user-based service applications because a user profile is associated with a target user. Every time the user accesses the device, the device automatically applies the configurations in the associated user profile.

## User profile configuration task list

| Task                                    | Remarks  |
|-----------------------------------------|----------|
| <a href="#">Creating a user profile</a> | Required |
| <a href="#">Applying a QoS policy</a>   | Required |
| <a href="#">Enabling a user profile</a> | Required |

## Creating a user profile

### Configuration prerequisites

Before you create a user profile, complete the following tasks:

- Configure authentication parameters on the device.
- Perform configurations on the client, the device, and the authentication server, for example, username, password, authentication scheme, domain, and binding a user profile with a user.

### Configuration procedure

| Step                                          | Command                                 | Remarks                                                                |
|-----------------------------------------------|-----------------------------------------|------------------------------------------------------------------------|
| 1. Enter system view.                         | <b>system-view</b>                      | N/A                                                                    |
| 2. Create a user profile, and enter its view. | <b>user-profile</b> <i>profile-name</i> | You can use the command to enter the view of an existing user profile. |

## Applying a QoS policy

You can apply QoS policies in user profile view to implement traffic management functions.

### Configuration guidelines

- After a user profile is created, apply a QoS policy in user profile view to implement restrictions on online users. The QoS policy takes effect when the user profile is enabled and a user using the user profile goes online.
- The QoS policies that can be applied to user profiles support only the **remark**, **car**, and **filter** actions.
- Do not apply an empty policy in user profile view because a user profile with an empty policy applied cannot be enabled.
- If a user profile is enabled, you cannot modify the applied QoS policy (including the ACL that is referenced by the QoS policy) or remove it.
- For information about QoS policy configurations, see *ACL and QoS Configuration Guide*.

### Configuration procedure

| Step                        | Command                                                                            | Remarks                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.       | <b>system-view</b>                                                                 | N/A                                                                                                                                                                                                                                                                                                                              |
| 2. Enter user profile view. | <b>user-profile</b> <i>profile-name</i>                                            | N/A                                                                                                                                                                                                                                                                                                                              |
| 3. Apply the QoS policy.    | <b>qos apply policy</b> <i>policy-name</i><br>{ <b>inbound</b>   <b>outbound</b> } | The <b>inbound</b> keyword applies the QoS policy to incoming traffic of the switch (traffic sent by online users).<br>The <b>outbound</b> keyword applies the QoS policy to outgoing traffic of the switch (traffic sent to online users).<br><br>The <b>outbound</b> keyword is not available on the HP 5500 SI Switch Series. |

## Enabling a user profile

Enable a user profile so that configurations in the profile can be applied by the device to restrict user behaviors. If the device detects that the user profile is disabled, the device denies the associated user even the user has been verified by the authentication server.

To enable a user profile:

| Step                      | Command                                               | Remarks                                |
|---------------------------|-------------------------------------------------------|----------------------------------------|
| 1. Enter system view.     | <b>system-view</b>                                    | N/A                                    |
| 2. Enable a user profile. | <b>user-profile</b> <i>profile-name</i> <b>enable</b> | A user profile is disabled by default. |

**NOTE:**

- You can only edit or remove the configurations in a disabled user profile.
- Disabling a user profile logs out the users that are using the user profile.

## Displaying and maintaining user profiles

| Task                                                     | Command                                                                                                        | Remarks               |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|-----------------------|
| Display information about all the created user profiles. | <b>display user-profile</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view |

---

# Configuring password control

## Password control overview

Password control refers to a set of functions provided by the local authentication server to control user login passwords, super passwords, and user login status based on predefined policies. The rest of this section describes the password control functions in detail.

1. Minimum password length

By setting a minimum password length, you can enforce users to use passwords long enough for system security. If a user specifies a shorter password, the system rejects the setting and prompts the user to re-specify a password.

2. Minimum password update interval

This function allows you to set the minimum interval at which users can change their passwords. If a non-manage level user logs in to change the password but the time that elapses since the last change is less than this interval, the system denies the request. For example, if you set this interval to 48 hours, a non-manage level user cannot change the password twice within 48 hours. This prevents users from changing their passwords frequently.

---

**NOTE:**

- This function is not effective for users of the manage level. For information about user levels, see *Fundamentals Configuration Guide*.
- This function is not effective for a user who is prompted to change the password at the first login or a user whose password has just been aged out.

---

3. Password aging

Password aging imposes a lifecycle on a user password. After the password aging time expires, the user needs to change the password.

If a user enters an expired password when logging in, the system displays an error message and prompts the user to provide a new password and to confirm it by entering it again. The new password must be a valid one and the user must enter exactly the same password when confirming it.

4. Early notice on pending password expiration

When a user logs in, the system checks whether the password will expire in a time equal to or less than the specified period. If so, the system notifies the user of the expiry time and provides a choice for the user to change the password. If the user provides a new password that is qualified, the system records the new password and the time. If the user chooses to leave the password or the user fails to change it, the system allows the user to log in using the present password.

---

**NOTE:**

Telnet, SSH, and terminal users can change their passwords by themselves, while FTP users can only have their passwords changed by the administrator.

---

5. Login with an expired password

You can allow a user to log in a certain number of times within a specified period of time after the password expires, so that the user does not need to change the password immediately. For

example, if you set the maximum number of logins with an expired password to three and the time period to 15 days, a user can log in three times within 15 days after the password expires.

## 6. Password history

With this feature enabled, the system maintains certain entries of passwords that a user has used. When a user changes the password, the system checks the new password against the used ones. The new password must be different from the used ones by at least four characters and the four characters must not be the same. Otherwise, you will fail to change the password and the system displays an error message.

You can set the maximum number of history password records for the system to maintain for each user. When the number of history password records exceeds your setting, the latest record will overwrite the earliest one.

## 7. Login attempt limit

Limiting the number of consecutive failed login attempts can effectively prevent password guessing.

If an FTP or virtual terminal line (VTY) user fails authentication due to a password error, the system adds the user to a password control blacklist. If a user fails to provide the correct password after the specified number of consecutive attempts, the system takes action as configured:

- Prohibiting the user from logging in until the user is removed from the password control blacklist manually.
- Allowing the user to try continuously and removing the user from the password control blacklist when the user logs in to the system successfully or the blacklist entry times out (the blacklist entry aging time is one minute).
- Prohibiting the user from logging in within a configurable period of time, and allowing the user to log in again after the period of time elapses or the user is removed from the password control blacklist.

A password control blacklist can contain up to 1024 entries.

A login attempt using a wrong username will undoubtedly fail but the username will not be added to the password control blacklist.

Web users failing login authentication are not added to the password control blacklist. Users accessing the system through the console or AUX interface are not blacklisted either, because the system is unable to obtain the IP addresses of these users and these users are privileged and therefore relatively secure to the system.

## 8. Password composition checking

A password can be a combination of characters from the following four categories:

- Uppercase letters A to Z
- Lowercase letters a to z
- Digits 0 to 9
- 32 special characters including blank space and ~`!@#\$\$%^&\*()\_+={}|[]\:"';<>,. /.

Depending on the system security requirements, you can set the minimum number of categories a password must contain and the minimum number of characters of each category.

There are four password combination levels: 1, 2, 3, and 4, each representing the number of categories that a password must at least contain. Level 1 means that a password must contain characters of one category, level 2 at least two categories, and so on.

When a user sets or changes the password, the system checks if the password satisfies the composition requirement. If not, the system displays an error message.

## 9. Password complexity checking

A less complicated password such as a password containing the username or repeated characters is more likely to be cracked. For higher security, you can configure a password complexity checking policy to make sure that all user passwords are relatively complicated. With such a policy configured, when a user configures a password, the system checks the complexity of the password. If the password is not qualified, the system refuses the password and displays a password configuration failure message.

You can impose the following password complexity requirements:

- A password cannot contain the username or the reverse of the username. For example, if the username is abc, a password such as abc982 or 2cba is unqualified.
- No character of the password is repeated three or more times consecutively. For example, password a111 is not qualified.

## 10. Password display in the form of a string of \*

For the sake of security, the password a user enters is displayed in the form of a string of \*.

## 11. Authentication timeout management

The authentication period is from when the server obtains the username to when the server finishes authenticating the user's password. If a Telnet user fails to log in within the configured period of time, the system tears down the connection.

## 12. Maximum account idle time

You can set the maximum account idle time to make accounts staying idle for this period of time become invalid and unable to log in again. For example, if you set the maximum account idle time to 60 days and user using the account **test** has never logged in successfully within 60 days after the last successful login, the account becomes invalid.

## 13. Logging

The system logs all successful password changing events and the events of adding users to the password control blacklist.

# Password control configuration task list

The password control functions can be configured in several views, and different views support different functions. The settings configured in different views or for different objects have different application ranges and different priorities:

- Global settings in system view apply to all local user passwords and super passwords.
- Settings in user group view apply to the passwords of all local users in the user group.
- Settings in local user view apply to only the password of the local user.
- Settings for super passwords apply to only super passwords.

The above four types of settings have different priorities:

- For local user passwords, the settings with a smaller application range have a higher priority.
- For super passwords, the settings configured specifically for super passwords, if any, override those configured in system view.

Complete the following tasks to configure password control:

| Task                      | Remarks  |
|---------------------------|----------|
| Enabling password control | Required |

| Task                                              | Remarks  |
|---------------------------------------------------|----------|
| Setting global password control parameters        | Optional |
| Setting user group password control parameters    | Optional |
| Setting local user password control parameters    | Optional |
| Setting super password control parameters         | Optional |
| Setting a local user password in interactive mode | Optional |

## Configuring password control

### Enabling password control

To enable password control functions, you need to:

1. Enable the password control feature in system view. Only after the password control feature is enabled globally, can password control configurations take effect.
2. Enable password control functions. Some password control functions need to be enabled individually after the password control feature is enabled globally. These functions include:
  - o Password aging
  - o Minimum password length
  - o Password history
  - o Password composition checking

You must enable a function for its relevant configurations to take effect.

To enable password control:

| Step                                                | Command                                                                   | Remarks                                                                        |
|-----------------------------------------------------|---------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| 1. Enter system view.                               | <b>system-view</b>                                                        | N/A                                                                            |
| 2. Enable the password control feature.             | <b>password-control enable</b>                                            | Disabled by default                                                            |
| 3. Enable a password control function individually. | <b>password-control { aging   composition   history   length } enable</b> | Optional<br>All of the four password control functions are enabled by default. |

#### NOTE:

After global password control is enabled, local user passwords configured on the device are not displayed when you use the corresponding display command.

### Setting global password control parameters

| Step                  | Command            | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | <b>system-view</b> | N/A     |

| Step                                                                                                                                           | Command                                                                                                                                         | Remarks                                                                                                                                                                             |
|------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2. Set the password aging time.                                                                                                                | <b>password-control aging</b> <i>aging-time</i>                                                                                                 | Optional<br>90 days by default                                                                                                                                                      |
| 3. Set the minimum password update interval.                                                                                                   | <b>password-control password update interval</b> <i>interval</i>                                                                                | Optional<br>24 hours by default                                                                                                                                                     |
| 4. Set the minimum password length.                                                                                                            | <b>password-control length</b> <i>length</i>                                                                                                    | Optional<br>10 characters by default                                                                                                                                                |
| 5. Configure the password composition policy.                                                                                                  | <b>password-control composition type-number</b> <i>policy-type</i><br>[ <b>type-length</b> <i>type-length</i> ]                                 | Optional<br>By default, the minimum number of password composition types is 1 and the minimum number of characters of a password composition type is 1 too.                         |
| 6. Configure the password complexity checking policy.                                                                                          | <b>password-control complexity</b><br>{ <b>same-character</b>   <b>user-name</b> }<br><b>check</b>                                              | Optional<br>By default, the system does not perform password complexity checking.                                                                                                   |
| 7. Set the maximum number of history password records for each user.                                                                           | <b>password-control history</b><br><i>max-record-num</i>                                                                                        | Optional<br>4 by default                                                                                                                                                            |
| 8. Specify the maximum number of login attempts and the action to be taken when a user fails to log in after the specified number of attempts. | <b>password-control login-attempt</b><br><i>login-times</i> [ <b>exceed</b> { <b>lock</b>   <b>unlock</b> }<br>  <b>lock-time</b> <i>time</i> ] | Optional<br>By default, the maximum number of login attempts is 3 and a user failing to log in after the specified number of attempts must wait for one minute before trying again. |
| 9. Set the number of days during which the user is warned of the pending password expiration.                                                  | <b>password-control alert-before-expire</b> <i>alert-time</i>                                                                                   | Optional<br>7 days by default                                                                                                                                                       |
| 10. Set the maximum number of days and maximum number of times that a user can log in after the password expires.                              | <b>password-control expired-user-login delay</b> <i>delay</i><br><b>times</b> <i>times</i>                                                      | Optional<br>By default, a user can log in three times within 30 days after the password expires.                                                                                    |
| 11. Set the authentication timeout time.                                                                                                       | <b>password-control authentication-timeout</b><br><i>authentication-timeout</i>                                                                 | Optional<br>60 seconds by default                                                                                                                                                   |
| 12. Set the maximum account idle time.                                                                                                         | <b>password-control login idle-time</b><br><i>idle-time</i>                                                                                     | Optional<br>90 days by default                                                                                                                                                      |

**NOTE:**

The specified action to be taken after a user fails to log in for the specified number of attempts takes effect immediately, and can thus affect the users already in the password control blacklist. Other password control configurations take effect only for users logging in later and passwords configured later.

## Setting user group password control parameters

| Step                                                             | Command                                                                                                                   | Remarks                                                                                    |
|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| 1. Enter system view.                                            | <b>system-view</b>                                                                                                        | N/A                                                                                        |
| 2. Create a user group and enter user group view.                | <b>user-group</b> <i>group-name</i>                                                                                       | N/A                                                                                        |
| 3. Configure the password aging time for the user group.         | <b>password-control aging</b> <i>aging-time</i>                                                                           | Optional<br>By default, the password aging time configured in system view is used.         |
| 4. Configure the minimum password length for the user group.     | <b>password-control length</b> <i>length</i>                                                                              | Optional<br>By default, the minimum password length configured in system view is used.     |
| 5. Configure the password composition policy for the user group. | <b>password-control composition</b><br><b>type-number</b> <i>type-number</i><br>[ <b>type-length</b> <i>type-length</i> ] | Optional<br>By default, the password composition policy configured in system view is used. |

## Setting local user password control parameters

| Step                                                             | Command                                                                                                                   | Remarks                                                                                                                                                                                                     |
|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                            | <b>system-view</b>                                                                                                        | N/A                                                                                                                                                                                                         |
| 2. Create a local user and enter local user view.                | <b>local-user</b> <i>user-name</i>                                                                                        | N/A                                                                                                                                                                                                         |
| 3. Configure the password aging time for the local user.         | <b>password-control aging</b> <i>aging-time</i>                                                                           | Optional<br>By default, the setting for the user group to which the local user belongs is used; if no aging time is configured for the user group, the setting in system view is used.                      |
| 4. Configure the minimum password length for the local user.     | <b>password-control length</b> <i>length</i>                                                                              | Optional<br>By default, the setting for the user group to which the local user belongs is used; if no minimum password length is configured for the user group, the setting in system view is used.         |
| 5. Configure the password composition policy for the local user. | <b>password-control composition</b><br><b>type-number</b> <i>type-number</i><br>[ <b>type-length</b> <i>type-length</i> ] | Optional<br>By default, the settings for the user group to which the local user belongs are used; if no password composition policy is configured for the user group, the settings in system view are used. |

## Setting super password control parameters

CLI commands fall into four levels: visit, monitor, system, and manage, in ascending order. Accordingly, login users fall into four levels, each corresponding to a command level. A user of a certain level can only use the commands at that level or lower levels.

To switch from a lower user level to a higher one, a user needs to enter a password for authentication. This password is called a super password. For more information on super passwords, see *Fundamentals Configuration Guide*.

To set super password control parameters:

| Step                                                              | Command                                                                                                           | Remarks                                                                                                                                                     |
|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                             | <b>system-view</b>                                                                                                | N/A                                                                                                                                                         |
| 2. Set the password aging time for super passwords.               | <b>password-control super aging</b><br><i>aging-time</i>                                                          | Optional<br>90 days by default                                                                                                                              |
| 3. Configure the minimum length for super passwords.              | <b>password-control super length</b><br><i>length</i>                                                             | Optional<br>10 characters by default                                                                                                                        |
| 4. Configure the password composition policy for super passwords. | <b>password-control super composition type-number</b><br><i>type-number [ type-length</i><br><i>type-length ]</i> | Optional<br>By default, the minimum number of password composition types is 1 and the minimum number of characters of a password composition type is 1 too. |

## Setting a local user password in interactive mode

You can set a password for a local user in interactive mode. When doing so, you need to confirm the password.

To set a password for a local user in interactive mode:

| Step                                                        | Command                            |
|-------------------------------------------------------------|------------------------------------|
| 1. Enter system view.                                       | <b>system-view</b>                 |
| 2. Create a local user and enter local user view.           | <b>local-user</b> <i>user-name</i> |
| 3. Set the password for the local user in interactive mode. | <b>password</b>                    |

## Displaying and maintaining password control

| Task                                                | Command                                                                                                                            | Remarks               |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Display password control configuration information. | <b>display password-control [ super ]</b><br>[   { <b>begin</b>   <b>exclude</b>   <b>include</b> }<br><i>regular-expression</i> ] | Available in any view |

| Task                                                               | Command                                                                                                                                                                                                                                     | Remarks                |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Display information about users in the password control blacklist. | <b>display password-control blacklist</b><br>[ <b>user-name</b> <i>name</i>   <b>ip</b><br><i>ipv4-address</i>   <b>ipv6</b> <i>ipv6-address</i> ]<br>[   { <b>begin</b>   <b>exclude</b>   <b>include</b> }<br><i>regular-expression</i> ] | Available in any view  |
| Delete users from the password control blacklist.                  | <b>reset password-control blacklist</b><br>[ <b>user-name</b> <i>name</i> ]                                                                                                                                                                 | Available in user view |
| Clear history password records.                                    | <b>reset password-control</b><br><b>history-record</b> [ <b>user-name</b> <i>name</i>  <br><b>super</b> [ <b>level</b> <i>level</i> ] ]                                                                                                     | Available in user view |

#### NOTE:

The **reset password-control history-record** command can delete the history password records of a specific user or all users even when the password history function is disabled.

## Password control configuration example

### Network requirements

Implementing the following global password control policy:

- An FTP or VTY user failing to provide the correct password in two successive login attempts is permanently prohibited from logging in.
- A user can log in five times within 60 days after the password expires.
- The password aging time is 30 days.
- The minimum password update interval is 36 hours.
- The maximum account idle time is 30 days.
- A password cannot contain the username or the reverse of the username.
- No character occurs consecutively three or more times in a password.

Implementing the following super password control policy:

- A super password must contain at least three types of valid characters, five or more of each type.

Implementing the following password control policy for local Telnet user **test**:

- The password must contain at least 12 characters.
- The password must consist of at least two types of valid characters, five or more of each type.
- The password aging time is 20 days.

### Configuration procedure

# Enable the password control feature globally.

```
<Sysname> system-view
[Sysname] password-control enable
```

# Prohibit the user from logging in forever after two successive login failures.

```
[Sysname] password-control login-attempt 2 exceed lock
```

# Set the password aging time to 30 days for all passwords.

```
[Sysname] password-control aging 30
```

```

Set the minimum password update interval to 36 hours.
[Sysname] password-control password update interval 36

Specify that a user can log in five times within 60 days after the password expires.
[Sysname] password-control expired-user-login delay 60 times 5

Set the maximum account idle time to 30 days.
[Sysname] password-control login idle-time 30

Refuse any password that contains the username or the reverse of the username.
[Sysname] password-control complexity user-name check

Specify that no character of the password can be repeated three or more times consecutively.
[Sysname] password-control complexity same-character check

Set the minimum number of composition types for super passwords to 3 and the minimum number of
characters of each composition type to 5.
[Sysname] password-control super composition type-number 3 type-length 5

Configure a super password.
[Sysname] super password level 3 simple 12345ABGFTweuix

Create a local user named test.
[Sysname] local-user test

Set the service type of the user to Telnet.
[Sysname-user-test] service-type telnet

Set the minimum password length to 12 for the local user.
[Sysname-user-test] password-control length 12

Set the minimum number of password composition types to 2 and the minimum number of characters
of each password composition type to 5 for the local user.
[Sysname-user-test] password-control composition type-number 2 type-length 5

Set the password aging time to 20 days for the local user.
[Sysname-user-test] password-control aging 20

Configure the password of the local user in interactive mode.
[Sysname-user-test] password
Password:*****
Confirm :*****
Updating user(s) information, please wait.....
[Sysname-user-test] quit

```

## Verifying the configuration

```

Display the global password control configuration information.
<Sysname> display password-control
Global password control configurations:
 Password control: Enabled
 Password aging: Enabled (30 days)
 Password length: Enabled (10 characters)
 Password composition: Enabled (1 types, 1 characters per type)
 Password history: Enabled (max history record:4)
 Early notice on password expiration: 7 days
 User authentication timeout: 60 seconds

```

```
Maximum failed login attempts: 2 times
Login attempt-failed action: Lock
Minimum password update time: 36 hours
User account idle-time: 30 days
Login with aged password: 5 times in 60 day(s)
Password complexity: Enabled (username checking)
 Enabled (repeated characters checking)
```

# Display the password control configuration information for super passwords.

```
<Sysname> display password-control super
Super password control configurations:
Password aging: Enabled (30 days)
Password length: Enabled (10 characters)
Password composition: Enabled (3 types, 5 characters per type)
```

# Display the password control configuration information for local user **test**.

```
<Sysname> display local-user user-name test
The contents of local user test:
State: Active
ServiceType: telnet
Access-limit: Disable Current AccessNum: 0
User-group: system
Bind attributes:
Authorization attributes:
Password aging: Enabled (20 days)
Password length: Enabled (12 characters)
Password composition: Enabled (2 types, 5 characters per type)
Total 1 local user(s) matched.
```

# Configuring HABP

## HABP overview

The HW Authentication Bypass Protocol (HABP) is intended to enable the downstream network devices of an access device to bypass 802.1X authentication and MAC authentication configured on the access device.

As shown in Figure 89, 802.1X authenticator Switch A has two switches attached to it: Switch B and Switch C. On Switch A, 802.1X authentication is enabled globally and on the ports connecting the downstream network devices. The end-user devices (the supplicants) run the 802.1X client software for 802.1X authentication. For Switch B and Switch D, where the 802.1X client is not supported (which is typical of network devices), the communication between them will fail because they cannot pass 802.1X authentication and their packets will be blocked on Switch A. To allow the two switches to communicate, you can use HABP.

Figure 89 Network diagram for HABP application

HABP is a link layer protocol that works above the MAC layer. It is built on the client-server model. Generally, the HABP server is enabled on the authentication device (which is configured with 802.1X or MAC authentication, such as Switch A in the above example), and the attached switches function as the HABP clients, such as Switch B through Switch E in the example. No device can function as both an HABP server and a client at the same time. Typically, the HABP server sends HABP requests to all its clients periodically to collect their MAC addresses, and the clients respond to the requests. After the server learns the MAC addresses of all the clients, it registers the MAC addresses as HABP entries. Then, link layer frames exchanged between the clients can bypass the 802.1X authentication on ports of the server without affecting the normal operation of the whole network. All HABP packets must travel in a specified VLAN. Communication between the HABP server and HABP clients is implemented through this VLAN.

In a cluster, if a member switch with 802.1X authentication or MAC authentication enabled is attached with some other member switches of the cluster, you also need to configure HABP server on this device.

Otherwise, the cluster management device will not be able to manage the devices attached to this member switch. For more information about the cluster function, see *Network Management and Monitoring Configuration Guide*.

## Configuring HABP

### Configuring the HABP server

An HABP server is usually configured on the authentication device enabled with 802.1X authentication or MAC address authentication. The HABP server sends HABP requests to the attached switches (HABP clients) at a specified interval, collecting their MAC addresses from the responses. HABP packets are transmitted in the VLAN specified on the HABP server.

To configure an HABP server:

| Step                                                                            | Command                                | Remarks                                                                                                                                                                 |
|---------------------------------------------------------------------------------|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                                           | <b>system-view</b>                     | N/A                                                                                                                                                                     |
| 2. Enable HABP.                                                                 | <b>habp enable</b>                     | Optional<br>Enabled by default                                                                                                                                          |
| 3. Configure HABP to work in server mode and specify the VLAN for HABP packets. | <b>habp server vlan</b> <i>vlan-id</i> | HABP works in client mode by default.<br>The VLAN specified on the HABP server for transmitting HABP packets must be the same as that to which the HABP clients belong. |
| 4. Set the interval to send HABP requests.                                      | <b>habp timer</b> <i>interval</i>      | Optional<br>20 seconds by default                                                                                                                                       |

### Configuring an HABP client

An HABP client is usually configured on each device that is attached to the authentication device. After receiving an HABP request from the HABP server, an HABP client responds to the request, delivering its MAC address to the server, and forwards the HABP request to its attached switches. HABP packets are transmitted in the VLAN to which the HABP client belongs.

To configure an HABP client:

| Step                                      | Command                 | Remarks                                           |
|-------------------------------------------|-------------------------|---------------------------------------------------|
| 1. Enter system view.                     | <b>system-view</b>      | N/A                                               |
| 2. Enable HABP.                           | <b>habp enable</b>      | Optional<br>Enabled by default                    |
| 3. Configure HABP to work in client mode. | <b>undo habp server</b> | Optional<br>HABP works in client mode by default. |

| Step                                                  | Command                                | Remarks                                                                                                                                                                                    |
|-------------------------------------------------------|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4. Specify the VLAN to which the HABP client belongs. | <b>habp client vlan</b> <i>vlan-id</i> | Optional<br>By default, an HABP client belongs to VLAN 1.<br>The VLAN to which an HABP client belongs must be the same as that specified on the HABP server for transmitting HABP packets. |

## Displaying and maintaining HABP

| Task                                    | Command                                                                                                        | Remarks               |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------|-----------------------|
| Display HABP configuration information. | <b>display habp</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]         | Available in any view |
| Display HABP MAC address table entries. | <b>display habp table</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]   | Available in any view |
| Display HABP packet statistics.         | <b>display habp traffic</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view |

## HABP configuration example

### Network requirements

As shown in [Figure 90](#), Switch A is attached with access devices Switch B and Switch C. 802.1X authentication is configured on Switch A for central authentication and management of users (Host A through Host D).

For communication between Switch B and Switch C, enable HABP server on Switch A, enable HABP client on Switch B and Switch C, and specify VLAN 1 for HABP packets.

Configure the HABP server to send HABP request packets to the HABP clients in VLAN 1 at an interval of 50 seconds.

Figure 90 Network diagram

## Configuration procedure

1. Configure Switch A:
  - # Perform 802.1X related configurations on Switch A (see "[Configuring 802.1X](#)").
  - # Enable HABP. (HABP is enabled by default. This configuration is optional.)

```
<SwitchA> system-view
[SwitchA] habp enable
```
  - # Configure HABP to work in server mode, and specify VLAN 1 for HABP packets.

```
[SwitchA] habp server vlan 1
```
  - # Set the interval at which the switch sends HABP request packets to 50 seconds.

```
[SwitchA] habp timer 50
```
2. Configure Switch B:
  - # Enable HABP. (HABP is enabled by default. This configuration is optional.)

```
<SwitchA> system-view
[SwitchB] habp enable
```
  - # Configure HABP to work in client mode. (HABP works in client mode by default. This configuration is optional.)

```
[SwitchB] undo habp server
```
  - # Specify the VLAN to which the HABP client belongs as VLAN 1. (An HABP client belongs to VLAN 1 by default. This configuration is optional.)

```
[SwitchB] habp client vlan 1
```
3. Configure Switch C:

Configurations on Switch C are similar to those on Switch B.
4. Verify your configuration:
  - # Display HABP configuration information.

```
<SwitchA> display habp
Global HABP information:
 HABP Mode: Server
 Sending HABP request packets every 50 seconds
 Bypass VLAN: 1
```

# Display HABP MAC address table entries.

```
<SwitchA> display habp table
MAC Holdtime Receive Port
001f-3c00-0030 53 GigabitEthernet1/0/2
001f-3c00-0031 53 GigabitEthernet1/0/1
```

# Managing public keys

## Overview

To protect data confidentiality during transmission, the data sender uses an algorithm and a key to encrypt the plain text data before sending the data out, and the receiver uses the same algorithm with the help of a key to decrypt the data, as shown in [Figure 91](#).

**Figure 91 Encryption and decryption**

The keys that participate in the conversion between the plain text and the cipher text can be the same or different, dividing the encryption and decryption algorithms into the following types:

- **Symmetric key algorithm**—The keys for encryption and decryption are the same.
- **Asymmetric key algorithm**—The keys for encryption and decryption are different, one is the public key, and the other is the private key. The information encrypted with the public key can only be decrypted with the corresponding private key, and vice versa. The private key is kept secret, and the public key may be distributed widely. The private key cannot be practically derived from the public key. Asymmetric key algorithms include the Revest-Shamir-Adleman Algorithm (RSA), and the Digital Signature Algorithm (DSA).

Asymmetric key algorithms can be used in two scenarios for two purposes:

- **To encrypt and decrypt data**—The sender uses the public key of the intended receiver to encrypt the information to be sent. Only the intended receiver, the holder of the paired private key, can decrypt the information. This mechanism guarantees confidentiality. Only RSA can be used for data encryption and decryption.
- **To authenticate a sender**—Also called digital signature. The sender "signs" the information to be sent by encrypting the information with its own private key. A receiver decrypts the information with the sender's public key and, based on whether the information can be decrypted, determines the authenticity of the information. RSA and DSA can be used for digital signature.

Asymmetric key algorithms are widely used in various applications. For example, Secure Shell (SSH), Secure Sockets Layer (SSL), and Public Key Infrastructure (PKI) use the algorithms for digital signature. For information about SSH, SSL, and PKI, see "[Configuring SSH2.0](#)," "[Configuring SSL](#)," and "[Configuring PKI](#)."

## Configuration task list

Public key configuration tasks enable you to manage the local asymmetric key pairs, and configure the peer host public keys on the local device. By completing these tasks, the local device is ready to work with applications such as SSH and SSL to implement data encryption/decryption, or digital signature.

Complete these tasks to configure public keys:

| Task                                                        | Remarks                                                                                                                                                                             |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Configuring a local asymmetric key pair on the local device | <a href="#">Creating a local asymmetric key pair</a><br><a href="#">Displaying or exporting the local host public key</a><br><a href="#">Destroying a local asymmetric key pair</a> |
| Specifying the peer public key on the local device          | Optional                                                                                                                                                                            |

## Creating a local asymmetric key pair

When you create an asymmetric key pair on the local device, follow these guidelines:

- Create an asymmetric key pair of the proper type to work with a target application.
- After you enter the command, specify a proper modulus length for the key pair. The following table compares the three types of key pairs.

**Table 13 A comparison between different types of asymmetric key pairs**

| Type | Number of key pairs                                                                                              | Modulus length                      | Remarks                                              |
|------|------------------------------------------------------------------------------------------------------------------|-------------------------------------|------------------------------------------------------|
| RSA  | Two key pairs, one server key pair and one host key pair. Each key pair comprises a public key and a private key | 512 to 2048 bits<br>1024 by default | To achieve high security, specify at least 768 bits. |
| DSA  | One key pair, the host key pair                                                                                  |                                     |                                                      |

### ⚠ IMPORTANT:

Only SSH1.5 uses the RSA server key pair.

To create a local asymmetric key pair:

| Step                                   | Command                                      | Remarks                                                                                                                                                                     |
|----------------------------------------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                  | <b>system-view</b>                           | N/A                                                                                                                                                                         |
| 2. Create a local asymmetric key pair. | <b>public-key local create { dsa   rsa }</b> | By default, no asymmetric key pair is created.<br>Key pairs created with the <b>public-key local create</b> command are saved automatically and can survive system reboots. |

## Displaying or exporting the local host public key

In SSH, to allow your local device to be authenticated by a peer device through digital signature, you must display or export the local host public key, which will then be specified on the peer device.

To display or export the local host public key, choose one of the following methods:

- [Displaying and recording the host public key information](#)
- [Displaying the host public key in a specific format and saving it to a file](#)
- [Exporting the host public key in a specific format to a file](#)

If your local device functions to authenticate the peer device, you must specify the peer public key on the local device. For more information, see "[Specifying the peer public key on the local device.](#)"

## Displaying and recording the host public key information

To display the local public key:

| Task                               | Command                                                                                                                             | Remarks                   |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| Display the local RSA public keys. | <b>display public-key local rsa public</b><br>[   { <b>begin</b>   <b>exclude</b>   <b>include</b> }<br><i>regular-expression</i> ] | Available in any view.    |
| Display the local host public key. | <b>display public-key local dsa public</b><br>[   { <b>begin</b>   <b>exclude</b>   <b>include</b> }<br><i>regular-expression</i> ] | Use at least one command. |

The **display public-key local rsa public** command displays both the RSA server and host public keys. Recording the RSA host public key is enough.

After displaying the host public key, record the key information for manual configuration of the key on the peer device.

## Displaying the host public key in a specific format and saving it to a file

To display the local host public key in a specific format:

| Step                                                                  | Command                                                                                                                                                                                                                                                                   | Remarks                   |
|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| 1. Enter system view.                                                 | <b>system-view</b>                                                                                                                                                                                                                                                        | N/A                       |
| 2. Display the local RSA or DSA host public key in a specific format. | <ul style="list-style-type: none"> <li>To display the local RSA host public key:<br/><b>public-key local export rsa { openssh   ssh1   ssh2 }</b></li> <li>To display the local DSA host public key:<br/><b>public-key local export dsa { openssh   ssh2 }</b></li> </ul> | Use at least one command. |

After you display the host public key in a specify format, save the key to a file, and transfer this file to the peer device.

## Exporting the host public key in a specific format to a file

After you export and save the host public key in a specify format to a file, transfer the file to the peer device.

To export and save the local host public key to a file:

| Step                                                                         | Command                                                                                                                                                                                                                                                                               | Remarks                   |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| 1. Enter system view.                                                        | <b>system-view</b>                                                                                                                                                                                                                                                                    | N/A                       |
| 2. Export a local RSA or DSA host public key in a specific format to a file. | <ul style="list-style-type: none"> <li>To export a local RSA host public key:<br/><b>public-key local export rsa { openssh   ssh1   ssh2 } filename</b></li> <li>To export a local DSA host public key:<br/><b>public-key local export dsa { openssh   ssh2 } filename</b></li> </ul> | Use at least one command. |

# Destroying a local asymmetric key pair

You may need to destroy a local asymmetric key pair and generate a new pair when an intrusion event has occurred, the storage media of the device is replaced, the asymmetric key has been used for a long time, or the local certificate expires. For more information about the local certificate, see "[Configuring PKI](#)."

To destroy a local asymmetric key pair:

| Step                                    | Command                                       |
|-----------------------------------------|-----------------------------------------------|
| 1. Enter system view.                   | <b>system-view</b>                            |
| 2. Destroy a local asymmetric key pair. | <b>public-key local destroy { dsa   rsa }</b> |

# Specifying the peer public key on the local device

In SSH, to enable the local device to authenticate a peer device, specify the peer public key on the local device. The device supports up to 20 peer public keys.

For information about displaying or exporting the host public key, see "[Displaying or exporting the local host public key](#)."

Take one of the following methods to specify the peer public key on the local device:

| Method                                                       | Prerequisites                                                                                                                                                                                                                                                                                                                                          | Remarks                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Import the public key from a public key file (recommended)   | <ol style="list-style-type: none"><li>Save the host public key of the intended asymmetric key pair in a file.</li><li>Transfer a copy of the file through FTP or TFTP in binary mode to the local device.</li></ol>                                                                                                                                    | During the import process, the system automatically converts the public key to a string in Public Key Cryptography Standards (PKCS) format.                                                                                                                                           |
| Manually configure the public key—input or copy the key data | <ul style="list-style-type: none"><li>Display and record the public key of the intended asymmetric key pair.</li><li>If the peer device is an HP device, use the <b>display public-key local public</b> command to view and record its public key. A public key displayed by other methods for the HP device may not be in a correct format.</li></ul> | <ul style="list-style-type: none"><li>The recorded public key must be in the correct format, or the manual configuration of a format-incompliant public key will fail.</li><li>Always use the first method if you are not sure about the format of the recorded public key.</li></ul> |

To import the host public key from a public key file to the local device:

| Step                                                    | Command                                               |
|---------------------------------------------------------|-------------------------------------------------------|
| 1. Enter system view.                                   | <b>system-view</b>                                    |
| 2. Import the host public key from the public key file. | <b>public-key peer keyname import sshkey filename</b> |

To manually configure the peer public key on the local device:

| Step                                                            | Command                               | Remarks                                                                            |
|-----------------------------------------------------------------|---------------------------------------|------------------------------------------------------------------------------------|
| 1. Enter system view.                                           | <b>system-view</b>                    | N/A                                                                                |
| 2. Specify a name for the public key and enter public key view. | <b>public-key peer</b> <i>keyname</i> | N/A                                                                                |
| 3. Enter public key code view.                                  | <b>public-key-code begin</b>          | N/A                                                                                |
| 4. Configure the peer public key.                               | Type or copy the key                  | Spaces and carriage returns are allowed between characters.                        |
| 5. Return to public key view.                                   | <b>public-key-code end</b>            | When you exit public key code view, the system automatically saves the public key. |
| 6. Return to system view.                                       | <b>peer-public-key end</b>            | N/A                                                                                |

## Displaying and maintaining public keys

| Task                                                               | Command                                                                                                                                                                | Remarks               |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Display the local public keys.                                     | <b>display public-key local</b> { <i>dsa</i>   <i>rsa</i> } <b>public</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ]           | Available in any view |
| Display the specified or all peer public keys on the local device. | <b>display public-key peer</b> [ <b>brief</b>   <b>name</b> <i>publickey-name</i> ] [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view |

## Public key configuration examples

### Manually specifying the peer public key on the local device

#### Network requirements

As shown in [Figure 92](#), to prevent illegal access, Device B (the local device) authenticates Device A (the peer device) through a digital signature. Before configuring authentication parameters on Device B, configure the public key of Device A on Device B.

- Configure Device B to use the asymmetric key algorithm of RSA to authenticate Device A.
- Manually specify the host public key of Device A's public key pair on Device B.

**Figure 92 Network diagram**

#### Configuration procedure

1. Configure Device A;  

```
Create local RSA key pairs on Device A, setting the modulus length to the default, 1024 bits.
<DeviceA> system-view
```

```
[DeviceA] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
```

```
Press CTRL+C to abort.
```

```
Input the bits of the modulus[default = 1024]:
```

```
Generating Keys...
```

```

```

The output shows that the host public key of Device A saved on Device B is consistent with the one created on Device A.

## Importing a peer public key from a public key file

### Network requirements

As shown in [Figure 93](#), to prevent illegal access, Device B (the local device) authenticates Device A (the peer device) through a digital signature. Before configuring authentication parameters on Device B, configure the public key of Device A on Device B.

- Configure Device B to use the asymmetric key algorithm of RSA to authenticate Device A.
- Import the host public key of Device A from the public key file to Device B.

**Figure 93 Network diagram**

### Configuration procedure

1. Create key pairs on Device A and export the host public key:

# Create local RSA key pairs on Device A, setting the modulus length to the default, 1024 bits.

```
<DeviceA> system-view
[DeviceA] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
++++++
++++++
+++++++
+++++++
```

```
Display the public keys of the local RSA key pairs.
```

```
[DeviceA] display public-key local rsa public
```

```
=====
```

```
Time of Key pair created: 09:50:06 2012/03/07
```

```

203010001
```

```
Export the RSA host public key HOST_KEY to a file named devicea.pub.
```

```
[DeviceA] public-key local export rsa ssh2 devicea.pub
```

2. Enable the FTP server function on Device A:

```
Enable the FTP server function, create an FTP user with the username ftp, password 123, and user level 3. This user level guarantees that the user has the permission to perform FTP operations.
```

```
[DeviceA] ftp server enable
```

```
[DeviceA] local-user ftp
```

```
[DeviceA-luser-ftp] password simple 123
```

```
[DeviceA-luser-ftp] service-type ftp
```

```
[DeviceA-luser-ftp] authorization-attribute level 3
```

```
[DeviceA-luser-ftp] quit
```

3. On Device B, get the public key file of Device A:

```
From Device B, use FTP to log in to Device A, and get the public key file devicea.pub with the file transfer mode of binary.
```

```
<DeviceB> ftp 10.1.1.1
```

```
Trying 10.1.1.1 ...
```

```
Press CTRL+K to abort
```

```
Connected to 10.1.1.1.
```

```
220 FTP service ready.
```

```
User(10.1.1.1:(none)):ftp
```

```
331 Password required for ftp.
```

```
Password:
```

```
230 User logged in.
```

```
[ftp] binary
```

```

200 Type set to I.
[ftp] get devicea.pub
227 Entering Passive Mode (10,1,1,1,5,148).
125 BINARY mode data connection already open, transfer starting for /devicea.pub.
226 Transfer complete.
FTP: 299 byte(s) received in 0.189 second(s), 1.00Kbyte(s)/sec.
[ftp] quit
221 Server closing.

```

4. Import the host public key of Device A to Device B:

# Import the host public key of Device A from the key file **devicea.pub** to Device B.

```

<DeviceB> system-view
[DeviceB] public-key peer devicea import sshkey devicea.pub

```

# Display the host public key of Device A on Device B.

```

[DeviceB] display public-key peer name devicea

```

```

```

The output shows that the host public key of Device A saved on Device B is consistent with the one created on Device A.

---

# Configuring PKI

## Overview

The Public Key Infrastructure (PKI) is a general security infrastructure used to provide information security through public key technologies.

PKI, also called asymmetric key infrastructure, uses a key pair to encrypt and decrypt the data. The key pair consists of a private key and a public key. The private key must be kept secret but the public key needs to be distributed. Data encrypted by one of the two keys can only be decrypted by the other.

A key problem with PKI is how to manage the public keys. PKI employs the digital certificate mechanism to solve this problem. The digital certificate mechanism binds public keys to their owners, helping distribute public keys in large networks securely.

With digital certificates, the PKI system provides network communication and e-commerce with security services such as user authentication, data non-repudiation, data confidentiality, and data integrity.

HP's PKI system provides certificate management for Secure Sockets Layer (SSL).

## PKI terms

- Digital certificate

A digital certificate is a file signed by a certificate authority (CA) for an entity. It includes mainly the identity information of the entity, the public key of the entity, the name and signature of the CA, and the validity period of the certificate. The signature of the CA ensures the validity and authority of the certificate. A digital certificate must comply with the international standard of ITU-T X.509. The most common standard is X.509 v3.

This document discusses two types of certificates: local certificate and CA certificate. A local certificate is a digital certificate signed by a CA for an entity. A CA certificate is the certificate of a CA. If multiple CAs are trusted by different users in a PKI system, the CAs will form a CA tree with the root CA at the top level. The root CA has a CA certificate signed by itself and each lower level CA has a CA certificate signed by the CA at the next higher level.

- CRL

An existing certificate might need to be revoked when, for example, the username changes, the private key leaks, or the user stops the business. Revoking a certificate removes the binding of the public key with the user identity information. In PKI, the revocation is made through certificate revocation lists (CRLs). Whenever a certificate is revoked, the CA publishes one or more CRLs to show all certificates that have been revoked. The CRLs contain the serial numbers of all revoked certificates and provide an effective way for checking the validity of certificates.

A CA might publish multiple CRLs when the number of revoked certificates is so large that publishing them in a single CRL might degrade network performance. A CA uses CRL distribution points to indicate the URLs of these CRLs.

- CA policy

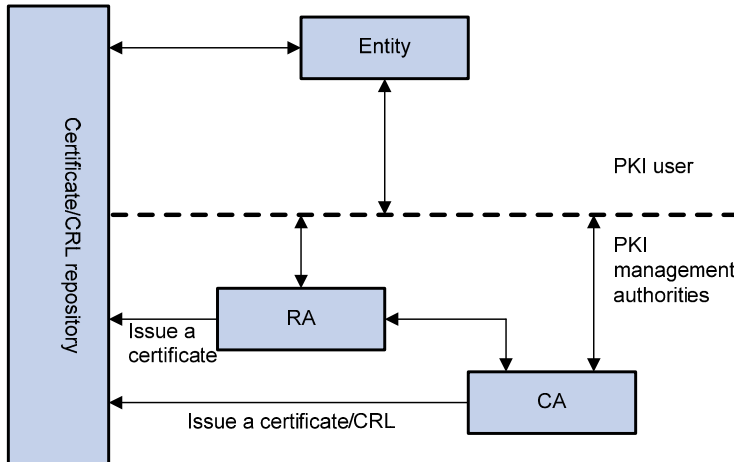

A CA policy is a set of criteria that a CA follows in processing certificate requests, issuing and revoking certificates, and publishing CRLs. Usually, a CA advertises its policy in the form of certification practice statement (CPS). A CA policy can be acquired through out-of-band means

such as phone, disk, and email. As different CAs might use different methods to examine the binding of a public key with an entity, make sure that you understand the CA policy before selecting a trusted CA for certificate request.

## PKI architecture

A PKI system consists of entities, a CA, a registration authority (RA) and a PKI repository.

**Figure 94 PKI architecture**

- Entity
 

An entity is an end user of PKI products or services, such as a person, an organization, a device, or a process running on a computer.
- CA
 

A CA is a trusted authority responsible for issuing and managing digital certificates. A CA issues certificates, specifies the validity periods of certificates, and revokes certificates as needed by publishing CRLs.
- RA
 

A registration authority (RA) is an extended part of a CA or an independent authority. An RA can implement functions including identity authentication, CRL management, key pair generation and key pair backup. The PKI standard recommends that an independent RA be used for registration management to achieve higher security.
- PKI repository
 

A PKI repository can be a Lightweight Directory Access Protocol (LDAP) server or a common database. It stores and manages information like certificate requests, certificates, keys, CRLs and logs when it provides a simple query function.

LDAP is a protocol for accessing and managing PKI information. An LDAP server stores user information and digital certificates from the RA server and provides directory navigation service. From an LDAP server, an entity can retrieve local and CA certificates of its own as well as certificates of other entities.

## PKI applications

The PKI technology can satisfy the security requirements of online transactions. As an infrastructure, PKI has a wide range of applications. Here are some application examples.

- **VPN**  
A virtual private network (VPN) is a private data communication network built on the public communication infrastructure. A VPN can leverage network layer security protocols (for instance, IPsec) in conjunction with PKI-based encryption and digital signature technologies for confidentiality.
- **Secure email**  
Emails require confidentiality, integrity, authentication, and non-repudiation. PKI can address these needs. The secure email protocol that is developing rapidly is Secure/Multipurpose Internet Mail Extensions (S/MIME), which is based on PKI and allows for transfer of encrypted mails with signature.
- **Web security**  
For web security, two peers can establish an SSL connection first for transparent and secure communications at the application layer. With PKI, SSL enables encrypted communications between a browser and a server. Both of the communication parties can verify each other's identity through digital certificates.

## How PKI operates

In a PKI-enabled network, an entity can request a local certificate from the CA and the device can check the validity of certificates. Here is how it operates:

1. An entity submits a certificate request to the RA.
2. The RA reviews the identity of the entity and then sends the identity information and the public key with a digital signature to the CA.
3. The CA verifies the digital signature, approves the application, and issues a certificate.
4. The RA receives the certificate from the CA, sends it to the LDAP server to provide directory navigation service, and notifies the entity that the certificate is successfully issued.
5. The entity retrieves the certificate. With the certificate, the entity can communicate with other entities safely through encryption and digital signature.
6. The entity makes a request to the CA when it needs to revoke its certificate. The CA approves the request, updates the CRLs and publishes the CRLs on the LDAP server.

## PKI configuration task list

| Task                                                                                                                                                                                                                                              | Remarks                           |

| <a href="#">Configuring an access control policy</a> | Optional. |

## Configuring an entity DN

A certificate is the binding of a public key and the identity information of an entity, where the identity information is identified by an entity distinguished name (DN). A CA identifies a certificate applicant uniquely by entity DN.

An entity DN is defined by these parameters:

- Common name of the entity.
- Country code of the entity, a standard 2-character code. For example, CN represents China and US represents the United States.
- Fully qualified domain name (FQDN) of the entity, a unique identifier of an entity on the network. It consists of a host name and a domain name and can be resolved to an IP address. For example, **www.whatever.com** is an FQDN, where **www** is a host name and **whatever.com** a domain name.
- IP address of the entity.
- Locality where the entity resides.
- Organization to which the entity belongs.
- Unit of the entity in the organization.
- State where the entity resides.

The configuration of an entity DN must comply with the CA certificate issue policy. You must determine, for example, which entity DN parameters are mandatory and which are optional. Otherwise, certificate requests might be rejected.

To configure an entity DN:

| Step                                          | Command                                | Remarks                                               |
|-----------------------------------------------|----------------------------------------|-------------------------------------------------------|
| 1. Enter system view.                         | <b>system-view</b>                     | N/A                                                   |
| 2. Create an entity and enter its view.       | <b>pki entity</b> <i>entity-name</i>   | No entity exists by default.                          |
| 3. Configure the common name for the entity.  | <b>common-name</b> <i>name</i>         | Optional.<br>No common name is specified by default.  |
| 4. Configure the country code for the entity. | <b>country</b> <i>country-code-str</i> | Optional.<br>No country code is specified by default. |
| 5. Configure the FQDN for the entity.         | <b>fqdn</b> <i>name-str</i>            | Optional.<br>No FQDN is specified by default.         |
| 6. Configure the IP address for the entity.   | <b>ip</b> <i>ip-address</i>            | Optional.<br>No IP address is specified by default.   |
| 7. Configure the locality for the entity.     | <b>locality</b> <i>locality-name</i>   | Optional.<br>No locality is specified by default.     |

| Step                                                | Command                                       | Remarks                                                    |
|-----------------------------------------------------|-----------------------------------------------|------------------------------------------------------------|
| 8. Configure the organization name for the entity.  | <b>organization</b> <i>org-name</i>           | Optional.<br>No organization is specified by default.      |
| 9. Configure the unit name for the entity.          | <b>organization-unit</b> <i>org-unit-name</i> | Optional.<br>No unit is specified by default.              |
| 10. Configure the state or province for the entity. | <b>state</b> <i>state-name</i>                | Optional.<br>No state or province is specified by default. |

#### NOTE:

The Windows 2000 CA server has some restrictions on the data length of a certificate request. If the entity DN in a certificate request goes beyond a certain limit, the server will not respond to the certificate request.

## Configuring a PKI domain

Before requesting a PKI certificate, an entity needs to be configured with some enrollment information, which is referred to as a PKI domain. A PKI domain is only intended for convenient reference by applications like SSL, and only has local significance. A PKI domain configured on a switch is invisible to the CA and other switches, and each PKI domain has its own parameters.

A PKI domain defines these parameters:

- **Trusted CA**—An entity requests a certificate from a trusted CA.
- **Entity**—A certificate applicant uses an entity to provide its identity information to a CA.
- **RA**—Generally, an independent RA is in charge of certificate request management. It receives the registration request from an entity, examines its qualification, and determines whether to ask the CA to sign a digital certificate. The RA only examines the application qualification of an entity; it does not issue any certificate. Sometimes, the registration management function is provided by the CA, in which case no independent RA is required. It is a good practice to deploy an independent RA.
- **URL of the registration server**—An entity sends a certificate request to the registration server through Simple Certification Enrollment Protocol (SCEP), a dedicated protocol for an entity to communicate with a CA. This URL is also called the certificate request URL.
- **Polling interval and count**—After an applicant makes a certificate request, the CA might need a long period of time if it verifies the certificate request manually. During this period, the applicant needs to query the status of the request periodically to get the certificate as soon as possible after the certificate is signed. You can configure the polling interval and count to query the request status.
- **IP address of the LDAP server**—An LDAP server is usually deployed to store certificates and CRLs. If this is the case, you must configure the IP address of the LDAP server.
- **Fingerprint for root certificate verification**—After receiving the root certificate of the CA, an entity needs to verify the fingerprint of the root certificate, namely, the hash value of the root certificate content. This hash value is unique to every certificate. If the fingerprint of the root certificate does not match the one configured for the PKI domain, the entity will reject the root certificate.

## Configuration guidelines

- Up to two PKI domains can be created on a switch.

- The CA name is required only when you retrieve a CA certificate. It is not used when in local certificate request.
- The certificate request URL does not support domain name resolution.

## Configuration procedure

To configure a PKI domain:

| Step                                                                                             | Command                                                                                                             | Remarks                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                                                            | <b>system-view</b>                                                                                                  | N/A                                                                                                                                                                                                                                                                                   |
| 2. Create a PKI domain and enter its view.                                                       | <b>pki domain</b> <i>domain-name</i>                                                                                | No PKI domain exists by default.                                                                                                                                                                                                                                                      |
| 3. Specify the trusted CA.                                                                       | <b>ca identifier</b> <i>name</i>                                                                                    | No trusted CA is specified by default.                                                                                                                                                                                                                                                |
| 4. Specify the entity for certificate request.                                                   | <b>certificate request entity</b><br><i>entity-name</i>                                                             | No entity is specified by default.<br>The specified entity must exist.                                                                                                                                                                                                                |
| 5. Specify the authority for certificate request.                                                | <b>certificate request from</b> { <b>ca</b>   <b>ra</b> }                                                           | No authority is specified by default.                                                                                                                                                                                                                                                 |
| 6. Configure the certificate request URL.                                                        | <b>certificate request url</b> <i>url-string</i>                                                                    | No certificate request URL is configured by default.                                                                                                                                                                                                                                  |
| 7. Configure the polling interval and attempt limit for querying the certificate request status. | <b>certificate request polling</b> { <b>count</b> <i>count</i>   <b>interval</b> <i>minutes</i> }                   | Optional.<br>The polling is executed for up to 50 times at the interval of 20 minutes by default.                                                                                                                                                                                     |
| 8. Specify the LDAP server.                                                                      | <b>ldap-server ip</b> <i>ip-address</i> [ <b>port</b> <i>port-number</i> ] [ <b>version</b> <i>version-number</i> ] | Optional.<br>No LDP server is specified by default.                                                                                                                                                                                                                                   |
| 9. Configure the fingerprint for root certificate verification.                                  | <b>root-certificate fingerprint</b> { <b>md5</b>   <b>sha1</b> } <i>string</i>                                      | Required when the certificate request mode is auto and optional when the certificate request mode is manual. In the latter case, if you do not configure this command, the fingerprint of the root certificate must be verified manually.<br>No fingerprint is configured by default. |

## Submitting a PKI certificate request

When requesting a certificate, an entity introduces itself to the CA by providing its identity information and public key, which will be the major components of the certificate. A certificate request can be submitted to a CA in offline mode or online mode. In offline mode, a certificate request is submitted to a CA by an "out-of-band" means such as phone, disk, or email.

An online certificate request can be submitted in manual mode or auto mode.

## Submitting a certificate request in auto mode

In auto mode, an entity automatically requests a certificate from the CA server if it has no local certificate for an application working with PKI, and then retrieves the certificate and saves the certificate locally. Before requesting a certificate, if the PKI domain does not have the CA certificate yet, the entity automatically retrieves the CA certificate.

To configure an entity to submit a certificate request in auto mode:

| Step                                         | Command                                                                                                                                               | Remarks           |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| 1. Enter system view.                        | <b>system-view</b>                                                                                                                                    | N/A               |
| 2. Enter PKI domain view.                    | <b>pki domain</b> <i>domain-name</i>                                                                                                                  | N/A               |
| 3. Set the certificate request mode to auto. | <b>certificate request mode auto</b><br>[ <b>key-length</b> <i>key-length</i>   <b>password</b> { <b>cipher</b>   <b>simple</b> } <i>password</i> ] * | Manual by default |

### ! IMPORTANT:

In auto mode, an entity does not automatically re-request a certificate to replace a certificate that is expiring or has expired. After the certificate expires, the service using the certificate might be interrupted.

## Submitting a certificate request in manual mode

In manual mode, you manually submit a certificate request for an entity. Before submitting a certificate request, you must make sure that an RSA key pair has been generated and the CA certificate has been retrieved and saved locally.

The CA certificate is required to verify the authenticity and validity of a local certificate. The public key of the key pair is an important part of the request information and will be transferred to the CA along with some other information. For more information about RSA key pair configuration, see *Security Configuration Guide*.

### Configuration guidelines

- If a PKI domain already has a local certificate, creating an RSA key pair will result in inconsistency between the key pair and the certificate. To generate a new RSA key pair, delete the local certificate and then issue the **public-key local create** command. For more information about the **public-key local create** command, see *Security Command Reference*.
- A newly created key pair will overwrite the existing one. If you perform the **public-key local create** command in the presence of a local RSA key pair, the system will ask you whether you want to overwrite the existing one.
- If a PKI domain already has a local certificate, you cannot request another certificate for it. This helps avoid inconsistency between the certificate and the registration information resulting from configuration changes. Before requesting a new certificate, use the **pki delete-certificate** command to delete the existing local certificate and the CA certificate stored locally.
- When it is impossible to request a certificate from the CA through SCEP, you can print the request information or save the request information to a local file, and then send the printed information or saved file to the CA by an out-of-band means. To print the request information, use the **pki request-certificate domain** command with the **pkcs10** keyword. To save the request information to a local file, use the **pki request-certificate domain** command with the **pkcs10 filename** *filename* option.

- Make sure the clocks of the entity and the CA are synchronous. Otherwise, the validity period of the certificate will be abnormal.
- The configuration made by the **pki request-certificate domain** command is not saved in the configuration file.

## Configuration procedure

To submit a certificate request in manual mode:

| Step                                            | Command                                                                                                                           | Remarks                                  |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| 1. Enter system view.                           | <b>system-view</b>                                                                                                                | N/A                                      |
| 2. Enter PKI domain view.                       | <b>pki domain</b> <i>domain-name</i>                                                                                              | N/A                                      |
| 3. Set the certificate request mode to manual.  | <b>certificate request mode manual</b>                                                                                            | Optional.<br>Manual by default.          |
| 4. Return to system view.                       | <b>quit</b>                                                                                                                       | N/A                                      |
| 5. Retrieve a CA certificate manually.          | See " <a href="#">Retrieving a certificate manually</a> "                                                                         | N/A                                      |
| 6. Generate a local RSA key pair.               | <b>public-key local create rsa</b>                                                                                                | No local RSA key pair exists by default. |
| 7. Submit a local certificate request manually. | <b>pki request-certificate domain</b><br><i>domain-name</i> [ <i>password</i> ]<br>[ <b>pkcs10</b> [ <i>filename filename</i> ] ] | N/A                                      |

## Retrieving a certificate manually

You can download CA certificates, local certificates, or peer entity certificates from the CA server and save them locally. To do so, use either the offline mode or the online mode. In offline mode, you must retrieve a certificate by an out-of-band means like FTP, disk, or email, and then import it into the local PKI system.

Certificate retrieval serves the following purposes:

- Locally store the certificates associated with the local security domain for improved query efficiency and reduced query count
- Prepare for certificate verification

## Configuration guidelines

- Before retrieving a local certificate in online mode, be sure to complete the LDAP server configuration.
- If a PKI domain already has a CA certificate, you cannot retrieve another CA certificate for it. This restriction helps avoid inconsistency between the certificate and registration information resulted from configuration changes. To retrieve a new CA certificate, use the **pki delete-certificate** command to delete the existing CA certificate and the local certificate first.
- The configuration made by the **pki retrieval-certificate** configuration is not saved in the configuration file.
- Make sure the switch's system time falls in the validity period of the certificate so that the certificate is valid.

## Configuration procedure

To retrieve a certificate manually:

| Step                                | Command                                                                                                                                                                                                                                                                                                                                                                              | Remarks             |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| 1. Enter system view.               | <b>system-view</b>                                                                                                                                                                                                                                                                                                                                                                   | N/A                 |
| 2. Retrieve a certificate manually. | <ul style="list-style-type: none"><li>In online mode:<br/><b>pki retrieval-certificate</b> { <b>ca</b>   <b>local</b> } <b>domain</b><br/><i>domain-name</i></li><li>In offline mode:<br/><b>pki import-certificate</b> { <b>ca</b>   <b>local</b> } <b>domain</b><br/><i>domain-name</i> { <b>der</b>   <b>p12</b>   <b>pem</b> } [ <b>filename</b><br/><i>filename</i> ]</li></ul> | Use either command. |

## Configuring PKI certificate verification

A certificate needs to be verified before being used. Certificate verification can examine whether the certificate is signed by the CA and whether the certificate has expired or been revoked.

You can specify whether to perform CRL checking during certificate verification. If you enable CRL checking, CRLs will be used in verification of a certificate, and you must retrieve the CA certificate and CRLs to the local switch before the certificate verification. If you disable CRL checking, you only need to retrieve the CA certificate.

## Configuration guidelines

- The CRL update period defines the interval at which the entity downloads CRLs from the CRL server. The CRL update period setting manually configured on the switch is prior to that carried in the CRLs.
- The configuration made by the **pki retrieval-crl domain** command is not saved in the configuration file.
- The URL of the CRL distribution point does not support domain name resolution.

## Configuring CRL-checking-enabled PKI certificate verification

| Step                                              | Command                               | Remarks                                                                                          |
|---------------------------------------------------|---------------------------------------|--------------------------------------------------------------------------------------------------|
| 1. Enter system view.                             | <b>system-view</b>                    | N/A                                                                                              |
| 2. Enter PKI domain view.                         | <b>pki domain</b> <i>domain-name</i>  | N/A                                                                                              |
| 3. Specify the URL of the CRL distribution point. | <b>crl url</b> <i>url-string</i>      | Optional.<br>No CRL distribution point URL is specified by default.                              |
| 4. Set the CRL update period.                     | <b>crl update-period</b> <i>hours</i> | Optional.<br>By default, the CRL update period depends on the next update field in the CRL file. |
| 5. Enable CRL checking.                           | <b>crl check enable</b>               | Optional.<br>Enabled by default.                                                                 |

| Step                                     | Command                                                                            | Remarks |
|------------------------------------------|------------------------------------------------------------------------------------|---------|
| 6. Return to system view.                | <b>quit</b>                                                                        | N/A     |
| 7. Retrieve the CA certificate.          | See " <a href="#">Retrieving a certificate manually</a> "                          | N/A     |
| 8. Retrieve CRLs.                        | <b>pki retrieval-crl domain</b><br><i>domain-name</i>                              | N/A     |
| 9. Verify the validity of a certificate. | <b>pki validate-certificate { ca   local }</b><br><b>domain</b> <i>domain-name</i> | N/A     |

## Configuring CRL-checking-disabled PKI certificate verification

To configure CRL-checking-disabled PKI certificate verification:

| Step                                       | Command                                                                            | Remarks            |
|--------------------------------------------|------------------------------------------------------------------------------------|--------------------|
| 1. Enter system view.                      | <b>system-view</b>                                                                 | N/A                |
| 2. Enter PKI domain view.                  | <b>pki domain</b> <i>domain-name</i>                                               | N/A                |
| 3. Disable CRL checking.                   | <b>crl check disable</b>                                                           | Enabled by default |
| 4. Return to system view.                  | <b>quit</b>                                                                        | N/A                |
| 5. Retrieve the CA certificate.            | See " <a href="#">Retrieving a certificate manually</a> "                          | N/A                |
| 6. Verify the validity of the certificate. | <b>pki validate-certificate { ca   local }</b><br><b>domain</b> <i>domain-name</i> | N/A                |

## Destroying a local RSA key pair

A certificate has a lifetime, which is determined by the CA. When the private key leaks or the certificate is about to expire, you can destroy the old RSA key pair and then create a pair to request a new certificate.

To destroy a local RSA key pair:

| Step                             | Command                             |
|----------------------------------|-------------------------------------|
| 1. Enter system view.            | <b>system-view</b>                  |
| 2. Destroy a local RSA key pair. | <b>public-key local destroy rsa</b> |

For more information about the **public-key local destroy** command, see *Security Command Reference*.

## Deleting a certificate

When a certificate requested manually is about to expire or you want to request a new certificate, you can delete the current local certificate or CA certificate.

To delete a certificate:

| Step                    | Command                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------|
| 1. Enter system view.   | <b>system-view</b>                                                                          |
| 2. Delete certificates. | <b>pki delete-certificate</b> { <b>ca</b>   <b>local</b> } <b>domain</b> <i>domain-name</i> |

## Configuring an access control policy

By configuring a certificate attribute-based access control policy, you can further control access to the server, providing additional security for the server.

To configure a certificate attribute-based access control policy:

| Step                                                                                                                   | Command                                                                                                                                                                                                                                                     | Remarks                                                                                                                  |
|------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                                                                                  | <b>system-view</b>                                                                                                                                                                                                                                          | N/A                                                                                                                      |
| 2. Create a certificate attribute group and enter its view.                                                            | <b>pki certificate attribute-group</b><br><i>group-name</i>                                                                                                                                                                                                 | No certificate attribute group exists by default.                                                                        |
| 3. Configure an attribute rule for the certificate issuer name, certificate subject name, or alternative subject name. | <b>attribute</b> <i>id</i> { <b>alt-subject-name</b> { <b>fqdn</b>   <b>ip</b> }   { <b>issuer-name</b>   <b>subject-name</b> } { <b>dn</b>   <b>fqdn</b>   <b>ip</b> } } { <b>ctn</b>   <b>equ</b>   <b>nctn</b>   <b>nequ</b> }<br><i>attribute-value</i> | Optional.<br>No restriction exists on the issuer name, certificate subject name and alternative subject name by default. |
| 4. Return to system view.                                                                                              | <b>quit</b>                                                                                                                                                                                                                                                 | N/A                                                                                                                      |
| 5. Create a certificate attribute-based access control policy and enter its view.                                      | <b>pki certificate access-control-policy</b><br><i>policy-name</i>                                                                                                                                                                                          | No access control policy exists by default.                                                                              |
| 6. Configure a certificate attribute-based access control rule.                                                        | <b>rule</b> [ <i>id</i> ] { <b>deny</b>   <b>permit</b> }<br><i>group-name</i>                                                                                                                                                                              | No access control rule exists by default.<br>A certificate attribute group must exist to be associated with a rule.      |

## Displaying and maintaining PKI

## PKI configuration examples

This section describes details about PKI configuration examples.

When the CA uses Windows Server, the SCEP add-on is required, and you must use the **certificate request from ra** command to specify that the entity request a certificate from an RA.

When the CA uses RSA Keon, the SCEP add-on is not required, and you must use the **certificate request from ca** command to specify that the entity request a certificate from a CA.

## Requesting a certificate from a CA server running RSA Keon

### Network requirements

The switch submits a local certificate request to the CA server. The switch acquires the CRLs for certificate verification.

Figure 95 Network diagram

### Configuring the CA server

1. Create a CA server named **myca**:

In this example, you need to configure these basic attributes on the CA server at first:

- **Nickname**—Name of the trusted CA.
- **Subject DN**—DN information of the CA, including the Common Name (CN), Organization Unit (OU), Organization (O), and Country (C).

Use the default values for the other attributes.

2. Configure extended attributes:

After configuring the basic attributes, perform configuration on the jurisdiction configuration page of the CA server. This includes selecting the proper extension profiles, enabling the SCEP autovetting function, and adding the IP address list for SCEP autovetting.

3. Configure the CRL distribution behavior:

After completing the configuration, you must perform CRL related configurations. In this example, select the local CRL distribution mode of Hypertext Transfer Protocol (HTTP) and set the HTTP URL to `http://4.4.4.133:447/myca.crl`.

After the configuration, make sure the system clock of the switch is synchronous to that of the CA, so that the switch can request certificates and retrieve CRLs properly.

## Configuring the switch

1. Configure the entity DN:

# Configure the entity name as **aaa** and the common name as **device**.

```
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name device
[Device-pki-entity-aaa] quit
```

2. Configure the PKI domain:

# Create PKI domain **torsa** and enter its view.

```
[Device] pki domain torsa
```

# Configure the name of the trusted CA as **myca**.

```
[Device-pki-domain-torsa] ca identifier myca
```

# Configure the URL of the registration server in the format of `http://host:port/Issuing Jurisdiction ID`, where Issuing Jurisdiction ID is a hexadecimal string generated on the CA server.

```
[Device-pki-domain-torsa] certificate request url
http://4.4.4.133:446/c95e970f632d27be5e8cbf80e971d9c4a9a93337
```

# Set the registration authority to **CA**.

```
[Device-pki-domain-torsa] certificate request from ca
```

# Specify the entity for certificate request as **aaa**.

```
[Device-pki-domain-torsa] certificate request entity aaa
```

# Configure the URL for the CRL distribution point.

```
[Device-pki-domain-torsa] crl url http://4.4.4.133:447/myca.crl
[Device-pki-domain-torsa] quit
```

3. Generate a local key pair using RSA:

```
[Device] public-key local create rsa
```

The range of public key size is (512 ~ 2048).

NOTES: If the key modulus is greater than 512,

It will take a few minutes.

Press CTRL+C to abort.

Input the bits in the modulus [default = 1024]:

Generating Keys...

```
+++++
+++++
+++++
+++++
```

4. Apply for certificates:

# Retrieve the CA certificate and save it locally.

```
[Device] pki retrieval-certificate ca domain torsa
```

Retrieving CA/RA certificates. Please wait a while.....

```

The trusted CA's finger print is:
 MD5 fingerprint:EDE9 0394 A273 B61A F1B3 0072 A0B1 F9AB
 SHA1 fingerprint: 77F9 A077 2FB8 088C 550B A33C 2410 D354 23B2 73A8

Is the finger print correct?(Y/N):y

Saving CA/RA certificates chain, please wait a moment.....
CA certificates retrieval success.
Retrieve CRLs and save them locally.
[Device] pki retrieval-crl domain torsa
Connecting to server for retrieving CRL. Please wait a while.....
CRL retrieval success!
Request a local certificate manually.
[Device] pki request-certificate domain torsa challenge-word
Certificate is being requested, please wait.....
[Device]
Enrolling the local certificate,please wait a while.....
Certificate request Successfully!
Saving the local certificate to device.....
Done!

```

## Verifying the configuration

# Use the following command to view information about the local certificate acquired.

```

[Device] display pki certificate local domain torsa
Certificate:

```

You can also use **display pki certificate ca domain** and **display pki crl domain** to display detailed information about the CA certificate and CRLs. For more information about the commands, see *Security Command Reference*.

## Requesting a certificate from a CA server running Windows 2003 Server

### Network requirements

Configure PKI entity Device to request a local certificate from the CA server.

Figure 96 Network diagram

### Configuring the CA server

1. Install the certificate service suites:
  - a. Select **Control Panel > Add or Remove Programs** from the start menu.
  - b. Select **Add/Remove Windows Components > Certificate Services**.
  - c. Click **Next** to begin the installation.
2. Install the SCEP add-on:

Because a CA server running the Windows 2003 server does not support SCEP by default, you must install the SCEP add-on so that the switch can register and obtain its certificate automatically. After the SCEP add-on installation completes, a URL is displayed, which you must configure on the switch as the URL of the server for certificate registration.

3. Modify the certificate service attributes:
  - a. Select **Control Panel > Administrative Tools > Certificate Authority** from the start menu.  
If the CA server and SCEP add-on have been installed successfully, there should be two certificates issued by the CA to the RA.
  - b. Right-click the CA server in the navigation tree and select **Properties > Policy Module**.
  - c. Click **Properties** and select **Follow the settings in the certificate template, if applicable. Otherwise, automatically issue the certificate**.
4. Modify the Internet Information Services (IIS) attributes:
  - a. Select **Control Panel > Administrative Tools > Internet Information Services (IIS) Manager** from the start menu.
  - b. Select **Web Sites** from the navigation tree.
  - c. Right-click **Default Web Site** and select **Properties > Home Directory**.
  - d. Specify the path for certificate service in the **Local path** text box.  
To avoid conflict with existing services, specify an available port number as the TCP port number of the default website.

After completing the configuration, make sure the system clock of the switch is synchronous to that of the CA server, so that that the switch can request a certificate normally.

## Configuring the switch

1. Configure the entity DN:
 

```
Configure the entity name as aaa and the common name as device.
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name device
[Device-pki-entity-aaa] quit
```
2. Configure the PKI domain:
 

```
Create PKI domain torsa and enter its view.
[Device] pki domain torsa

Configure the name of the trusted CA as myca.
[Device-pki-domain-torsa] ca identifier myca

Configure the URL of the registration server in the format of http://host:port/
certsrv/mscep/mscep.dll, where host:port indicates the IP address and port number of the CA
server.
[Device-pki-domain-torsa] certificate request url
http://4.4.4.1:8080/certsrv/mscep/mscep.dll

Set the registration authority to RA.
[Device-pki-domain-torsa] certificate request from ra

Specify the entity for certificate request as aaa.
[Device-pki-domain-torsa] certificate request entity aaa
```
3. Generate a local key pair using RSA:
 

```
[Device] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
```

```
Input the bits in the modulus [default = 1024]:
Generating Keys...
+++++
+++++
+++++
+++++
```

#### 4. Apply for certificates:

**# Retrieve the CA certificate and save it locally.**

```
[Device] pki retrieval-certificate ca domain torsa
Retrieving CA/RA certificates. Please wait a while.....
The trusted CA's finger print is:
 MD5 fingerprint:766C D2C8 9E46 845B 4DCE 439C 1C1F 83AB
 SHA1 fingerprint:97E5 DDED AB39 3141 75FB DB5C E7F8 D7D7 7C9B 97B4
```

```
Is the finger print correct?(Y/N):y
```

```
Saving CA/RA certificates chain, please wait a moment.....
CA certificates retrieval success.
```

**# Request a local certificate manually.**

```
[Device] pki request-certificate domain torsa challenge-word
Certificate is being requested, please wait.....
[Device]
Enrolling the local certificate,please wait a while.....
Certificate request Successfully!
Saving the local certificate to device.....
Done!
```

### Verifying the configuration

**# Use the following command to view information about the local certificate acquired.**

```
[Device] display pki certificate local domain torsa

You can also use some other **display** commands to display more information about the CA certificate. For more information about the **display pki certificate ca domain** command, see *Security Command Reference*.

## Configuring a certificate attribute-based access control policy

### Network requirements

The client accesses the remote HTTP Secure (HTTPS) server through the HTTPS protocol.

Configure SSL to make sure that only legal clients log into the HTTPS server, and create a certificate attribute-based access control policy to control access to the HTTPS server.

Figure 97 Network diagram

## Configuration procedure

The configuration procedure involves SSL configuration and HTTPS configuration. For more information about SSL configuration, see "Configuring SSL." For more information about HTTPS configuration, see *Fundamentals Configuration Guide*.

The PKI domain to be referenced by the SSL policy must exist. For how to configure a PKI domain, see "Configure the PKI domain."

The configuration procedure is as follows:

1. Configure the HTTPS server:

# Configure the SSL policy for the HTTPS server to use.

```
<Device> system-view
[Device] ssl server-policy myssl
[Device-ssl-server-policy-myssl] pki-domain 1
[Device-ssl-server-policy-myssl] client-verify enable
[Device-ssl-server-policy-myssl] quit
```

2. Configure the certificate attribute group:

# Create certificate attribute group **mygroup1** and add two attribute rules. The first rule defines that the DN of the subject name includes the string **aabbcc**, and the second rule defines that the IP address of the certificate issuer is 10.0.0.1.

```
[Device] pki certificate attribute-group mygroup1
[Device-pki-cert-attribute-group-mygroup1] attribute 1 subject-name dn ctn aabbcc
[Device-pki-cert-attribute-group-mygroup1] attribute 2 issuer-name ip equ 10.0.0.1
[Device-pki-cert-attribute-group-mygroup1] quit
```

# Create certificate attribute group **mygroup2** and add two attribute rules. The first rule defines that the FQDN of the alternative subject name does not include the string of **apple**, and the second rule defines that the DN of the certificate issuer name includes the string **aabbcc**.

```
[Device] pki certificate attribute-group mygroup2
[Device-pki-cert-attribute-group-mygroup2] attribute 1 alt-subject-name fqdn nctn apple
[Device-pki-cert-attribute-group-mygroup2] attribute 2 issuer-name dn ctn aabbcc
[Device-pki-cert-attribute-group-mygroup2] quit
```

3. Configure the certificate attribute-based access control policy:

# Create the certificate attribute-based access control policy of **myacp** and add two access control rules.

```
[Device] pki certificate access-control-policy myacp
[Device-pki-cert-acp-myacp] rule 1 deny mygroup1
[Device-pki-cert-acp-myacp] rule 2 permit mygroup2
```

```
[Device-pki-cert-acp-myacp] quit
```

4. Apply the SSL server policy and certificate attribute-based access control policy to HTTPS service and enable HTTPS service:

```
Apply SSL server policy myssl to HTTPS service.
```

```
[Device] ip https ssl-server-policy myssl
```

```
Apply the certificate attribute-based access control policy of myacp to HTTPS service.
```

```
[Device] ip https certificate access-control-policy myacp
```

```
Enable HTTPS service.
```

```
[Device] ip https enable
```

## Troubleshooting PKI

### Failed to retrieve a CA certificate

#### Symptom

Failed to retrieve a CA certificate.

#### Analysis

Possible reasons include:

- The network connection is not proper. For example, the network cable might be damaged or loose.
- No trusted CA is specified.
- The URL of the registration server for certificate request is not correct or not configured.
- No authority is specified for certificate request.
- The system clock of the switch is not synchronized with that of the CA.

#### Solution

- Make sure that the network connection is physically proper.
- Check that the required commands are configured properly.
- Use the **ping** command to verify that the RA server is reachable.
- Specify the authority for certificate request.
- Synchronize the system clock of the switch with that of the CA.

### Failed to request a local certificate

#### Symptom

Failed to request a local certificate.

#### Analysis

Possible reasons include:

- The network connection is not proper. For example, the network cable might be damaged or loose.
- No CA certificate has been retrieved.
- The current key pair has been bound to a certificate.
- No trusted CA is specified.

- The URL of the registration server for certificate request is not correct or not configured.
- No authority is specified for certificate request.
- Some required parameters of the entity DN are not configured.

### Solution

- Make sure that the network connection is physically proper.
- Retrieve a CA certificate.
- Regenerate a key pair.
- Specify a trusted CA.
- Use the **ping** command to verify that the RA server is reachable.
- Specify the authority for certificate request.
- Configure the required entity DN parameters.

## Failed to retrieve CRLs

### Symptom

Failed to retrieve CRLs.

### Analysis

Possible reasons include:

- The network connection is not proper. For example, the network cable might be damaged or loose.
- No CA certificate has been retrieved before you try to retrieve CRLs.
- The IP address of LDAP server is not configured.
- The CRL distribution URL is not configured.
- The LDAP server version is wrong.

### Solution

- Make sure that the network connection is physically proper.
- Retrieve a CA certificate.
- Specify the IP address of the LDAP server.
- Specify the CRL distribution URL.
- Re-configure the LDAP version.

---

# Configuring IPsec

## Overview

IP Security (IPsec) is a security framework defined by the Internet Engineering Task Force (IETF) for securing IP communications. It is a Layer 3 virtual private network (VPN) technology that transmits data in a secure tunnel established between two endpoints.

IPsec guarantees the confidentiality, integrity, and authenticity of data and provides anti-replay service at the IP layer in an insecure network environment.

- **Confidentiality**—The sender encrypts packets before transmitting them over the Internet.
- **Data integrity**—The receiver verifies the packets received from the sender to ensure they are not tampered with during transmission.
- **Data origin authentication**—The receiver verifies the authenticity of the sender.
- **Anti-replay**—The receiver examines packets and drops outdated and duplicate packets.

IPsec delivers these benefits:

- Reduced key negotiation overheads and simplified maintenance by supporting the Internet Key Exchange (IKE) protocol. IKE provides automatic key negotiation and automatic IPsec security association (SA) setup and maintenance.
- Good compatibility. You can apply IPsec to all IP-based application systems and services without modifying them.
- Encryption on a per-packet rather than per-flow basis. Per-packet encryption allows for flexibility and greatly enhances IP security.

## IPsec implementation

IPsec comprises a set of protocols for IP data security, including Authentication Header (AH), Encapsulating Security Payload (ESP), IKE, and algorithms for authentication and encryption. AH and ESP provide security services and IKE performs key exchange.

IPsec provides two security mechanisms: authentication and encryption. The authentication mechanism allows the receiver of an IP packet to authenticate the sender and check if the packet has been tampered with. The encryption mechanism ensures data confidentiality and protects the data from being eavesdropped en route.

IPsec can use two security protocols:

- **AH (protocol 51)**—Provides data origin authentication, data integrity, and anti-replay services by adding an AH header to each IP packet. AH is suitable only for transmitting non-critical data because it cannot prevent eavesdropping, although it can prevent data tampering. AH supports authentication algorithms such as Message Digest (MD5) and Secure Hash Algorithm (SHA-1).
- **ESP (protocol 50)**—Provides data encryption as well as data origin authentication, data integrity, and anti-replay services by inserting an ESP header and an ESP trailer in IP packets. Unlike AH, ESP encrypts data before encapsulating the data to ensure data confidentiality. ESP supports encryption algorithms such as Data Encryption Standard (DES), 3DES, and Advanced Encryption Standard (AES), and authentication algorithms such as MD5 and SHA-1. The authentication function is optional to ESP.

Both AH and ESP provide authentication services, but the authentication service provided by AH is stronger. In practice, you can choose either or both security protocols. When both AH and ESP are used, an IP packet is encapsulated first by ESP and then by AH. [Figure 98](#) shows the format of IPsec packets.

## Basic concepts

### Security association

A security association is an agreement negotiated between two communicating parties called IPsec peers. It comprises a set of parameters for data protection, including security protocols, encapsulation mode, authentication and encryption algorithms, and shared keys and their lifetime. SAs can be set up manually or through IKE.

An SA is unidirectional. At least two SAs are needed to protect data flows in a bidirectional communication. If two peers want to use both AH and ESP to protect data flows between them, they construct an independent SA for each protocol.

An SA is uniquely identified by a triplet, which consists of the security parameter index (SPI), destination IP address, and security protocol identifier (AH or ESP).

An SPI is a 32-bit number for uniquely identifying an SA. It is transmitted in the AH/ESP header. A manually configured SA requires an SPI to be specified manually for it; an IKE created SA will have an SPI generated at random.

A manually configured SA never ages out. An IKE created SA has a specified period of lifetime, which comes in two types:

- Time-based lifetime, which defines how long the SA can be valid after it is created.
- Traffic-based lifetime, which defines the maximum traffic that the SA can process.

The SA becomes invalid when either of the lifetime timers expires. Before the SA expires, IKE negotiates a new SA, which takes over immediately after its creation.

### Encapsulation modes

IPsec supports the following IP packet encapsulation modes:

- **Tunnel mode**—IPsec protects the entire IP packet, including both the IP header and the payload. It uses the entire IP packet to calculate an AH or ESP header, and then encapsulates the original IP packet and the AH or ESP header with a new IP header. If you use ESP, an ESP trailer is also encapsulated. Tunnel mode is typically used for protecting gateway-to-gateway communications.
- **Transport mode**—IPsec protects only the IP payload. It uses only the IP payload to calculate the AH or ESP header, and inserts the calculated header between the original IP header and payload. If you use ESP, an ESP trailer is also encapsulated. The transport mode is typically used for protecting host-to-host or host-to-gateway communications.

[Figure 98](#) shows how the security protocols encapsulate an IP packet in different encapsulation modes.

**Figure 98 Encapsulation by security protocols in different modes**

| Mode<br>Protocol | Transport            | Tunnel                  |
|------------------|----------------------|-------------------------|
| AH               | IP AH Data           | IP AH IP Data           |
| ESP              | IP ESP Data ESP-T    | IP ESP IP Data ESP-T    |
| AH-ESP           | IP AH ESP Data ESP-T | IP AH ESP IP Data ESP-T |

## Authentication algorithms and encryption algorithms

- Authentication algorithms

IPsec uses hash algorithms to perform authentication. A hash algorithm produces a fixed-length digest for an arbitrary-length message. IPsec peers respectively calculate message digests for each packet. If the resulting digests are identical, the packet is considered intact.

IPsec supports the following hash algorithms for authentication:

- MD5, which takes as input a message of arbitrary length and produces a 128-bit message digest.
- SHA-1, which takes as input a message of a maximum length less than the 64th power of 2 in bits and produces a 160-bit message digest.

Compared with SHA-1, MD5 is faster but less secure.

- Encryption algorithms

IPsec mainly uses symmetric encryption algorithms, which encrypt and decrypt data by using the same keys. The following encryption algorithms are available for IPsec on the switch:

- Data Encryption Standard (DES), which encrypts a 64-bit plain text block with a 56-bit key. DES is the least secure but the fastest algorithm. It is sufficient for general security requirements.
- Triple DES (3DES), which encrypts plain text data with three 56-bit DES keys. The key length totals up to 168 bits. It provides moderate security strength and is slower than DES.
- Advanced Encryption Standard (AES), which encrypts plain text data with a 128-bit, 192-bit, or 256-bit key. AES provides the highest security strength and is slower than 3DES.

## IPsec SA setup modes

There are two IPsec SA setup modes:

- Manual mode. In this mode, you manually configure and maintain all SA settings. Advanced features like periodical key update are not available. However, this mode implements IPsec independently of IKE.
- ISAKMP mode. In this mode, IKE automatically negotiates and maintains IPsec SAs for IPsec.

If the number of IPsec tunnels in your network is small, use the manual mode. If the number of IPsec tunnels is large, use the ISAKMP mode.

## IPsec tunnel

An IPsec tunnel is a bidirectional channel created between two peers. An IPsec tunnel comprises one or more pairs of SAs.

## IPsec for IPv6 routing protocols

You can use IPsec to protect routing information and defend against attacks for these IPv6 routing protocols: OSPFv3, IPv6 BGP, and RIPng. The HP 5500 EI switches support using IPsec for OSPFv3, IPv6 BGP, and RIPng; the HP 5500 SI switches only support using IPsec for RIPng.

IPsec enables these IPv6 routing protocols to encapsulate outbound protocol packets and de-encapsulate inbound protocol packets with the AH or ESP protocol. If an inbound protocol packet is not IPsec protected, or fails to be de-encapsulated, for example, due to decryption or authentication failure, the routing protocol discards that packet.

You must manually configure SA parameters in an IPsec policy for IPv6 routing protocols. The IKE key exchange mechanism is applicable only to one-to-one communications. IPsec cannot implement automatic key exchange for one-to-many communications on a broadcast network, where routers must use the same SA parameters (SPI and key) to process packets for a routing protocol.

### Protocols and standards

- RFC 2401, *Security Architecture for the Internet Protocol*
- RFC 2402, *IP Authentication Header*
- RFC 2406, *IP Encapsulating Security Payload*
- RFC 4552, *Authentication/Confidentiality for OSPFv3*

## Configuring IPsec for IPv6 routing protocols

The following is the generic configuration procedure for configuring IPsec for IPv6 routing protocols:

1. Configure an IPsec proposal to specify the security protocols, authentication and encryption algorithms, and encapsulation mode.
2. Configure a manual IPsec policy to specify the keys and SPI.
3. Apply the IPsec policy to an IPv6 routing protocol.

Complete the following tasks to configure IPsec for IPv6 routing protocols:

| Task                                                 | Remarks                                                          |
|------------------------------------------------------|------------------------------------------------------------------|
| <a href="#">Configuring an IPsec proposal</a>        | Required.                                                        |
| <a href="#">Configuring an IPsec policy</a>          | Required.                                                        |
| Applying an IPsec policy to an IPv6 routing protocol | Required.<br>See <i>Layer 3—IP Routing Configuration Guide</i> . |

### Configuring an IPsec proposal

An IPsec proposal, part of an IPsec policy or an IPsec profile, defines the security parameters for IPsec SA negotiation, including the security protocol, the encryption and authentication algorithms, and the encapsulation mode.

To configure an IPsec proposal:

| Step                                                                | Command                                                                                                                                                                                                                                                                                                                                                                                                                                               | Remarks                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                               | <b>system-view</b>                                                                                                                                                                                                                                                                                                                                                                                                                                    | N/A                                                                                                                                                                                                                                                                                                                                         |
| 2. Create an IPsec proposal and enter its view.                     | <b>ipsec proposal</b> <i>proposal-name</i>                                                                                                                                                                                                                                                                                                                                                                                                            | By default, no IPsec proposal exists.<br><br>Optional.<br>ESP by default.                                                                                                                                                                                                                                                                   |
| 3. Specify the security protocol for the proposal.                  | <b>transform</b> { <b>ah</b>   <b>ah-esp</b>   <b>esp</b> }                                                                                                                                                                                                                                                                                                                                                                                           | Only when a security protocol is selected, can you configure security algorithms for it. For example, you can specify the ESP-specific security algorithms only when you select ESP as the security protocol. ESP supports three IP packet protection schemes: encryption only, authentication only, or both encryption and authentication. |
| 4. Specify the security algorithms.                                 | <ul style="list-style-type: none"> <li>Specify the encryption algorithm for ESP:<br/><b>esp encryption-algorithm</b> { <b>3des</b>   <b>aes</b> [ <i>key-length</i> ]   <b>des</b> }</li> <li>Specify the authentication algorithm for ESP:<br/><b>esp authentication-algorithm</b> { <b>md5</b>   <b>sha1</b> }</li> <li>Specify the authentication algorithm for AH:<br/><b>ah authentication-algorithm</b> { <b>md5</b>   <b>sha1</b> }</li> </ul> | Optional.<br><br>By default, the encryption algorithm for ESP is DES, the authentication algorithm for ESP is MD5, and the authentication algorithm for AH is MD5.                                                                                                                                                                          |
| 5. Specify the IP packet encapsulation mode for the IPsec proposal. | <b>encapsulation-mode</b> { <b>transport</b>   <b>tunnel</b> }                                                                                                                                                                                                                                                                                                                                                                                        | Optional.<br>Tunnel mode by default.<br>Transport mode applies only when the source and destination IP addresses of data flows match those of the IPsec tunnel.<br>IPsec for IPv6 routing protocols supports only the transport mode.                                                                                                       |

**NOTE:**

Changes to an IPsec proposal affect only SAs negotiated after the changes. To apply the changes to existing SAs, execute the **reset ipsec sa** command to clear the SAs so that they can be set up using the updated parameters.

## Configuring an IPsec policy

IPsec policies define which IPsec proposals should be used to protect which data flows. An IPsec policy is uniquely identified by its name and sequence number.

The switch supports only manual IPsec policies. The parameters of a manual IPsec policy are all configured manually, such as the keys and the SPIs.

### Configuration guidelines

To ensure successful SA negotiations, follow these guidelines when configuring manual IPsec policies:

- Within a certain routed network scope, the IPsec proposals used by the IPsec policies on all routers must have the same security protocols, security algorithms, and encapsulation mode. For OSPFv3, the scope can be directly connected neighbors or an OSPFv3 area. For RIPng, the scope can be directly connected neighbors or a RIPng process. For IPv6 BGP, the scope can be directly connected neighbors or a neighbor group.
- All SAs (both inbound and outbound) within the routed network scope must use the same SPI and keys.
- Configure the keys on all routers within the routed network scope in the same format. For example, if you input the keys in hexadecimal format on one router, do so across the routed network scope.

### Configuration procedure

To configure a manual IPsec policy:

| Step                                                | Command                                                                                         | Remarks                                                                                                                                                                                                                  |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                               | <b>system-view</b>                                                                              | N/A                                                                                                                                                                                                                      |
| 2. Create a manual IPsec policy and enter its view. | <b>ipsec policy</b> <i>policy-name seq-number</i><br><b>manual</b>                              | By default, no IPsec policy exists.                                                                                                                                                                                      |
| 3. ## IPsec for RIPng configuration example

The IPsec configuration procedures for protecting OSPFv3 and IPv6 BGP are similar. For more information about RIPng, OSPFv3, and IPv6 BGP, see *Layer 3—IP Routing Configuration Guide*. Only the HP 5500 EI switches support IPsec for OSPFv3 and IPv6 BGP.

## Network requirements

As shown in [Figure 99](#), Switch A, Switch B, and Switch C are connected. They learn IPv6 routing information through RIPng.

Configure IPsec for RIPng so that RIPng packets exchanged between the switches are transmitted through an IPsec tunnel. Configure IPsec to use the security protocol ESP, the encryption algorithm DES, and the authentication algorithm SHA1-HMAC-96.

**Figure 99 Network diagram**

## Configuration considerations

To meet the requirements, perform the following configuration tasks:

- Configure basic RIPng parameters.
- Configure a manual IPsec policy.
- Apply the IPsec policy to a RIPng process to protect RIPng packets in this process or to an interface to protect RIPng packets traveling through the interface.

## Configuration procedure

### 1. Configure Switch A:

# Assign an IPv6 address to each interface. (Details not shown.)

# Create a RIPng process and enable it on VLAN-interface 100.

```
<SwitchA> system-view
[SwitchA] ripng 1
[SwitchA-ripng-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ripng 1 enable
[SwitchA-Vlan-interface100] quit
```

# Create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1-HMAC-96.

```
[SwitchA] ipsec proposal tran1
[SwitchA-ipsec-proposal-tran1] encapsulation-mode transport
[SwitchA-ipsec-proposal-tran1] transform esp
[SwitchA-ipsec-proposal-tran1] esp encryption-algorithm des
[SwitchA-ipsec-proposal-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-proposal-tran1] quit
```

# Create an IPsec policy named **policy001**, specify the manual mode for it, and set the SPIs of the inbound and outbound SAs to 123456, and the keys for the inbound and outbound SAs using ESP to abcdefg.

```
[SwitchA] ipsec policy policy001 10 manual
[SwitchA-ipsec-policy-manual-policy001-10] proposal tran1
[SwitchA-ipsec-policy-manual-policy001-10] sa spi outbound esp 123456
[SwitchA-ipsec-policy-manual-policy001-10] sa spi inbound esp 123456
[SwitchA-ipsec-policy-manual-policy001-10] sa string-key outbound esp abcdefg
```

```
[SwitchA-ipsec-policy-manual-policy001-10] sa string-key inbound esp abcdefg
[SwitchA-ipsec-policy-manual-policy001-10] quit
Apply IPsec policy policy001 to the RIPng process.
[SwitchA] ripng 1
[SwitchA-ripng-1] enable ipsec-policy policy001
[SwitchA-ripng-1] quit
```

## 2. Configure Switch B

# Assign an IPv6 address to each interface. (Details not shown.)

# Create a RIPng process and enable it on VLAN-interface 100 and VLAN-interface 200.

```
<SwitchB> system-view
[SwitchB] ripng 1
[SwitchB-ripng-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ripng 1 enable
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ripng 1 enable
[SwitchB-Vlan-interface100] quit
```

# Create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1-HMAC-96.

```
[SwitchB] ipsec proposal tran1
[SwitchB-ipsec-proposal-tran1] encapsulation-mode transport
[SwitchB-ipsec-proposal-tran1] transform esp
[SwitchB-ipsec-proposal-tran1] esp encryption-algorithm des
[SwitchB-ipsec-proposal-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-proposal-tran1] quit
```

# Create an IPsec policy named **policy001**, specify the manual mode for it, and configure the SPIs of the inbound and outbound SAs to 123456, and the keys for the inbound and outbound SAs using ESP to abcdefg.

```
[SwitchB] ipsec policy policy001 10 manual
[SwitchB-ipsec-policy-manual-policy001-10] proposal tran1
[SwitchB-ipsec-policy-manual-policy001-10] sa spi outbound esp 123456
[SwitchB-ipsec-policy-manual-policy001-10] sa spi inbound esp 123456
[SwitchB-ipsec-policy-manual-policy001-10] sa string-key outbound esp abcdefg
[SwitchB-ipsec-policy-manual-policy001-10] sa string-key inbound esp abcdefg
[SwitchB-ipsec-policy-manual-policy001-10] quit
```

# Apply IPsec policy **policy001** to the RIPng process.

```
[SwitchB] ripng 1
[SwitchB-ripng-1] enable ipsec-policy policy001
[SwitchB-ripng-1] quit
```

## 3. Configure Switch C

# Assign an IPv6 address to each interface. (Details not shown.)

# Create a RIPng process and enable it on VLAN-interface 200.

```
<SwitchC> system-view
[SwitchC] ripng 1
```

```
[SwitchC-ripng-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] ripng 1 enable
[SwitchC-Vlan-interface200] quit
```

# Create an IPsec proposal named **tran1**, and set the encapsulation mode to transport mode, the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1-HMAC-96.

```
[SwitchC] ipsec proposal tran1
[SwitchC-ipsec-proposal-tran1] encapsulation-mode transport
[SwitchC-ipsec-proposal-tran1] transform esp
[SwitchC-ipsec-proposal-tran1] esp encryption-algorithm des
[SwitchC-ipsec-proposal-tran1] esp authentication-algorithm sha1
[SwitchC-ipsec-proposal-tran1] quit
```

# Create an IPsec policy named **policy001**, specify the manual mode for it, and configure the SPIs of the inbound and outbound SAs to 123456, and the keys for the inbound and outbound SAs using ESP to abcdefg.

```
[SwitchC] ipsec policy policy001 10 manual
[SwitchC-ipsec-policy-manual-policy001-10] proposal tran1
[SwitchC-ipsec-policy-manual-policy001-10] sa spi outbound esp 123456
[SwitchC-ipsec-policy-manual-policy001-10] sa spi inbound esp 123456
[SwitchC-ipsec-policy-manual-policy001-10] sa string-key outbound esp abcdefg
[SwitchC-ipsec-policy-manual-policy001-10] sa string-key inbound esp abcdefg
[SwitchC-ipsec-policy-manual-policy001-10] quit
```

# Apply IPsec policy **policy001** to the RIPng process.

```
[SwitchC] ripng 1
[SwitchC-ripng-1] enable ipsec-policy policy001
[SwitchC-ripng-1] quit
```

#### 4. Verify the configuration

After the configuration, Switch A, Switch B, and Switch C learns IPv6 routing information through RIPng. SAs are set up successfully, and the IPsec tunnel between two peers is up for protecting the RIPng packets.

Using the **display ripng** command on Switch A, you will see the running status and configuration information of the specified RIPng process. The output shows that IPsec policy policy001 is applied to this process successfully.

```
<SwitchA> display ripng 1
 RIPng process : 1
 Preference : 100
 Checkzero : Enabled
 Default Cost : 0
 Maximum number of balanced paths : 8
 Update time : 30 sec(s) Timeout time : 180 sec(s)
 Suppress time : 120 sec(s) Garbage-Collect time : 120 sec(s)
 Number of periodic updates sent : 186
 Number of trigger updates sent : 1
 IPsec policy name: policy001, SPI: 123456
```

Using the **display ipsec sa** command on Switch A, you will see the information about the inbound and outbound SAs.

```
<SwitchA> display ipsec sa
=====
Protocol: RIPng
=====

IPsec policy name: "policy001"
sequence number: 10
mode: manual

connection id: 1
encapsulation mode: transport
perfect forward secrecy:
tunnel:
flow:

[inbound ESP SAs]
spi: 123456 (0x3039)
proposal: ESP-ENCRYPT-DES ESP-AUTH-SHA1
No duration limit for this sa

[outbound ESP SAs]
spi: 123456 (0x3039)
proposal: ESP-ENCRYPT-DES ESP-AUTH-SHA1
No duration limit for this sa
```

Similarly, you can view the information on Switch B and Switch C. (Details not shown.)

# Configuring SSH2.0

## Overview

### Introduction to SSH2.0

Secure Shell (SSH) offers an approach to logging in to a remote device securely. Using encryption and strong authentication, SSH protects devices against attacks such as IP spoofing and plain text password interception.

The switch can not only work as an SSH server to support connections with SSH clients, but also work as an SSH client to allow users to establish SSH connections with a remote device acting as the SSH server.

Unless otherwise noted, SSH in this document refers to SSH2.0.

---

**NOTE:**

When acting as an SSH server, the switch supports SSH2.0 and SSH1. When acting as an SSH client, the switch supports SSH2.0 only.

---

## SSH operation

To establish an SSH connection and communicate with each other through the connection, an SSH client and the SSH server go through the stages listed in [Table 14](#).

**Table 14 Stages in session establishment and interaction between an SSH client and the server**

| Stages                        | Description                                                                                                                                                                      |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Version negotiation           | SSH1 and SSH2.0 are supported. The two parties negotiate a version to use.                                                                                                       |
| Key and algorithm negotiation | SSH supports multiple algorithms. The two parties negotiate algorithms for communication, and use the DH key exchange algorithm to generate the same session key and session ID. |
| Authentication                | The SSH server authenticates the client in response to the client's authentication request.                                                                                      |
| Session request               | After passing authentication, the client sends a session request to the server.                                                                                                  |
| Interaction                   | After the server grants the request, the client and the server start to communicate with each other.                                                                             |

### Version negotiation

1. The server opens port 22 to listen to connection requests from clients.
2. The client sends a TCP connection request to the server.
3. After the TCP connection is established, the server sends a packet that carries a version information string to the client. The version information string is in the format SSH-<primary protocol version number>.<secondary protocol version number>-<software version number>. The primary and

secondary protocol version numbers constitute the protocol version number. The software version number is used for debugging.

4. After receiving the packet, the client resolves the packet and compares the server's protocol version number with that of its own. If the server's protocol version is lower and supportable, the client uses the protocol version of the server; otherwise, the client uses its own protocol version. In either case, the client sends a packet to the server to notify the server of the protocol version that it decides to use.
5. The server compares the version number carried in the packet with that of its own. If the server supports the version, the negotiation succeeds and the server and the client proceed with key and algorithm negotiation. Otherwise, the negotiation fails, and the server breaks the TCP connection.

---

**NOTE:**

All the packets involved in the preceding steps are transferred in plain text.

---

## Key and algorithm negotiation

**IMPORTANT:**

Before the key and algorithm negotiation, the server must have already generated a DSA or RSA key pair, which is used in generating the session key and session ID, and by the client to authenticate the identity of the server. For more information about DSA and RSA key pairs, see "[Managing public keys.](#)"

---

The server and the client send algorithm negotiation packets to each other, notifying the peer of the supported public key algorithms, encryption algorithms, Message Authentication Code (MAC) algorithms, and compression algorithms.

Based on the received algorithm negotiation packets, the server and the client figure out the algorithms to be used. If the negotiation of any type of algorithm fails, the algorithm negotiation fails and the server tears down the connection with the client.

The server and the client use the DH key exchange algorithm and parameters such as the host key pair to generate the session key and session ID, and the client authenticates the identity of the server.

Through the steps, the server and the client get the same session key and session ID. The session key will be used to encrypt and decrypt data exchanged between the server and client later. The session ID will be used to identify the session established between the server and client and will be used in the authentication stage.

## Authentication

SSH supports the following authentication methods:

- **Password authentication**—The SSH server uses AAA for authentication of the client. During password authentication, the SSH client encrypts its username and password, encapsulates them into a password authentication request, and sends the request to the server. After receiving the request, the SSH server decrypts the username and password, checks the validity of the username and password locally or by a remote AAA server, and then informs the client of the authentication result. If the remote AAA server requires the user for a password re-authentication, it carries a prompt in the authentication response sent to the client. The prompt is transparently transmitted to the client, and displayed on the client to notify the user to enter a specified password. After the user enters the correct password and passes validity check on the remote AAA server, the server returns an authentication success message to the client.
- **Publickey authentication**—The server authenticates the client by the digital signature. During publickey authentication, the client sends the server a publickey authentication request that contains

its username, public key, and publickey algorithm information. The server checks whether the public key is valid. If the public key is invalid, the authentication fails. Otherwise, the server authenticates the client by the digital signature. Finally, the server sends a message to the client to inform it of the authentication result. The switch supports using the publickey algorithms RSA and DSA for digital signature.

An SSH2.0 server might require the client to pass both password authentication and publickey authentication or either of them. However, if the client is running SSH1, the client only needs to pass either authentication, regardless of the requirement of the server.

The following gives the steps of the authentication stage:

1. The client sends the server an authentication request that includes the username, the authentication method, and the information related to the authentication method (for example, the password in the case of password authentication).
2. The server authenticates the client. If the authentication fails, the server sends the client a message to inform the client of the failure and the methods available for re-authentication.
3. The client selects a method from the list to initiate another authentication.
4. The preceding process repeats until the authentication succeeds or the number of failed authentication attempts exceeds the maximum of authentication attempts. In the latter case, the server tears the session down.

---

**NOTE:**

Only clients running SSH2.0 or a later version support password re-authentication that is initiated by the switch acting as the SSH server.

---

## Session request

After passing authentication, the client sends a session request to the server, and the server listens to and processes the request from the client. If the server successfully processes the request, the server sends an SSH\_MSG\_SUCCESS packet to the client and goes on to the interaction stage with the client. Otherwise, the server sends an SSH\_MSG\_FAILURE packet to the client to indicate that the processing has failed or it cannot resolve the request.

## Interaction

In this stage, the server and the client exchanges data as follows:

1. The client encrypts and sends the command to be executed to the server.
2. The server decrypts and executes the command, and then encrypts and sends the result to the client.
3. The client decrypts and displays the result on the terminal.

In the interaction stage, you can execute commands from the client by pasting the commands in text format (the text must be within 2000 bytes). The commands must be available in the same view. Otherwise, the server might not be able to perform the commands correctly.

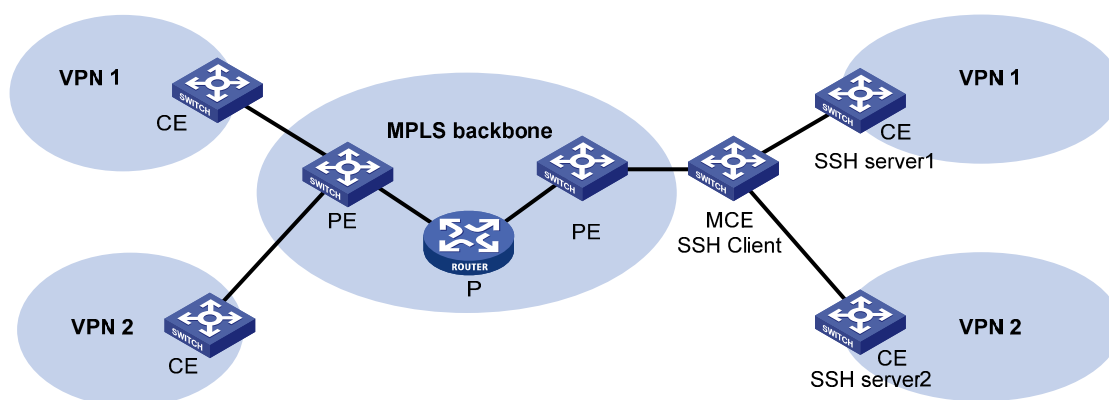

If the command text exceeds 2000 bytes, you can execute the commands by saving the text as a configuration file, uploading the configuration file to the server through Secure FTP (SFTP), and then using the configuration file to restart the server.

# SSH connection across VPNs (available only on the HP 5500 EI)

With this function, you can configure the device as an SSH client to establish connections with SSH servers in different VPNs.

As shown in [Figure 100](#), the hosts in VPN 1 and VPN 2 access the MPLS backbone through PEs, with the services of the two VPNs isolated. After an HP 5500 EI switch that acts as an MCE device is enabled with the SSH client function, it can establish SSH connections with CEs in different VPNs that are enabled with the SSH server function to implement secure access to the CEs and secure transfer of log file.

**Figure 100 Network diagram**

For more information about MCE, see *Layer 3—IP Routing Configuration Guide*.

## Configuring the switch as an SSH server

### SSH server configuration task list

| Task                                                                      | Remarks                                                                                    |
|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">Generating DSA or RSA key pairs</a>                           | Required                                                                                   |
| <a href="#">Enabling the SSH server function</a>                          | Required                                                                                   |
| <a href="#">Configuring the user interfaces for SSH clients</a>           | Required                                                                                   |
| <a href="#">Configuring a client public key</a>                           | Required for publickey authentication users and optional for password authentication users |

| <a href="#">Setting the SSH management parameters</a>                     | Optional                                                                                   |
| <a href="#">Setting the DSCP value for packets sent by the SSH server</a> | Optional                                                                                   |

### Generating DSA or RSA key pairs

In the key and algorithm negotiation stage, the DSA or RSA key pairs are used to generate the session key and session ID and for the client to authenticate the server.

To support SSH clients that use different types of key pairs, generate both DSA and RSA key pairs on the SSH server.

## Generating procedure

To generate DSA or RSA key pairs on the SSH server:

| Step                              | Command                                      | Remarks                                          |
|-----------------------------------|----------------------------------------------|--------------------------------------------------|
| 1. Enter system view.             | <b>system-view</b>                           | N/A                                              |
| 2. Generate DSA or RSA key pairs. | <b>public-key local create { dsa   rsa }</b> | By default, neither DSA nor RSA key pairs exist. |

## Commands for generating DSA or RSA key pairs

The **public-key local create rsa** command generates a server RSA key pair and a host RSA key pair. Each of the key pairs consists of a public key and a private key. The public key in the server key pair of the SSH server is used in SSH1 to encrypt the session key for secure transmission of the key. As SSH2.0 uses the DH algorithm to generate the session key on the SSH server and client, no session key transmission is required in SSH2.0 and the server key pair is not used.

The length of the modulus of RSA server keys and host keys must be in the range of 512 to 2048 bits. Some SSH2.0 clients require that the length of the key modulus be at least 768 bits on the SSH server side.

The **public-key local create dsa** command generates only the host key pair. SSH1 does not support the DSA algorithm.

The length of the modulus of DSA host keys must be in the range of 512 to 2048 bits. Some SSH2.0 clients require that the length of the key modulus be at least 768 bits on the SSH server side.

For more information about the **public-key local create** command, see *Security Command Reference*.

## Enabling the SSH server function

| Step                               | Command                  | Remarks             |
|------------------------------------|--------------------------|---------------------|
| 1. Enter system view.              | <b>system-view</b>       | N/A                 |
| 2. Enable the SSH server function. | <b>ssh server enable</b> | Disabled by default |

## Configuring the user interfaces for SSH clients

### Configuration guidelines

An SSH client accesses the switch through a VTY user interface. You must configure the user interfaces for SSH clients to allow SSH login. The configuration takes effect only for clients that log in after the configuration.

If you configure a user interface to support SSH, be sure to configure the corresponding authentication mode with the **authentication-mode scheme** command.

For a user interface configured to support SSH, you cannot change the authentication mode. To change the authentication mode, undo the SSH support configuration first.

## Configuration procedure

To configure the protocols for a user interface to support:

| Step                                                         | Command                                                             | Remarks                                                  |
|--------------------------------------------------------------|---------------------------------------------------------------------|----------------------------------------------------------|
| 1. Enter system view.                                        | <b>system-view</b>                                                  | N/A                                                      |
| 2. Enter user interface view of one or more user interfaces. | <b>user-interface vty</b> <i>number</i><br>[ <i>ending-number</i> ] | N/A                                                      |
| 3. Set the login authentication mode to <b>scheme</b> .      | <b>authentication-mode scheme</b>                                   | By default, the authentication mode is <b>password</b> . |
| 4. Configure the user interface(s) to support SSH login.     | <b>protocol inbound</b> { <b>all</b>   <b>ssh</b> }                 | Optional.<br>All protocols are supported by default.     |

For more information about the **authentication-mode** and **protocol inbound** commands, see *Fundamentals Command Reference*.

## Configuring a client public key

This configuration task is only necessary for SSH users using publickey authentication.

To allow an SSH user to pass publickey authentication and log in to the server, you must configure the client's DSA or RSA host public key on the server, and configure the client to use the corresponding host private key, so that the server uses the digital signature to authenticate the client.

You can manually configure the public key of an SSH client on the server, or import it from the public key file:

- **Configure it manually**—You can type or copy the public key to the SSH server. The public key must have not been converted and be in the Distinguished Encoding Rules (DER) encoding format.
- **Import it from the public key file**—During the import process, the server will automatically convert the public key in the public key file to a string in Public Key Cryptography Standards (PKCS) format, and save it locally. Before importing the public key, you must upload the public key file (in binary) to the server through FTP or TFTP.

### NOTE:

HP recommends you to configure a client public key by importing it from a public key file.

## Configuring a client public key manually

| Step                                                                  | Command                                  | Remarks                                                                            |
|-----------------------------------------------------------------------|------------------------------------------|------------------------------------------------------------------------------------|
| 1. Enter system view.                                                 | <b>system-view</b>                       | N/A                                                                                |
| 2. Enter public key view.                                             | <b>public-key peer</b> <i>keyname</i>    | N/A                                                                                |
| 3. Enter public key code view.                                        | <b>public-key-code begin</b>             | N/A                                                                                |
| 4. Configure a client's host public key.                              | Enter the content of the host public key | Spaces and carriage returns are allowed between characters.                        |
| 5. Return to public key view and save the configured host public key. | <b>public-key-code end</b>               | When you exit public key code view, the system automatically saves the public key. |

| Step                      | Command                    | Remarks |
|---------------------------|----------------------------|---------|
| 6. Return to system view. | <b>peer-public-key end</b> | N/A     |

## Importing a client public key from a public key file

| Step                                             | Command                                                                    |
|--------------------------------------------------|----------------------------------------------------------------------------|
| 1. Enter system view.                            | <b>system-view</b>                                                         |
| 2. Import the public key from a public key file. | <b>public-key peer</b> <i>keyname</i> <b>import sshkey</b> <i>filename</i> |

For more information about client public key configuration, see "[Managing public keys](#)."

## Configuring an SSH user

To configure an SSH user that uses publickey authentication, you must perform the procedure in this section.

To configure an SSH user that uses password authentication, whether together with publickey authentication or not, you must configure a local user account by using the **local-user** command in "[Configuring AAA](#)" for local authentication, or configure an SSH user account on an authentication server, for example, a RADIUS server, for remote authentication.

For password-only SSH users, you do not need to perform the procedure in this section to configure them unless you want to use the **display ssh user-information** command to display all SSH users, including the password-only SSH users, for centralized management.

### Configuration guidelines

When you perform the procedure in this section to configure an SSH user, follow these guidelines:

You can set the service type to Stelnet, SFTP, and SCP (Secure copy). For more information about Stelnet, see "[Overview](#)." For more information about SFTP, see "[Configuring SFTP](#)." For more information about SCP, see "[Configuring SCP](#)."

- You can enable one of the following authentication modes for the SSH user:
  - **Password**—The user must pass password authentication.
  - **Publickey authentication**—The user must pass publickey authentication.
  - **Password-publickey authentication**—As an SSH2.0 user, the user must pass both password and publickey authentication. As an SSH1 user, the user must pass either password or publickey authentication.
  - **Any**—The user can use either password authentication or publickey authentication.
- If publickey authentication, whether with password authentication or not, is used, the command level accessible to the user is set by the **user privilege level** command on the user interface. If only password authentication is used, the command level accessible to the user is authorized by AAA.
- SSH1 does not support SCP and SFTP. For an SSH1 client, you must set the service type to **stelnet** or **all**.
- For an SCP or SFTP user, the working folder depends on the authentication method:
  - If only password authentication is used, the working folder is authorized by AAA.
  - If publickey authentication, whether with password authentication or not, is used, the working folder is set by using the **ssh user** command.

- If you change the authentication mode or public key for an SSH user that has been logged in, the change can take effect only at the next login of the user.

## Configuration procedure

To configure an SSH user and specify the service type and authentication method:

| Step                                                                           | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Remarks             |
|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| 1. Enter system view.                                                          | <b>system-view</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | N/A                 |
| 2. Create an SSH user, and specify the service type and authentication method. | <ul style="list-style-type: none"> <li>• For Stelnet users:<br/> <b>ssh user <i>username</i> service-type stelnet authentication-type { password   { any   password-publickey   publickey } assign publickey <i>keyname</i> }</b> </li> <li>• For all users, SCP or SFTP users:<br/> <b>ssh user <i>username</i> service-type { all   scp   sftp } authentication-type { password   { any   password-publickey   publickey } assign publickey <i>keyname</i> work-directory <i>directory-name</i> }</b> </li> </ul> | Use either command. |

## Setting the SSH management parameters

SSH management includes:

- Enabling the SSH server to be compatible with SSH1 client
- Setting the RSA server key pair update interval, applicable to users using SSH1 client
- Setting the SSH user authentication timeout period
- Setting the maximum number of SSH authentication attempts

Setting these parameters can help avoid malicious guessing at and cracking of the keys and usernames, securing your SSH connections.

### IMPORTANT:

Authentication fails if the number of authentication attempts (including both publickey and password authentication) exceeds that specified in the **ssh server authentication-retries** command.

To set the SSH management parameters:

| Step                                              | Command                                       | Remarks                                                        |
|---------------------------------------------------|-----------------------------------------------|----------------------------------------------------------------|
| 1. Enter system view.                             | <b>system-view</b>                            | N/A                                                            |
| 2. Enable the SSH server to support SSH1 clients. | <b>ssh server compatible-ssh1x [ enable ]</b> | Optional.<br>By default, the SSH server supports SSH1 clients. |

| Step                                                      | Command                                                        | Remarks                                                                                 |
|-----------------------------------------------------------|----------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| 3. Set the RSA server key pair update interval.           | <b>ssh server rekey-interval</b> <i>hours</i>                  | Optional.<br>By default, the interval is 0, and the RSA server key pair is not updated. |
| 4. Set the SSH user authentication timeout period.        | <b>ssh server authentication-timeout</b> <i>time-out-value</i> | Optional.<br>60 seconds by default.                                                     |
| 5. Set the maximum number of SSH authentication attempts. | <b>ssh server authentication-retries</b> <i>times</i>          | Optional.<br>3 by default.                                                              |

## Setting the DSCP value for packets sent by the SSH server

| Step                                                      | Command                                                                                                                                                                                                                                                                           | Remarks                                                                                                                               |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                     | <b>system-view</b>                                                                                                                                                                                                                                                                | N/A                                                                                                                                   |
| 2. Set the DSCP value for packets sent by the SSH server. | <ul style="list-style-type: none"> <li>Set the DSCP value for packets sent by the IPv4 SSH server:<br/><b>ssh server dscp</b> <i>dscp-value</i></li> <li>Set the DSCP value for packets sent by the IPv6 SSH server:<br/><b>ssh server ipv6 dscp</b> <i>dscp-value</i></li> </ul> | Optional.<br>By default, the DSCP value is 16 in packets sent by the IPv4 SSH server and is 0 in packets sent by the IPv6 SSH server. |

## Configuring the switch as an SSH client

### SSH client configuration task list

| Task                                                                        | Remarks  |
|-----------------------------------------------------------------------------|----------|
| <a href="#">Specifying a source IP address/interface for the SSH client</a> | Optional |
| <a href="#">Configuring whether first-time authentication is supported</a>  | Optional |
| <a href="#">Establishing a connection between the SSH client and server</a> | Required |
| <a href="#">Setting the DSCP value for packets sent by the SSH client</a>   | Optional |

### Specifying a source IP address/interface for the SSH client

This configuration task allows you to specify a source IP address or interface for the client to access the SSH server, improving service manageability.

To specify a source IP address or interface for the client:

| Step                  | Command            | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | <b>system-view</b> | N/A     |

| Step                                                            | Command                                                                                                                                                                                                                                                                                                                                                                                                                                         | Remarks                                                                                                                                                                        |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2. Specify a source IP address or interface for the SSH client. | <ul style="list-style-type: none"> <li>Specify a source IPv4 address or interface for the SSH client:<br/><b>ssh client source</b> { <b>ip</b> <i>ip-address</i>   <b>interface</b> <i>interface-type interface-number</i> }</li> <li>Specify a source IPv6 address or interface for the SSH client:<br/><b>ssh client ipv6 source</b> { <b>ipv6</b> <i>ipv6-address</i>   <b>interface</b> <i>interface-type interface-number</i> }</li> </ul> | <p>Select either approach.</p> <p>By default, an SSH client uses the IP address of the outbound interface defined by the route to the SSH server to access the SSH server.</p> |

## Configuring whether first-time authentication is supported

When the switch acts as an SSH client and connects to the SSH server, you can configure whether the switch supports first-time authentication.

- With first-time authentication, when an SSH client not configured with the server host public key accesses the server for the first time, the user can continue accessing the server, and save the host public key on the client. When accessing the server again, the client will use the saved server host public key to authenticate the server.
- Without first-time authentication, a client not configured with the server host public key will refuse to access the server. To enable the client to access the server, you must configure the server host public key and specify the public key name for authentication on the client in advance.

### Enabling the switch to support first-time authentication

| Step                                                       | Command                                        | Remarks                                                                      |
|------------------------------------------------------------|------------------------------------------------|------------------------------------------------------------------------------|
| 1. Enter system view.                                      | <b>system-view</b>                             | N/A                                                                          |
| 2. Enable the switch to support first-time authentication. | <b>ssh client first-time</b> [ <b>enable</b> ] | Optional.<br>By default, first-time authentication is supported on a client. |

### Disabling first-time authentication

For successful authentication of an SSH client not supporting first-time authentication, the server host public key must be configured on the client and the public key name must be specified.

To disable first-time authentication:

| Step                                               | Command                                                                                  | Remarks                                                                                                                                 |
|----------------------------------------------------|------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                              | <b>system-view</b>                                                                       | N/A                                                                                                                                     |
| 2. Disable first-time authentication support.      | <b>undo ssh client first-time</b>                                                        | By default, first-time authentication is supported on a client.                                                                         |
| 3. Configure the server host public key.           | See " <a href="#">Configuring a client public key</a> "                                  | The method for configuring the server host public key on the client is similar to that for configuring client public key on the server. |
| 4. Specify the host public key name of the server. | <b>ssh client authentication server</b><br><b>server assign publickey</b> <i>keyname</i> | N/A                                                                                                                                     |

## Establishing a connection between the SSH client and server

| Task                                                                                                                                                                                               | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Remarks                                                                                                             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Establish a connection between the SSH client and the server, and specify the public key algorithm, preferred encryption algorithm, preferred HMAC algorithm and preferred key exchange algorithm. | <ul style="list-style-type: none"> <li>For an IPv4 server:<br/> <code>ssh2 server [ port-number ] [ vpn-instance vpn-instance-name ] [ identity-key { dsa   rsa }   prefer-ctos-cipher { 3des   aes128   des }   prefer-ctos-hmac { md5   md5-96   sha1   sha1-96 }   prefer-kex { dh-group-exchange   dh-group1   dh-group14 }   prefer-stoc-cipher { 3des   aes128   des }   prefer-stoc-hmac { md5   md5-96   sha1   sha1-96 } ] *</code> </li> <li>For an IPv6 server:<br/> <code>ssh2 ipv6 server [ port-number ] [ vpn-instance vpn-instance-name ] [ identity-key { dsa   rsa }   prefer-ctos-cipher { 3des   aes128   des }   prefer-ctos-hmac { md5   md5-96   sha1   sha1-96 }   prefer-kex { dh-group-exchange   dh-group1   dh-group14 }   prefer-stoc-cipher { 3des   aes128   des }   prefer-stoc-hmac { md5   md5-96   sha1   sha1-96 } ] *</code> </li> </ul> | <p>Use either command in user view.</p> <p>Only the HP 5500 EI switches support the <b>vpn-instance</b> option.</p> |

## Setting the DSCP value for packets sent by the SSH client

| Step                                                      | Command                                                                                                                                                                                                                                                                             | Remarks                                                                                                                                          |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. For more information about the **display public-key local** and **display public-key peer** commands, see *Security Command Reference*.

## SSH server configuration examples

### When the switch acts as a server for password authentication

#### Network requirements

As shown in [Figure 101](#), a host (the SSH client) and a switch (the SSH server) are directly connected. Configure an SSH user on the switch so that the host can securely log in to the switch after passing password authentication. Configure a username and password for the user on the switch.

**Figure 101 Network diagram**

#### Configuration procedure

1. Configure the SSH server:

```
Generate the RSA key pairs.
```

```
<Switch> system-view
```

```
[Switch] public-key local create rsa
```

```
The range of public key size is (512 ~ 2048).
```

```
NOTES: If the key modulus is greater than 512,
```

```
It will take a few minutes.
```

```
Press CTRL+C to abort.
```

```
Input the bits of the modulus[default = 1024]:
```

```
Generating Keys...
```

```

+++++++
+++++++
+++++
+++++++
Generate a DSA key pair.
[Switch] public-key local create dsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
+++++++
+++++++
Enable the SSH server.
[Switch] ssh server enable
Configure an IP address for VLAN-interface 1. This address will serve as the destination of the
SSH connection.
[Switch] interface vlan-interface 1
[Switch-Vlan-interface1] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface1] quit
Set the authentication mode for the user interfaces to AAA.
[Switch] user-interface vty 0 15
[Switch-ui-vty0-15] authentication-mode scheme
Enable the user interfaces to support SSH.
[Switch-ui-vty0-15] protocol inbound ssh
[Switch-ui-vty0-15] quit
Create local user client001, and set the user command privilege level to 3
[Switch] local-user client001
[Switch-luser-client001] password simple aabbcc
[Switch-luser-client001] service-type ssh
[Switch-luser-client001] authorization-attribute level 3
[Switch-luser-client001] quit
Specify the service type for user client001 as stelnet, and the authentication method as password.
This step is optional.
[Switch] ssh user client001 service-type stelnet authentication-type password

```

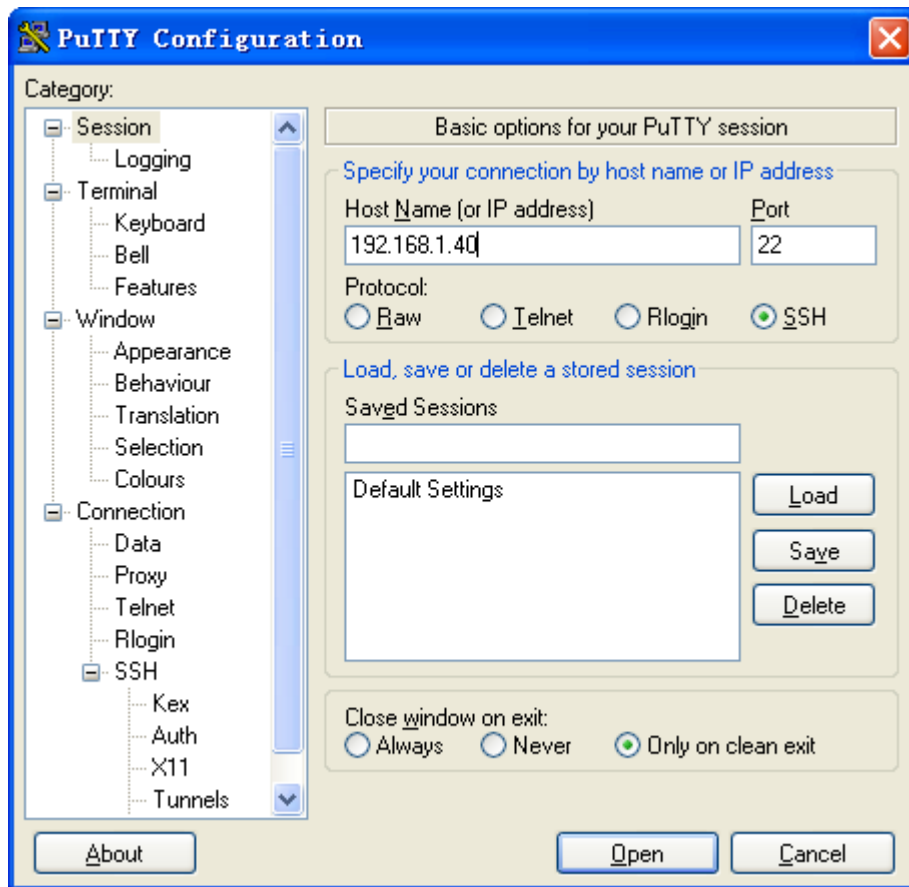

**2.** Establish a connection between the SSH client and the SSH server:

The switch supports a variety of SSH client software, such as PuTTY, and OpenSSH. The following example uses PuTTY Version 0.58.

# Establish a connection to the SSH server.

Launch PuTTY.exe to enter the following interface. In the **Host Name (or IP address)** text box, enter the IP address of the server (192.168.1.40).

Figure 102 Specifying the host name (or IP address)

Click **Open** to connect to the server. If the connection is normal, you will be prompted to enter the username and password. After entering the username (**client001**) and password (**aabbcc**), you can enter the configuration interface of the server.

## When the switch acts as a server for publickey authentication

### Network requirements

As shown in Figure 103, a host (the SSH client) and a switch (the SSH server) are directly connected. Configure an SSH user on the switch so that the host can securely log in to the switch after passing publickey authentication. Use the RSA public key algorithm.

Figure 103 Network diagram

### Configuration procedure

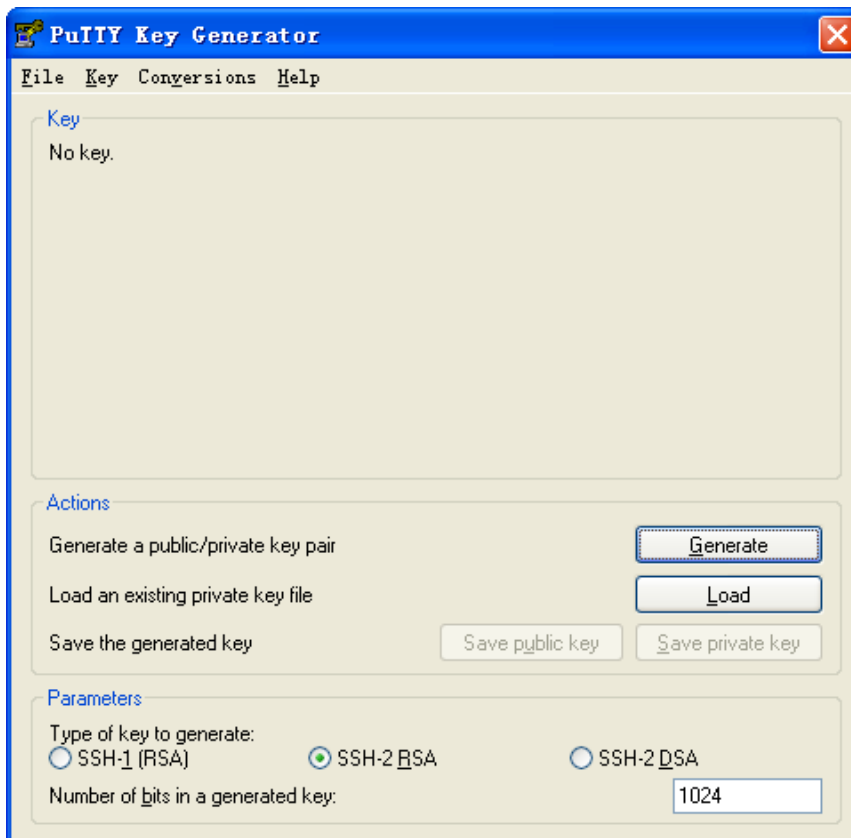

### IMPORTANT:

During SSH server configuration, the client public key is required. Use the client software to generate RSA key pairs on the client before configuring the SSH server.

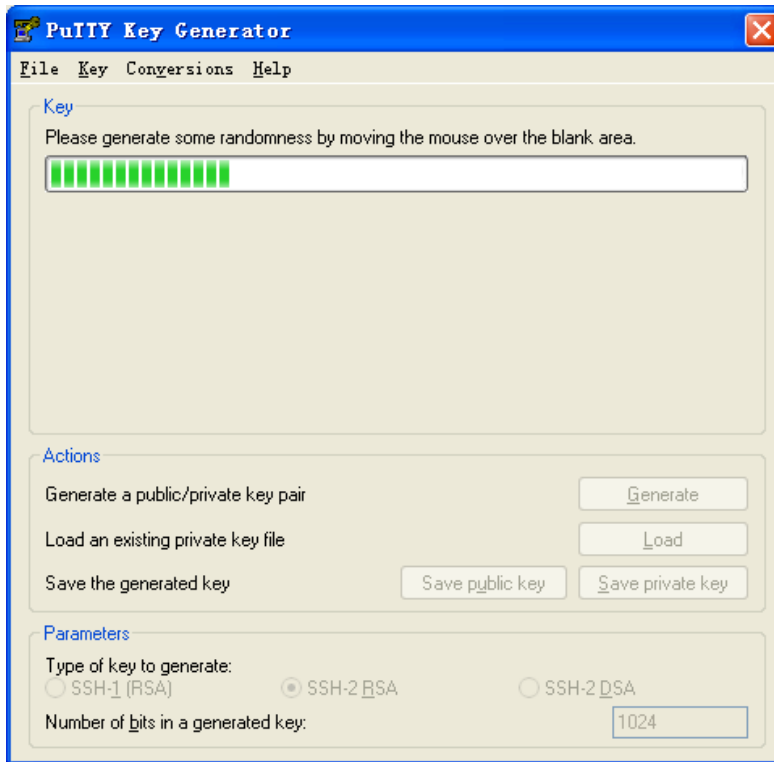

1. Configure the SSH client:
  - # Generate the RSA key pairs.
  - Run PuTTYGen.exe, select **SSH-2 RSA** and click **Generate**.

Figure 104 Generating the key pair on the client

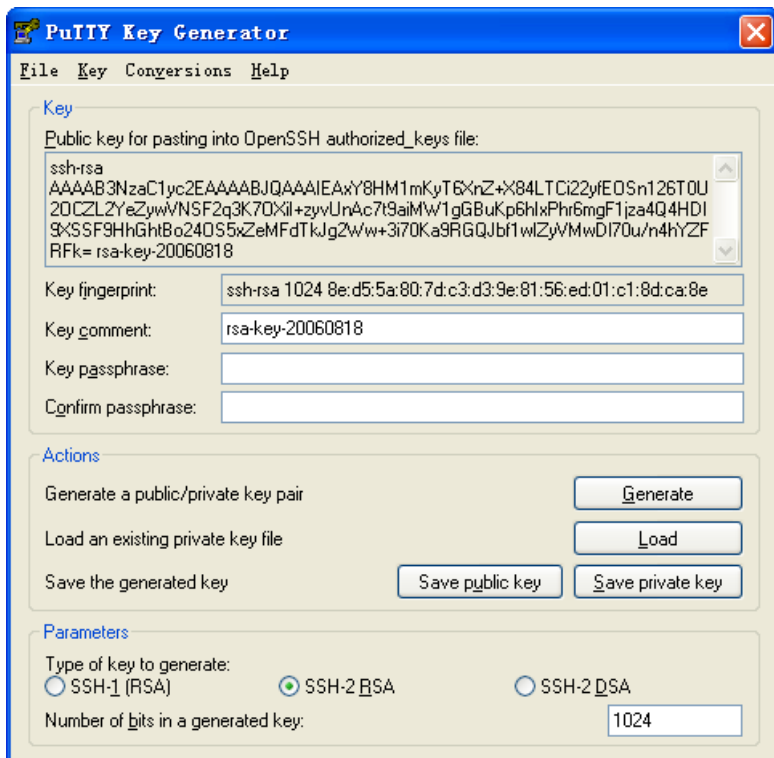

When the generator is generating the key pair, you must move the mouse continuously and keep the mouse off the green progress bar shown in Figure 105. Otherwise, the progress bar stops moving and the key pair generating process will be stopped.

Figure 105 Generating process

After the key pair is generated, click **Save public key** and specify the file name as **key.pub** to save the public key.

Figure 106 Saving the key pair on the client

Likewise, to save the private key, click **Save private key**. A warning window pops up to prompt you whether to save the private key without any protection. Click **Yes** and enter the name of the file for saving the key (**private.ppk** in this case).

Then, transmit the public key file to the server through FTP or TFTP.

## 2. Configure the SSH server:

# Generate the RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
+++++++
+++++
+++++
+++++
```

# Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
+++++
```

# Enable the SSH server.

```
[Switch] ssh server enable
```

# Configure an IP address for VLAN-interface 1. This address will serve as the destination of the SSH connection.

```
[Switch] interface vlan-interface 1
[Switch-Vlan-interface1] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface1] quit
```

# Set the authentication mode for the user interfaces to AAA.

```
[Switch] user-interface vty 0 15
[Switch-ui-vty0-15] authentication-mode scheme
```

# Enable the user interfaces to support SSH.

```
[Switch-ui-vty0-15] protocol inbound ssh
```

# Set the user command privilege level to 3.

```
[Switch-ui-vty0-15] user privilege level 3
[Switch-ui-vty0-15] quit
```

# Import the client's public key from file **key.pub** and name it **Switch001**.

```
[Switch] public-key peer Switch001 import sshkey key.pub
```

# Specify the authentication method for user **client002** as **publickey**, and assign the public key **Switch001** to the user.

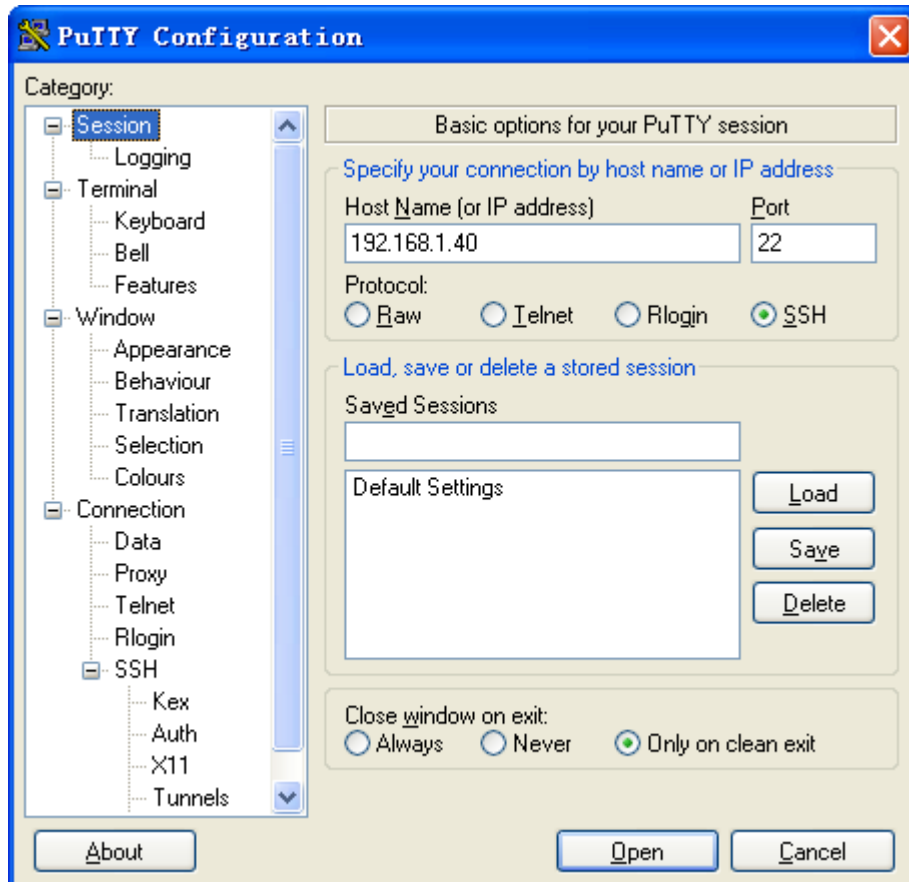

```
[Switch] ssh user client002 service-type stelnet authentication-type publickey assign publickey Switch001
```

3. Establish a connection between the SSH client and the SSH server:

# Specify the private key file and establish a connection to the SSH server

Launch PuTTY.exe to enter the following interface. In the **Host Name (or IP address)** text box, enter the IP address of the server (192.168.1.40).

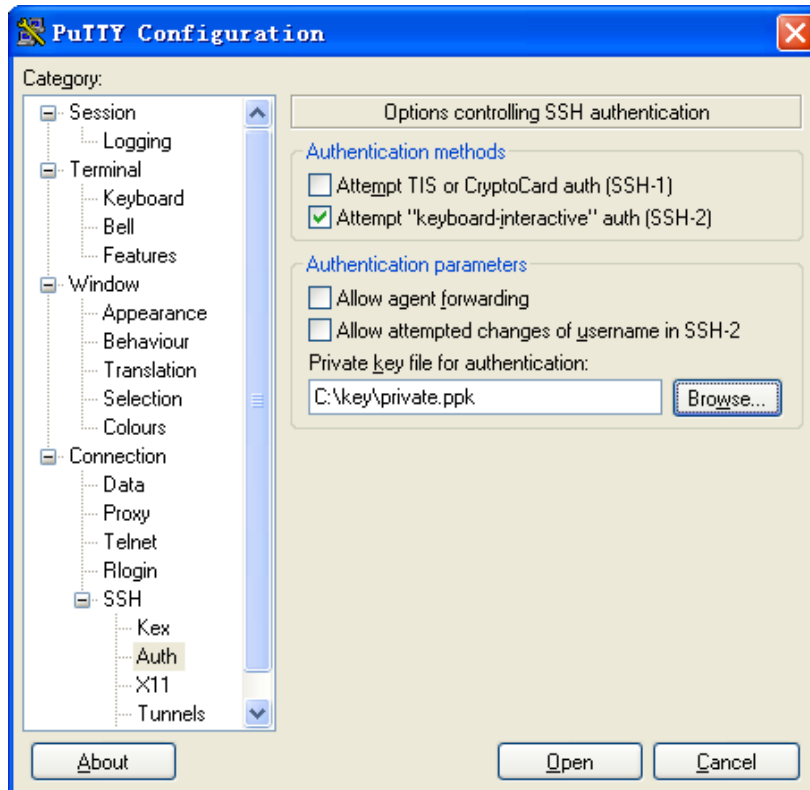

Figure 107 Specifying the host name (or IP address)

Select **Connection > SSH > Auth** from the navigation tree. The following window appears. Click **Browse...** to bring up the file selection window, navigate to the private key file (**private.ppk**) and click **OK**.

Figure 108 Specifying the private key file

Click **Open** to connect to the server. If the connection is normal, you will be prompted to enter the username. After entering the username (**client002**), you can enter the configuration interface of the server.

## SSH client configuration examples

### When switch acts as client for password authentication

#### Network requirements

As shown in Figure 109, Switch A (the SSH client) must pass password authentication to log in to Switch B (the SSH server) through the SSH protocol. Configure the username **client001** and the password **aabbcc** for the SSH client on Switch B.

Figure 109 Network diagram

#### Configuration procedure

1. Configure the SSH server:  
# Generate the RSA key pairs.  
<SwitchB> system-view

```

[SwitchB] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
+++++++
+++++
+++++
+++++
+++++
Generate a DSA key pair.
[SwitchB] public-key local create dsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
+++++
+++++
Enable the SSH server.
[SwitchB] ssh server enable
Configure an IP address for VLAN-interface 1, which the SSH client will use as the destination for
SSH connection.
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 10.165.87.136 255.255.255.0
[SwitchB-Vlan-interface1] quit
Set the authentication mode for the user interfaces to AAA.
[SwitchB] user-interface vty 0 15
[SwitchB-ui-vty0-15] authentication-mode scheme
Enable the user interfaces to support SSH.
[SwitchB-ui-vty0-15] protocol inbound ssh
[SwitchB-ui-vty0-15] quit
Create local user client001.
[SwitchB] local-user client001
[SwitchB-luser-client001] password simple aabbcc
[SwitchB-luser-client001] service-type ssh
[SwitchB-luser-client001] authorization-attribute level 3
[SwitchB-luser-client001] quit
Specify the service type for user client001 as stelnet, and the authentication method as password.
This step is optional.
[SwitchB] ssh user client001 service-type stelnet authentication-type password

```

**2.** Establish a connection between the SSH client and the SSH server:

```

Configure an IP address for VLAN-interface 1.
<SwitchA> system-view
[SwitchA] interface vlan-interface 1

```

```
[SwitchA-Vlan-interface1] ip address 10.165.87.137 255.255.255.0
[SwitchA-Vlan-interface1] quit
[SwitchA] quit
```

- If the client supports first-time authentication, you can directly establish a connection from the client to the server.

# Establish an SSH connection to server 10.165.87.136.

```
<SwitchA> ssh2 10.165.87.136
Username: client001
Trying 10.165.87.136 ...
Press CTRL+K to abort
Connected to 10.165.87.136 ...
```

```
The Server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
Enter password:
```

After you enter the correct password, you can log in to Switch B successfully.

- If the client does not support first-time authentication, perform the following configurations.

# Disable first-time authentication.

```
[SwitchA] undo ssh client first-time
```

# Configure the host public key of the SSH server. You can get the server host public key by using the **display public-key local dsa public** command on the server.

```

## When switch acts as client for publickey authentication

### Network requirements

As shown in [Figure 110](#), Switch A (the SSH client) must pass publickey authentication to log in to Switch B (the SSH server) through the SSH protocol. Use the DSA public key algorithm.

**Figure 110 Network diagram**

### Configuration procedure

#### IMPORTANT:

During SSH server configuration, the client public key is required. Use the client software to generate a DSA key pair on the client before configuring the SSH server.

#### 1. Configure the SSH client:

# Create VLAN-interface 1 and assign an IP address to it.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 10.165.87.137 255.255.255.0
[SwitchA-Vlan-interface1] quit
```

# Generate a DSA key pair.

```
[SwitchA] public-key local create dsa
```

The range of public key size is (512 ~ 2048).

NOTES: If the key modulus is greater than 512,

It will take a few minutes.

Press CTRL+C to abort.

Input the bits of the modulus[default = 1024]:

Generating Keys...

```
+++++
+++++
```

# Export the DSA public key to file **key.pub**.

```
[SwitchA] public-key local export dsa ssh2 key.pub
[SwitchA] quit
```

Then, transmit the public key file to the server through FTP or TFTP.

## 2. Configure the SSH server:

# Generate the RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
```

```
++++++
```

```
+++++
```

```
+++++
```

```
+++++
```

# Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
```

```
+++++
```

# Enable the SSH server.

```
[SwitchB] ssh server enable
```

# Configure an IP address for VLAN-interface 1, which the SSH client will use as the destination for SSH connection.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 10.165.87.136 255.255.255.0
[SwitchB-Vlan-interface1] quit
```

# Set the authentication mode for the user interfaces to AAA.

```
[SwitchB] user-interface vty 0 15
[SwitchB-ui-vty0-15] authentication-mode scheme
```

# Enable the user interfaces to support SSH.

```
[SwitchB-ui-vty0-15] protocol inbound ssh
```

# Set the user command privilege level to 3.

```
[SwitchB-ui-vty0-15] user privilege level 3
[SwitchB-ui-vty0-15] quit
```

# Import the peer public key from the file **key.pub**.

```
[SwitchB] public-key peer Switch001 import sshkey key.pub
```

# Specify the authentication method for user **client002** as **publickey**, and assign the public key **Switch001** to the user.

```
[SwitchB] ssh user client002 service-type stelnet authentication-type publickey
assign publickey Switch001
```

**3.** Establish a connection between the SSH client and the SSH server:

# Establish an SSH connection to the server (10.165.87.136).

```
<SwitchA> ssh2 10.165.87.136
Username: client002
Trying 10.165.87.136 ...
Press CTRL+K to abort
Connected to 10.165.87.136 ...
```

```
The Server is not authenticated. Continue? [Y/N]:y
```

```
Do you want to save the server public key? [Y/N]:n
```

Later, you will find that you have logged in to Switch B successfully.

# Configuring SFTP

## Overview

The Secure File Transfer Protocol (SFTP) is a new feature in SSH2.0.

SFTP uses the SSH connection to provide secure data transfer. The switch can serve as the SFTP server, allowing a remote user to log in to the SFTP server for secure file management and transfer. The switch can also serve as an SFTP client, enabling a user to log in from the switch to a remote device for secure file transfer.

With SSH connection across VPNs, you can configure the switch as an SFTP client to establish connections with SFTP servers in different MPLS VPNs. For more information about this function, see "[Configuring SSH2.0](#)."

## Configuring the switch as an SFTP server

Before you configure this task, complete the following tasks:

- Configure the SSH server.
- Use the **ssh user service-type** command to set the service type of SSH users to **sftp** or **all**.

For more information about the configuration procedures, see "[Configuring SSH2.0](#)."

## Enabling the SFTP server

This configuration task will enable the SFTP service so that a client can log in to the SFTP server through SFTP.

When the switch functions as the SFTP server, only one client can access the SFTP server at a time. If the SFTP client uses WinSCP, a file on the server cannot be modified directly. It can only be downloaded to a local place, modified, and then uploaded to the server.

To enable the SFTP server:

| Step                       | Command                   | Remarks              |
|----------------------------|---------------------------|----------------------|
| 1. Enter system view.      | <b>system-view</b>        | N/A                  |
| 2. Enable the SFTP server. | <b>sftp server enable</b> | Disabled by default. |

## Configuring the SFTP connection idle timeout period

Once the idle period of an SFTP connection exceeds the specified threshold, the system automatically tears the connection down.

To configure the SFTP connection idle timeout period:

| Step                  | Command            | Remarks |
|-----------------------|--------------------|---------|
| 1. Enter system view. | <b>system-view</b> | N/A     |

| Step                                                  | Command                                                  | Remarks                             |
|-------------------------------------------------------|----------------------------------------------------------|-------------------------------------|
| 2. Configure the SFTP connection idle timeout period. | <b>sftp server idle-timeout</b><br><i>time-out-value</i> | Optional.<br>10 minutes by default. |

## Configuring the switch as an SFTP client

### Specifying a source IP address or interface for the SFTP client

You can configure a client to use only a specified source IP address or interface to access the SFTP server, enhancing the service manageability.

To specify a source IP address or interface for the SFTP client:

| Step                                                             | Command                                                                                                                                                                                                                                                                                                                                                                                     | Remarks                                                                                                                                                           |
|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                            | <b>system-view</b>                                                                                                                                                                                                                                                                                                                                                                          | N/A                                                                                                                                                               |
| 2. Specify a source IP address or interface for the SFTP client. | <ul style="list-style-type: none"> <li>Specify a source IPv4 address or interface for the SFTP client:<br/><b>sftp client source { ip ip-address   interface interface-type interface-number }</b></li> <li>Specify a source IPv6 address or interface for the SFTP client:<br/><b>sftp client ipv6 source { ipv6 ipv6-address   interface interface-type interface-number }</b></li> </ul> | <p>Use either command.</p> <p>By default, an SFTP client uses the IP address of the interface specified by the route of the switch to access the SFTP server.</p> |

### Establishing a connection to the SFTP server

This configuration task will enable the SFTP client to establish a connection to the remote SFTP server and enter SFTP client view.

To enable the SFTP client:

| Task                                                                         | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Remarks                                                                                                                                      |

| Establish a connection to the remote SFTP server and enter SFTP client view. | <ul style="list-style-type: none"> <li>Establish a connection to the remote IPv4 SFTP server and enter SFTP client view:<br/> <b>sftp server</b> [ <i>port-number</i> ] [ <b>vpn-instance</b> <i>vpn-instance-name</i> ] [ <b>identity-key</b> { <i>dsa</i>   <i>rsa</i> }   <b>prefer-ctos-cipher</b> { <i>3des</i>   <i>aes128</i>   <i>des</i> }   <b>prefer-ctos-hmac</b> { <i>md5</i>   <i>md5-96</i>   <i>sha1</i>   <i>sha1-96</i> }   <b>prefer-kex</b> { <i>dh-group-exchange</i>   <i>dh-group1</i>   <i>dh-group14</i> }   <b>prefer-stoc-cipher</b> { <i>3des</i>   <i>aes128</i>   <i>des</i> }   <b>prefer-stoc-hmac</b> { <i>md5</i>   <i>md5-96</i>   <i>sha1</i>   <i>sha1-96</i> } ] *</li> <li>Establish a connection to the remote IPv6 SFTP server and enter SFTP client view:<br/> <b>sftp ipv6 server</b> [ <i>port-number</i> ] [ <b>vpn-instance</b> <i>vpn-instance-name</i> ] [ <b>identity-key</b> { <i>dsa</i>   <i>rsa</i> }   <b>prefer-ctos-cipher</b> { <i>3des</i>   <i>aes128</i>   <i>des</i> }   <b>prefer-ctos-hmac</b> { <i>md5</i>   <i>md5-96</i>   <i>sha1</i>   <i>sha1-96</i> }   <b>prefer-kex</b> { <i>dh-group-exchange</i>   <i>dh-group1</i>   <i>dh-group14</i> }   <b>prefer-stoc-cipher</b> { <i>3des</i>   <i>aes128</i>   <i>des</i> }   <b>prefer-stoc-hmac</b> { <i>md5</i>   <i>md5-96</i>   <i>sha1</i>   <i>sha1-96</i> } ] *</li> </ul> | <p>Use either command in user view.</p> <p>Only the HP 5500 EI switches support the <b>vpn-instance</b> <i>vpn-instance-name</i> option.</p> |

## Working with SFTP directories

SFTP directory operations include:

- Changing or displaying the current working directory
- Displaying files under a directory or the directory information
- Changing the name of a directory on the server
- Creating or deleting a directory

To work with the SFTP directories:

| Step                                                                | Command                                                                                                                                                                               | Remarks                                                                 |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 1. Enter SFTP client view.                                          | For more information, see " <a href="#">Establishing a connection to the SFTP server.</a> "                                                                                           | Execute the command in user view.                                       |
| 2. Change the working directory of the remote SFTP server.          | <b>cd</b> [ <i>remote-path</i> ]                                                                                                                                                      | Optional.                                                               |
| 3. Return to the upper-level directory.                             | <b>cdup</b>                                                                                                                                                                           | Optional.                                                               |
| 4. Display the current working directory of the remote SFTP server. | <b>pwd</b>                                                                                                                                                                            | Optional.                                                               |
| 5. Display files under a directory.                                 | <ul style="list-style-type: none"> <li>• <b>dir</b> [ <b>-a</b>   <b>-l</b> ] [ <i>remote-path</i> ]</li> <li>• <b>ls</b> [ <b>-a</b>   <b>-l</b> ] [ <i>remote-path</i> ]</li> </ul> | Optional.<br>The <b>dir</b> command functions as the <b>ls</b> command. |
| 6. Change the name of a directory on the SFTP server.               | <b>rename</b> <i>oldname newname</i>                                                                                                                                                  | Optional.                                                               |

| Step                                                    | Command                                 | Remarks   |
|---------------------------------------------------------|-----------------------------------------|-----------|
| 7. Create a new directory on the remote SFTP server.    | <b>mkdir</b> <i>remote-path</i>         | Optional. |
| 8. Delete one or more directories from the SFTP server. | <b>rmdir</b> <i>remote-path</i> &<1-10> | Optional. |

## Working with SFTP files

SFTP file operations include:

- Changing the name of a file
- Downloading a file
- Uploading a file
- Displaying a list of the files
- Deleting a file

To work with SFTP files:

| Step                                                           | Command                                                                                                                                                                               | Remarks                                                                        |
|----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| 1. Enter SFTP client view.                                     | For more information, see " <a href="#">Establishing a connection to the SFTP server.</a> "                                                                                           | Execute the command in user view.                                              |
| 2. Change the name of a file on the SFTP server.               | <b>rename</b> <i>old-name new-name</i>                                                                                                                                                | Optional.                                                                      |
| 3. Download a file from the remote server and save it locally. | <b>get</b> <i>remote-file</i> [ <i>local-file</i> ]                                                                                                                                   | Optional.                                                                      |
| 4. Upload a local file to the remote SFTP server.              | <b>put</b> <i>local-file</i> [ <i>remote-file</i> ]                                                                                                                                   | Optional.                                                                      |
| 5. Display the files under a directory.                        | <ul style="list-style-type: none"> <li>• <b>dir</b> [ <b>-a</b>   <b>-l</b> ] [ <i>remote-path</i> ]</li> <li>• <b>ls</b> [ <b>-a</b>   <b>-l</b> ] [ <i>remote-path</i> ]</li> </ul> | Optional.<br>The <b>dir</b> command functions as the <b>ls</b> command.        |
| 6. Delete one or more directories from the SFTP server.        | <ul style="list-style-type: none"> <li>• <b>delete</b> <i>remote-file</i>&amp;&lt;1-10&gt;</li> <li>• <b>remove</b> <i>remote-file</i>&amp;&lt;1-10&gt;</li> </ul>                    | Optional.<br>The <b>delete</b> command functions as the <b>remove</b> command. |

## Displaying help information

This configuration task will display a list of all commands or the help information of an SFTP client command, such as the command format and parameters.

To display a list of all commands or the help information of an SFTP client command:

| Step                       | Command                                                                                     | Remarks                           |
|----------------------------|---------------------------------------------------------------------------------------------|-----------------------------------|
| 1. Enter SFTP client view. | For more information, see " <a href="#">Establishing a connection to the SFTP server.</a> " | Execute the command in user view. |

| Step | Command                                                                           | Remarks                                         |
|------|-----------------------------------------------------------------------------------|-------------------------------------------------|
| 2.   | Display a list of all commands or the help information of an SFTP client command. | <code>help [ all   command-name ]</code><br>N/A |

## Terminating the connection to the remote SFTP server

| Step | Command                                                                     | Remarks                                                                                                                                                                                             |
|------|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.   | Enter SFTP client view.                                                     | For more information, see " <a href="#">Establishing a connection to the SFTP server.</a> "<br>Execute the command in user view.                                                                    |
| 2.   | Terminate the connection to the remote SFTP server and return to user view. | <ul style="list-style-type: none"> <li><code>bye</code></li> <li><code>exit</code></li> <li><code>quit</code></li> </ul> Use any of the commands.<br>These three commands function in the same way. |

## Setting the DSCP value for packets sent by the SFTP client

| Step | Command                                                 | Remarks                                                                                                                                                                                                                                                                                                                                                                                                                     |

## SFTP client configuration example

### Network requirements

As shown in [Figure 111](#), an SSH connection is required between Switch A and Switch B. Switch A, an SFTP client, needs to log in to Switch B for file management and file transfer. Use publickey authentication and the RSA public key algorithm.

**Figure 111 Network diagram**

### Configuration procedure

---

**IMPORTANT:**

During SFTP server configuration, the client public key is required. Use the client software to generate RSA key pairs on the client before configuring the SFTP server.

---

**1. Configure the SFTP client:**

# Create VLAN-interface 1 and assign an IP address to it.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface1] quit
```

# Generate the RSA key pairs.

```
[SwitchA] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
```

```
Input the bits of the modulus[default = 1024]:
```

```
Generating Keys...
```

```
++++++
```

```
+++++
```

```
+++++
```

```
+++++
```

# Export the host public key to file **pubkey**.

```
[SwitchA] public-key local export rsa ssh2 pubkey
[SwitchA] quit
```

Then, transmit the public key file to the server through FTP or TFTP.

**2. Configure the SFTP server:**

# Generate the RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
```

```
Input the bits of the modulus[default = 1024]:
```

```
Generating Keys...
```

```
++++++
```

```
+++++
```

```
+++++
```

```
+++++
```

# Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
```

```
Input the bits of the modulus[default = 1024]:
```

Generating Keys...

```
+++++
```

# Enable the SSH server.

```
[SwitchB] ssh server enable
```

# Enable the SFTP server.

```
[SwitchB] sftp server enable
```

# Configure an IP address for VLAN-interface 1, which the SSH client uses as the destination for SSH connection.

```
[SwitchB] interface vlan-interface 1
```

```
[SwitchB-Vlan-interface1] ip address 192.168.0.1 255.255.255.0
```

```
[SwitchB-Vlan-interface1] quit
```

# Set the authentication mode on the user interfaces to AAA.

```
[SwitchB] user-interface vty 0 15
```

```
[SwitchB-ui-vty0-15] authentication-mode scheme
```

# Set the protocol that a remote user uses to log in as **SSH**.

```
[SwitchB-ui-vty0-15] protocol inbound ssh
```

```
[SwitchB-ui-vty0-15] quit
```

# Import the peer public key from the file **pubkey**.

```
[SwitchB] public-key peer Switch001 import sshkey pubkey
```

# For user **client001**, set the service type as SFTP, authentication method as publickey, public key as **Switch001**, and working folder as **flash:/**

```
[SwitchB] ssh user client001 service-type sftp authentication-type publickey assign publickey Switch001 work-directory flash:/
```

### 3. Establish a connection between the SFTP client and the SFTP server:

# Establish a connection to the remote SFTP server and enter SFTP client view.

```
<SwitchA> sftp 192.168.0.1 identity-key rsa
```

```
Input Username: client001
```

```
Trying 192.168.0.1 ...
```

```
Press CTRL+K to abort
```

```
Connected to 192.168.0.1 ...
```

```
The Server is not authenticated. Continue? [Y/N]:y
```

```
Do you want to save the server public key? [Y/N]:n
```

```
sftp-client>
```

# Display files under the current directory of the server, delete the file named **z**, and check if the file has been deleted successfully.

```
sftp-client> dir
```

```
-rwxrwxrwx 1 noone nogroup 1759 Aug 23 06:52 config.cfg

```
sftp-client>
Terminate the connection to the remote SFTP server.
sftp-client> quit
Bye
Connection closed.
<SwitchA>
```

## SFTP server configuration example

### Network requirements

As shown in [Figure 112](#), an SSH connection is required between the host and the switch. The host, an SFTP client, needs to log in to the switch for file management and file transfer. Use password authentication and configure the username **client002** and the password **aabbcc** for the client on the switch.

**Figure 112 Network diagram**

### Configuration procedure

1. Configure the SFTP server:

```
Generate the RSA key pairs.
```

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
+++++++
++++
++++
++++
++++
++++
Generate a DSA key pair.
[Switch] public-key local create dsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
+++++
```

```
Enable the SSH server.
```

```

[Switch] ssh server enable
Enable the SFTP server.
[Switch] sftp server enable
Configure an IP address for VLAN-interface 1, which the client will use as the destination for SSH
connection.
[Switch] interface vlan-interface 1
[Switch-Vlan-interface1] ip address 192.168.1.45 255.255.255.0
[Switch-Vlan-interface1] quit
Set the authentication mode of the user interfaces to AAA.
[Switch] user-interface vty 0 15
[Switch-ui-vty0-15] authentication-mode scheme
Enable the user interfaces to support SSH.
[Switch-ui-vty0-15] protocol inbound ssh
[Switch-ui-vty0-15] quit
Configure a local user named client002 with the password being aabbcc and the service type
being SSH.
[Switch] local-user client002
[Switch-luser-client002] password simple aabbcc
[Switch-luser-client002] service-type ssh
[Switch-luser-client002] quit
Configure the user authentication method as password and service type as SFTP.
[Switch] ssh user client002 service-type sftp authentication-type password

```

**2.** Establish a connection between the SFTP client and the SFTP server:

The switch supports a variety of SFTP client software. The following example uses PSFTP of PuTTY Version 0.58.

---

**NOTE:**

PSFTP supports only password authentication.

---

# Establish a connection to the remote SFTP server.

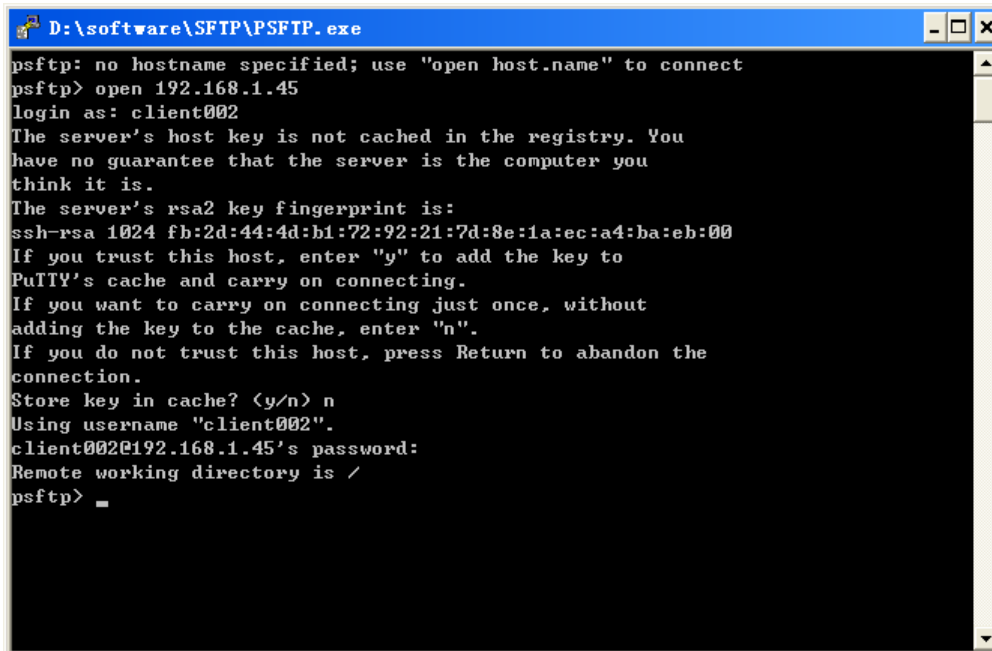

Run the psftp.exe to launch the client interface as shown in [Figure 113](#), and enter the following command:

```
open 192.168.1.45
```

Enter username **client002** and password **aabbcc** as prompted to log in to the SFTP server.

Figure 113 SFTP client interface

```
D:\software\SFTP\PSFTP.exe
psftp: no hostname specified; use "open host.name" to connect
psftp> open 192.168.1.45
login as: client002
The server's host key is not cached in the registry. You
have no guarantee that the server is the computer you
think it is.
The server's rsa2 key fingerprint is:
ssh-rsa 1024 fb:2d:44:4d:b1:72:92:21:7d:8e:1a:ec:a4:ba:eb:00
If you trust this host, enter "y" to add the key to
PuTTY's cache and carry on connecting.
If you want to carry on connecting just once, without
adding the key to the cache, enter "n".
If you do not trust this host, press Return to abandon the
connection.
Store key in cache? (y/n) n
Using username "client002".
client002@192.168.1.45's password:
Remote working directory is /
psftp> _
```

# Configuring SCP

## Overview

Secure copy (SCP) is based on SSH2.0 and offers a secure approach to copying files.

SCP uses SSH connections for copying files. The switch can act as the SCP server, allowing a user to log in to the switch for file upload and download. The switch can also act as an SCP client, enabling a user to log in from the switch to a remote server for secure file transfer.

### NOTE:

When the switch acts as an SCP server, only one of the FTP, SFTP or SCP user can access the switch.

## Configuring the switch as an SCP server

| Step                                                                                                                                          | Command                                                                                                                                                                                                                                                                                                                                      | Remarks                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                                                                                                         | <b>system-view</b>                                                                                                                                                                                                                                                                                                                           | N/A                                                                                                                                                                                                                                          |
| 2. Configure the SSH server.                                                                                                                  | For more information, see the security guide for your switch.                                                                                                                                                                                                                                                                                | N/A                                                                                                                                                                                                                                          |
| 3. Create an SSH user for a SCP client, set the service type to <b>all</b> or <b>scp</b> , and specify the authentication method.             | <b>ssh user</b> <i>username</i> <b>service-type</b> { <b>all</b>   <b>scp</b> }<br><b>authentication-type</b> { <b>password</b>   { <b>any</b>   <b>password-publickey</b>   <b>publickey</b> } <b>assign</b><br><b>publickey</b> <i>keyname</i> <b>work-directory</b> <i>directory-name</i> }                                               | N/A                                                                                                                                                                                                                                          |
| 4. Create a user account and assign a working directory for the SSH user on the switch or a remote server if password authentication is used. | <ul style="list-style-type: none"><li>On the remote server (Details not shown.)</li><li>On the switch:<ul style="list-style-type: none"><li><b>a. local-user</b></li><li><b>b. password</b></li><li><b>c. service-type ssh</b></li><li><b>d. authorization-attribute</b><br/><b>work-directory</b> <i>directory-name</i></li></ul></li></ul> | <p>Skip this step if publickey authentication, whether with password authentication or not, is used.</p> <p>Make sure that the local user account has the name <i>username</i> as the username specified in the <b>ssh user</b> command.</p> |

When you set the working directory for the user, follow these guidelines:

- If only password authentication is used, the working directory specified in the **ssh user** command does not take effect. You must set the working directory on the remote server or in the local user account for the SSH user.
- If publickey authentication, whether with password authentication or not, is used, you must set the working directory in the **ssh user** command.

## Configuring the switch as the SCP client

To upload or download files to or from an SCP server:

| Step                                   | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Remarks                  |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| 1. Upload a file to an SCP server.     | <ul style="list-style-type: none"> <li>Upload a file to the IPv4 SCP server:<br/> <code>scp server [ port-number ] put source-file-path [ destination-file-path ] [ identity-key { dsa   rsa }   prefer-ctos-cipher { 3des   aes128   des }   prefer-ctos-hmac { md5   md5-96   sha1   sha1-96 }   prefer-kex { dh-group-exchange   dh-group1   dh-group14 }   prefer-stoc-cipher { 3des   aes128   des }   prefer-stoc-hmac { md5   md5-96   sha1   sha1-96 } ] *</code></li> <li>Upload a file to the IPv6 SCP server:<br/> <code>scp ipv6 server [ port-number ] put source-file-path [ destination-file-path ] [ identity-key { dsa   rsa }   prefer-ctos-cipher { 3des   aes128   des }   prefer-ctos-hmac { md5   md5-96   sha1   sha1-96 }   prefer-kex { dh-group-exchange   dh-group1   dh-group14 }   prefer-stoc-cipher { 3des   aes128   des }   prefer-stoc-hmac { md5   md5-96   sha1   sha1-96 } ] *</code></li> </ul>                       | Use one of the commands. |
| 2. Download a file from an SCP server. | <ul style="list-style-type: none"> <li>Download a file from the remote IPv4 SCP server:<br/> <code>scp server [ port-number ] get source-file-path [ destination-file-path ] [ identity-key { dsa   rsa }   prefer-ctos-cipher { 3des   aes128   des }   prefer-ctos-hmac { md5   md5-96   sha1   sha1-96 }   prefer-kex { dh-group-exchange   dh-group1   dh-group14 }   prefer-stoc-cipher { 3des   aes128   des }   prefer-stoc-hmac { md5   md5-96   sha1   sha1-96 } ] *</code></li> <li>Download a file from the remote IPv6 SCP server:<br/> <code>scp ipv6 server [ port-number ] get source-file-path [ destination-file-path ] [ identity-key { dsa   rsa }   prefer-ctos-cipher { 3des   aes128   des }   prefer-ctos-hmac { md5   md5-96   sha1   sha1-96 }   prefer-kex { dh-group-exchange   dh-group1   dh-group14 }   prefer-stoc-cipher { 3des   aes128   des }   prefer-stoc-hmac { md5   md5-96   sha1   sha1-96 } ] *</code></li> </ul> | Available in user view.  |

#### IMPORTANT:

File transfer interruption during a downloading process can result in file fragments on the switch. You must manually delete them.

## SCP client configuration example

### Network requirements

As shown in [Figure 114](#), switch A acts as a client and download the file **remote.bin** from switch B. The user has the username **test** and uses the password authentication method.

**Figure 114 Network diagram**

### Configuration procedure

# Create VLAN-interface 1 and assign an IP address to it.

```

<SwitchA> system-view
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface1] quit

```

# Download the file **remote.bin** from the SCP server, save it locally and change the file name to **local.bin**.

```

<SwitchA> scp 192.168.0.1 get remote.bin local.bin
Username: test
Trying 192.168.0.1 ...
Press CTRL+K to abort
Connected to 192.168.0.1 ...

```

```

The Server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
Enter password:
18471 bytes transferred in 0.001 seconds.

```

## SCP server configuration example

### Network requirements

As shown in [Figure 115](#), the switch acts as the SCP server, and the host acts as the SCP client. The host establishes an SSH connection to the switch. The user uses the username **test** and the password **aabbcc**. The username and password are saved on the switch for local authentication.

**Figure 115 Network diagram**

### Configuration procedure

# Generate the RSA key pairs.

```

<Switch> system-view
[Switch] public-key local create rsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,
It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
+++++++
+++++
+++++
+++++
+++++++

```

# Generate the DSA key pair.

```

[Switch] public-key local create dsa
The range of public key size is (512 ~ 2048).
NOTES: If the key modulus is greater than 512,

```

```

It will take a few minutes.
Press CTRL+C to abort.
Input the bits of the modulus[default = 1024]:
Generating Keys...
+++++
+++++

Enable the SSH server function.
[Switch] ssh server enable

Configure an IP address for VLAN-interface 1, which the client will use as the destination for SSH
connection.
[Switch] interface vlan-interface 1
[Switch-Vlan-interface1] ip address 192.168.1.45 255.255.255.0
[Switch-Vlan-interface1] quit

Set the authentication mode of the user interfaces to AAA.
[Switch] user-interface vty 0 15
[Switch-ui-vty0-15] authentication-mode scheme

Enable the user interfaces to support all protocols including SSH.
[Switch-ui-vty0-15] protocol inbound all
[Switch-ui-vty0-15] quit

Create a local user named test.
[Switch] local-user test
[Switch-luser-test] password simple aabbcc
[Switch-luser-test] service-type ssh
[Switch-luser-test] quit

Configure the SSH user authentication method as password and service type as scp.
[Switch] ssh user test service-type scp authentication-type password

```

# Configuring SSL

## Overview

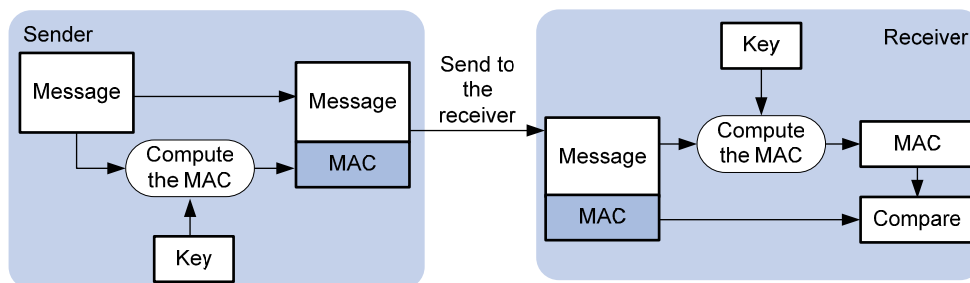

Secure Sockets Layer (SSL) is a security protocol that provides secure connection services for TCP-based application layer protocols such as Hypertext Transfer Protocol (HTTP). It is widely used in e-business and online banking to ensure secure data transmission over the Internet.

## SSL security mechanism

Secure connections provided by SSL have these features:

- **Confidentiality**—SSL uses a symmetric encryption algorithm to encrypt data and uses the asymmetric key algorithm of Rivest, Shamir, and Adelman (RSA) to encrypt the key to be used by the symmetric encryption algorithm.
- **Authentication**—SSL supports certificate-based identity authentication of the server and client by using the digital signatures. The SSL server and client obtain certificates from a certificate authority (CA) through the Public Key Infrastructure (PKI).
- **Reliability**—SSL uses the key-based message authentication code (MAC) to verify message integrity. A MAC algorithm transforms a message of any length to a fixed-length message. With the key, the sender uses the MAC algorithm to compute the MAC value of a message. Then, the sender suffixes the MAC value to the message and sends the result to the receiver. The receiver uses the same key and MAC algorithm to compute the MAC value of the received message, and compares the locally computed MAC value with that received. If the two values match, the receiver considers the message intact; otherwise, the receiver considers that the message has been tampered with in transit and discards the message.

Figure 116 Message integrity verification by a MAC algorithm

For more information about symmetric key algorithms, asymmetric key algorithm RSA and digital signature, see "[Managing public keys.](#)"

For more information about PKI, certificate, and CA, see "[Configuring PKI.](#)"

## SSL protocol stack

The SSL protocol consists of two layers of protocols: the SSL record protocol at the lower layer and the SSL handshake protocol, change cipher spec protocol, and alert protocol at the upper layer.

**Figure 117 SSL protocol stack**

- **SSL record protocol**—Fragments data to be transmitted, computes and adds MAC to the data, and encrypts the data before transmitting it to the peer end.
- **SSL handshake protocol**—Negotiates the cipher suite to be used for secure communication (including the symmetric encryption algorithm, key exchange algorithm, and MAC algorithm), securely exchanges the key between the server and client, and implements identity authentication of the server and client. Through the SSL handshake protocol, a session is established between a client and the server. A session consists of a set of parameters, including the session ID, peer certificate, cipher suite, and master secret.
- **SSL change cipher spec protocol**—Used for notification between the client and the server that the subsequent packets are to be protected and transmitted based on the newly negotiated cipher suite and key.
- **SSL alert protocol**—Enables the SSL client and server to send alert messages to each other. An alert message contains the alert severity level and a description.

## Configuration task list

| Task                                             | Remarks  |
|--------------------------------------------------|----------|
| <a href="#">Configuring an SSL server policy</a> | Required |
| <a href="#">Configuring an SSL client policy</a> | Optional |

## Configuring an SSL server policy

An SSL server policy is a set of SSL parameters for a server to use when booting up. An SSL server policy takes effect only after it is associated with an application layer protocol such as HTTP.

Before configuring an SSL server policy, configure the PKI domain for the SSL server policy to use to obtain a certificate for the SSL server. For more information about PKI domain configuration, see "[Configuring PKI.](#)"

SSL mainly comes in these versions: SSL 2.0, SSL 3.0, and TLS 1.0, where TLS 1.0 corresponds to SSL 3.1. When the switch acts as an SSL server, it can communicate with clients running SSL 3.0 or TLS 1.0, and can identify the SSL 2.0 Client Hello message from a client supporting SSL 2.0 and SSL 3.0/TLS 1.0 and notify the client to use SSL 3.0 or TLS 1.0 to communicate with the server.

To configure an SSL server policy:

| Step                  | Command                  | Remarks |
|-----------------------|--------------------------|---------|
| 1. Enter system view. | <code>system-view</code> | N/A     |

| Step                                                                                          | Command                                                                                                                                                                                      | Remarks                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2. Create an SSL server policy and enter its view.                                            | <b>ssl server-policy</b> <i>policy-name</i>                                                                                                                                                  | N/A                                                                                                                                                                                                                                                                                     |
| 3. Specify a PKI domain for the SSL server policy.                                            | <b>pki-domain</b> <i>domain-name</i>                                                                                                                                                         | By default, no PKI domain is specified for an SSL server policy.<br>If the client requires certificate-based authentication for the SSL server, you must use this command to specify a PKI domain for the server and request a local certificate for the server through the PKI domain. |
| 4. Specify the cipher suite(s) for the SSL server policy to support.                          | <b>ciphersuite</b><br>[ <i>rsa_3des_edc_cbc_sha</i>   <i>rsa_aes_128_cbc_sha</i>   <i>rsa_aes_256_cbc_sha</i>   <i>rsa_des_cbc_sha</i>   <i>rsa_rc4_128_md5</i>   <i>rsa_rc4_128_sha</i> ] * | Optional.<br>By default, an SSL server policy supports all cipher suites.                                                                                                                                                                                                               |
| 5. Set the handshake timeout time for the SSL server.                                         | <b>handshake timeout</b> <i>time</i>                                                                                                                                                         | Optional.<br>3,600 seconds by default.                                                                                                                                                                                                                                                  |
| 6. Set the SSL connection close mode.                                                         | <b>close-mode</b> <i>wait</i>                                                                                                                                                                | Optional.<br>Not wait by default.                                                                                                                                                                                                                                                       |
| 7. Set the maximum number of cached sessions and the caching timeout time.                    | <b>session</b> { <i>cache-size size</i>   <i>timeout time</i> } *                                                                                                                            | Optional.<br>The defaults are as follows: <ul style="list-style-type: none"> <li>• 500 for the maximum number of cached sessions.</li> <li>• 3600 seconds for the caching timeout time.</li> </ul>                                                                                      |
| 8. Enable the SSL server to perform digital certificate-based authentication for SSL clients. | <b>client-verify</b> <i>enable</i>                                                                                                                                                           | Optional.<br>By default, the SSL server does not require clients to be authenticated.                                                                                                                                                                                                   |
| 9. Enable SSL client weak authentication.                                                     | <b>client-verify</b> <i>weaken</i>                                                                                                                                                           | Optional.<br>Disabled by default.<br>This command takes effect only when the <b>client-verify enable</b> command is configured.                                                                                                                                                         |

## SSL server policy configuration example

### Network requirements

As shown in [Figure 118](#), users need to access and control the device through web pages.

For security of the device and to make sure that data is not eavesdropped or tampered with, configure the device so that users must use HTTPS (Hypertext Transfer Protocol Secure, which uses SSL) to log in to the web interface of the device.

Figure 118 Network diagram

## Configuration considerations

To achieve the goal, perform the following configurations:

- Configure Device to work as the HTTPS server and request a certificate for Device.
- Request a certificate for Host so that Device can authenticate the identity of Host.
- Configure a CA server to issue certificates to Device and Host.

## Configuration procedure

In this example, Windows Server works as the CA server and the Simple Certificate Enrollment Protocol (SCEP) plug-in is installed on the CA server.

Before performing the following configurations, make sure the switch, the host, and the CA server can reach each other.

1. Configure the HTTPS server (Device):

# Create a PKI entity named **en**, and configure the common name as **http-server1** and the FQDN as **ssl.security.com**.

```
<Device> system-view
[Device] pki entity en
[Device-pki-entity-en] common-name http-server1

**2.** Configure the HTTPS client (Host):

On Host, launch IE, enter `http://10.1.2.2/certsrv` in the address bar and request a certificate for Host as prompted.

**3.** Verify your configuration:

Launch IE on the host, enter `https://10.1.1.1` in the address bar, and select the certificate issued by the CA server. The web interface of the switch should appear. After entering username **usera** and password **123**, you should be able to log in to the web interface to access and manage the switch.

For more information about PKI configuration commands, see "[Configuring PKI](#)."

For more information about the **public-key local create rsa** command, see *Security Command Reference*.

For more information about HTTPS, see *Fundamentals Configuration Guide*.

## Configuring an SSL client policy

An SSL client policy is a set of SSL parameters for a client to use when connecting to the server. An SSL client policy takes effect only after it is associated with an application layer protocol.

If the SSL server is configured to authenticate the SSL client, you must configure the PKI domain for the SSL client policy to use to obtain the certificate of the client. For more information about PKI domain configuration, see "[Configuring PKI](#)."

To configure an SSL client policy:

| Step                                                      | Command                                     | Remarks |
|-----------------------------------------------------------|---------------------------------------------|---------|
| <b>1.</b> Enter system view.                              | <b>system-view</b>                          | N/A     |
| <b>2.</b> Create an SSL client policy and enter its view. | <b>ssl client-policy</b> <i>policy-name</i> | N/A     |

| Step                                                                                     | Command                                                                                                                                                                                                     | Remarks                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3. Specify a PKI domain for the SSL client policy.                                       | <b>pki-domain</b> <i>domain-name</i>                                                                                                                                                                        | Optional.<br>No PKI domain is configured by default.<br>If the SSL server requires certificate-based authentication for SSL clients, you must use this command to specify a PKI domain for the client and request a local certificate for the client through the PKI domain. |
| 4. Specify the preferred cipher suite for the SSL client policy.                         | <b>prefer-cipher</b><br>{ <i>rsa_3des_edc_cbc_sha</i>  <br><i>rsa_aes_128_cbc_sha</i>  <br><i>rsa_aes_256_cbc_sha</i>  <br><i>rsa_des_cbc_sha</i>  <br><i>rsa_rc4_128_md5</i>  <br><i>rsa_rc4_128_sha</i> } | Optional.<br><b>rsa_rc4_128_md5</b> by default.                                                                                                                                                                                                                              |
| 5. Specify the SSL protocol version for the SSL client policy.                           | <b>version</b> { <i>ssl3.0</i>   <i>tls1.0</i> }                                                                                                                                                            | Optional.<br>TLS 1.0 by default.                                                                                                                                                                                                                                             |
| 6. Enable the SSL client to perform certificate-based authentication for the SSL server. | <b>server-verify</b> <b>enable</b>                                                                                                                                                                          | Optional.<br>Enabled by default.                                                                                                                                                                                                                                             |

## Displaying and maintaining SSL

| Task                                   | Command                                                                                                                                                          | Remarks               |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Display SSL server policy information. | <b>display ssl server-policy</b><br>{ <i>policy-name</i>   <b>all</b> } [   { <b>begin</b>  <br><b>exclude</b>   <b>include</b> }<br><i>regular-expression</i> ] | Available in any view |
| Display SSL client policy information. | <b>display ssl client-policy</b><br>{ <i>policy-name</i>   <b>all</b> } [   { <b>begin</b>  <br><b>exclude</b>   <b>include</b> }<br><i>regular-expression</i> ] | Available in any view |

## Troubleshooting SSL

### Symptom

As the SSL server, the switch fails to handshake with the SSL client.

### Analysis

SSL handshake failure may result from the following causes:

- The SSL client is configured to authenticate the SSL server, but the SSL server has no certificate or the certificate is not trusted.

- The SSL server is configured to authenticate the SSL client, but the SSL client has no certificate or the certificate is not trusted.
- The server and the client have no matching cipher suite.

## Solution

1. Issue the **debugging ssl** command and view the debugging information to locate the problem:
  - If the SSL client is configured to authenticate the SSL server but the SSL server has no certificate, request one for it.
  - If the server's certificate cannot be trusted, install the root certificate of the CA that issued the local certificate to the SSL server on the SSL client, or let the server request a certificate from the CA that the SSL client trusts.
  - If the SSL server is configured to authenticate the client, but the SSL client has no certificate or the certificate cannot be trusted, request and install a certificate for the client.
2. Use the **display ssl server-policy** command to view the cipher suites that the SSL server policy supports. If the server and the client have no matching cipher suite, use the **ciphersuite** command to modify the cipher suite configuration of the SSL server.

---

# Configuring TCP attack protection

## Overview

An attacker can attack the switch during the process of establishing a TCP connection. To prevent such an attack, the switch provides the SYN Cookie feature.

## Enabling the SYN Cookie feature

As a general rule, the establishment of a TCP connection involves the following three handshakes.

1. The request originator sends a SYN message to the target server.
2. After receiving the SYN message, the target server establishes a TCP connection in the SYN\_RECEIVED state, returns a SYN ACK message to the originator, and waits for a response.
3. After receiving the SYN ACK message, the originator returns an ACK message, establishing the TCP connection.

Attackers may mount SYN Flood attacks during TCP connection establishment. They send a large number of SYN messages to the server to establish TCP connections, but they never make any response to SYN ACK messages. As a result, a large number of incomplete TCP connections are established, resulting in heavy resource consumption and making the server unable to handle services normally.

The SYN Cookie feature can prevent SYN Flood attacks. After receiving a TCP connection request, the server directly returns a SYN ACK message, instead of establishing an incomplete TCP connection. Only after receiving an ACK message from the client can the server establish a connection, and then enter the ESTABLISHED state. In this way, incomplete TCP connections could be avoided to protect the server against SYN Flood attacks.

Follow these guidelines when you enable the SYN Cookie feature:

- If you enable MD5 authentication for TCP connections on the HP 5500 EI, the SYN Cookie configuration is ineffective. Then, if you disable MD5 authentication for TCP connections, the SYN Cookie configuration automatically becomes effective. For more information about MD5 authentication, see *Layer 3—IP Routing Configuration Guide*.
- With the SYN Cookie feature enabled, only the maximum segment size (MSS), is negotiated during TCP connection establishment, instead of the window's zoom factor and timestamp.

To enable the SYN Cookie feature:

| Step                              | Command                      | Remarks            |
|-----------------------------------|------------------------------|--------------------|
| 1. Enter system view.             | <b>system-view</b>           | N/A                |
| 2. Enable the SYN Cookie feature. | <b>tcp syn-cookie enable</b> | Enabled by default |

## Displaying and maintaining TCP attack protection

| Task                                  | Command                                                                                                      | Remarks               |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------|-----------------------|
| Display current TCP connection state. | <b>display tcp status</b> [   { <b>begin</b>   <b>exclude</b>   <b>include</b> } <i>regular-expression</i> ] | Available in any view |

# Configuring IP source guard

## Overview

IP source guard is intended to improve port security by blocking illegal packets. For example, it can prevent illegal hosts from using a legal IP address to access the network.

IP source guard can filter packets according to the packet source IP address and source MAC address. IP source guard entries fall into the following types:

- IP-port binding entry
- MAC-port binding entry
- IP-MAC-port binding entry

After receiving a packet, an IP source guard-enabled port obtains the key attributes (source IP address and source MAC) of the packet and then looks them up in the IP source guard entries. If there is a match, the port forwards the packet. Otherwise, the port discards the packet, as shown in [Figure 119](#).

**Figure 119 Diagram for the IP source guard function**

A binding entry can be statically configured or dynamically added.

## Static IP source guard entries

A static IP source guard entry is configured manually. It is suitable for scenarios where few hosts exist on a LAN and their IP addresses are manually configured. For example, you can configure a static binding entry on a port that connects a server, allowing the port to receive packets from and send packets to only the server.

A static IPv4 source guard entry filters IPv4 packets received by the port or cooperates with ARP detection to check the validity of users. A static IPv6 source guard entry filters IPv6 packets received by the port cooperates with the ND detection feature to check the validity of users.

For information about ARP detection, see "[Configuring ARP attack protection](#)." For information about ND detection, see "[Configuring ND attack defense](#)."

A static IP source guard entry can be a global or port-based static binding entry.

## Global static binding entry

A global static binding entry is a MAC-IP binding entry configured in system view. It is effective on all ports. A port forwards a packet when the packet's IP address and MAC address both match those of a global static binding entry or a static binding entry configured on the port.

Global static binding entries are used to protect against host spoofing attacks, which exploit the IP address or MAC address of a legal user host.

## Port-based static binding entry

A port-based static binding entry binds an IP address, MAC address, or any combination of the three with a port. Such an entry is effective on only the specified port. A port forwards a packet only when the IP address and MAC address (if any) of the packet all match those in a static binding entry on the port or a global static binding entry. All other packets will be dropped.

Port-based static binding entries are used to check the validity of users who are trying to access a port.

## Dynamic IP source guard entries

Dynamic IP source guard entries are generated dynamically according to client entries on the DHCP snooping or DHCP relay agent device. They are suitable for scenarios where many hosts reside on a LAN and obtain IP addresses through DHCP. Once DHCP allocates an IP address to a client, IP source guard automatically adds the client entry to allow the client to access the network. A user using an IP address not obtained through DHCP cannot access the network. Dynamic IPv6 source guard entries can also be obtained from client entries on the ND snooping device.

- Dynamic IPv4 source guard entries are generated dynamically based on DHCP snooping or DHCP relay entries to filter incoming IPv4 packets on a port.
- Dynamic IPv6 source guard entries are generated dynamically based on DHCPv6 snooping or ND snooping entries to filter incoming IPv6 packets on a port.

For information about DHCP snooping, DHCP relay, DHCPv6 snooping, and ND snooping, see *Layer 3—IP Services Configuration Guide*.

## Configuration task list

Complete the following tasks to configure IPv4 source guard:

| Task                                                                    | Remarks  |
|-------------------------------------------------------------------------|----------|
| <a href="#">Configuring IPv4 source guard on a port</a>                 | Required |
| <a href="#">Configuring a static IPv4 source guard entry</a>            | Optional |
| <a href="#">Setting the maximum number of IPv4 source guard entries</a> | Optional |

Complete the following tasks to configure IPv6 source guard:

| Task                                                                    | Remarks  |
|-------------------------------------------------------------------------|----------|
| <a href="#">Configuring IPv6 source guard on a port</a>                 | Required |
| <a href="#">Configuring a static IPv6 source guard entry</a>            | Optional |
| <a href="#">Setting the maximum number of IPv6 source guard entries</a> | Optional |

# Configuring the IPv4 source guard function

You cannot enable IPv4 source guard on a link aggregation member port or a service loopback group. If IPv4 source guard is enabled on a port, you cannot assign the port to a link aggregation group or a service loopback group.

## Configuring IPv4 source guard on a port

The IPv4 source guard function must be configured on a port before the port can obtain dynamic IPv4 source guard entries and use static and dynamic IPv4 source guard entries to filter packets.

- For how to configure a static binding entry, see "[Configuring a static IPv4 source guard entry.](#)"
- On a Layer 2 Ethernet port, IP source guard cooperates with DHCP snooping, dynamically obtains the DHCP snooping entries generated during dynamic IP address allocation, and generates IP source guard entries accordingly.
- On a VLAN interface, IP source guard cooperates with DHCP relay, dynamically obtains the DHCP relay entries generated during dynamic IP address allocation across network segments, and generates IP source guard entries accordingly.

Dynamic IPv4 source guard entries can contain such information as the MAC address, IP address, VLAN tag, ingress port information, and entry type (DHCP snooping or DHCP relay), where the MAC address, IP address, or VLAN tag information may not be included depending on your configuration. IP source guard applies these entries to the port to filter packets.

To generate IPv4 binding entries dynamically based on DHCP entries, make sure that DHCP snooping or DHCP relay is configured and working normally. For information about DHCP snooping configuration and DHCP relay configuration, see *Layer 3—IP Services Configuration Guide*.

If you repeatedly configure the IPv4 source guard function on a port, only the last configuration takes effect.

To configure the IPv4 source guard function on a port:

| Step                                        | Command                                                                                                  | Remarks                                                                                                                                                               |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                       | <b>system-view</b>                                                                                       | N/A                                                                                                                                                                   |
| 2. Enter interface view.                    | <b>interface</b> <i>interface-type</i><br><i>interface-number</i>                                        | The term <i>interface</i> collectively refers to the following types of ports and interfaces: Bridge mode (Layer 2) Ethernet ports, VLAN interfaces, and port groups. |
| 3. Configure IPv4 source guard on the port. | <b>ip verify source</b> { <b>ip-address</b>  <br><b>ip-address mac-address</b>  <br><b>mac-address</b> } | Not configured by default.                                                                                                                                            |

### NOTE:

Although dynamic IPv4 source guard entries are generated based on DHCP entries, the number of dynamic IPv4 source guard entries is not necessarily the same as that of the DHCP entries.

# Configuring a static IPv4 source guard entry

Static IPv4 binding entries take effect only on the ports configured with the IPv4 source guard function (see "Configuring IPv4 source guard on a port").

Port-based static IPv4 source guard entries and dynamic IPv4 source guard entries take precedence over global static IPv4 source guard entries. A port matches a packet against global static binding entries only when the packet does not match any port-based static binding entry or dynamic binding entry on the port.

## Configuring global static IPv4 binding entries

A global static binding entry defines the IP address and MAC address of the packets that can be forwarded by ports. It takes effect on all ports of the device.

To configure a global static IPv4 binding entry:

| Step                                             | Command                                                                | Remarks                                                       |
|--------------------------------------------------|------------------------------------------------------------------------|---------------------------------------------------------------|
| 1. Enter system view.                            | <b>system-view</b>                                                     | N/A                                                           |
| 2. Configure a global static IPv4 binding entry. | <b>ip source binding ip-address ip-address mac-address mac-address</b> | No global static IPv4 binding entry is configured by default. |

## Configuring port-based static IPv4 binding entries

Follow these guidelines to configure port-based static IPv4 source guard entries:

- You cannot repeatedly configure the same static binding entry on one port, but you can configure the same static entry on different ports.
- IP source guard does not use the VLAN information (if specified) in static IPv4 binding entries to filter packets.
- When the ARP detection function is configured, be sure to specify the VLAN where ARP detection is configured in static IPv4 binding entries. Otherwise, ARP packets are discarded because they cannot match any static IPv4 binding entry.
- If a static binding entry to be added denotes the same binding as an existing dynamic binding entry, the new static binding entry overwrites the dynamic binding entry.

To configure a static IPv4 binding entry on a port:

| Step                                                       | Command                                                                                                                                       | Remarks                                                           |
|------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| 1. Enter system view.                                      | <b>system-view</b>                                                                                                                            | N/A                                                               |
| 2. Enter Layer 2 interface view.                           | <b>interface interface-type interface-number</b>                                                                                              | N/A                                                               |
| 3. Configure a static IPv4 source guard entry on the port. | <b>ip source binding { ip-address ip-address   ip-address ip-address mac-address mac-address   mac-address mac-address } [ vlan vlan-id ]</b> | By default, no static IPv4 binding entry is configured on a port. |

## Setting the maximum number of IPv4 source guard entries

The maximum number of IPv4 source guard entries is used to limit the total number of static and dynamic IPv4 source guard entries on a port. When the number of IPv4 binding entries on a port reaches the maximum, the port does not allowed new IPv4 binding entries any more.

If the maximum number of IPv4 binding entries to be configured is smaller than the number of existing IPv4 binding entries on the port, the maximum number can be configured successfully, and the existing entries are not affected. New IPv4 binding entries, however, cannot be added until the number of IPv4 binding entries on the port drops below the configured maximum.

To configure the maximum number of IPv4 binding entries allowed on a port:

| Step                                                                         | Command                                                           | Remarks                                                                                                        |
|------------------------------------------------------------------------------|-------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| 1. Enter system view.                                                        | <b>system-view</b>                                                | N/A                                                                                                            |
| 2. Enter Layer 2 Ethernet interface view.                                    | <b>interface</b> <i>interface-type</i><br><i>interface-number</i> | N/A                                                                                                            |
| 3. Configure the maximum number of IPv4 binding entries allowed on the port. | <b>ip verify source max-entries</b><br><i>number</i>              | Optional.<br>By default, the maximum number is 1500 on the HP 5500 EI series and 640 on the HP 5500 SI series. |

## Configuring the IPv6 source guard function

You cannot enable IPv6 source guard on a link aggregation member port or a service loopback port. If IPv6 source guard is enabled on a port, you cannot assign the port to a link aggregation group or a service loopback group.

### Configuring IPv6 source guard on a port

The IPv6 source guard function must be configured on a port before the port can obtain dynamic IPv6 source guard entries and use static and dynamic IPv6 source guard entries to filter packets.

- For how to configure a static IPv6 static binding entry, see "[Configuring a static IPv6 source guard entry.](#)"
- Cooperating with DHCPv6 snooping, IP source guard dynamically generates IP source guard entries based on the DHCPv6 snooping entries that are generated during dynamic IP address allocation.
- Cooperating with ND snooping, IP source guard dynamically generates IP source guard entries based on dynamic ND snooping entries.

Dynamic IPv6 source guard entries can contain such information as the MAC address, IPv6 address, VLAN tag, ingress port information and entry type (DHCPv6 snooping or ND snooping), where the MAC address, IPv6 address, and/or VLAN tag information may not be included depending on your configuration. IP source guard applies these entries to the port, so that the port can filter packets accordingly.

Follow these guidelines when you configure IPv6 source guard:

- If you repeatedly configure the IPv6 source guard function, only the last configuration takes effect.

- To obtain dynamic IPv6 source guard entries, make sure that DHCPv6 snooping or ND snooping is configured and works normally. For DHCPv6 and ND snooping configuration information, see *Layer 3—IP Services Configuration Guide*.
- If you configure both ND snooping and DHCPv6 snooping on the device, IPv6 source guard uses the type of entries that generated first. Because DHCPv6 snooping entries are usually generated first in such a case, IPv6 source guard usually uses the DHCPv6 snooping entries to filter packets on a port.

To configure the IPv6 source guard function on a port:
